# Welcome to the TMS 2011 Annual Meeting & Exhibition!

Dear Colleagues and Friends:

As president of TMS, I welcome our members, exhibitors, and society guests here to sunny San Diego for our 140th annual gathering!

This year, the heart of our annual meeting—technical programming—has grown to four full days! This is an unprecedented opportunity to reap the ultimate in professional development through a robust menu of high quality, engaging presentations. We are also focusing on inspiring a renewed sense of volunteerism as a key to building a bigger and better TMS.

I invite you to visit the Volunteer Concierge booth here at the San Diego Convention Center to learn how to get involved in society activities. Get further engaged by attending the Annual Meeting of Membership on Monday.

Here is a brief synopsis of the other invaluable offerings here at TMS 2011:

**Technical & Poster Sessions** – Over 70 symposia will spotlight the efforts of some of the world's greatest materials science and engineering minds. Technical areas include Aluminum and Magnesium; Advanced Characterization, Modeling & Materials Performance; High Performance Materials; Materials & Society: Energy & Sustainable Production; Materials Processing & Production; Nanoscale & Amorphous Materials; Professional Development.

**Continuing Education** – Knowledge is the power that fuels developments in research and builds careers. TMS 2011 features five compelling courses and workshops designed to enhance your conference experience through education.

**Networking** – Your presence at TMS 2011 contributes to one of the greatest benefits: connecting with colleagues from around the world! Gather with professionals in your field at one of our 12 symposia-related welcome receptions on Sunday evening. Then, join all attendees at the President's Welcoming Reception on Monday and Happy Hour on Tuesday. All receptions will be at the San Diego Convention Center.

**Special Lectures** – One of the hallmarks of our annual meeting are the special lectures presented by prestigious professionals in the materials field. Whether you attend a luncheon lecture, plenary talk, or awards presentation, you will learn from the accomplishments of your colleagues. See page 15 for speakers.

**Awards Presentation** – Celebrating the accomplishments of fellow colleagues builds our society. The TMS and AIME Awards Dinner is a must-attend event on Tuesday evening. See page 16 for a preview.

**Student Events** –The future of TMS is fulfilled by its student members. Visit the Student Poster Contest and see what students are working on, and enjoy their competitive spirit at the Materials Bowl sponsored by Alcoa. Details are on page 18.

Welcome to TMS 2011. Let's make the most of all this conference has to offer.

Sincerely,

George T. "Rusty" Gray III

## Table of Contents

|                            |    |                         |    |

# TMS 2011

## 140th Annual Meeting & Exhibition

### Full Conference Registration

Your full conference badge provides you admission to each of these premier events!

- Technical & Poster Sessions
- Exhibition
- President's Welcoming Reception in the Exhibit Hall
- Symposia-Related Welcome Receptions/Poster Sessions
- Hosted Exhibit Hall Reception
- Young Leaders Tutorial Lecture
- Women in Science Breakfast (pre-registration required)
- Student Poster Contest
- Student Materials Bowl
- Lunch & Learn Sessions

### Internet Options

Free wireless access will be available on the upper level of the San Diego Convention Center in the Sails Pavilion (Authors' Coffee area) Sunday - Thursday, and in the Exhibit Hall concession area Monday - Wednesday. Username: TMS2011, Password: MATERIALS

Cyber Center Internet work stations sponsored by Stellar Materials Inc. will be available in the exhibit hall at the San Diego Convention Center during regular show hours.

### Policies

#### Badges

All attendees must wear registration badges at all times during the conference to ensure free admission to events included in the paid fee such as technical sessions, exhibition and receptions. "Exhibit Only" badges provide exclusive admittance to the show floor for events in the exhibit hall. "Guest" badges are for spouses or companions of registered attendees and used as identification only. "Guest" and "Exhibit Only" may not attend technical sessions.

#### Refunds

The deadline for all refunds was February 2, 2011. No refunds will be issued at the conference. Fees and tickets are nonrefundable.

#### Americans with Disabilities Act

 TMS strongly supports the federal Americans with Disabilities Act (ADA) which prohibits discrimination against, and promotes public accessibility for those with disabilities. In support of, and in compliance with, ADA, we ask those requiring specific equipment or services to contact TMS Meeting Services in advance.

#### Audio/Video Recording Policy

TMS reserves the right to all audio and video reproduction of presentations at TMS sponsored meetings. Recording of sessions (audio, video, still photography, etc.) intended for personal use, distribution, publication, or copyright without the express written consent of TMS and the individual authors is strictly prohibited. Contact TMS Technical Programming at (724) 776-9000, ext 212, to obtain a copy of the waiver release form.

#### Photography Notice

By registering for the meeting, all attendees acknowledge that they may be photographed by TMS personnel while at events. Photos may be used for promotional purposes in print and online.

#### Cell Phone Use

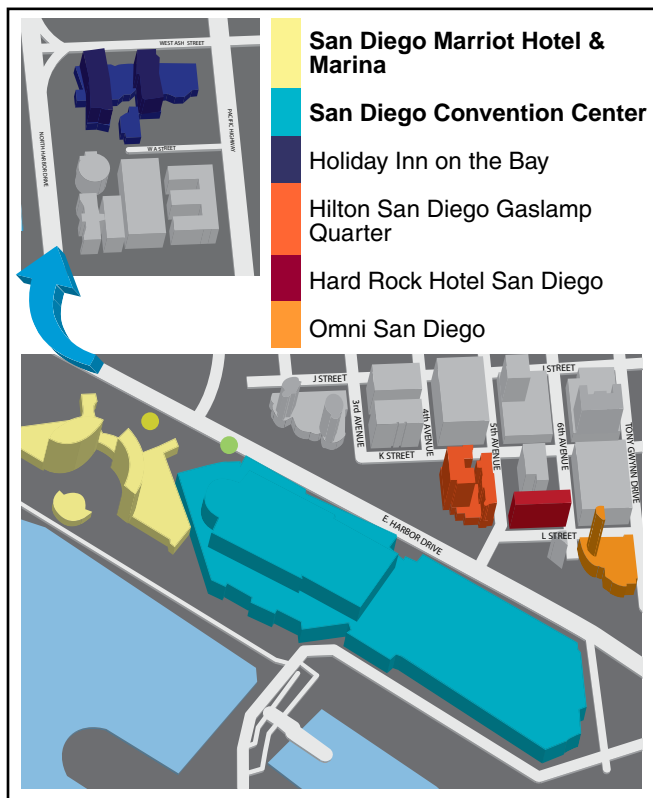

In consideration of attendees and presenters, TMS kindly requests that you minimize disturbances by setting all cell phones or PDA's on "silent" while in meeting rooms.

#### Recycling

##### Be Materials Minded!

Join TMS in reusing and recycling. Deposit discarded badges and programs in the bins located in the lobby of the San Diego Convention Center.

MEETING INFORMATION

## Schedule of Events

as of January 18, 2011

TMS Meetings & Events are scheduled on the following days, times and locations:

Key: **C** San Diego Convention Center

**M** San Diego Marriott Hotel & Marina

### SATURDAY, FEBRUARY 26

#### COMMITTEE MEETINGS

|  |                  |   |            |
|--|------------------|---|------------|
| Professional Registration Workshop and Committee Meeting | 9 a.m. to 5 p.m. | M | Point Loma |
|--|------------------|---|------------|

#### SOCIAL FUNCTIONS

|  |              |   |          |
|--|--------------|---|----------|
| Cal Poly Materials Engineering Alumni and Friends Get-Together | 7 to 10 p.m. | - | Off-Site |
|--|--------------|---|----------|

### SUNDAY, FEBRUARY 27

|                           |                      |   |                              |
|---------------------------|----------------------|---|------------------------------|
| REGISTRATION              | 11 a.m. to 7:30 p.m. | C | Exhibit Hall AB1             |
| TMS MEMBER WELCOME CENTER | 11 a.m. to 7:30 p.m. | C | Ground Level, Outside Hall A |

#### WORKSHOPS, SHORT COURSES, FORUMS & TUTORIALS

|  |                        |   |          |
|--|------------------------|---|----------|
| Lead-Free Solder Technology 2011                 | 8:30 a.m. to 5:30 p.m. | C | Room 31C |
| Proper Anode Baking Furnace Operations-How & Why | 8:30 a.m. to 4 p.m.    | C | Room 33B |
| Casting & Solidification of Metals               | 8:30 a.m. to 4 p.m.    | C | Room 33C |

#### STUDENT EVENTS

|                          |                |   |                     |
|--------------------------|----------------|---|---------------------|
| Materials Bowl           |                |   |                     |
| Elimination Rounds       | noon to 3 p.m. | M | Marina Ballroom G   |
| Championship Round       | 8:30 p.m.      | M | Marina Ballroom G   |
| Student Networking Mixer | 9 to 11 p.m.   | M | Marina Ballroom E&F |

#### SOCIAL FUNCTIONS

|   |                   |   |             |
|---|-------------------|---|-------------|
| Fellows and Invited Guests Reception                                | 4:30 to 6:30 p.m. | M | Torrance    |
| Young Leader/New Member Reception                                   | 5 to 6 p.m.       | M | Solana      |
| Microstructural Processes in Irradiated Materials Poster Reception  | 6 to 8 p.m.       | C | Room 3      |
| Polycrystal Modeling with Experimental Integration Poster Reception | 6 to 8 p.m.       | C | Ballroom 6C |
| Frontiers in Solidification Science Poster Session                  | 6 to 8 p.m.       | C | Ballroom 6E |
| Computational Thermodynamics & Kinetics Reception                   | 6 to 8 p.m.       | C | Room 9      |
| 2011 Functional and Structural Nanomaterials Reception              | 6 to 8 p.m.       | C | Room 8      |

**M** San Diego Marriott Hotel & Marina

MEETING INFORMATION

|   |             |          |             |
|---|-------------|----------|-------------|
| Neutron and X-Ray Studies of Advanced Materials IV Poster Session   | 6 to 8 p.m. | <b>C</b> | Room 10     |
| Light Metals Reception  | 6 to 8 p.m. | <b>C</b> | Room 17A    |
| Magnesium Technology 2011 Reception   | 6 to 8 p.m. | <b>C</b> | Ballroom 6F |
| Pb-Free Solders and other Materials for Emerging Interconnect and Packaging Technologies Reception                          | 6 to 8 p.m. | <b>C</b> | Room 7B     |
| Physical and Mechanical Metallurgy of Shape Memory Alloys for Actuator Applications Reception                               | 6 to 8 p.m. | <b>C</b> | Room 11B    |
| Materials Processing Fundamentals Poster Session  | 6 to 8 p.m. | <b>C</b> | Room 12     |
| Silicon Production, Purification and Recycling for Photovoltaic Cells Poster Session  | 6 to 8 p.m. | <b>C</b> | Room 14A    |
| Characterization of Minerals, Metals and Materials Reception  | 6 to 8 p.m. | <b>C</b> | Room 14B    |
| Biological Materials Science Reception  | 6 to 8 p.m. | <b>C</b> | Room 15A    |
| The Second Symposium on the Recycling of Electronic Wastes Poster Session   | 6 to 8 p.m. | <b>C</b> | Room 15B    |
| Chloride 2011 Poster Session  | 6 to 8 p.m. | <b>C</b> | Room 19     |
| Surfaces and Heterostructures at Nano or Micro Scale and Their Characterization, Properties and Applications Poster Session | 6 to 8 p.m. | <b>C</b> | Room 31B    |
| Approaches for Investigating Phase Transformations At the Atomic Scale Poster Session                                       | 6 to 8 p.m. | <b>C</b> | Room 32B    |
| Processing and Properties of Powder-Based Materials Poster Session  | 6 to 8 p.m. | <b>C</b> | Room 33A    |

#### COMMITTEE MEETINGS

|  |                      |          |                   |
|--|----------------------|----------|-------------------|
| Financial Planning Committee                     | 7 to 9 a.m.          | <b>M</b> | Leucadia          |
| Professional Registration Leadership Committee   | 8 to 10 a.m.         | <b>M</b> | Business Suite 3  |
| TMS Board of Directors Orientation               | 9 to 10 a.m.         | <b>M</b> | Point Loma        |
| TMS Board of Directors Meeting                   | 10 a.m. to 1:30 p.m. | <b>M</b> | Point Loma        |
| Recycling & Environmental Technologies Committee | noon to 1:30 p.m.    | <b>M</b> | Del Mar           |
| Young Leader Committee Business Meeting          | 12:30 to 2 p.m.      | <b>M</b> | Balboa            |
| Accreditation Committee                          | 12:30 to 2:30 p.m.   | <b>M</b> | Solana            |
| Magnesium Committee                              | 1:30 to 3:15 p.m.    | <b>M</b> | Rancho Las Palmas |
| Pyrometallurgy Committee                         | 1:30 to 3 p.m.       | <b>M</b> | Carlsbad          |

#### Programming Booth

The programming booth will be located in the Ballroom 6 Lobby on the Upper Level of the San Diego Convention Center. TMS staff will be available to answer programming questions or provide participation certificates.

## Schedule of Events

as of January 18, 2011

Key: **C** San Diego Convention Center

**M** San Diego Marriott Hotel & Marina

|   |                   |   |                   |
|---|-------------------|---|-------------------|
| Nominating Committee                            | 2 to 3 p.m.       | M | Boardroom         |
| Aluminum Committee                              | 3 to 4:30 p.m.    | M | Pacific           |
| Materials Characterization Committee            | 3 to 5 p.m.       | M | Del Mar           |

| Content Development and Dissemination Committee | 5 to 7 p.m.       | M | Newport Beach     |
| Nanomechanical Materials Behavior Committee     | 5:45 to 6:45 p.m. | M | Point Loma        |
| Mechanical Behavior of Materials Committee      | 7 to 8:30 p.m.    | M | Point Loma        |
| Alloy Phases Committee                          | 7:30 to 9:30 p.m. | M | Rancho Las Palmas |
| Phase Transformation Committee                  | 7:30 to 9:30 p.m. | M | Mission Hills     |

## Networking Receptions

Join your colleagues for some informal discussions at these networking events:

### Sunday

Symposia-related Welcome Receptions and Poster Sessions  
(All receptions are held at the San Diego Convention Center from 6 to 8 p.m.)

- 2011 Functional and Structural Nanomaterials: Fabrication, Properties, Applications & Implications ..... Room 8
- Light Metals: Alumina and Bauxite; Aluminum Reduction Technology; Electrode Technology for Aluminium Production ..... Room 17A
- Biological Materials Science ..... Room 15A
- Characterization of Minerals, Metals and Materials ..... Room 14B
- Computational Thermodynamics and Kinetics ..... Room 9
- Magnesium Technology 2011 ..... Room 6F
- Microstructural Processes in Irradiated Materials ..... Room 3
- Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies ..... Room 7B
- Physical and Mechanical Metallurgy of Shape Memory Alloys for Actuator Applications ..... Room 11B
- Polycrystal Modelling with Experimental Integration: A Symposium Honoring Carlos Tomé ..... Room 6C

### Monday

- President's Welcoming Reception ..... 5 to 6:30 p.m. .... Exhibit Hall

### Tuesday

- Happy Hour Reception ..... 5 to 6 p.m. .... Exhibit Hall

# TMS 2011

### MONDAY LUNCH & LEARN

#### **TMS Annual Meeting of the Membership**

**Time: 12:30 to 1:30 p.m.**

#### **Speakers:**

Garry Warren ..... 2011 TMS President  
George T. "Rusty" Gray III .. 2010 TMS President  
Warren Hunt, Jr. .... TMS Executive Director  
Stanley M. Howard..... TMS Board of Directors,  
Financial Planning Officer

**Lunch & Learn Area, Exhibit Hall  
San Diego Convention Center**

**Get engaged in your Society!** Attend this inaugural meeting to participate in discussions and learn about:

- Recent accomplishments of the society
- Recent and expected financial performance
- Preview of 2011 initiatives
- Strategic projects

# TMS 2011

## 140th Annual Meeting & Exhibition

### Schedule of Events

as of January 18, 2011

Key: **C** San Diego Convention Center

**M** San Diego Marriott Hotel & Marina

#### TUESDAY, MARCH 1

|                           |                      |   |                              |
|---------------------------|----------------------|---|------------------------------|
| AUTHORS' COFFEE           | 7:30 to 8:30 a.m.    | C | Upper Level, Sails Pavilion  |
| REGISTRATION              | 7 a.m. to 6 p.m.     | C | Exhibit Hall AB1             |
| TMS MEMBER WELCOME CENTER | 7 a.m. to 6 p.m.     | C | Ground Level, Outside Hall A |
| GENERAL POSTER SESSION    | 10:30 a.m. to 6 p.m. | C | Exhibit Hall AB1             |

#### 2011 TMS EXHIBITION

|                      |                      |   |                  |
|----------------------|----------------------|---|------------------|
| Exhibit Hours        | 10:30 a.m. to 6 p.m. | C | Exhibit Hall AB1 |
| Happy Hour Reception | 5 to 6 p.m.          | C | Exhibit Hall AB1 |

#### POSTER CONTESTS

|   |                      |   |                  |
|---|----------------------|---|------------------|
| Technical Division Student Poster Contest And Biological Materials Science Poster Contest | 10:30 a.m. to 6 p.m. | C | Exhibit Hall AB1 |
|---|----------------------|---|------------------|

#### STUDENT EVENTS

|  |                     |   |                  |
|--|---------------------|---|------------------|
| Technical Division Student Poster Contest Awards | 12:15 to 12:45 p.m. | C | Exhibit Hall AB1 |
| Student Career Forum                             | 3 to 5 p.m.         | C | Exhibit Hall AB1 |

#### WORKSHOPS, SHORT COURSES, FORUMS & TUTORIALS

|   |                |   |                   |
|---|----------------|---|-------------------|
| Young Leaders Tutorial Lecture/Luncheon | noon to 2 p.m. | M | Marina Ballroom E |
| Lunch & Learn: Energy with Cindy Belt   | noon to 2 p.m. | C | Exhibit Hall AB1  |

#### TMS-AIME ANNUAL AWARDS BANQUET

|                   |                   |   |                       |
|-------------------|-------------------|---|-----------------------|
| Reception         | 6:30 to 7:15 p.m. | M | Marina Ballroom Foyer |
| Dinner and Awards | 7:15 to 10 p.m.   | M | Marina Ballroom F&G   |

#### SOCIAL FUNCTIONS

|   |                  |   |               |
|---|------------------|---|---------------|
| Guest Hospitality                                 | 7 to 10 a.m.     | M | Laguna        |
| Acta Materialia, Inc. Board of Governors Luncheon | 8 a.m. to 5 p.m. | M | Warner Center |

#### TECHNICAL DIVISION LUNCHEON

|                   |                   |   |         |
|-------------------|-------------------|---|---------|
| EPD/MPMD Luncheon | noon to 2:15 p.m. | C | Room 6B |
|-------------------|-------------------|---|---------|

## Schedule of Events

as of January 18, 2011

Key: **C** San Diego Convention Center

**M** San Diego Marriott Hotel & Marina

| COMMITTEE MEETINGS   |                    |   |                   |
|--|--------------------|---|-------------------|
| Electronic Packaging & Interconnection Committee           | 7 to 8 a.m.        | M | Solana            |
| Met Trans "B" Board of Review                              | 7 to 8 a.m.        | M | Oceanside         |
| MPMD Council Meeting                                       | 7 to 9 a.m.        | M | Leucadia          |
| Fellows Award Committee                                    | 7:30 to 9 a.m.     | M | Rancho Las Palmas |
| Mathewson, Hume-Rothery & IOM/Mehl Awards Subcommittee     | 7:30 to 9 a.m.     | M | Rancho Las Palmas |
| Chalmers, Smith & Cohen Awards Subcommittee                | 7:30 to 9 a.m.     | M | Rancho Las Palmas |
| Leadership, Scott, Educator & Practice Awards Subcommittee | 7:30 to 9 a.m.     | M | Rancho Las Palmas |
| Acta Materialia, Inc. Board of Governors Meeting           | 8 a.m. to 5 p.m.   | M | Torrance          |
| Honors & Professional Recognition Award Committee          | 9 to 10 a.m.       | M | Rancho Las Palmas |
| TMS Executive Committee                                    | 11:00 a.m. to noon | M | President's Suite |
| SMD Council Meeting  | noon to 2 p.m.     | M | Solana            |
| Powder Materials Committee                                 | 12:30 to 2 p.m.    | C | Room 12           |
| MetSoc/TMS Leadership Meeting                              | 2:30 to 3:30 p.m.  | M | Presidents Suite  |
| Women in Materials Science & Engineering Committee         | 3 to 4:30 p.m.     | M | Point Loma        |
| IOMMMS Leadership Meeting                                  | 4 to 5 p.m.        | M | Leucadia          |
| Energy Committee   | 5 to 6 p.m.        | C | Room 16A          |
| High Temperature Alloys Committee                          | 5:30 to 7 p.m.     | M | Carlsbad          |
| Refractory Metals & Materials Committee                    | 5:30 to 6:30 p.m.  | M | Del Mar           |
| Shaping & Forming Committee                                | 6 to 8 p.m.        | M | Leucadia          |
| Titanium Committee   | 6 to 7 p.m.        | C | Room 17B          |
| Corrosion & Environmental Effects Committee                | 6:30 to 7:30 p.m.  | C | Room 11B          |

