## TECHNICAL THRUST

Environmentally induced materials problems cause a significant portion of nuclear power plant outage time and are of great economic and safety concern both for operating light water reactors that continue to age and for the next-generation systems that are currently being designed. The purpose of this conference is to foster the exchange of ideas about such problems and their remedies in nuclear power plants using water coolant.

The conference will continue to focus on the degradation of nickel base alloys, stainless steels, pressure vessel and piping steels, zircaloys, and other alloys in water environments relevant to reactor vessels and internals, steam generators, fuel cladding, irradiated components, fuel storage containers, and balance of plant components and systems. A new topic for the 12th conference is materials degradation issues for supercritical water-cooled reactors and other generation IV water-cooled nuclear energy systems.

The established conference format allows scientists and engineers concerned with environmental degradation processes (corrosion, mechanical, and radiation effects) to exchange views and present their latest results through a combination of invited and contributed presentations. The conference will be of interest to utility engineers, reactor vendor engineers, plant architect engineers, and consultants involved in design, construction, and operation of water reactors, as well as to researchers concerned with the fundamental nature of materials degradation. This meeting promises to be a highly beneficial forum where new insights into materials, methods, and techniques will be shared and gained by everyone.