MEETING INFORMATION

### TUESDAY LUNCH & LEARN

#### **Energy Management: Things Your Mother Didn't Teach You**

**Time: Noon to 2 p.m.**

**Lunch & Learn Area, Exhibit Hall  
San Diego Convention Center**

#### **Speakers:**

Cindy Belt, consulting energy engineer, previously with Superior Industries and Aleris International

Brajendra Mishra, professor and associate director, Kroll Institute for Extractive Metallurgy and Advanced Coatings & Surface Engineering Laboratory, Colorado School of Mines

Steve Coppinger, director, energy services, CalPortland Company

# TMS 2011

## 140th Annual Meeting & Exhibition

### Schedule of Events

as of January 18, 2011

Key: **C** San Diego Convention Center      **M** San Diego Marriott Hotel & Marina

#### WEDNESDAY, MARCH 2

|                           |                         |   |                              |
|---------------------------|-------------------------|---|------------------------------|
| AUTHORS' COFFEE           | 7:30 to 8:30 a.m.       | C | Upper Level, Sails Pavilion  |
| REGISTRATION              | 7 a.m. to 5 p.m.        | C | Exhibit Hall AB1             |
| TMS MEMBER WELCOME CENTER | 7 a.m. to 5 p.m.        | C | Ground Level, Outside Hall A |
| GENERAL POSTER SESSION    | 10:30 a.m. to 2:30 p.m. | C | Exhibit Hall AB1             |

#### 2011 TMS EXHIBITION

|               |                      |   |                  |
|---------------|----------------------|---|------------------|
| Exhibit Hours | 10:30 a.m. to 3 p.m. | C | Exhibit Hall AB1 |
|---------------|----------------------|---|------------------|

#### TECHNICAL DIVISION LUNCHEON

|              |                   |   |         |
|--------------|-------------------|---|---------|
| LMD Luncheon | noon to 2:00 p.m. | C | Room 6B |
|--------------|-------------------|---|---------|

#### WORKSHOPS, SHORT COURSES, FORUMS & TUTORIALS

|  |                |   |                  |
|--|----------------|---|------------------|
| Lunch & Learn: Materials Cyberinfrastructure | noon to 2 p.m. | C | Exhibit Hall AB1 |
|--|----------------|---|------------------|

#### SOCIAL FUNCTIONS

|                   |              |   |        |
|-------------------|--------------|---|--------|
| Guest Hospitality | 7 to 10 a.m. | M | Laguna |
|-------------------|--------------|---|--------|

#### COMMITTEE MEETINGS

|  |                    |   |            |
|--|--------------------|---|------------|
| TMS Board of Directors Meeting             | 7:30 to 11:30 a.m. | M | Point Loma |
| TMS Advocacy Strategy Session              | noon to 4 p.m.     | M | Pacific    |
| PRICM-8 International Organizing Committee | 1 to 3 p.m.        | M | Solana     |
| Medalist, Hardy & ECFE Awards Subcommittee | 3:30 to 5:00 p.m.  | M | Oceanside  |
| Aluminum Processing Committee              | 6:30 to 8 p.m.     | M | Leucadia   |

MEETING INFORMATION

### WEDNESDAY LUNCH & LEARN

#### Materials Cyberinfrastructure

**Time: Noon to 1:50 PM**

**Lunch & Learn Area, Exhibit Hall  
San Diego Convention Center**

#### Speakers:

John Allison, *University of Michigan*..... Noon

The following speakers will provide live demonstrations of computer platforms:

Paul Mason, *ThermoCalc, Inc., Thermocalc*..... 12:30 p.m.

Andy Geltmacher, *Naval Research Laboratory, 3D Materials Atlas* ..... 1:10 p.m.

Alejandro Strachan, *Purdue University, NanoHub*..... 1:30 p.m.

Laura Bartolo, *Kent State University, MatDL/MatForge*..... 1:50 p.m.

## Schedule of Events

as of January 18, 2011

Key: **C** San Diego Convention Center

**M** San Diego Marriott Hotel & Marina

### THURSDAY, MARCH 3

|                           |                     |          |                              |
|---------------------------|---------------------|----------|------------------------------|
| AUTHORS' COFFEE           | 7:30 to 8:30 a.m.   | <b>C</b> | Upper Level, Sails Pavilion  |
| REGISTRATION              | 7 a.m. to 2:30 p.m. | <b>C</b> | Exhibit Hall AB1             |
| TMS MEMBER WELCOME CENTER | 7 a.m. to 2:30 p.m. | <b>C</b> | Ground Level, Outside Hall A |

### WORKSHOPS, SHORT COURSES, FORUMS & TUTORIALS

|   |                  |          |             |
|---|------------------|----------|-------------|
| Workshop on the Development of a Reference Self-Diffusion Mobility Database for the Pure Elements | 9 a.m. to 3 p.m. | <b>C</b> | Ballroom 6B |
|---|------------------|----------|-------------|

### SOCIAL FUNCTIONS

|                   |              |          |        |
|-------------------|--------------|----------|--------|
| Guest Hospitality | 7 to 10 a.m. | <b>M</b> | Lagana |
|-------------------|--------------|----------|--------|

### TECHNICAL DIVISION LECTURE

|  |                   |          |          |
|--|-------------------|----------|----------|
| Extraction & Processing Division Distinguished Lecture | 8:30 to 9:10 a.m. | <b>C</b> | Room 16A |
|--|-------------------|----------|----------|

### COMMITTEE MEETINGS

|   |                   |          |          |
|---|-------------------|----------|----------|
| Hydrometallurgy & Electrometallurgy Committee | 4:45 to 6:15 p.m. | <b>C</b> | Room 16A |
|---|-------------------|----------|----------|

## TMS 2011 Fun Facts

|                 |  |
|-----------------|--|
| <b>4</b>        | Full Days of Technical Programming                           |
| <b>4</b>        | The Total Number of Gaslamps in San Diego's Gaslamp District |
| <b>7</b>        | Technical Themes   |
| <b>12</b>       | Welcoming Receptions   |
| <b>25</b>       | Years Since the First TMS Exhibition                         |
| <b>54</b>       | Number of U.S. Navy Ships Docked in San Diego Harbor         |
| <b>Over 68</b>  | Countries Represented  |
| <b>70</b>       | In Degrees Fahrenheit, the Average Temperature in San Diego  |
| <b>Over 70</b>  | Unique Symposia  |
| <b>Over 700</b> | Formal lectures, keynotes, invited and plenary talks         |
| <b>450</b>      | Posters  |
| <b>3,397</b>    | Presentations  |
| <b>4,000</b>    | Population of 'Residents' at the San Diego Zoo               |

- TORRANCE
- RANCHO LAS PALMAS
- NEWPORT BEACH
- LOS ANGELES

## MEETING INFORMATION

## Lectures & Luncheons

### Young Leaders Tutorial Luncheon Lecture

*"Integrative Materials-Process-Component Design: A Prospective View"*

**Tuesday • Noon • Marriott, Marina Ballroom E**

Speaker: **Diana Lados**,  
Assistant Professor, Worcester  
Polytechnic Institute, USA

About the Topic: The challenges in modern materials process component design revolve around the successful integration of several important and sometimes competing concepts such as high performance & reliability, societal impact, and economics. This generates a fertile future of opportunities for the clever materials engineer to develop a holistic approach based on a fundamental understanding in tandem with suitable and sustainable application driven design and manufacturing strategies. These ideas will be systematically reviewed and discussed in the context of needs and developments, and exciting materials research opportunities will be presented.

### Light Metals Division Luncheon Lecture

*"The Intersection of Materials, Design and Manufacturing with Lightweight Materials"*

**Wednesday • Noon**  
**Convention Center, Room 6B**

Speaker: **Anil K. Sachdev**,  
Inventor, General Motors Global  
Research & Development Center,  
USA

About the Topic: There is an increasing need for lightweight materials in automotive applications due to their large impact on fuel economy, emissions, and performance. This need also extends to other industries like aerospace and consumer electronics. Sachdev will describe opportunities for lightweight materials from a perspective that includes their properties, product design, and manufacturing, all aimed at driving the total sub-system cost to minimize cost penalty for their pervasive use. Sachdev will also discuss the many challenges that need to be addressed, including improved computational methods to develop higher performance materials including corrosion mitigation; robust materials processing that provides properties with narrow distributions; and manufacturing methods that can produce the designs optimized for minimum mass.

### Extraction & Processing/ Materials Processing & Manufacturing Joint Division Luncheon

*"Advances in Sulfide Smelting-A Practical Overview"*

**Tuesday • Noon**  
**Convention Center, Room 6B**

Speaker: **David George**,  
Principal Advisor of Processing,  
Technology and Innovation,  
Rio Tinto, USA

About the Topic: Over the last 40 years, environmental and cost pressures fostered technology advances that have redefined the copper smelting industry. In the United States, Japan and Europe, the small, primitive and polluting mine site-based smelters have nearly all been shut down. Clean, high capacity, and energy efficient smelting technology is now the standard for new smelters and this technology is rapidly being adopted in China. A review of the last 40 years of technology advances may give some hints about the opportunities for improvement in the coming decades.

### Extraction & Processing Division Distinguished Lecture

*"The Removal of Arsenic, Selenium and Metals from Aqueous Solution by Iron Precipitation and Reduction Techniques"*

**Thursday • 8:30 a.m.**  
**Convention Center, Room 16A**

Speaker: **Larry Twidwell**,  
Professor Emeritus, Montana Tech  
of the University of Montana, USA

About the Topic: The removal of arsenic, selenium, and metal species from hydrometallurgical solutions and waste water continues to be an important research topic. This presentation includes a discussion of the research conducted at Montana Tech of the University of Montana over the past 20 years along with current literature studies. The discussion will focus on removal of arsenic by co-precipitation with Fe(III) and Fe(II), co-precipitation with Fe(III) and Al(III), reduction using elemental iron; the removal of selenium by elemental iron and catalysed iron; and the removal of cadmium, copper, nickel, zinc by co-precipitation with Fe(III) and Al(III).

## Award-Winning Speakers

### William Hume-Rothery Award Lecture

*"Thermodynamics and Diffusion Coupling in Alloys - Application Driven Science"*

**Monday • 8:40 to 9:20 a.m.**  
**Convention Center, Room 31A**

Speaker: **John Agren**,  
*Professor, Royal Institute of Technology, Sweden*

About the Topic: As emphasized by Stokes in 1997, the common assumption of a linear progression from basic research (science) via applied research, to technological innovations (engineering),

should be questioned. This presentation will address some of them, as well as the effect of various ordering phenomena on activation barriers, the strength and practical importance of correlation effects, etc.

### Institute of Metals/Robert Franklin Mehl Lecture

*"The Ubiquitous Interfacial Free Energy in Phase Transformations"*

**Monday • 10:15 a.m.**  
**Convention Center, Room 32B**

Speaker: **David Seidman**,  
*Walter P. Murphy Professor of Materials Science & Engineering, Northwestern University, USA*

About the Topic: In this talk, the focus is on the diverse roles played by interfacial free energy in phase transformations in multi-component metallic alloys, which are studied experimentally by atom-probe tomography and transmission electron microscopy. The results of simulations employing lattice kinetic Monte Carlo, where the phase transformation is mediated by a vacancy mechanism, will be presented and compared in detail with experimental observations. First-principles calculations of interfacial energies in the same metallic alloys will be discussed in terms of their relevance to the aforementioned.

### SPOTLIGHT EVENT

#### Technical Division Student Poster Contest Awards

**Tuesday 12:15 to 12:45 p.m.**  
 Exhibit Hall, San Diego Convention Center

### Vittorio de Nora Prize Lecture

*"Recycling of Contaminated Aluminum Scrap"*

**Wednesday • 2:05 p.m.**  
**Convention Center, Room 12**

Speaker: **Anne Kvithyld**,  
*SINTEF, Norway*

Kvithyld holds a doctorate in aluminum recycling and has worked extensively with the decoating of aluminum and other light metals. She is a member of the society's Recycling and Environmental Technologies Committee, and recently organized an aluminum recycling workshop. Through her dedication to aluminum recycling, she has emerged as a respected leader in the light metals professional community.

The Vittorio de Nora Prize was established last year by the TMS Foundation to honor its namesake, who was both a pioneer in the materials processing field and one of the great Italian technologists of the 20th century. Kvithyld will receive a \$20,000 cash prize as the recipient of this prestigious award.

About the Topic: Recycling is important in the aluminum industry. Removal of contaminants such as the coat and organic materials—applied for protection and appearance—are the tail that wags the recycling dog. Successful removal of contaminants from scrap would ensure that more aluminum be recycled, minimize losses and prevent downgrading of the resource.

### JIM International Scholar Award Winners

*"Fracture Mechanism and Toughness in Fine- and Coarse-Grained Magnesium Alloys"*

**Monday • 12:10 to 12:30 p.m.**  
**Convention Center, Room 6F**

*(During the Magnesium Technology 2011 Opening Session)*

Speaker: **Hidetoshi Somekawa**,  
*National Institute for Materials Science*

*"Crack Tip Dislocations and the Sequential Multiplication Process of Dislocation Sources along the Crack Front Revealed by HVEM-Tomography"*

**Wednesday • 10 to 10:30 a.m.**  
**Convention Center, Room 32 A**

*(During the David Pope Honorary Symposium)*

Speaker: **Masaki Tanaka**, *Kyushu University*

# 140th TMS and AIME Dinner, Awards Presentation, and Installation of the 2011 President

## Garry Warren, 2011 TMS President

### About 2011 TMS President Garry Warren

Garry Warren is a professor in the Department of Metallurgical and Materials Engineering at the University of Alabama, Tuscaloosa. He joined the university in 1986 after spending

eight years as a faculty member at Carnegie Mellon University in Pittsburgh, Pennsylvania. Warren received both a B.S. and M.S. in metallurgical engineering from the University of Texas – El Paso and his Ph.D. in metallurgy from the University of Utah.

He has also served in various capacities within the Extraction & Processing Division (EPD), chairing the following committees: Programming, Continuing Education, and Publications, which included editorship of the EPD Congress proceedings for 1994–1996. He is also on the editorial review board for Metallurgical Transactions B, and was the faculty advisor for the University of Alabama Material Advantage Student Chapter. The chapter was named a “Chapter of Excellence” for four consecutive years 1994–1997, and again in 2000.

Warren’s research efforts have focused on the electrochemistry and leaching behavior of various sulfide minerals, corrosion behavior of NdFeB permanent magnets, degradation of metal particle recording media, use of electrochemical techniques to evaluate the protective ability of polymers and polymer coatings, and the corrosion of Ti-Al intermetallics.

The TMS-AIME Awards Banquet will be held **Tuesday, March 1, at 7 p.m.** at the **San Diego Marriott Hotel & Marina in Marina Ballrooms F&G**. The event will begin with a reception from 6:30 to 7:15 p.m., followed by dinner and the awards presentation through 10 p.m. After the awards ceremony, 2010 President George T. “Rusty” Gray III will present the annual address to the society. Gray will then introduce 2011 TMS President Garry Warren.

## Society Awards

### Presented by George T. “Rusty” Gray III

George T. “Rusty” Gray III Gray, the 2010 TMS President, is a laboratory fellow at Los Alamos National Laboratory in Los Alamos, New Mexico. He is a member of the TMS Titanium and Mechanical Metallurgy committees and has served as the Structural Materials Division representative to the TMS Program Committee.

### TMS Fellows Class of 2011

- David Bourell *University of Texas, USA*
- Kazuhiro Hono *National Institute for Materials Science, Japan*
- Marc A. Meyers *University of California – La Jolla, USA*
- Anthony Rollett *Carnegie Mellon University, USA*
- Steven Zinkle *Oak Ridge National Laboratory, USA*

- Application to Practice Award *Brian Thomas, University of Illinois, USA*
- Bruce Chalmers Award *Peter Voorhees, Northwestern University, USA*
- Champion H. Mathewson Award *Christopher Szczepanski, University Technology Corp / AFRL, USA*  
*Sushant K. Jha, Universal Technology Corp., USA*  
*James M. Larsen, U.S. Air Force, USA*  
*J. Wayne Jones, University of Michigan, USA*
- Early Career Faculty Fellow Award *Diana Lados, Worcester Polytechnic Institute, USA*
- Educator Award *Krishan Chawla, University of Alabama, USA*
- Institute of Metals/Robert Franklin Mehl Award *David Seidman, Northwestern University, USA*
- John Bardeen Award *Stephen Pearton, University of Florida, USA*
- Leadership Award *Y. Austin Chang, University of Wisconsin, USA*
- Robert Lansing Hardy Award *Shriram Ramanathan, Harvard University, USA*
- William Hume-Rothery Award *John Agren, Royal Institute of Technology, Sweden*
- Shri Ram Arora Award *Vivek Verma, Indian Institute of Technology, India*
- Vittorio de Nora Prize for Environmental Improvements in Metallurgical Industries *Anne Kvithyld, SINTEF, Norway*

## AIME Awards

### Presented by Brajendra Mishra

Brajendra Mishra is president-elect designate of The American Institute of Mining, Metallurgical, and Petroleum Engineers. A member of TMS since 1992, Mishra served as president in 2006. He is a professor of metallurgical and materials engineering and the associate director of the Kroll Institute for Extractive Metallurgy and the Advanced Coatings and Surface Engineering Laboratory, Colorado School of Mines. He is also the associate director of the National Science Foundation Industry-University Cooperative Research Center for Resource, Recovery and Recycling.

**AIME Distinguished Service Award** Dan Thoma, *Los Alamos National Laboratory, USA*  
**AIME Rossiter W. Raymond Memorial Award** Markus Buehler, *Massachusetts Institute of Technology, USA*

## TMS Division Awards

These awards are presented at special technical division events.

### Electronic, Magnetic & Photonic Materials Division

#### Distinguished Scientist/Engineer Award

Long-Qing Chen, *Pennsylvania State University, USA*

#### Distinguished Service Award

Sinn-wen Chen, *National Tsing Hua University, Taiwan*

#### EMPMD/JEM Best Paper

Christopher Kinney, *University of California – Berkeley, USA*

### Extraction & Processing Division

#### Distinguished Lecturer Award

Larry Twidwell, *Montana Tech of the University of Montana, USA*

#### Distinguished Service Award

William Imrie, *Bechtel Mining & Metals, Australia*

#### Science Award

Dimitrios Filippou  
Guillaume Hudon  
*Rio Tinto Iron & Titanium, Canada*

#### Technology Award

Min Zhou  
Aidong Wan  
Guang Li  
*Jinchuan Non-Ferrous Metals Corporation, China*  
Ross Baldock, *Outotec, Australia*  
Harry Li, *Ausmelt, Australia*

### Light Metals Division

#### Distinguished Service Award

Halvor Kvande, *Hydro Aluminium AS, Norway*

#### Technology Award

Adam Gesing, *Gesing Consultants Inc, Canada*

#### Light Metals Award

Bodil Monsen  
Arne Petter Ratvik  
*SINTEF Materials and Chemistry, Norway*  
Lorentz Petter Lossius, *Hydro Aluminium – PMT, Norway*

#### Aluminum Reduction Technology Award

Tian Yingfu, *Chongqing Tiantai Aluminum Industry Co. Ltd, China*  
Feng Naixiang  
Peng Jianping  
Wang Yaowu  
Qi Xiquan  
Tu Ganfeng  
*Northeastern University, China*

#### Bauxite & Alumina Award

Joanne Loh  
Greta Bodie  
Fatima Naim  
*CSIRO Light Metals Flagship (CSIRO Minerals), Australia*

#### Warren Peterson Cast Shop for Aluminum Production Award

Don Doutre, *Novelis Global Technology Center, Canada*

#### Energy Best Paper –

**Professional Award**  
James E. Miller, *Sandia National Laboratories, USA*

#### JOM Best Paper Award

Subodh K. Das  
*Phinix, LLC*  
John A.S. Green  
*JASG Consulting USA*

#### Magnesium Best Paper – Application Award

John Grandfield, *Grandfield Technology Pty Ltd, Australia*

Mark Turski  
Tim Wilks  
*Magnesium Elektron, UK*  
Bruce Davis  
Rick DeLorme  
*Magnesium Elektron North America, USA*  
Kyu Cho, *U.S. Army Research Laboratory, USA*

#### Magnesium Best Paper – Fundamental Research Award

Young B. Chun  
Christopher Davies  
*Monash University, Australia*

#### Magnesium Best Paper – Student Award

Jin-kyu Lee  
Shae K. Kim  
*Korea Institute of Industrial Technology, Korea*

### Material Processing & Manufacturing Division

#### Distinguished Scientist/Engineer Award

Amit Misra, *Los Alamos National Laboratory, USA*

### Structural Materials Division

#### Distinguished Scientist/Engineer Award

Tresa Pollock, *University of California Santa Barbara, USA*

#### Distinguished Service Award

Tresa Pollock, *University of California Santa Barbara, USA*

#### JOM Best Paper Award

Rebecca A. MacKay  
Timothy P. Gabb  
James L. Smialek  
Michael V. Nathal  
*NASA Glenn Research Center, USA*

## Student Activities

TMS 2011 features a number of events designed to captivate and educate young materials science minds. Registered student attendees are invited to:

### Sunday

#### 2011 Materials Bowl

(Sponsored by Alcoa)

Elimination Rounds Noon to 3 p.m.  
Championship Round 8:30 p.m.  
Marriott, Marina Ballroom G

#### Student Networking Mixer

(GE Global Research sponsor)

imagination at work

9 to 11 p.m. • Marriott, Marina Ballroom E&F

The TMS Graduate Student Advisory Council (GSAC) invites TMS members to attend the student mixer. The student mixer has a welcoming atmosphere that is ideal for informally meeting new people and engaging in casual conversations.

### Monday

#### Poster Contest

5 to 6:30 p.m. • Exhibit Hall

Undergraduate and graduate students will vie for cash prizes at the annual TMS Technical Division Student Poster Contest sponsored by the five technical divisions of TMS – Electronic, Magnetic & Photonic Materials; Extraction & Processing; Light Metals; Materials Processing & Manufacturing, and Structural Materials. Participants in this dynamic and interactive event compete for a \$500 prize in each division for the best undergraduate and best graduate poster. A top prize of \$500 will be awarded for the “Best of Show” poster in undergraduate and graduate.

### Tuesday

#### Graduate Student Advisory Council

9 to 10 a.m. • Marriott, Leucadia Room

All graduate students are invited to attend the Graduate Student Advisory Council meeting. The council focuses on meeting the unique needs of graduate students within the Material Advantage program and offers graduate students a forum to share their ideas and concerns. Because the meeting is scheduled between sessions, you can participate in the advisory council without missing a technical presentation.

#### Poster Contest Judging, Best of Show

Exhibit Hall  
12:15 p.m.

#### Student Career Forum

3 to 5 p.m. • Exhibit Hall AB1

Organized by the TMS Young Leader Committee, this session will feature a panel of speakers from a variety of materials science backgrounds and career stages who discuss how to navigate a career path to ultimate goals.

#### Early Career Panel

Brad Boyce, *Sandia National Laboratories, USA*  
Eric Brown, *Los Alamos National Laboratory, USA*  
Amy Clark, *Los Alamos National Laboratory, USA*  
Rachel DeLucas, *H.C. Starck, USA*  
Paul Edwards, *Boeing Research and Technology, USA*  
Julia Greer, *California Institute of Technology, USA*  
Subu Nayak, *Science Tomorrow, LLC, USA*  
Greg Thompson, *University of Alabama, USA*  
Dallas Trinkle, *University of Illinois Urbana-Champaign, USA*  
Ben Poquette, *GE Healthcare, USA*

#### A Note to Student Monitors:

Report to the Programming Desk at 7:15 a.m. each day you are scheduled to monitor session(s) to receive your assignments. There will be a training session each day at 7:50 a.m. After receiving your assignments, you should go to authors' coffee to meet with your session chair(s).

# The Valuable Resource that Keeps on Giving...

## TMS 2011 Annual Meeting Proceedings

The following proceedings volumes are available from the TMS 2011 Annual Meeting:

- 2nd International Symposium on High-Temperature Metallurgical Processing
- Energy Technology 2011: Carbon Dioxide and Other Greenhouse Gas Reduction Metallurgy and Waste Heat Recovery
- EPD Congress 2011
- Friction Stir Welding and Processing VI
- Light Metals 2011
- Magnesium Technology 2011
- Recycling of Electronic Waste II, Proceedings of the Second Symposium
- Sensors, Sampling and Simulation for Process Control
- Shape Casting: Fourth International Symposium 2011
- Supplemental Proceedings: Volume 1: Materials Processing and Energy Materials
- Supplemental Proceedings: Volume 2: Materials Fabrication, Properties, Characterization, and Modeling
- Supplemental Proceedings: Volume 3: General Paper Selections

Attendees may purchase books at the Wiley Bookstore, located in the ground level lobby of the San Diego Convention Center. After the conference, orders can be placed at [www.wiley.com](http://www.wiley.com).

### Collected Proceedings CD-ROM

A collected proceedings CD-ROM containing select TMS 2011 presentations is available free of charge for all full conference registrants including TMS members, senior members, recent graduates, nonmember authors, nonmembers and exhibitors. This valuable resource offers endless use for future research and educational purposes.

Additional copies of the Collected Proceedings CD-ROM may be purchased on the Registration Form and will not be available after the meeting. The cost is \$150, with a special student rate of \$75 plus 8.25% California sales tax. All CD-ROMS must be picked up at the meeting. Shipping is not available.

## TMS 2010-2011 Leadership Executive Committee

### President:

George T. "Rusty" Gray III,  
Los Alamos National Laboratory, USA

### Past President:

Ray D. Peterson,  
Aleris International Inc., USA

### Vice President:

Garry Warren,  
University of Alabama – Tuscaloosa, USA  
Wolfgang Schneider,  
Hydro Aluminum GMBH (incoming), Norway

### Financial Planning Officer:

Stanley Howard,  
South Dakota School of Mines and Technology, USA

## FUNCTIONAL AREA DIRECTORS

### Professional Development

David Shifler, Office of Naval Research, USA

### Membership and Student Development

Ellen K. Cerreta, Los Alamos National Laboratory, USA

### Programming

Hani Henein, University of Alberta, Canada

### Information Technology

Nikhilesh Chawla, Arizona State University, USA  
Jud Ready, Georgia Institute of Technology, USA  
(incoming)

### Public and Governmental Affairs

Kevin J. Hemker, Johns Hopkins University, USA

### Publications

Elizabeth Holm, Sandia National Laboratories, USA  
Carl Cady, Los Alamos National Laboratory, USA  
(incoming)

## TECHNICAL DIVISION DIRECTORS

### Electronic, Magnetic & Photonic Materials

Zi-Kui Liu, The Pennsylvania State University, USA  
Srinivas Chada, Henkel of America (incoming), USA

### Extraction & Processing

Thomas P. Battle, Midrex Technologies, USA  
Adrian C. Deneys, Praxair, Inc, USA (incoming)

### Light Metals

John N. Hryn, Argonne National Laboratory, USA

### Materials Processing & Manufacturing

James W. Sears, South Dakota School of Mines & Technology, USA

### Structural Materials

Dennis M. Dimiduk, U.S. Air Force Research Laboratory

## TMS 2010 ANNUAL MEETING TECHNICAL PROGRAM COMMITTEE

### Director/Chairperson:

Hani Henein, University of Alberta, Canada  
Electronic, Magnetic & Photonic Materials Division

### Electronic, Magnetic & Photonic Materials Division Representatives:

Long Qing Chen, The Pennsylvania State University, USA  
Sung K. Kang, IBM, USA  
Mark A. Palmer, Kettering University, USA

### Extraction & Processing Division Representatives:

Boyd R. Davis, Kingston Process Metallurgy, Canada  
Jian Li, Natural Resources Canada

### Light Metals Division Representatives:

Alan A. Luo, General Motors Corp., USA  
Eric A. Nyberg, Pacific Northwest National Laboratory, USA

### Materials Processing & Manufacturing Division Representatives:

Corbett C. Battaile, Sandia National Laboratories, USA  
Thomas R. Bieler, Michigan State University, USA  
Amit Misra, Los Alamos National Laboratory, USA

### Structural Materials Division Representatives:

Robert J. Hanrahan, Jr., National Nuclear Security Administration, USA  
Eric Allen Ott, GE Aviation, USA  
Judy Schneider, Mississippi State University, USA

25th Exhibition Anniversary

# TMS 2011

## 25th EXHIBITION

February 27 - March 3, 2011 • San Diego Convention Center  
San Diego, California USA

### **Exhibit Hours**

Monday, February 28 ..... Noon to 6:30 p.m.  
Tuesday, March 1 ..... 10:30 a.m. to 6 p.m.  
Wednesday, March 2 ..... 10:30 a.m. to 3 p.m.

### **Table of Contents**

Exhibiting Companies ..... 22  
Exhibit Floor Plan ..... 23  
Products & Services Index ..... 24  
Company Descriptions ..... 25  
Sponsors ..... Inside Front Cover

# TMS2011

## 140th Annual Meeting & Exhibition

### Exhibiting Companies

(as of January 18, 2011)

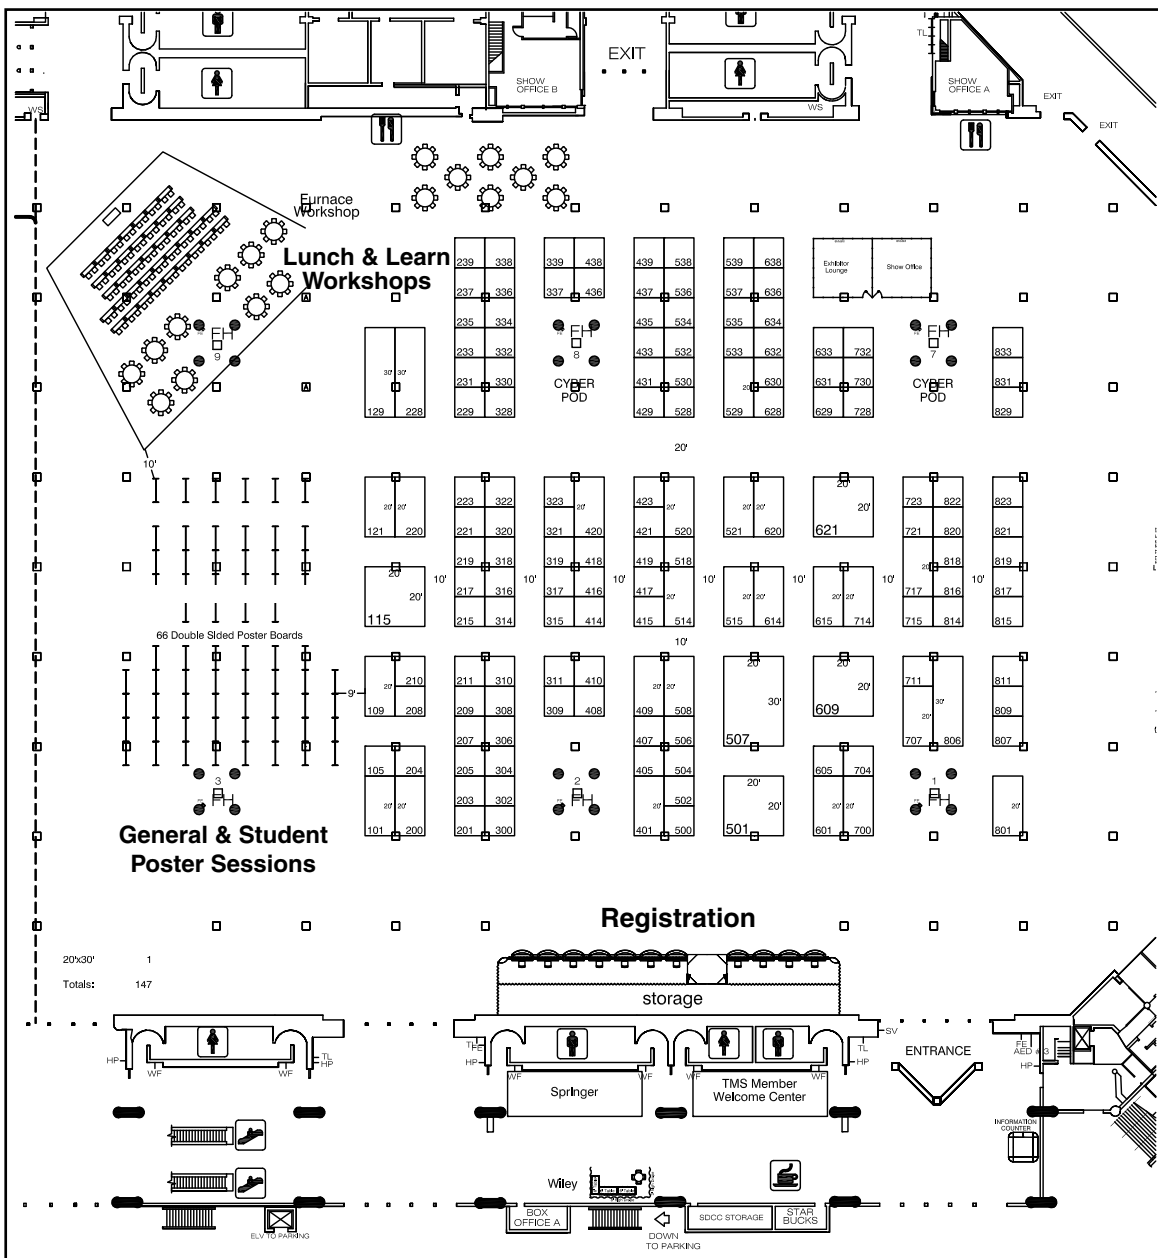

| Company   | Booth number | Company  | Booth number |
|---|--------------|--|--------------|
| ABB Bomem   | 700          | Hertwich Engineering                             | 506          |
| Advanced Dynamics   | 807          | Hysitron   | 614          |
| Agilent   | 420          | Innovatherm                                      | 429          |
| Almeq Norway AS   | 515          | IPI (Initiatives et Projets Industriels)         | 817          |
| Almex USA   | 321          | Jervis B. Webb Company                           | 508          |
| Alstom  | 529          | John Wiley & Sons, Inc.                          | Lobby        |
| Aluminium International Journal                           | 308          | Kempe Engineering                                | 514          |
| Aluminium International Today                             | 721          | L.P. Royer, Inc.                                 | 414          |
| Aluminium Network   | 304          | Light Metal Age                                  | 417          |
| Aluminum Times  | 518          | Major  | 811          |
| ATR National Scientific User Facility                     | 405          | Maney Publishing                                 | 304          |
| AUMUMD Holding BV   | 504          | Metal 7  | 306          |
| B&P Process Equipment                                     | 801          | Metallurgy and Materials Society of CIM (MetSoc) | 723          |
| Beijing General Research Institute of Mining & Metallurgy | 728          | Micro Materials                                  | 818          |
| Big C   | 823          | Microtrac  | 630          |
| Bloom Engineering   | 821          | Momentum Press                                   | 416          |
| Boreal Laser  | 629          | MTI Corporation                                  | 528          |
| BUSS ChemTech   | 520          | MTS Systems, Inc.                                | 819          |
| C A Picard Intl   | 221          | NFC  | 521          |

## Company Descriptions

### ABB

ABB Analytical Business Unit designs, manufactures and markets high-performance analytical system solutions and spectroradiometers for petroleum, chemical, life science, semiconductor, metallurgy and remote sensing/aerospace markets. Building on its 37 years of experience in analytical instrumentation, the company's dedicated team of engineers offers the best solutions with its complete range of reliable analytical instruments for inclusions and dissolved hydrogen measurement: AISCAN, LIMCA II, LIMCA CM, Prefil®-Footprinter, PoDFA and Metallographic Analysis Service.

### Advanced Dynamics

For over four decades, Advanced Dynamics (ADCL) has supplied our global customer base with state-of-the-art material handling systems for carbon plants and cast houses. Our handling technology includes fully automated or semi-automated equipment for anode handling and cleaning, aluminum ingot and T-Bar handling, sawing and packaging systems. We also have experience in specialty systems for the magnesium, copper, zinc, steel and lead industries.

ADCL is a one-stop shop for your material handling needs including mechanical and controls engineering, fabrication, assembly, test and commissioning. Whether you need a new system or upgrades to existing systems or simply individual pieces of equipment, we can help improve your company's productivity. Remember "Our ingenuity delivers productivity" when you think of ADCL for your next project.

### Agilent Technologies

Agilent Technologies, the premier measurement company, offers a wide range of high precision measurement and imaging systems to meet your unique research needs. Agilent's industry-leading nanomechanical testing systems are the world's most accurate flexible and user friendly for nanoscale mechanical testing. Electromagnetic actuation technology allows the systems to achieve unparalleled dynamic range in force and displacement.

Agilent is introducing the compact 8500FE-SEM that has been optimized for low-voltage imaging, extremely high surface contrast, and resolution typically found only in much larger and more expensive field emission microscopes. About the size of a laser printer, the easy-to-install 8500 provides convenient plug-and-play performance. No dedicated facilities are required, only an AC power outlet. The novel scientific-grade system offers several imaging techniques for enhancing surface contrast allowing nanoscale features to be observed. Please stop by the booth for a demonstration.

### Alstom

Alstom is a global leader in the world of power generation, power transmission and rail infrastructure and sets the benchmark for innovative and environmentally friendly technologies.

Alstom builds the fastest train and the highest capacity automated metro in the world. It provides turnkey integrated power plant solutions and associated services for a wide variety of energy sources, including hydro, nuclear, gas, coal and wind, and it offers a wide range of solutions for power transmission, with a focus on smart grids. The Group employs 96,500 people in more than 70 countries, and had sales of over 23 billion\* in 2009-10. (\*Pro forma figures)

### ALUMINIUM International Journal

(Giesel Verlag GmbH)

ALUMINIUM International, journal for industry, research and applications, is the leading international journal (bilingual: German/English) for more than 80 years.

It deals with everything that concerns the material—its extraction, processing, recycling and applications. Matters of economics and the ecological consequences of using aluminium are also considered. The scope of the month-by-month reporting includes scientific contributions and condensed information about new technologies and applications. The journal addresses aluminium producers, semis manufacturers, foundries, processors, metal and semis traders and, not least, research institutes concerned with aluminium. ALUMINIUM is circulated in over 40 countries worldwide – made in Germany, distributed to the world. [www.giesel-verlag.de](http://www.giesel-verlag.de)

### Aluminium International Today

Aluminium International Today is the aluminum industry's leading international publication reporting on aluminum production and processing. Founded in 1989, it provides a wealth of technical features aimed at equipping producers and processors with information on latest developments. Added to this is a digest of industry news, contracts, events, new technology, and conference reports.

Supported by the Aluminium Federation in the UK, Aluminium International Today publishes six times a year in English plus two Chinese issues and two Russian issues. It is the main sponsoring publication for the ALUMINIUM series of exhibitions and conferences in Essen, Shanghai, Mumbai and Chicago. [aluminium@quartzltd.com](mailto:aluminium@quartzltd.com), web [www.aluminiumtoday.com](http://www.aluminiumtoday.com).

### Aluminium Network

**Booth #304**

A Global Network for the Primary Aluminium Industry aluminiumNetwork.com is your internet based portal to supply and support you with a wide range of services; your meeting place with like-minded partners who can assist in improving your business and accelerate your project.

The main focus of aluminiumnetwork.com is the primary aluminum industry and it is aimed particularly at:

- Primary producers
- Suppliers of raw materials or intermediates
- Equipment suppliers
- Providers of services, including consulting services and project support.

The AluminiumNetwork.com Consultants / Freelancers data base is the perfect source for independent expertise in all of the engineering disciplines, from alumina through to primary aluminum production, including all the support functions of the process. By providing a global platform, AluminiumNetwork.com is THE place to meet with Consultants and Freelancers within the primary aluminum industry. The clients of AluminiumNetwork.com will have access to the Consultants and Freelancers database and will be able to select their required need by qualification and skills.

Please visit [www.AluminiumNetwork.com](http://www.AluminiumNetwork.com) for detailed information

### Aluminum Times

**Booth #518**

### ATR National Scientific User Facility

**Booth #405**

The ATR National Scientific User Facility offers materials science engineers and scientists the opportunity to test materials in an irradiation environment and perform analyses on the irradiated specimens. Capabilities available include three test reactors and a host of post irradiation examination facilities across the United States. Non-proprietary research is cost free to U.S. university led teams.

Access to facilities is through a solicitation and review process. The kinds of research solicited include, but are not limited to, advanced materials for high performance reactor systems, understanding light water reactor core materials including austenitic steels and nickel alloys, determining properties of material joints after exposure to a neutron irradiation environment and the applicability of nanostructured materials to radiation resistant applications. To learn more about ATR NSUF, please visit our website at: <http://atrnsl.inl.gov>.

### AUMUMD Holding BV

**Booth #504**

### B&P Process Equipment

**Booth #801**

At B&P Process Equipment, we take our traditional strengths in engineering high-precision, high-reliability machines and add a customized dimension of innovation. We are manufacturers of Continuous anode paste mixers used in Primary aluminum production.

Our new generation mixers have become more nimble, more agile and versatile. Increased efficiency, improved wear life and greater anode density are the benefits of a B&P system. Instead of trying to keep up as your needs change, we're becoming the driving force of change itself. Our products are customer-driven. Each machine is engineered to solve specific problems, meet unique challenges and seize opportunities!

We made the first batch mixer used in anode Paste mixing in 1897. For over 120 years, customer satisfaction has remained the hallmark of the B&P name. Today, when it comes to anode paste mixers, No other supplier brings the longevity, performance and experience that B&P offers the world over.

### Beijing General Research Institute of Mining & Metallurgy

**Booth #728**

BGRIMM is a premier Chinese technology corporate delivering innovative technologies, diverse products, quality engineering and project management in mineral and material industries. Established as a research institute in 1956, BGRIMM quickly built a reputation for providing technical support in the mining and metallurgy industry. Since 1999, BGRIMM became a large state technology corporation directly under SASAC (State-owned Assets Supervision and Administration Commission of the State Council). Today, BGRIMM has grown into a multi-disciplined technology corporate primarily engaged in providing integrate solutions, advanced material technology and products, and effective engineering service to clients in mineral and material industries.

For the aluminum industry, BGRIMM developed aluminum alloy tablets in 1988, which were then protected by two patents. Ever since then BGRIMM has been delivering the high quality and environmentally-friendly products and most conscientious service. BGRIMM will continue to invest on research and development, manufacturing technology and capacity to support our customers around the world.

### Big C

**Booth #823**

Big C offers the Dino-Lite Portable Digital Microscope, which provides high-quality microscopy video interfacing to PC and MAC with clear and steady imaging and 10X-200X magnification. The included software "DinoCapture" makes it easy and convenient to take snapshots, record videos, manipulate images, and save and e-mail discoveries. It is a single lens device with diverse applications.

## Company Descriptions

### Bloom Engineering

Booth #821

### Boreal Laser

Booth #629

Boreal Laser makes GasFinder laser based toxic and hazardous gas detectors that are used in a variety of open path (ambient, environmental and safety), stack, vent and process monitoring applications. Portable GasFinders are light, battery operated and easy to set up and use. Multiple path/point GasFinder MC systems can monitor up to eight paths or points with a single analyzer. Both portable and fixed GasFinders are self-calibrating, robust, reliable and maintenance free. GasFinders benefits also include fast one second response, lack of interference from other gases and low cost of ownership. GasFinders are currently available for hydrogen fluoride (HF), hydrogen chloride (HCl), hydrogen sulfide (H<sub>2</sub>S), ammonia (NH<sub>3</sub>), methane (CH<sub>4</sub>), carbon dioxide (CO<sub>2</sub>), hydrogen cyanide (HCN), ethylene (C<sub>2</sub>H<sub>4</sub>) and acetylene (C<sub>2</sub>H<sub>2</sub>). Typical applications include Aluminum smelting, Refineries (esp. HF Alkylation), Petrochemical and Chemical Plants, Gas Production and Processing, Green House Gas applications, plus Bricks and Ceramics.

### BUSS ChemTech

Booth#520

### CANMET Natural Resources Canada Booth #530

In collaboration with industry, CANMET-MTL a Federal laboratory of Natural Resources Canada, develops and deploys technologies to improve all aspects of producing and using value-added products from minerals and metals. Specifically, CANMET-MTL focuses on research related to metal processing (casting, forming, joining, advanced materials and prototype development) and maintains in-depth competencies for materials assessment (microstructural characterization, corrosion, physical and mechanical testing) to:

- Achieve higher performance from metal alloys and metal- or mineral-based materials for a wide range of end-use applications
- Develop advanced materials for next-generation vehicles
- Improve the reliability of the energy infrastructure, such as oil and gas pipelines and nuclear power generation systems
- Develop specialized materials for current and future industrial systems to help companies use energy efficiently and reduce air emissions and waste
- Provide sound technical input to standards and codes development
- Promote innovation and enhance the competitiveness of Canada's value-added and related product industries
- Assist firms to use more efficient production techniques, resulting in energy and cost savings.

### C.A. PICARD International

Booth #711

C.A. PICARD is specialized in manufacturing of high quality wear parts for continuous kneaders for the manufacture of green anodes for the primary aluminum industry.

PICARD manufactures kneading teeth, wearing plates / liners and screw flights out of high wear resistant qualities.

### Center for Advanced Energy Studies

Booth #336

The Center for Advanced Energy Studies is a research partnership between Boise State University, Idaho National Laboratory, Idaho State University and University of Idaho.

### Chongqing Runji Alloys/OKAYA

Booth #809

We specialize in producing all kinds of alloying tablets. We are continuing to improve, modernize and expand our company's production capacity in order to increase productivity and efficiency. This includes the acquisition last year of the biggest Mn ore mines in Jingxi County, Guangxi province of China. The capacity of this Mn ore mine is more than 3 million tons and our new production line of Mn flakes has also been completed. The new capacity is 30,000 tons per year. With the development of these programs along with our state-of-the-art production management, technologies and facilities, we can guarantee enough raw material supply at very competitive price levels while maintaining our high level of quality.

Information about our partners: Okaya (U.S.A.), Inc. is an international trading house that provides representation in North America for Chongqing Runji Alloy Company, LTD. This partnership is an example of Okaya's expansion of our business domain from its core area of iron and steel to various related fields of business. We can also perform marketing, logistics and processing functions to fulfill our role as the "Best Global Sourcing Partner". As an independent trading company with a high level of flexibility, Okaya will continue to propose insightful and creative business opportunities by looking at various areas with a broad perspective.

Also visit us online at [www.okaya.co.jp/en](http://www.okaya.co.jp/en)

## Company Descriptions

### CIMM Group

**Booth #815**

As the company certified by ISO 9001:2008 and the International Projects Contractor accredited by P.R.China, CIMM GROUP is a healthy and fast growing integrated multinational corporation professionally engaged in providing technology, engineering, manufacturing, trade and EPC service in fields of aluminum and Steel, Mineral, Metals and Metallurgy, cement and construction, refinery and petrochemical, ports and shipyards, oil and gas, power generation and transmission, green resource, and energy, etc.

Our main products for aluminum smelting is Anode blocks, Cathode blocks, Aluminum fluoride, cryolite, silicon nitride bonded silicon carbide blocks, refractory bricks, insulations bricks, CPC, silicon metal, aluminium tablets, etc. which have been supplied to overseas market to establish good and steady relationships with Greece, Brazil, Australia, Egypt, India, Kazakhstan, Turkey, Dubai, etc. The supplied products have a great reputation among our customers. CIMM GROUP is always committed to be a trustworthy business partner.

### Claudius Peters Projects GmbH

**Booth#419**

### Colt

**Booth #302**

Colt is a global supplier and manufacturer of natural and mechanical ventilation systems.

The principal activity of Colt is the supply of specialist products and systems in the field of building services with particular emphasis on gravity ventilation and the environmental control of industrial and commercial buildings. Especially for the aluminum industries, Colt is supplier of Static roof Ventilators and air intake louvers for potroom buildings, anode bake buildings and cast houses. The product folio also includes perforated, reinforced fiber walls.

#### MISSION STATEMENT:

Our vision is to make the world a better place in which to live and work by helping to make the environment associated with buildings healthy, safe, productive and comfortable.

### Computherm

**Booth #309**

### Conductix-Wampfler

**Booth#204**

Conductix-Wampfler is the world's leading designer and manufacturer of energy and data transmission products. We have specific expertise in "mill-duty" conductor bar, cable festoon systems, cable reeling equipment, and cable chain systems. Our rugged products have been field-tested in the most demanding environments. We also design and build custom slip rings for pot line cranes, rotary casters, and similar equipment. Lastly, we offer a series of push button

pendants and radio controls designed for mill use. And we can service what we sell, too, to keep you operations running 24/7/365. If you want the right solution for the applications, contact Conductix-Wampfler. We Move Your Business!

### CSM Instruments

**Booth#310**

### Cytec Industries

**Booth #620**

Cytec collaborates with mining companies to optimize their operations through the delivery of innovative chemical technologies. We utilize our superior application expertise to develop solutions based on our customer's specific needs.

We offer technologies that:

- Decrease the cost of operations
- Provide better recovery and selectivity
- Process difficult ores
- Prevent or limit employee's exposure to hazards
- Optimize the use of natural resources
- Minimize waste and re-tooling
- Do not require on-staff scientists or engineers

Cytec is committed to partnering with our customers to meet their needs. Our network of technical staff provides on-site technical assistance worldwide. We are dedicated to on-time delivery, even to the worlds harder to reach areas. Our unique approach to servicing our customers has made Cytec the leading provider of reagents to the mining industry.

### Dantherm Filtration

**Booth #314**

Dantherm Filtration / Nederman is a leading supplier of Dust Control and Air Pollution Control solutions for a wide range of industries all over the world. Dantherm Filtration focuses on individual solutions for individual customer needs. Since May 2010 Dantherm Filtration is part of the Swedish Nederman Group. We combine the experience and expertise of the internationally recognized suppliers to provide the customers with high efficiency, unbeatable reliability, low energy consumption, and full compliance with all mandatory requirements. Our focuses are: Foundry industry, non iron-industry, quarry industry, asphalt industry, primary and secondary aluminum industry, waste incineration and waste to energy industry and Cement industry. Our reference list reflects more than 40 years of experience and broad application expertise.

### Dubai Aluminium Company

**Booth #717**

Dubai Aluminium Company Limited ("DUBAL") owns and operates one of the world's largest primary aluminium smelters. The DUBAL complex comprises a 990,000 mtpa smelter, a 2,350 MW power station (at 30°C), a large carbon plant, casthouse operations, a water desalination plant, and other facilities.

High quality aluminum products are made in three main

## Company Descriptions

forms: foundry alloy for automotive applications; extrusion billet for construction, industrial, transportation and forging purposes in automotive industries; and high purity aluminum for electronics and aerospace. More than 250 customers are served in at least 45 countries predominantly in the Far East, Europe, the ASEAN region, the MENA region, and North America. The company holds ISO 9001, ISO/TS 16949, ISO/IEC 27001, ISO/IEC 20000, ISO 14001 and OHSAS 18001 certification. Over 4,000 people are employed, 22% of whom are UAE Nationals. DUBAL also owns 50% of Emirates Aluminium Company Limited ("EMAL"), a green-field smelter development at Al Taweelah, Abu Dhabi.

### EBSD Analytical

**Booth #217**

EBSD Analytical offers micro structural analysis services specializing in EBSD and EDS. With over 15 years experience in EBSD, we guarantee the highest quality results with a quick turnaround.

We also specialize in preparation of difficult materials for EBSD analysis. Call us today to see how we can help with your specific needs, whether it is grain size, texture, misorientation, phase ID, local deformation, or any number of additional applications.

### ECEFast

**Booth # 219**

Temperature sensor manufacturer making "Excalibur" fully swaged sensor for Carbon Bake Furnace Flue application. Featuring long life with zero maintenance, unbreakable and not prone to distortion, the Excalibur offers the lowest cost of ownership of any sensor used in this application to 1190C. Supplied normally in N to provide minimum drift over the operating life, but K is available. Cost is somewhat higher than Inconel 601 tube + wire & bead, but life is more than double with no insert replacement. [www.ecefast.com.au](http://www.ecefast.com.au)

### ECL

**Booth #500**

With over 60 years experience, ECL is the world leading smelter equipment manufacturer with a long time dedication to the aluminum industry. ECL offers complete solutions for the smelter's reduction, carbon and metal sectors.

From design and manufacturing to erection, through training, maintenance, audit and refurbishment, ECL provides products and services adapted to the needs and demands of its customers, whatever the reduction technology. A high level of innovation and an unmatched expertise allow ECL to offer solutions, from single machines to complete turnkey projects that help aluminum smelters in their productivity and HSE efforts.

### EDAX

**Booth #223**

EDAX is the technical innovator and the world's largest supplier of EDS, EBSD, WDS and Micro-XRF systems. Smart Features are at the core of our new TEAM EDS system providing analytical intelligence to easily obtain exceptional results. EDAX's EBSD Data Collection provides a powerful and easy to use environment for acquiring EBSD data in the SEM. The EBSD Analysis has virtually unlimited potential for interrogating the wealth of information contained in EBSD data. EDAX offers detector solutions to meet all your EBSD needs. Combined with the power of WDS to enhance qualitative and quantitative analysis, EDAX provide today's scientist with the ultimate materials characterization solution, offering vastly improved speed and accuracy. Orbis provides analytical flexibility for MicroXRF applications. EDAX products provide a powerful and unique combination of elemental and structural information providing a complete solution.

Trident Image Caption: Trident is the ultimate materials characterization tool integrating the latest technologies of EDS, EBSD and WDS. [www.edax.com](http://www.edax.com)

### Eirich Machines, Inc.

**Booth #315**

### ENERGOPROM Group

**Booth #530**

ENERGOPROM MANAGEMENT (EPM) is one of the most efficient companies in non-raw material sector of the Russian economy. We are doing business all over the world, supplying more than 50% of our carbon and graphite products to the world market. EPM's Novochoerkassk, Novosibirsk and Chelyabinsk electrode plants manufacture graphite and carbon products for the steel, aluminum, silicon, ferroalloy and other industries. All enterprises of the Company are furnished with up-to-date and highly productive equipment. Our products and applied technologies have no comparison in the world. Our products satisfy the requirements of world standards. In order to boost our competitive capacity, our plants have been comprehensively modernized and rebuilt. We have built new facilities to meet the requirements of the most advanced metallurgical producers, as well as to satisfy the growing global demand for carbon and graphite products.

## Company Descriptions

### Evans Analytical Group

Booth #311

Evans Analytical Group (EAG) is the leading provider of surface analysis and materials characterization services to the materials supply chain and to high technology industries. We specialize in providing the widest range of characterization techniques available, such as GDMS, ICPMS, SIMS, SEM, (S) TEM (including EELS and EDS), Auger, XPS and XRD, via our network of laboratories in North America, Asia and Europe.

Our aim is to provide our customers with the most reliable, highest quality data as quickly as possible, to enable them to meet their goals regarding materials development and process optimization. EAG is certified to ISO17025 and ISO9001.

### Fives Solios

Booth #609

FIVES SOLIOS is one of the companies of Fives, a major International Group, with considerable experience in industrial engineering and management of large projects all over the world. Fives Solios is specifically dedicated to the Aluminium Industry and develops innovative solutions in order to comply with more and more stringent environmental standards while increasing safety and reliability. Fives Solios most particularly works on reducing energy consumption in its process technologies.

- Reduction: Gas Treatment Centers on electrolysis pots and Bath Processing Units.
- Carbon: High Capacity Green Anode Plants, Pitch storage and processing, Liquid Pitch Marine Terminal, Firing & Control Systems for anode baking furnaces, and Fume Treatment Centers on anode baking furnaces.
- Casthouse Area: Melting and Holding furnaces including water cooling systems as well as integration of downstream casting machines, Heat Treatment furnaces for rolling mills and associated control systems.

[www.fivesgroup.com](http://www.fivesgroup.com)

### FLSmidth

Booth #714

FLSmidth is your major equipment supplier from Bauxite Mining and Refining through Calcination and Smelting. Every day, worldwide, our equipment crushes, conveys, grinds, digests, clarifies, precipitates, stores, and calcinates bauxite to produce alumina. Combining the respected brand names of MÖLLER, KOCH-MVT, FULLER-TRAYLOR, WEMCO, EIMCO, DORR-OLIVER, PNEUMAPRESS, KREBS, ABON, RAHCO, CEntry, Conveyor Engineering and Raptor, FLSmidth offers a broad range of equipment and processes while increasing recoveries, lowering energy consumption, and providing proven reliability. We also offer metallurgical testing utilizing the expertise of FLSmidth Dawson's metallurgical laboratories. FLSmidth is your One Source, One Partner providing integrated solutions that will save you valuable time on your project schedule!

### Friggi

Booth #316

Friggi is a manufacturer of high quality band saws, waterjets and plasma machines. Specialized high-speed machines for rapid cutting of aluminum with tight tolerances.

### Gautschi Engineering GmbH

Booth#317

Gautschi Engineering GmbH is a leading supplier of equipment for primary aluminum casthouses and recycling plants. The product range of Gautschi™ includes:

- Melting – and holding furnaces
- Pusher-type furnaces for rolling slab
- Homogenizing furnaces for extrusion billet and rolling slab
- Multiple chamber furnaces for coil and foil annealing
- Single coil annealing furnaces
- Horizontal D.C. casting plants
- Open mould ingot casting and stacking plants
- Vertical D.C. Casters for extrusion billet and rolling slab
- AIR GLIDE® and AIRSOL VEIL® mould technology

### Gillespie & Powers, Inc.

Booth #806

### GLAMA

Booth #615

### Gouda Refractories

Booth #415

Gouda Refractories is an innovative refractory producer (refractory bricks, castables, mortar, self-flowing castables, complex pre-cast shapes) with global experience and a long track record of supplying superior quality refractories all over the world, combined with innovative installation technology for more than 100 years.

Gouda Refractories develops, manufactures, sells and installs top quality refractory linings. Gouda's solutions play an important role in, non-ferrous metal (mainly aluminium), petrochemical, environmental and energy industries. Based on an industry-oriented structure and highly competent employees, Gouda Refractories guarantees an optimal support which results in efficiency and reduction of refractory cost. Gouda Refractories supplies total solutions to customers which are cost effective, state of the art, and reliable. Gouda's R&D department is conducted in close co-operation with its customers and renowned research institutes. Gouda's quality assurance is based on the international ISO 9001 standard.

## Company Descriptions

### Hebei Sitong New Metal Material Co., Ltd

**Booth #109**

As the leading excellent manufacturer of master alloy in China, we mainly produce the followed items:

- Aluminum master alloy: AlTi5B1 AlTi10,AlSr10,AlZr10,AlMn20,AlB4,AlV5
- Shape:Coil, Cut Rod, Waffle, Ingot
- Application: Widely applied in manufacture of Aluminum Profile,Strip, Foil, Castings Electricity, Automobile, Aerospace etc.

This booth is presented in cooperation with Leway International Fairs, one of the leading international exhibition agencies in China. Located in Beijing, Leway has served in over 500 important overseas exhibitions in its eight-year history and has served nearly 2,000 Chinese companies. Leway provides comprehensive one-stop solution services for Chinese companies.

### Hencon

**Booth #300**

A profound knowledge of special vehicles, over 50 years of experience, creativity, robustness, stamina and entrepreneurship makes Hencon a world leader in the design, manufacturing and service of special vehicles in the aluminium industry.

### Hereaus Electro-Nite

**Booth #621**

### Hertwich Engineering

**Booth #506**

### Hysitron

**Booth #614**

As world leader in nanomechanical testing, Hysitron is dedicated to providing testing solutions for nanoscale mechanical characterization. Hysitron's nanomechanical test instruments provide high-speed in-situ SPM imaging in addition to the quantitative measurement of many mechanical properties, including hardness, modulus, fracture toughness, and wear resistance. Our instruments feature advanced techniques such as nanoDMA™ for time dependent and viscoelastic materials, Modulus Mapping for quantitative large area property mapping, and nanoECR™ enabling simultaneous electrical and mechanical property measurements. We are excited to demonstrate the TI 950 Tribolndenter™ nanomechanical test system featuring 25x faster feedback, a nanoNewton to Newton force range, and an unprecedented <30nN noise floor. Stop by our booth to see how the TI 950 redefines the world of nanomechanical testing. Hysitron will also be showcasing the PI 95 and PI 85 PicoIndenter™, the truly quantitative depth-sensing indenters capable of direct-observation testing inside a TEM and SEM.

### Light Metal Age

**Booth #417**

Light Metal Age is the pre-eminent magazine of the light metal world. For over 69 years, Light Metal Age has covered primary production and semi fabrication of the light metals aluminum, titanium, and magnesium. Circulation is international and goes to primary and secondary smelters; casthouses; extrusion operations; rolling mills; sheet, rod, and wire mills; and foundries. Coverage of associated metal processes and equipment includes DC casting, anodizing, furnaces and melting, degassing and filtration, automation and instrumentation, and handling. Recipients are executives, general managers, plant managers, technicians, metallurgists, chemists, and engineers responsible for fabrication, production, and operations.

Light Metal Age also produces select article archive content on CDs, including the Titanium Article Archives (Nov. 1945 – Aug. 2009) and the Magnesium Article Archive (May 1943 – April 2009). For more information, visit Light Metal Age on the web at [www.lightmetalage.com](http://www.lightmetalage.com).

### L.P. Royer, Inc.

**Booth #414**

### Major

**Booth #811**

### Maney Publishing

**Booth #304**

Maney delivers a personalized service to authors, societies, readers and libraries for the publishing and international dissemination of high quality, peer-reviewed scholarship and research.

Specializing in print and electronic journal publishing, Maney is committed to technical and editorial innovation combined with traditional values of quality and collaboration. Maney publishes an impressive collection of highly regarded, peer-reviewed journals covering both niche and general topics in materials science and engineering. Coverage ranges from fundamental research to engineering application and from the extraction and refining of minerals to the characterization, processing and fabrication of materials and their performance in service.

## Company Descriptions

### Metal 7

Metal 7 has been providing services to the primary industry since February 1974, specializing in the design and production of high performance equipment for the primary sector. Metal 7 has a very sound knowledge of the iron ore, aluminum smelter and pulp and paper industries. It distinguishes itself from its competitors due to its expertise in surface engineering. Thanks to its leading expertise, the company stands out from its competitors by proposing extremely sophisticated, high-performance solutions. This competitive edge allows the company to thrive on the international market with numerous important companies in the metallurgical sector, like Aluminerie Alouette, Rio Tinto, ArcelorMittal, Outotec, etc.

Each year, Metal 7 invests important sums in research and development (R&D). These investments are targeted towards developing new coatings and new applications for those coatings, as well as improving the manufacturing processes and the products made by Metal 7.

### Metallurgy and Materials Society of CIM

### Booth #306

### Booth #723

We are a world class Canadian organization that serves society and the needs of professionals in the global metallurgy and materials community. The purpose of MetSoc is to serve our members, society and others involved in the research, development and application of the science and technologies for the environmentally responsible extraction, fabrication, utilization and recycling of metals and materials.

### Micro Materials

### Booth #718

The NanoTest system from MML offers a range of methods of materials characterization, including nanoindentation, nano-impact and nano-scratch and wear measurements.

In recent years, MML have pioneered nanomechanical testing in real-world conditions. The NanoTest offers unique testing modules, among them the high temperature testing module, which allows testing of a sample heated up to temperatures of 750°C.

### Microtrac

### Booth #630

Our focus is rapid particle size analysis utilizing advanced solid state tri-laser technology. The S3500 line of particle size analyzers provide the broadest size range with compact design from .02 to 3000 microns. Features include rapid wet to dry conversion, advanced Flex software, small footprint, and TurboTrac dry feeder. The NanoTrac Dynamic Light Scatter units are available for nanometer sizing, while the Ultra is for low concentration < 20nm applications. New Blue Laser Technology "Bluewave" next generation is here. Zeta potential, surface area and imaging systems will also be shown.

### Momentum Press

### Booth #416

Momentum Press provides the very best information and knowledge on today's advancements in science, engineering, and applied technology. We publish books in traditional print, as well as electronically, for practitioners, researchers, educational faculty, and students. Some of our bestselling titles include: Alarm Management for Process Control by Doug Rothenberg; Protecting Industrial Control Systems from Electronic Threats by Joe Weiss; and Characterization in Silicon Processing by Yale E. Strausser. We are happy to publish individual authors as well as to work with schools and institutions in publishing such collective works as proceedings, seminar materials, and various types of instructional tools. We have sales offices throughout the world, with a particularly strong presence in Asia, North America, and Latin America, as well as Europe and the Middle East.

### MTI Corporation

### Booth #528

### MTS Systems Corporation

### Booth #819

Engineers and researchers worldwide rely on MTS for the testing technology and expertise required to support the research and development of advanced metals, composites and ceramics. Reliable, high-performance MTS solutions are deployed across a diversity of industries such as aerospace, power generation, civil engineering and automotive, accurately and efficiently meeting the most demanding materials testing requirements.

The MTS portfolio is engineered to address a full spectrum of materials testing requirements - from tension/compression to fracture mechanics to complex multi-axial fatigue studies at elevated temperatures. This portfolio features: high-performance servohydraulic and electromechanical testing systems; versatile, high-resolution controls; proven application software; precision accessories; robust environmental simulation systems; and unmatched service and support.

Explore the MTS booth and discover how innovative MTS test solutions and decades of industry expertise can optimize the effectiveness and efficiency of your specific materials research and advanced development program.

### NFC

### Booth #521

### National Institute of Standards and Technology (NIST)

### Booth #322

NIST Standard Reference Materials supports accurate and compatible measurements by certifying and providing over 1100 Standard Reference Materials with well-characterized composition or properties, or both. SRMs are used to perform instrument calibrations as part of overall quality assurance programs, verify the accuracy of specific measurements and

## Company Descriptions

support the development of new measurement methods. The Standard Reference Data Group has provided well-documented numeric data to scientists and engineers for use in technical problem-solving, research, and development. The Calibration Services are designed to help the makers and users of precision instruments achieve high levels of measurement quality and productivity.

### **NIST Technology Innovation Program Booth #320**

The Technology Innovation Program (TIP) at the National Institute of Standards and Technology is a cost-shared, federal funding program to support, promote, and accelerate innovation in the U.S. through high-risk, high-reward research in areas of critical national need. TIP funds innovation research that is expected to transform the Nation's capacity to deal with major societal challenges that are not being addressed. Participants in TIP include U.S. businesses and institutions of higher education or other organizations, such as national laboratories and nonprofit research institutions.

### **NKM Noell Special Cranes GmbH Booth #707**

### **Olympus Innov – X Booth #811**

Olympus Innov-X provides portable handheld X-Ray Fluorescence (HHXRF) analyzers for simple, non-destructive sorting of challenging grade separations, alloy chemistry and grade ID in seconds. They provide highly specific material chemistry to rapidly and accurately identify pure metals and alloy grades. HHXRFs allow for testing of literally thousands of types of materials anywhere, anytime. For scrap recycling applications, our HHXRFs provide reliable ID in 1-2 seconds for most grades. They are designed for durability – to withstand the tough processing environment. Our HHXRFs are used for fast, reliable alloy sorting and analysis for a wide variety of ferrous and non-ferrous material. We provide optimized HHXRF configurations for cost-effective analysis when time is of the essence and when materials cannot be transported, damaged, or altered. Our X-5000 Mobile XRF analyzers offer maximum portable power with a closed beam configuration and large touch screen interface.

### **Opsis Booth #715**

### **Outotec Booth #507**

Outotec develops and provides technology solutions for the sustainable use of Earth's natural resources. As the global leader in minerals and metals processing technology, Outotec has developed several breakthrough technologies. Outotec serves the light metals industries including the provision of cutting-edge alumina refineries and aluminum smelters. The company has over 50 years experience helping customers worldwide in both segments of the aluminum process to reach their goals. What sets Outotec apart from its competition? They are there to help their customers from start to finish in terms of plant design, and they customize solutions to fit a client's specific needs. Outotec's processes and equipment have become industry standards and their references stretch back decades – a track record that has led to their current reputation as a leading innovative technology partner. The company also offers innovative solutions for the chemical industry, industrial water treatment and the utilization of alternative energy sources.

### **Parker Hannifin Booth #409**

Parker is the world's leading diversified manufacturer of motion and control technologies and systems. Parker provides precision engineered solutions for a variety of commercial mobile, industrial and aerospace markets. We design and manufacture optimal systems using fluid connectors, hydraulics, pneumatics, instrumentation, refrigeration, filters, electromechanical components, and seals required in motion-control systems.

Parker's experience in the aluminum industry spans more than 40 years. Parker has equipped machinery in all phases of aluminum production including smelters, casters and extruders through grinders, rolling mills and strip processing lines, etc.

## Company Descriptions

### RHI AG

**Booth #816**

Refractory competence for the non ferrous metals industry: RHI is the world's leading supplier of high-grade ceramic refractory products and services. As a reliable and competent partner it is our constant aim to add value to the process of our customers by achieving the best price/performance ratio with our refractory system solutions.

The comprehensive program of products and services ranges from basic and non-basic mixes and bricks to prefabricated products, slide gate plates, purging plugs, as well as computer simulations like CFD or FEM. We also offer special machines, repair systems and technical equipment used to install refractory products into the various production units of the non ferrous metals industry. Our metallurgists are active around the globe and cooperate with renowned research facilities and universities to support the improvement of metallurgical processes and furnace integrity.

### Riedhammer GmbH

**Booth #605**

Since 1924 dedicated to the design and construction of furnace plants for carbon products (OPEN as well as CLOSED type), RIEDHAMMER is presently the only independent supplier worldwide being able to deliver complete solutions and technology for baking of anodes, cathodes, electrodes and special carbon products. More than 85 years of experience and know-how guarantee a high economic efficiency and reliability of the plants. In total RIEDHAMMER has executed more than 300 bake furnace projects in 25 countries. Our reference list includes major global players in the production of primary aluminum with pre-baked technology as well as top suppliers of cathodes and electrodes respectively for the aluminum and steel industry.

### Rio Tinto Alcan

**Booth #501**

Global leader in the aluminium industry Building on more than a century of experience and expertise, Rio Tinto Alcan is a global leader in the aluminium industry. We supply high quality bauxite, alumina and aluminium worldwide and our AP smelting technology is the industry benchmark. Our enviable hydroelectric power position delivers significant competitive advantages in today's carbon constrained world. Rio Tinto Alcan is the aluminium product group of Rio Tinto, a leading international business involved in each stage of metal and mineral production. The Group is listed on the London Stock Exchange and Australian Securities Exchange under the symbol RIO. Rio Tinto's major products are aluminium, copper, diamonds, coal, iron ore, uranium, gold and industrial minerals.

### Romidot Ltd

**Booth #401**

### Sente Software

**Booth #810**

### Shanghai Electric Import And Export Co.,Ltd

**Booth #210**

Main products include: alloy welding material, coils, aluminum alloy slabs, hot rolled plate, tubes, ground bar, electric steel.

This booth is presented in cooperation with Leway International Fairs, one of the leading international

exhibition agencies in China. Located in Beijing, Leway has served in over 500 important overseas exhibitions in its eight-year history and has served nearly 2,000 Chinese companies. Leway provides comprehensive one-stop solution services for Chinese companies.

### Shanghai Zhengyu Special Alloys Co., Ltd

**Booth #829**

Shanghai Zhengyu Special Alloy Co., Ltd. is one of the Chinese major and professional manufacturers in China. Our main products AlSi, AlTiB, AlTi & aluminum alloy additives etc, are reviewed favorably and accepted widely in world market.

### SIMULIA

**Booth #408**

SIMULIA is the Dassault Systems brand that delivers a scalable portfolio of Realistic Simulation solutions including the Abaqus product suite for Unified Finite Element Analysis, multiphysics solutions for insight into challenging engineering problems, and lifecycle management solutions for managing simulation data, processes, and intellectual property. By building on established technology, respected quality, and superior customer service, SIMULIA makes realistic simulation an integral business practice that improves product performance, reduces physical prototypes, and drives innovation. Headquartered in Providence, RI, USA, with R&D centers in Providence and in Velizy, France, SIMULIA provides sales, services, and support through a global network of over 30 regional offices and distributors. [www.simulia.com](http://www.simulia.com)

### SLM Co., Ltd

**Booth #229**

We are an Aluminium Master Alloys Manufacturer located in Korea. Our company is specialized in Grain Refiners(AlTiB Alloys), Modifiers(AlSi Alloys) and Other Aluminium Alloys such as AlTi, AlB, AlV, AlMg, AlMn etc. We produce aluminium alloys in various form such as Rod in coil, Cut Rod, Bar and Plate.

We have been producing high quality of Aluminium Master Alloys for 19 years and we export to over 20 countries. We supply high quality materials at competitive price.

We are looking for distributors now. Please visit our stand!

## Company Descriptions

### Sohar Aluminium

**Booth #211**

One of the newest additions to the Middle East's metals circuit and Oman's first foray into the Aluminium industry Sohar Aluminium Company was formed in September 2004. Jointly owned by Oman Oil Company, TAQA and Rio Tinto Alcan, Sohar Aluminium has already won global acclaim for its superior, environmentally-friendly and energy-efficient technology. By implementing decades of industry insight in its design, specification and construction Sohar Aluminium has been created to ensure efficiency, environmental protection and the utmost safety of its workforce. Noteworthy examples include the world's highest known capacity ingot casters and innovative elevated walkways traversing the entire site to keep man and machine separate except when absolutely necessary. In addition, Sohar Aluminium has since inception achieved 70% Omanisation of its workforce; invested 53% of its total spend in the local market and established a growing network of local downstream companies. In many ways, Sohar Aluminium's development mirrors the Sultanate of Oman's own emergence onto the world stage - driving forward at a formidable pace, but all the while mindful and respectful of its cultural heritage and values.

### STAS

**Booth #601**

### Stratronics, Inc. & Optomec Inc.

**Booth #407**

Stratronics, Inc. will exhibit the ThermaViz® Sensor, an innovative two-wavelength imaging pyrometer that provides accurate, high resolution temperature maps for intelligent metals processing in real time. This online imaging pyrometer has been developed to monitor the temperature distribution of the melt pool in laser additive manufacturing processes. ThermaViz, with Windows based analysis software, is now an integrated option to Optomec's LENS technology.

Optomec® is the world-leading provider of additive manufacturing solutions for high performance applications in the Electronics, Solar, Medical, and Aerospace & Defense markets. These systems utilize Optomec's patented Aerosol Jet Printed Electronics technology and LENS powder-metal fabrication technology. The company has a global customer base of more than 100 users that includes many industry-leading manufacturers and Universities.

Stratronics and Optomec will present "On-Line Imaging Pyrometer for Laser Deposition Processing" in the Sensors, Sampling, and Simulation for Process Control Symposium.

### Sunstone

**Booth #822**

### Techmo Car S.p.A

**Booth #502**

Techmo is an Italian independent company focused in the engineering and production of special mobile and stationary equipment for the aluminium and non ferrous metals industry. The full range of purpose designed machines covers different types of equipment performing a large number of operations in pot-rooms, rodding shops and cast-houses. The Company's aim is to provide the most innovative, rational, cost effective and user friendly technical solutions. Among the most significant families of mobile equipment are the Tapping Vehicles, Anode Transporters, Crucible Transporters and Tilters, Alumina/ AIF3 Feeding Vehicles, Furnace Charging Vehicles and Furnace Tending Vehicles, Multipurpose Anode Changers and Crust Breakers. Beside its line of purposed designed vehicles, Techmo provides a number of stationary equipment such as Crucible Cleaning Machines, the Crucible Tilting stations and the Anode Butts Cleaning Stations.

### Thermo Scientific

**Booth #423**

### Thermo Scientific Niton Analyzers

**Booth #421**

When it comes to accurate analysis of metal alloys, Thermo Scientific Niton XRF analyzers set the industry standard. With a unique library of 400+ alloy grades, our handheld instruments provide immediate, nondestructive chemical analysis of aluminum, titanium, and nickel alloys; superalloys; stainless steel; and more. They deliver superior performance through faster analysis, lower detection limits, and unparalleled analytical precision, meaning decreased potential for material mix-ups and instant recovery of lost traceability.

Using the Niton® XL3t with GOLDD technology, you not only gain rapid grade identification and lab-quality composition, but also improvements in light element detection, overall sensitivity, and measurement times.

### Thermo-Calc Software

**Booth #814**

Thermo-Calc Software is a leading developer of software and databases for calculations involving computational thermodynamics and diffusion controlled simulations. Thermo-Calc is a powerful tool for performing thermodynamic calculations for multicomponent systems. Calculations are based on thermodynamic databases produced by expert evaluation of experimental data. Databases are available for steels, Ti, Al, Ni-superalloys and other materials. Programming interfaces are available which enable Thermo-Calc to be called directly from in-house developed software or MatLab. DICTRA is used for accurate simulations of diffusion in multicomponent alloys. Applications include: homogenization of alloys, microsegregation during solidification, coarsening of precipitates, and welding.

## Company Descriptions

### UES, Inc.

**Booth #628**

UES, Inc. is an innovative science and technology company that provides its industry and government customers with superior research and development expertise. We create products and services from our technology breakthroughs and successfully commercialize them.

RoboMet.3D™ is a fully automated, serial sectioning system that generates two-dimensional data for three-dimensional reconstruction.

Robo-Met.3D™ enables more time for data analysis and characterization and ensures repeatable and accurate data is collected in an efficient and cost-effective manner.

Additional areas of expertise for UES include materials science, metallurgy, ceramics, processing science, modeling and simulation, surface engineering, materials characterization, biotechnology, sensor development and nanomaterials.

### Veik Thermal Textiles Coating Industrial

**Booth #328**

Veik Thermal Textiles Coating Industrial, Our Manufacturing facility is located in China. Here we skillfully produce various styles of PTFE & Silicone coated fiberglass fabric and other products to the highest of professional standards. With advanced technology, strict quality control and unbeatable after-sales service, we can ensure our customers will receive high-quality products.

### XIAMEN C&D ALUMINIUM CO., LTD Booth #208

Wholly invested by Xiamen C&D INC. (Stock: C&D INC. Code: 600153), Xiamen C&D Aluminium Co., Ltd., is a trade company specializing in aluminum industry. We mostly engage in aluminum products' domestic trading, and importing and exporting for more than ten years. The company has strong overall operational capabilities, rich experience in international trade, and the stable procurement channels and is in the markets of aluminum sheet, coil, profiles, aluminum circle, aluminum foil etc.

This booth is presented in cooperation with Leway International Fairs, one of the leading international exhibition agencies in China. Located in Beijing, Leway has served in over 500 important overseas exhibitions in its eight-year history and has served nearly 2,000 Chinese companies. Leway provides comprehensive one-stop solution services for Chinese companies.

### York Linings

# PROGRAM AT-A-GLANCE

## 2011 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: Poster Session

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Nanomaterials Committee

*Program Organizers:* Jiyoung Kim, Univ of Texas; David Stollberg, Georgia Tech Research Institute; Seong Jin Koh, University of Texas at Arlington; Nitin Chopra, The University of Alabama; Suveen Mathaudhu, U.S. Army Research Office

Sun PM-Thurs PM Room: 8  
Feb 27-Mar 3, 2011 Location: San Diego Conv. Ctr

*Session Chairs:* Jiyoung Kim, University of Texas at Dallas; Seong Jin Koh, University of Texas at Arlington; David Stollberg, GTRI

### A Novel Type of Carbon Coated Sulfur Nanoparticles for Li/S Batteries:

*Yan Yuan*<sup>1</sup>; Elton Cairns<sup>1</sup>; <sup>1</sup>LBNL

This kind of carbon coated sulfur nanoparticles have been synthesized via a novel liquid-synthesis technique, this reaction in the presence of a surfactant (polyethylene glycol-400) has been developed to get S-C nanoparticles by using sublimed sulfur powders, sodium sulfide, formic acid and carbon black (battery grade) under room temperature. It has been physically characterized by scanning electron microscopy, EDS, and thermogravimetric analysis instrument. The SEM image shows that the size of carbon coated sulfur nanoparticles is around 30nm. The TGA result shows that the S-C sample is quite pure, and the ratio of sulfur and carbon is equal to what we set initially. Besides, it can be used as cathode in Li/S batteries, it improved the electrochemical performance of Li/S batteries.

**Chemical Deposited CdS Nanoparticles on TiO<sub>2</sub> Nanotube Arrays:** *Amin Azizi*<sup>1</sup>; *Mojtaba Hamed*<sup>2</sup>; *Seyyed Khatiboleslam Sadmezhaad*<sup>2</sup>; <sup>1</sup>Tulane University; <sup>2</sup>Sharif Univesity of Technology

In this research, chemically deposition of CdS nanoparticles on the surface of TiO<sub>2</sub> nanotube-arrays is report. Highly-ordered TiO<sub>2</sub> nanotube arrays with the diameter of ~100nm were synthesized by anodization of a titanium foil. According to the results, the surface of nanotube arrays was homogenously covered by a thin layer of the CdS nanoparticulates consist of spherical nanoparticles with ~50 nm diameter.

**Chemical Synthesis and Characterization of Manganese Nanoparticles:** *Lei Zhang*<sup>1</sup>; *David Nikles*<sup>1</sup>; *Gregory Thompson*<sup>1</sup>; <sup>1</sup>University of Alabama

Metallic phase manganese nanoparticles have drawn attention because of its unique structure and magnetic properties. The stable phase of manganese has an A12 structure with 58 atoms in a cubic cell, and is paramagnetic with a Neel temperature of TN=95K. Manganese nanoparticles were prepared by an n-butyl lithium reduction of manganese chloride in phenyl ether at elevated temperature with oleic acid. The particles had a thin oxide layer and oleic acid coating, which stabilized them in air. The particle sizes were altered by varying the oleic acid concentration and the reaction temperature. X-ray diffraction and transmission electron microscopy, including convergent electron beam diffraction, were done to determine the crystal structure as a function of particle size.

**Effect of Mn on AOT Capped CdS Nanoparticles and Thin Films:** *Dhanasekaran Venkatesan*<sup>1</sup>; *Dorairaj Deepan*<sup>2</sup>; *Ram Kumar*<sup>3</sup>; *S. Moorthy Babu*<sup>3</sup>; *Prabhu Megharaj*<sup>4</sup>; *Gokula Krishna Muralidharan*<sup>2</sup>; *Guruhariharan Rajendran*<sup>2</sup>; <sup>1</sup>KTH, Royal Institute of Technology, Sweden; <sup>2</sup>KU Leuven; <sup>3</sup>Anna University Chennai; <sup>4</sup>University of Cincinnati

Diocetyl sodium sulfosuccinate (AOT) capped CdS nanoparticles are prepared using CdCl<sub>2</sub> and Na<sub>2</sub>S as precursors. Concentration of AOT is optimized and it is found that 0.04M AOT, the particle is found to have smaller size, the absorption peak is at 422 nm. Varying mol % of Mn is added to CdS system. The UV-Vis absorption peak is found at 459 nm is observed for the Mn doped CdS nanoparticles. In PL, the emission at 488nm

is due to the surface defect in CdS system and 575 nm is due to the 4T<sub>1</sub> → 6A<sub>1</sub> transition of Mn<sup>2+</sup> ion. FT-IR spectra shows the C=O band at 1643 cm<sup>-1</sup> and C-H band at 2800-2900cm<sup>-1</sup>. Thin films are casted on the glass substrate. XRD patterns confirm the hexagonal crystal structure of CdS, shifts are observed in doped sample. SEM images reveal the agglomerated nanoparticles, found to be 50 to 100 nm. EDX shows varying percentage of Mn content and Cd:S were found to be in ratio 1:2.2. The low temperature Electro Paramagnetic Spectrometer spectrum line width of samples is due magnetic interactions between manganese ions.

**Preparation and Characterization of ZnS Thin Films Using Chemical Bath Deposition Method: Effects of Deposition Time and Thermal Treatment:** *Way-Ming Hsieh*<sup>1</sup>; *Kong-Wei Cheng*<sup>1</sup>; *Shing-jiang Jessie Lue*<sup>1</sup>; <sup>1</sup>Chang Gung University

This research focuses on zinc sulphide thin film preparation using the chemical bath deposition (CBD) method. The obtained product is to be used as the Cd-free buffer layer for CIGS solar cells. The zinc sulfate, thiourea, hydrazine, and ammonia parameters were carefully selected to obtain ZnS thin films. The deposition time and annealing effects on the optical properties and electrical properties were studied. Scanning electron microscope images show that the film surface consists of small uniform grains (about 40 nm in size), free of pin-hole defects. Hall Effect measurements show the synthesized ZnS was an n-type semiconductor with a resistivity of 1 × 10<sup>3</sup> Ω cm. The UV-visible spectrometry analysis showed the high transmittance film thickness increased from 50 to 120 nm. The transmittance values decreased after annealing. The resulting chemical composition of the ZnS thin films are discussed in terms of the CBD process parameters.

**Enhanced Photocatalytic Activity of Modified TiO<sub>2</sub> for Degradation of CH<sub>2</sub>O in Aqueous Suspension:** *Tong Haixia*<sup>1</sup>; *Yang Daowu*<sup>1</sup>; <sup>1</sup>Changsha University of Science and Technology

Butyltitanate, ethanol and glacial acetic acid were chosen as titanium source, solvent and chelating agent respectively via a sol - gel method combined impregnation method to prepare N, Fe co-doped and WO<sub>3</sub> compounded photocatalyst TiO<sub>2</sub> powder. The synthesized products were characterized by X-ray diffraction (XRD), Diffuse reflectance UV-Vis spectra (UV-DRS), and scanning electron microscopy(SEM). The catalytic activity investigated employing photocatalytic degradation of formaldehyde. The results show that when the concentration of N is fixed on, the optimum proportioning ratio of n (Fe): n (W): n (Ti) is 0.5:2:100, and the degradation rate is 77.61% in 180min under UV light irradiation.

**Fabrication of ITO Nano-Powder:** *Mingyu Zhang*<sup>1</sup>; *Liping Wang*<sup>1</sup>; <sup>1</sup>Central South University

At present, the products of ITO nanopowder mainly comes from China. The precursor of ITO nanopowder is fabricated by chemical coprecipitation method and dispersed in the ethanol. Then, ITO nanopowder was achieved after 600 centigrade degree. The ITO nanopowder was characterized by SEM, TEM, BET, XRD,small-angle X-ray scattering(SAXS), ZETA potential analysis. The diameters of ITO nanopowder were among 10nm and 50nm, spherical particles. The formation mechanism was investigated and proposed on the basis of previous study.

**Selective Area ALD Deposition with Nanolithography:** *Jie Huang*<sup>1</sup>; *Mingun Lee*<sup>1</sup>; *Jiyoung Kim*<sup>1</sup>; <sup>1</sup>University of Texas at Dallas

In this presentation, self-assembled monolayers (SAMs) have been investigated as a soft mask materials for future nano-lithography. While a conventional photo-resist (or hard mask) acts as a local protection layer during etching process, a novel SAMs can modify characteristics of surface, e.g. from hydrophilic to hydrophobic, so thin film growth occurs selectively where surface conditions are appropriate. We have evaluated selective ALD of dielectrics in conjunction with patterned OTS as a surface modifier on top of SiO<sub>2</sub>/Si substrate. We also explored the limitation of scaling down of selective ALD with EBL as well as a modified nano-imprint methodology. Well-defined nano-patterned surfaces after metal-oxide deposition will be introduced in our presentation. Acknowledgement: CNMT

(code#2010K000351, '21st Century Frontier R&D Programs' of the MEST, Korea) and FUSION (COSAR/MKE, Korea).

**Steel Mesh Coated with Carbon Nanotubes: Its Superhydrophobicity and W/O Emulsion Dewatering Capability:** Chee Huei Lee<sup>1</sup>; Nick Johnson<sup>1</sup>; Jaroslav Drellich<sup>1</sup>; Yoke Khin Yap<sup>1</sup>; <sup>1</sup>Michigan Technological University

Dense structures of multi-walled carbon nanotubes (CNTs) having a diameter of 10 to 50 nm and length > 5 μm were grown on a stainless steel (SS) mesh using thermal vapor chemical deposition. This 3-dimensional and porous SS-CNTs substrate was found to be superhydrophobic and superoleophilic, and could serve as phase separation membrane. Water advancing contact angles were 145-150 degrees for water drops suspended on the SS-CNTs mesh in air and oil (gasoline, isooctane). Oil, on the other hand, completely wet the SS-CNTs mesh. Simple filtration tests demonstrate the potential application of the SS-CNTs mesh as a filtration screen in dewatering of the water-in-oil emulsions.

**Synthesis of CuO-NiO Nanopowders via Alkalinization Precipitation Process:** R. Roohibakhsh<sup>1</sup>; H.R. Rezaei<sup>1</sup>; H. Razavizadeh<sup>1</sup>; <sup>1</sup>Iran University of Science and Technology

The aim of this study is to achieve a new method to synthesize CuO-NiO nanopowders via hydrometallurgical method. Influence of nickel content on characteristics of the synthesized nanopowders was investigated. Copper and nickel sulfate and sodium hydroxide were used as raw materials. Copper sulfate/nickel sulfate solution was precipitated by addition of sodium hydroxide. Considering the information obtained from STA result, calcination was done on precipitates. Eventually to study the formed phases and microstructure in each stage, X-ray diffraction (XRD) and scanning electron microscopy (SEM) were performed on the precipitates and obtained nanopowders after calcination. The final particle size of nanopowders was in the range of 29-31 nanometers.

**Application of Biomass Waste Materials in the Nano Mineral Synthesis:** Abram Bishay<sup>1</sup>; <sup>1</sup>NMA

Voluminous biowaste materials are produced every year which represent occasional hazardous problem through uncontrolled disposal. Some of the biomass waste material were effectively applied to the nano-sized minerals synthesis under controlled boundary experimental conditions. The produced nano minerals have a characteristic photocatalytic behaviour that could be applied in many environmental applications and safe treatment of many industrial and mine waste effluents. The advantage of such treatment can be summarized in the recycling of the biomass waste, enhancing mineral processing conditions (economically and environmentally) as well as cheap production of different nano particle forms for environmental and industrial applications.

**Characterization of Hybrid Carbon-Nanotube Composite Interfaces as a Function of Length Scale:** Harry Malecki<sup>1</sup>; Michael Duffy<sup>1</sup>; Sam Markkula<sup>1</sup>; Marc Zupan<sup>1</sup>; <sup>1</sup>University of Maryland Baltimore County

The use of carbon nanotubes (CNTs) in composite materials is studied to improve overall performance and provide multi-functionality. More specifically, because the elements of these nano-materials are engineered and span across multiple length scales, the incorporation of CNTs is expected to improve interfacial properties by affecting the small scale mechanisms which govern various interactions in the material structure. In the research presented, CNT-based hybrid filaments produced via a continuous in situ growth process are used to understand the effect of well aligned and dispersed CNTs on the strength of the filament reinforcement and the interfacial properties of the resulting bulk structure. Because of the multiple processing steps used to produce hybrid fibers, the effect of CNT incorporation on filament tensile properties is demonstrated using single filament and dry tow tests. Understanding the fiber properties, interfacial properties of the nano-scale structure are evaluated through nano-indentation of the multiple engineered interfaces.

**Development of Polymer-Based Position-Sensitive Photodetectors:** Dmitri Nassyrov<sup>1</sup>; Malte Schmidt<sup>1</sup>; Ovidio Peña<sup>1</sup>; Alejandro R. Goñi<sup>1</sup>; M. Isabel Alonso<sup>1</sup>; Miquel Garriga<sup>1</sup>; Mariano Campoy-Quiles<sup>1</sup>; <sup>1</sup>Institute of Materials Science of Barcelona (ICMAB-CSIC)

Organic photodetectors provide a cost-effective alternative to conventional inorganic devices due to the possibility of fabricating them via solution-based deposition methods such as coating and printing. Recently, postdeposition treatments such as vapour annealing have been shown to promote crystallisation of the materials, which proportionally improves the optoelectronic properties of the organic devices by enhancing light absorption and charge transport. Here, we first show that the degree of crystallisation of the active layer depends on the vapour annealing time. Then, we use this method to locally enhance light absorption in polythiophene:fullerene blends in order to create films exhibiting lateral gradients of the degree of crystallisation that could be used in applications such as position-sensitive photodetectors. The procedure developed permits us to produce devices with reproducible performance. Ellipsometry and photometry measurements allowed us to elucidate the local nanostructure of the thin films with a resolution at a level of tens of microns.

**Electrochemical Performances of Nanoporous Carbon Anode for Super Lithium Ion Capacitor:** Zhou Xiangyang<sup>1</sup>; Lou Shiju<sup>1</sup>; Yang Juan<sup>1</sup>; <sup>1</sup>Central South University

Hierarchical nanoporous carbon (HNC) anode material with average pore size of 4.7nm and Brunauer Emmett Teller (BET) surface area of 248.66 m<sup>2</sup>/g was prepared for super lithium ion capacitor by using phenolic resin as raw materials and Ni(OH)<sub>2</sub> / NaNO<sub>3</sub> / NaOH composites as templates. The electrochemical performance of the carbon electrode was tested in both electric double-layer capacitor (EDLC) and lithium ion battery (LIB). Voltage-current profiles for the carbon electrode in EDLC exhibit non-ideal rectangular response to different scan rates from 10 mV/s to 100 mV/s, confirming the double-layer behavior and high reversibility of the carbon studied. When acting as LIB anode, it exhibits a good cyclability after the initial irreversibility, associated with a stable capacity of 234 mAh/g during the first 50 cycles at a reasonable current density (0.2C).

**Integration of Surface Treatment Techniques for Uniform and Conformal ALD High-k Dielectric on Graphene:** Greg Mordt<sup>1</sup>; Srikar Jandhyala<sup>1</sup>; Bongki Lee<sup>1</sup>; Jiyoung Kim<sup>1</sup>; <sup>1</sup>University of Texas at Dallas

Graphene, a purely two-dimensional (2D) hexagonal carbon lattice is considered to be a potential candidate for future nanoelectronics because of its exceptional electronics properties. The need to integrate graphene with high quality insulating films that act as gate dielectrics for graphene field effect transistors is essential. Atomic layer deposition (ALD) provides a means to deposit high quality and uniform dielectric films on graphene while avoiding damages to the graphene layer. However, to ensure uniform, continuous films on graphene, a nucleation layer is required due to the chemical inertness of a pristine graphene layer. We investigate various surface treatment techniques prior to the ALD deposition process as a means to functionalize graphene surface to achieve a uniformly deposited high-k dielectric. We employ atomic force microscopy and Raman spectroscopy to characterize the samples and we extract electrical properties such as leakage current and dielectric capacitance. Acknowledgement: SWAN (SRC-NRI)

**Microfluidic Synthesis of Nickel Nanoparticles:** Ravindranadh Eluri<sup>1</sup>; Brian Paul<sup>1</sup>; <sup>1</sup>Oregon State University

Nickel nanoparticles has many applications varying from industrial (brazing filler) to bio medical (MRI contrasting agent). Conventional chemical synthesis of these nanoparticles in a flask results in wide size ranges and not always repeatable. Properties of nanoparticles are very sensitive to their sized due to their significant effect on surface-to-volume ratio. In the current investigation, we aim at synthesizing nickel nanoparticles of nearly monosize particles using microfluidic devices. These devices consist of microchannels of high surface-to-volume ratio leading to short diffusional distances and high diffusion rates. Effect of salt (NiCl<sub>2</sub>.6H<sub>2</sub>O) to reducing agent ratio (N<sub>2</sub>H<sub>4</sub>, NaBH<sub>4</sub>), surface capping agent, flow rate and concentration on particle size are analyzed using SEM, TEM and dynamic

light scattering (DLS) particle size analyzer. Keywords: Nickel nanoparticles, microfluidics, SEM and DLS

**Nanowire Rearrangement by the Pick-and-Place Nano-Manipulation Technique:** *Mingun Lee*<sup>1</sup>; Jie Huang<sup>1</sup>; Kook-Nyung Lee<sup>2</sup>; Moon Kim<sup>1</sup>; Jiyoung Kim<sup>1</sup>; <sup>1</sup>University of Texas at Dallas; <sup>2</sup>Korea Electronics Technology Institute (KETI)

Constructing a nano-device of minimum footprint from nano-components such as nanotubes and nanowires requires precise movement of the constituents. This can be achieved by locating the building blocks with an SEM and rearranging them via pick-and-place with a nano-manipulator inside the chamber. Our research presents every step of pick-and-place by nano-manipulation with Si nanowire, including preparation, and evaluates feasibility of nanowire rearrangement. For the sake of advancing our related study on nanotube-based sensors, we have coated the nanowires with TiO<sub>2</sub> for appropriate electrical conductance. Also discussed in the text are potential implementations of this technology in arranged nanowire devices of the future. Acknowledgement: CNMT(code #:2010K000351, MEST, Korea), and FUSION (COSAR/MKE, Korea).

**Reactive Nanoparticles for Bacteria Decontamination:** *David Stollberg*<sup>1</sup>; <sup>1</sup>Georgia Tech Research Institute

A significant challenge today is protection and decontamination of personnel in environments contaminated with chemicals and/or biological substances which pose acute or chronic health risks through exposure routes of skin, mucus membranes, and/or respiratory tracts. To increase maneuverability, low-weight, low-restriction garments capable of protecting against chemical and biological contaminants are needed. The development of uniquely functionalized nanoparticles and nanomaterials could address needs for enhanced reactive chemical and biological barrier materials and neutralization technologies for contaminated environments. The current work has focused on increased reactivity of nanomaterials, specifically silver and titania nanoparticles, for direct neutralization and/or decontamination of *Staphylococcus aureus*.

**Size Tunable Synthesis of Monodispersed Hexadecylamine -Capped ZnSe Nanoparticles:** *Oluwafemi Oluwatobi*<sup>1</sup>; *Vuyelwa Ncapayi*<sup>1</sup>; *Sandile Songca*<sup>1</sup>; <sup>1</sup>Walter Sisulu University

We herein report the synthesis of hexadecylamine-capped ZnSe nanoparticles via an environmentally benign method. By varying the reduction time we systematically studied the size, optical and structural properties of the as-synthesized nanoparticles. All the particles show quantum confinement with band edge luminescence in their optical spectra and were stable upon aging for several months. The sharpness of the absorption edges and excitonic shoulder increases as the reduction times increases while the emission width decreases as the reduction time decreases. The TEM images show well defined, monodispersed, small spherical particles with increase in particle sizes as the reduction time decreases. The XRD pattern of the particles show that they are of sphalerite cubic phase with increase in crystallinity as the reduction time decreases while the FTIR spectra confirmed the capping of the as-synthesized

**Sonochemistry as a Tool for Synthesis of Ion-Substituted Calcium Phosphate Nanoparticles:** *Ali Shokuhfar*<sup>1</sup>; *Milad Mohebbali*<sup>1</sup>; <sup>1</sup>K.N.Toosi Univ. of Technology

Calcium phosphates are of special interest for biomedical applications in hard tissue engineering. Indeed, the mineral phase of hard tissues in body is not a calcium phosphate, but rather a complex structure of ion-substituted calcium phosphate in form of nanoparticles with low crystallinity. Sonochemistry is known to alter chemical reactions in a number of ways such as changing the kinetics of reactions or activating some, which don't take place in normal conditions. In this study, a particular attention is given to these effects of sonochemistry for fabrication of ion-substituted calcium-phosphates like fluoroapatite and Mg-whitlockite. It's been tried to use calcium, phosphorous and ion precursors which do not contain foreign elements, in order to avoid subsequent treatments for their removal, which might have adverse effects on the structure of the as-synthesized nanoparticles.

**Structure and Mechanical Stability Studies of Tethered Lipid Bilayer Membranes Assembled on Template-Stripped Gold:** *Xi Wang*<sup>1</sup>; *Regina Ragan*<sup>1</sup>; <sup>1</sup>University of California, Irvine

Tethered phospholipid bilayer membrane (tLBM), an artificial membrane system, attracts considerable interest due to its potential application as biosensing platforms for studying transmembrane protein functions and membrane-protein interactions. TLBMs have a polymer spacer between LBM and substrate, preventing transmembrane proteins denaturation. AFM topography and force measurements acquired in fluid confirmed tLBM formation for vesicles composed of 2.5%DSPE-PEG-PDP/97.5%POPC, indicating the sulfur-containing PDP group promotes tLBM formation on template-stripped gold (TSG) via gold-thiolate bonds. Breakthrough distances relating to membrane thickness are analyzed from force-distance curves. The yielded breakthrough distance of tLBM on TSG (4.8±0.4nm) is 1.7nm thicker than that of POPC LBM on mica, demonstrating the presence of a PEG spacer layer between tLBM and TSG. Fluorescence microscopy results indicate tLBMs have greater mechanical stability than LBMs on mica. Our work yields robust tLBM on TSG without need of functionalizing TSG, providing potential for membrane microarray fabrication used for protein analysis.

**The Versatility of Catalytic LCVD Technique to Grow Carbon Nanotubes:** *Iuliana Soare*<sup>1</sup>; *Ion Morjan*<sup>2</sup>; *Rodica Alexandrescu*<sup>2</sup>; *Catalin Luculescu*<sup>2</sup>; *Eugeniu Vasile*<sup>3</sup>; *Monica Scarisoreanu*<sup>2</sup>; *Ernest Popovici*<sup>2</sup>; *Elena Dutu*<sup>2</sup>; *Lavinia Gavrilă Florescu*<sup>2</sup>; *Ion Voicu*<sup>2</sup>; <sup>1</sup>IMT-Bucharest; <sup>2</sup>National Institute for Lasers, Plasma and Radiation Physics; <sup>3</sup>METAV-R&D

The catalytic LCVD offers the advantage of high versatility and control since it separates the catalyst preparation from the catalytic growth of nanotubes. The method is characterized by the CO<sub>2</sub> laser thermal dissociation of volatile carbon-containing precursors over silicon substrates. Different iron based core-shell nanocomposites (iron-based core surrounded by carbon, iron oxide) were employed as catalysts. Gas mixtures containing ethylene, acetylene and ammonia were used. Other main experimental parameters such as laser power and total gas pressure were also varied. It cannot be excluded that impurities like nitrogen may promote formation of coiled carbon nanotubes. Structural characterization of the samples by SEM, TEM, Raman spectroscopy and X-ray diffraction was performed.

**Towards Integrated Systems of Nanopillar Devices:** *Liang-Chieh Ma*<sup>1</sup>; *Seong Jin Koh*<sup>1</sup>; <sup>1</sup>University of Texas at Arlington

One-dimensional nanoscale building blocks such as nanowires, nanotubes, and nanopillars have been investigated as functional elements for future nanoscale devices and sensors. For their practical implementations, however, these one-dimensional entities need to be placed on desired locations as well as connected to the outside macroscopic world. We present an integrated approach where bottom-up and CMOS-compatible top-down techniques are systematically combined to produce nanopillar devices that are individually addressable and probed. The fabrication was carried out in complete parallel processing over a large area. The nanopillars were created through two-step reactive ion etching (RIE); ~50nm Au nanoparticles were used as RIE hardmasks to produce silicon oxide nanopillars, which in turn served as hardmasks to produce desired Cr nanopillars with diameter of ~30nm and height of ~200nm. These nanopillars were selectively created only between the source and drain contacts. Application of this integrated fabrication scheme to single-electron transistor fabrication will be discussed.

**Zn-Ni Ferrite Spinels via Salt-matrix Heat Treatment:** *Amin Azizi*<sup>1</sup>; *Seyyed Mohammad Mostafavi*<sup>2</sup>; *Seyyed Khatiboleslam Sadrnezhad*<sup>2</sup>; *Ziarat Ali Nemati*<sup>2</sup>; <sup>1</sup>Department of Chemical and Biomolecular Engineering, Tulane University; <sup>2</sup>Department of Materials Science and Engineering, Sharif University of Technology

The capability of a salt-matrix (NaCl as a dispersion medium) for prevention of particle growth and agglomeration during annealing of mechanically alloyed Zn-Ni ferrite powders was examined via microstructure observation and magnetic measurements. Using the solid salt-matrix resulted in excellent avoidance of the sintering and growth of the particles as well as significant magnetic properties improvements. TEM observation showed that cube

shape nanoparticles with the average size of ~30 nm were formed by salt-matrix annealing of the milled powders at 700°C for 1 h. The magnetization saturation of the as-milled particles considerably increased and the coercivity also reduced after the salt-matrix heat treatment.

**Development of Hafnia Based Thermal Barrier Coating and Its Microstructural Analysis:** *Mohammed Noor-A-Alam*<sup>1</sup>; Chandan Roy<sup>1</sup>; Christopher Bradley<sup>1</sup>; Ahsan Choudhuri<sup>1</sup>; Chintalapalle Ramana<sup>1</sup>; <sup>1</sup>University of Texas at El Paso

The development of nano-structured hafnia based thermal barrier coatings (TBC) which have very high temperature tolerance are investigated in the present work. Ytria stabilized hafnia (YSH) coatings have been fabricated by magnetron sputtering onto the nickel-based super alloy (Inconel-738) and 403-stainless steel substrates. The coatings have been grown at various temperatures. Characterization of the coatings has been performed by studying their micro-structural and mechanical properties. The thickness of the coatings evaluated using the cross sectional imaging is about 500 nm. The structural characterization performed by X-ray diffraction (XRD) indicates the cubic crystal structure of YSH. The microstructure evaluated by scanning electron microscopy (SEM) shows the columnar structure of all the coatings. The microhardness investigated by using a diamond tip microhardness testing machine indicates the hardness of the coatings is ~3 GPa. The temperature stability of the coatings examined by thermal cycling at various temperatures indicates the stability of the coatings.

**Effect of Temperature Schedule on the Particle Size of NiFe2O4 Spinel Nanopowder during Solid-State Reactions:** *Zhigang Zhang*<sup>1</sup>; Guangchun Yao<sup>1</sup>; Yihan Liu<sup>1</sup>; Jinjing Du<sup>1</sup>; <sup>1</sup>Northeastern University

NiFe2O4 spinel nanopowder was synthesized by solid-state reactions in air using a two-step heat treatment process. The dependence of the particle size and morphology of nanopowder on the temperature schedule was investigated emphatically. The temperature was held for 5h at an intermediate temperature before heating to the target temperature of 800 °C for 1.5h. Although more heat was consumed and the technological process was more complicated, the powders synthesized by the two-step heat treatment method showed a smaller particle size with better dispersity than those produced by direct heating. Scanning electron microscopy (SEM) and laser particle analyzer indicated that the powder prepared at the intermediate temperature of 500 °C for 5h was spherical and well-dispersed with the average particle size of 50 nm, while it was more than 80 nm with particle agglomeration for direct heating to the same target temperature of 800 °C.

**Femtosecond Laser-Induced Synthesis of Colloidal AuAg Nanoalloys from Aqueous Mixture of Metallic Ions:** *Yuliati Herbani*<sup>1</sup>; Takahiro Nakamura<sup>1</sup>; Shunichi Sato<sup>1</sup>; <sup>1</sup>Institute of Multidisciplinary Research for Advanced Materials/Tohoku University

The synthesis of colloidal AuAg nanoalloys of various compositions has been performed by femtosecond laser irradiation of the aqueous mixture of metallic ions. The mixture of silver-ammonia complex and chloroaurate ions was simply introduced into a glass vial and exposed for several minutes to tightly focused femtosecond laser pulses which induced a strong optical breakdown in the solution and promoted the formation of reactive species to reduce the metallic ions. Homogeneous AuAg nanoalloys have been produced as indicated by the presence of surface plasmon bands that were linearly shifted from 400 to 528 nm with the increase of gold molar fraction in the solution. The result suggested that the atomic gold fraction in the nanoparticles were the same as the gold molar fractions in the solution. Oxidation of Ag nanoparticles possibly caused by oxygen species produced upon the irradiation was not observed.

**Interfacial Properties of Cu-Nb Multilayers as a Function of Dislocation/Disconnection Content:** *Niaz Abdulrahim*<sup>1</sup>; Ioannis Mastorakos<sup>1</sup>; Hussein Zbib<sup>1</sup>; David Bahr<sup>1</sup>; <sup>1</sup>washington state university

Nanoscale metallic multilayers (NMM) exhibit very high strength compared to bulk materials. For layer thickness less than 50 nm, the role of the interface in defining the whole behavior of the structure becomes very significant. The interface properties evolve continuously during deformation

because of dislocations passing through it or being absorbed by it, leaving disconnections at the interface. The disconnections which basically can be defined as the composition of a dislocation and a step, act as extra barriers for slip transmission. The effect of such disconnections, with different heights, on the strengthening mechanisms of nanolayers is explored using MD simulations. The interfacial strain energy and shear stresses are computed for a various dislocation configurations. Particularly, we develop energy maps for sheared interface as a function of dislocation content and disconnection density. Such measurements can be used in the development of a hardening law for NMM with incoherent interfaces.

**Investigation of Effect on BET Specific Surface Area of ACF/CNT Composites:** *Liping Wang*<sup>1</sup>; Zhucheng Huang<sup>1</sup>; Mingyu Zhang<sup>1</sup>; <sup>1</sup>Central South University

ACF/CNT composites were fabricated by chemical vapor deposition (CVD) method. The properties of ACF/CNT composites were characterized by SEM and BET specific surface area measurements. Three major variables effects on BET specific surface area of ACF/CNT composites were evaluated. The results show that BET specific surface area decreases with pyrolysis temperature increasing in the range of 550□-850□, while increases as the concentration of catalyst precursor from 0.02 mol/L to 0.1 mol/L. BET specific surface area reaches to minimum with pyrolysis time 40 min, while augments with more longer or shorter pyrolysis time.

**Synthesis and Characterization of Mullite:** *Kasturi Paithankar*<sup>1</sup>; Dipika Barbadikar<sup>1</sup>; Dilip Peshwe<sup>1</sup>; Ashutosh Gandhi<sup>2</sup>; <sup>1</sup>Visvesvaraya National Institute of Technology; <sup>2</sup>Indian Institute of Technology - Madras

In the current paper, an attempt is made to synthesize a mullite EBCs using sol-gel synthesis. Two general procedures were practiced for preparing mullite gel. First, by ageing the Aluminium Nitrate Nona Hydrate and Tetra Ethyl Ortho Silicate (TEOS) in solution of Ethyl Alcohol at various temperatures and Second, by preparing Aluminium Isopropoxide from continuous stirring of Aluminium Chloride (AlCl3) with 2-Propanol in different amounts in Refluxing vessel for 24 hrs and then mixing it with TEOS at various pH values. Characterization of the synthesized mullite has been performed by X-Ray Diffraction (XRD), Fourier Transformation Infra-Red Spectroscopy (FTIR) as well as Scanning Electron Microscopy (SEM). The effects of variations in the processing parameters such as pH, ageing temperatures, amount of propan-2-ol and calcinations temperatures have been discussed. Keywords: Environmental barrier coatings, sol-gel technique, Mullite.

**Synthesis and Characterization of Nanostructure Forsterite Bioceramic for Tissue Engineering Applications:** *Fariborz Tavangarian*<sup>1</sup>; Rahmatollah Emadi<sup>1</sup>; *Mohammad Hossein Enayati*<sup>1</sup>; <sup>1</sup>Isfahan University of Technology

Modern technologies require new biomaterials to match better with natural bone in terms of mechanical properties. Recently, forsterite (Mg2SiO4) has been introduced as a possible bioceramics due to its good biocompatibility. It has a better bending strength and fracture toughness than those of commercially available hydroxyapatite ceramics. The aim of the present work was synthesis, characterization, and bioactivity evaluation of nanostructure forsterite powder. Furthermore, the influence of crystallinity on apatite formation ability and degradation rate was investigated. Nanostructure forsterite powder unlike micron sized forsterite showed apatite formation ability. The bioactivity, biocompatibility, and good mechanical properties of nanostructure forsterite ceramic make it a suitable candidate for tissue engineering.

**Synthesis and Microstructure of Bulk Nanostructured Cu by Spark Plasma Sintering of Cryomilled Powders:** *Haiming Wen*<sup>1</sup>; Yonghao Zhao<sup>1</sup>; Zhihui Zhang<sup>1</sup>; Ying Li<sup>1</sup>; Osman Ertorer<sup>1</sup>; Enrique Lavernia<sup>1</sup>; <sup>1</sup>University of California, Davis

Powder metallurgy is widely used to synthesize bulk nanostructured metals. Cryomilling is one of the commonly used approaches to producing nanostructured metal powders. Spark plasma sintering (SPS) is an efficient consolidation technique. However, it has been found that it is difficult to fully densify cryomilled powders of some pure metals such as Al, Ni and Cu

by SPS. In this study, densification of cryomilled Cu powders by SPS, and microstructure of consolidated bulk nanostructured Cu were related to the change of microstructure and chemistry of cryomilled Cu powders during SPS. It was revealed that although with very low contents, O and N in the cryomilled Cu powders, which were introduced by oxidation and cryomilling respectively, significantly influenced the SPS process. In addition, how O and N exist in the cryomilled Cu powders was ascertained through the combined study of electron microscopy and thermal analysis.

**Synthesis and Sintering of W-Cu-Ag Composite Powders Produced by Co-Precipitation Method:** G. Taghavi<sup>1</sup>; H.R. Rezaie<sup>1</sup>; H. Razavizadeh<sup>1</sup>; <sup>1</sup>Iran University of Science and Technology

W-10wtCu-10wtAg powders were prepared by a precipitation process. In order to synthesis W-Cu-Ag composite powders, the dried precipitates were calcined in air at 600°C for 2h. Then calcined precipitates, reduced at 850°C for 2h in hydrogen atmosphere in a tube type electrical furnace to obtain W,Cu and Ag powders. The reduced powders consisted of metallic phases after mixing with PVA were uni-axially compacted at a pressure of 200 MPa. The effect of sintering temperature was investigated on densification of the synthesized powders. The powders were characterized by X-ray diffraction (XRD) technique. The morphologies of the powders were investigated by scanning electron microscopy (SEM).

**Fe-Based Amorphous-Nanocrystalline Thermal Spray Coatings:** B. Movahedi<sup>1</sup>; M.H. Enayati<sup>2</sup>; <sup>1</sup>Isfahan University; <sup>2</sup>Isfahan University of Technology

In this work, a new composition of Fe-15Cr-4Mo-5P-4B-1C-1Si (wt.%) amorphous powder was produced by mechanical alloying of elemental powder mixture. Thermal spraying of amorphous powder was done by high velocity oxy fuel spraying technique at various spraying conditions to obtain the desirable amorphous and nanocrystalline coatings. It was found that a-Fe based supersaturated solid solution is first formed during mechanical alloying which transforms to amorphous structure at longer milling times. The crystallization kinetic parameters suggest that the crystallization mechanism is dominantly governed by a three-dimensional diffusion-controlled growth. The crystallization of amorphous structure occurs in one single stage. By carefully controlling the spraying parameters and proper selection of powder composition, the desired microstructure with different fraction of amorphous and nanocrystalline phases and therefore with different properties could be obtained.

**High Performance Dye Sensitized Solar Cells Based on Surfactant Templated Mesoporous Titania Coatings:** Saquib Ahmed<sup>1</sup>; Dunbar Birnie<sup>1</sup>; Teddy Asefa<sup>1</sup>; <sup>1</sup>Rutgers University

We have prepared crystalline, high surface area mesoporous titania using surfactant-based supramolecular self-assembly of Titanium Oxy-Sulfate precursor. XRD of the synthesized titania (denoted S1 from hereon) revealed a fully anatase phase, which is corroborated by characteristic diffraction rings in SAED from TEM studies. BET studies showed a specific surface area of S1 over three times that of P25. DSSC films were fabricated using both S1 as well as P25 as a standard. Dye loading capacity using Beer-Lambert analysis and UV-spectroscopy revealed a much better performance of S1 over P25. Actual I-V data giving cell performance showed more than a 1% improvement by using S1 over P25 at optimal film thickness. EIS was conducted to study and compare electron motion and recombination kinetics at the titania/dye/electrolyte interface between S1 with respect to P25 at various film thicknesses. Mercury Porosimetry corroborated pore size and structure seen by SEM imaging of samples.

**Magnetic Properties of Chemically-Synthesized FeRh/FePt Nanocomposites:** Zhiyong Jia<sup>1</sup>; R.D.K Misra<sup>1</sup>; <sup>1</sup>University of Louisiana at Lafayette

We report here the synthesis and magnetization behavior of FeRh/FePt nanocomposites. FeRh and FePt nanoparticles were fabricated individually using a polyol co-reduction process. Subsequently, FeRh and FePt nanoparticles were mixed in the ratio of 4:1 (by volume). Magnetic measurements were made for the nanocomposites films on silicon

wafers both before and after the annealing at different temperatures. The temperature dependent magnetization measurement of Fe51Rh49/Fe52Pt48 nanocomposite annealed at 500°C for 30 minutes indicated antiferromagnetic-ferromagnetic transition consistent with x-ray diffraction measurements. However, Fe51Rh49/Fe52Pt48 nanocomposite annealed at 700°C for 30 minutes, the magnetization behavior was typical of a ferromagnetic material. High-resolution transmission electron microscopy (HRTEM) suggested that ferromagnetic L10 FePtRh ternary alloy was partially formed during the annealing process at 700°C for 30 minutes.

**Optical Gas Sensors for Advanced Coal-Fired Power Plants:** Paul Ohodnicki<sup>1</sup>; Congjun Wang<sup>1</sup>; Douglas Kauffman<sup>1</sup>; Kristi Kauffman<sup>1</sup>; Christopher Matrangola<sup>1</sup>; <sup>1</sup>National Energy Technology Laboratory

The National Energy Technology Laboratory is developing technologies for the next generation of higher-efficiency, lower emission fossil plants including more efficient oxy-fuel combustion processes and coal gasification to produce H<sub>2</sub>-rich synthetic gas which can be converted to electrical power using solid-oxide fuel cells or gas turbines. Advanced remote sensor technologies that can operate under extreme conditions (high temperature, high pressure, corrosive gases) are needed for process control. Commercially available metal oxide-based conductometric gas sensors are not adequate and advanced materials / novel gas sensing techniques are required. Optical sensors based on metal oxides are important candidates and an improved understanding of the fundamental link between optical properties and the presence of various gas species under relevant conditions is needed to aid in sensor development efforts. Early results on synthesis and characterization of metal oxide-based films will be presented and plans for future work will be outlined.

**Managing High Strength and High Ductility in UFG IF-Steel by ECAE plus Post-ECAE Annealing:** Gencaga Purcek<sup>1</sup>; Onur Saray<sup>1</sup>; Ibrahim Karaman<sup>2</sup>; Hans Maier<sup>3</sup>; <sup>1</sup>Karadeniz Technical University; <sup>2</sup>Texas A&M University; <sup>3</sup>University of Paderborn

The UFG IF-steel produced by equal-channel angular extrusion/pressing (ECAE/P) following different routes and number of passes have been annealed for different annealing time intervals and temperatures in order to obtain an IF-steel having both high strength and high ductility. Firstly, the recrystallization curves showing thermal stability were obtained for all conditions. After that, stress-strain curves of the samples that were annealed at a specific temperature for different time intervals were determined to get a good strain hardening rate (high uniform elongation). A bimodal grain size distribution inside the previously deformed microstructure was formed at 600°C for different annealing times. In this microstructure, while the larger grains facilitate the motion and accumulation of dislocations and caused to enhance the ductility, the finer grains contribute to strength increase.

**Texture, Dislocation Structure, and Interface Structure of Nanolamellar Metallic Composites Fabricated via Rolling and Accumulated Roll Bonding:** John Carpenter<sup>1</sup>; Sven Vogel<sup>1</sup>; Thomas Wynn<sup>1</sup>; Robert Dickerson<sup>1</sup>; Rod McCabe<sup>1</sup>; Irene Beyerlein<sup>1</sup>; Nate Mara<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

The use of rolling and accumulated roll bonding (ARB) as alternate techniques to physical vapor deposition (PVD) in the fabrication of metallic multilayer composites with nanoscale layer thicknesses is explored. 200 nm/200 nm Cu/Ag multilayers that were initially fabricated via PVD to a total thickness of 40  $\mu$ m are rolled to nominal reductions of 10%, 20%, 30%, and 50% and compared to cast and rolled Cu/Ag lamellar eutectic material. In addition, Cu/Nb multilayers are fabricated via ARB after initially starting with single layers of polycrystalline Cu and Nb. Cu/Nb multilayers with individual layer thicknesses ranging from tens of microns to tens of nanometers are fabricated. Neutron diffraction is performed on the samples in order to ascertain texture and transmission electron microscopy (TEM) is performed in order to look at local dislocation and interface structures. Deformation behavior and microstructure of the ARB composites is compared with as-deposited multilayers produced via PVD.

## Structural and Dielectric Properties of Polar Polymer Nanocomposites:

Mulayam Gaur<sup>1</sup>; <sup>1</sup>Hindustan College of Science and Technology

The polar materials exhibit a high dielectric constant and are therefore also investigated as high-k polymers in semiconductor sensor industry. The present paper demonstrate the factors such as preparation mechanism, size of nanoparticles, amorphous and crystalline nature of polymer, precondition of samples affecting the dielectric and structural properties of polar polymers. We have chosen the polymethylmethacrylate (PMMA), polysulfone, polyvinylidene fluoride (PVDF) as polymer and TiO<sub>2</sub>, ZnO, SiO<sub>2</sub> as a nanoparticle. We have observed that TiO<sub>2</sub> strongly affected the structural and dielectric properties of PVDF by drastic increase of dielectric constant and formation of nanocluster. The XRD spectra of nanocomposite shows the crystallinity of nanocomposite increases upto certain ratio of nanoparticles and then decreases, however glass transition temperature increases significantly. The dielectric relaxation could be studied using thermally stimulated depolarization technique. It is found that the Maxwell Wagner and dipolar polarization are dominating factor.

## A Detailed Study of Ozone Process on Graphene for Ozone-Based

Atomic Layer Deposition: Bongki Lee<sup>1</sup>; Geunsiik Lee<sup>2</sup>; Greg Mordis<sup>1</sup>; Srikanth Jandhyala<sup>1</sup>; Robert Wallace<sup>1</sup>; Jiyoung Kim<sup>1</sup>; <sup>1</sup>University of Texas at Dallas; <sup>2</sup>POSTECH

Dielectric deposition on graphene has been an object of great interest because the chemically inert nature of the graphene surface inhibits the deposition of conformal dielectric films. We have reported an O<sub>3</sub>-based atomic layer deposition method for depositing a high quality of ALD dielectric on graphene. Here, we study that the O<sub>3</sub> reaction with single-layer graphene using in-situ electrical characterization. We find that O<sub>3</sub> exposure on graphene at 25°C results in the positive shift in the Dirac voltage, indicating that O<sub>3</sub> adsorption on graphene is likely governed by physisorption. This observation is consistent with the density of state calculation of the graphene-adsorbate system. We also explore the effects of dielectric deposition using O<sub>3</sub> process on graphene at different temperatures. Finally, we will demonstrate that the O<sub>3</sub> process can be successfully applied for dielectric deposition on graphene. ## Graphene-CNT Hybrid Structure Based Transparent and Flexible Field Emission Device:

Indranil Lahiri<sup>1</sup>; Ved Prakash Verma<sup>1</sup>; Wonbong Choi<sup>1</sup>;

<sup>1</sup>Florida International University

In recent years, graphene has been promoted as a very important material for future electronics. One of such future applications is transparent, flexible electronic devices. We present here our recent research efforts in developing all-graphene based cathode and anode structures as flexible and transparent field emission device. Graphene film was grown on Cu foil by thermal chemical vapor deposition process and transferred to polymer substrate through hot press lamination. Cathode of the field emission device was prepared by spin-coating multiwall carbon nanotubes (MWCNT) onto graphene film on the transparent, flexible substrate. A green-phosphor coated graphene-PET film was used as the anode. The device offered appreciable emission current and showed good transparency and flexibility. Processing techniques followed in this study can easily be up-scaled and be modified for any transparent and flexible substrate. Our results offer exciting applications of graphene in foldable electronics.

## Development of Al-TiB<sub>2</sub> Nanocomposite:

Z. Sadeghian<sup>1</sup>; M.H. Enayati<sup>2</sup>;

B. Lotfi<sup>1</sup>; P. Beiss<sup>3</sup>; <sup>1</sup>Shahid Chamran University; <sup>2</sup>Isfahan University of

Technology; <sup>3</sup>RWTH Aachen University

Al-20 wt.% TiB<sub>2</sub> nanocomposite was prepared by mechanical alloying (MA) of elemental Ti, B and Al powder mixture. A double step process was used to prevent the formation of undesirable phases. The resulting powder was consolidated by spark plasma sintering (SPS) followed by hot extrusion. The structural characteristics of powder particles and consolidated samples were studied by X-ray diffractometry (XRD), scanning electron microscopy (SEM) and transmission electron microscopy (TEM). The hardness and the tensile behavior of samples were evaluated. The results showed that the prepared Al-20wt.%TiB<sub>2</sub> nanocomposite has good thermal stability against

grain growth and particle coarsening. Extruded Al-20wt. %TiB<sub>2</sub> showed a hardness value of 180 VHN and yield and tensile strength of 480 and 540 MPa, respectively which are much higher than those reported for similar composites made by other processes.

## Polymer-Graphene-Polymer Composite Structured Flexible Nonvolatile Bistable Organic Memory Devices:

Won Kook Choi<sup>1</sup>; Dong-Ick Son<sup>1</sup>;

<sup>1</sup>Korea Institute of Science and Technology

The I-V curves at 300 K for the Al/PMMA/graphene(ultra thin graphite)/PMMA/ITO/PET devices exhibited electrical bistable behaviors before and after bending. Current-time, and current-cycle measurements in flat and bent conditions demonstrated the memory stabilities of the bistable organic memory (BOM) devices. Flexible organic memory device showed the maximum  $I_{on}/I_{off}$  ratio of the I-V curves of  $5 \times 10^6$ , a retention stability of  $4.8 \times 10^4$ s and the endurance to electrical stress above  $1 \times 10^5$  cycles. The memory characteristics of the BOM devices after bending maintained almost the same values as those of the devices before bending and were stable during repetitive bendings of the BOM devices. From the results, we discuss carrier transport mechanism of a bistable behavior for the fabricated bistable organic memory devices structures

## Hydrogen Production by Reacting Water with Mechanically Milled Composite Aluminum-Metal Oxide Powders:

Paul Dupiano<sup>1</sup>; Demitrios

Stamatis<sup>1</sup>; Edward Dreizin<sup>1</sup>;

<sup>1</sup>New Jersey Institute of Technology

Composite aluminum-metal oxide powders were prepared by mechanical milling and considered for hydrogen production in the Al-water split reaction. The powders included compositions capable of independent, highly exothermic thermite reaction between components: Al•MoO<sub>3</sub>, Al•Bi<sub>2</sub>O<sub>3</sub>, and Al•CuO, as well as chemically inert compositions, Al•MgO and Al•Al<sub>2</sub>O<sub>3</sub>. Experiments used a water displacement method to quantify hydrogen production. The hydrogen yield was close to 100 % for all compositions. Reaction rates and rate variations were affected by the specific composition, temperature, and thermal cycling of samples. Al-water split reaction initiated at 80 °C completely stopped when flask was cooled to room temperature. The reaction could be resumed at its original rate by heating the flask back to 80 °C. Redox reactions interfered with the Al-water split reaction so that metallic Bi and Cu were produced when respectively Al•Bi<sub>2</sub>O<sub>3</sub> and Al•CuO composites were used.

## Atomic Scale Investigation of Nano Structures in Ni-Based Superalloy through Advanced Characterization:

Gopal Viswanathan<sup>1</sup>; Rajarshi

Banerjee<sup>2</sup>; R Srinivasan<sup>3</sup>; S Nag<sup>2</sup>; A Shiveley<sup>4</sup>; J Tiley<sup>1</sup>; Hamish Fraser<sup>5</sup>;

<sup>1</sup>Air Force Research Laboratory; <sup>2</sup>University of North Texas; <sup>3</sup>ExxonMobil

Research and Engineering; <sup>4</sup>UTC, Dayton; <sup>5</sup>The Ohio State University

The atomic-scale investigation in complex multi-phase multicomponent systems is a challenging but important undertaking. This study highlights the coupling of recently developed advanced characterization techniques such as high resolution scanning transmission electron microscopy, carried out in an aberration-corrected microscope, and atom probe tomography, to study two vital issues related to nickel-base superalloys, namely (i) to study the complexity of the structural and compositional transition at the atomic scale across  $\gamma$ (FCC Ni)/ $\gamma'$ (ordered Ni<sub>3</sub>Al) solid-solid interface and (ii) to capture the early formation of  $\gamma'$  the ordered Ni<sub>3</sub>Al phase within  $\gamma$  disordered matrix. Possible implications of such investigations on the understanding of physical and mechanical properties will be discussed.

## Thermal Stability and Mechanical Behavior of Cu-Nb and Cu-Nb-Ag Super-Saturated Metastable Solid Solutions Prepared by Mechanical Alloying:

Suhrit Mula<sup>1</sup>; K. Youssef<sup>2</sup>; M. Atwater<sup>2</sup>; H. Bahmanpour<sup>2</sup>; Ron

Scattergood<sup>2</sup>; Carl Koch<sup>2</sup>; <sup>1</sup>North Carolina State University, Raleigh, USA

and National Institute of Technology, Rourkela, India; <sup>2</sup>North Carolina State

University, Raleigh

Blend compositions of Cu<sub>92.5</sub>Nb<sub>7.5</sub>, Cu<sub>92.5</sub>Nb<sub>2.5</sub>Ag<sub>5</sub> and Cu<sub>87.5</sub>Nb<sub>7.5</sub>Ag<sub>5</sub> were

subjected to high-energy ball-milling at room temperature(RT) to study metastable solid solubility extension of Nb/Ag in Cu. XRD and TEM studies revealed that 7.5%Nb, or 7.5%(Nb+Ag) was metastably dissolved in Cu at RT, and the solid solutions are stable up to 500°C. This is in contrast to the

equilibrium solid solubility of either element in Cu, whereas, complete solid solubility was not detected when Ag+Nb content exceeds 7.5%. Enhancement of lattice parameter is more effective for  $\text{Cu}_{92.5}\text{Nb}_{2.5}\text{Ag}_5$  and this is possibly due to dissolution of larger Ag atoms. Hardness decreased from 5.5GPa for  $\text{Cu}_{92.5}\text{Nb}_{7.5}$  to 4.35GPa for  $\text{Cu}_{92.5}\text{Nb}_{2.5}\text{Ag}_5$ , although crystallite size was almost same (10nm). But, higher electrical conductivity was achieved in  $\text{Cu}_{92.5}\text{Nb}_{2.5}\text{Ag}_5$ . Stabilization of matrix grains by formation of solid solution and possible segregation of Nb and/or Ag along grain boundaries may play pivotal role for the high strength.

**Scaling Theory of Continuum Dislocation Dynamics in Two and Three Dimensions:** *Yong Chen*<sup>1</sup>; *Woosong Choi*<sup>1</sup>; *Stefanos Papanikolaou*<sup>1</sup>; *James Sethna*<sup>1</sup>; <sup>1</sup>Cornell University

When crystalline materials deform plastically, complex dislocation structures have been observed experimentally<sup>1</sup>. We provide a continuum plasticity theory to study the emergent self-similar morphologies<sup>2</sup>. We analyze the self-similarity in terms of critical exponents for correlation functions of dislocation density, crystalline orientation and plastic distortion, and explore the connection to the power spectrum of the total free energy. In two and three dimensions, we apply anisotropic loadings, and observe little anisotropy in the critical properties. We explore the addition of quenched disorders to our continuum theory, to investigate the relation between dynamics (plasticity avalanches) and static dislocation morphologies. <sup>1</sup>P. Hahner et al., Phys. Rev. Lett. 81, 2470, 1998. <sup>2</sup>Y.S.Chen et al., Phys. Rev. Lett. 105, 105501, 2010.

**Synthesis and Characterization of Vertically Oriented Sr-doped TiO<sub>2</sub> Nanotubes Using Electrochemical Anodization Process:** *Hoda Amani Hamedani*<sup>1</sup>; *Nageh Khalaf Allam*<sup>1</sup>; *Hamid Garmestani*<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology

The present work reports on fabrication of self-organized strontium-doped titania nanotubes arrays as a potential material for photocatalysis applications. Doping process was performed in two ways: during electrochemical anodization process and using spray pyrolysis technique. The microstructure and morphology of as-prepared and heat treated doped-nanotubes were characterized by field emission scanning electron microscopy (FESEM) and high resolution transmission electron microscopy (HRTEM). Also, composition of the synthesized materials was analyzed by energy dispersive X-ray diffraction (EDX) and x-ray photoelectron spectroscopy (XPS). Results showed that the length, morphology and diameter of the nanotubes can be controlled by adjusting the anodization parameters such as the PH of the electrolyte, applied voltage and processing time. Photocatalytic activity of the fabricated materials was also investigated to evaluate the proper doping level as well as the quality of doped nanotubes for use in photoelectrochemical applications.

**Synthesis of W-25 Wt%Cu Composite Powders Using Ammonium Paratungstate and Copper Nitrate as Precursors:** *Mojtaba Babapour Naseri*<sup>1</sup>; <sup>1</sup>Cabok

An investigation has been made to prepare homogeneous powders of  $\text{CuWO}_4$  and  $\text{WO}_3$  from ammonium paratungstate and copper nitrate to prepare nanosized W-Cu powder. Hence, a mixture of ammonium paratungstate and copper nitrate with predetermined weight proportion was made in distilled water; while the content of the beaker was being stirred at a certain speed to reach the desired composition of W-25wt %Cu. Mixture was heated to 80-100C for 6 h. Also, pH range was adjusted at about 3-4. The mixture was then evaporated and dried in the air. To reach W-Cu composite powder, the precursor powders burned out at 520C for 2 h in the air to form W-Cu oxide powder and then were ball milled and reduced in H<sub>2</sub> atmosphere to convert it into W-Cu composite powder. The resulting powders were evaluated using scanning electron microscopy, X-ray diffraction, thermogravimetric analysis and differential thermal analysis techniques. The results showed that homogeneous powders of W-Cu with particle size of about 100 nm and a nearly spherical shape could be obtained by this process.

**Effect of Welding on the Fatigue Strength of Welded Joints Using the GMAW Process in Transformation Induced Plasticity Steels (TRIP) Used in the Automotive Industry:** *Victor Lopez*<sup>1</sup>; *Arturo Reyes*<sup>1</sup>; *Patricia Zambrano*<sup>2</sup>; *Joaquin Del prado*<sup>3</sup>; <sup>1</sup>Corporacion Mexicana de Investigacion en Materiales; <sup>2</sup>universidad autonoma de nuevo leon; <sup>3</sup>METALSA

GMAW is the welding process used in the automotive industry, for joining mild steels. TRIP steel, however don't offer the same ease of welding, and control welding parameters is critical. The effects of the heat input variations is important and TRIP steel has a narrower parameters window in which acceptable welds can be made. Mechanical and Metallurgical properties of the lap joints of TRIP 780 steel 2.8 mm thickness is analyzed fusion welds were evaluated using optical and SEM microscopy. Static and fatigue tests were conducted on these joints for different heat inputs. Fatigue testing was conducted under a different number of stress ranges to obtain the S/N curves of the weld joints. It was found that welding process parameters, especially travel speed, have significant impact on static and fatigue performance of the lap joints. Failure location of static and fatigue tested lap joints will also be analyzed.

**Effect of Initial Microstructure on the Processing of Titanium Using Equal Channel Angular Pressing:** *Shehreen Dheda*<sup>1</sup>; *Nima Farhi*<sup>1</sup>; *Farghalli Mohamed*<sup>1</sup>; <sup>1</sup>University of California, Irvine

Equal channel angular pressing (ECAP) is a metal processing technique that is used to produce materials with ultrafine (< 1 μm) grain sizes. In this work, the effect of the initial microstructure on ECAP of commercially pure titanium (CP Ti), a material used in many industrial applications, was investigated. To produce different initial microstructures, samples of CP Ti were exposed to several different annealing treatments. Samples associated with each treatment were subjected to one pass of ECAP and the resulting microstructures were analyzed using SEM and TEM, and compared to the microstructures before ECAP. Microhardness and tensile tests were also performed on the samples. The results are discussed in terms of the microstructures associated with each treatment before and after one pass of ECAP and the effect of these microstructures on mechanical properties.

**Production and Mechanical Properties of Nanostructured Copper and Copper Zinc Alloys:** *Mohsen Samadi Khoshkoo*<sup>1</sup>; *Hamed Bahmanpour*<sup>2</sup>; *Sergio Scudino*<sup>1</sup>; *Jens Freudenberger*<sup>1</sup>; *Michael Zehetbauer*<sup>3</sup>; *Carl Koch*<sup>2</sup>; *Jürgen Eckert*<sup>1</sup>; <sup>1</sup>Leibniz Institute for Solid State and Materials Research (IFW); <sup>2</sup>Department of Materials Science and Engineering, North Carolina State University; <sup>3</sup>University of Vienna

In this work, bulk nanocrystalline (NC) and ultrafine-grained (UFG) Cu-based samples have been produced by in-situ consolidation during mechanical alloying as well as by conventional ex-situ consolidation of the milled powders through hot extrusion. The effect of the milling parameters (e.g. milling temperature and intensity) on the structure of the milled materials was studied in detail and particular attention was paid to reach the optimal conditions for successful in-situ consolidation during milling. Extrusion experiments were carried out at the lowest possible temperature in order to limit grain growth. Room temperature compression tests of the samples produced by the different processing routes reveal very encouraging mechanical properties regarding the combination of high strength (600 - 1100 MPa) and good plastic deformation (> 50 %) and indicate that NC/UFG materials with specific combination of properties can be produced by the optimization of the processing parameters.

**Experimental Investigation of Deformation Mechanisms Present in Ultra-Fine-Grained Metals:** *Adam Kammer*<sup>1</sup>; *Samantha Daly*<sup>1</sup>; <sup>1</sup>The University of Michigan

This talk presents an experimental investigation into UFG metals in order to determine the active deformation mechanisms and the relative contributions of different deformation modes that result in their remarkable capacity for high strength and ductility. UFG pure aluminum and an AZ-61 magnesium alloy produced by equal-channel angular pressing (ECAP) are investigated. A new experimental methodology is used, in which an optical metrology known as Digital Image Correlation (DIC) is combined with scanning electron microscopy to track the quantitative development of full-

field strains on the length scale of the microstructure. The results obtained through the combined SEM and DIC approach, and corresponding electron backscatter diffraction (EBSD) analysis, enable the investigators to track the real-time, micro-scale evolution of Lagrangian strain and to determine the deformation inside the grains and across grain boundaries as the material is heated and strained.

**Thermal Stability of Electrodeposited Nanocrystalline Copper:** *Ming-Je Sung*<sup>1</sup>; Farghalli Mohammed<sup>1</sup>; <sup>1</sup>University of California, Irvine

Electrodeposition is a process in which metal films are obtained by electroplating from a suspension of small particles that are deposited with the plated metal. In this work, nanocrystalline copper was fabricated by *Pulsed Current Electrodeposition* (PED). Samples were heat treated for several different temperatures. The results showed the presence of highly thermal stable copper nano-twinning. Also, results on preferred orientations and microstructures are presented.

**Ultrahigh Strength and Good Ductility in Bulk Nanostructured TWIP Steel:** *Hongning Kou*<sup>1</sup>; Jian Lu<sup>2</sup>; <sup>1</sup>The Hongkong Polytechnic University; <sup>2</sup>City University of HongKong

Different from varieties of nanocrystalline metals and alloys that usually achieve their ultrahigh strength at the expense of ductility, we present nanostructured TWIP (twinning induced plasticity) steel samples subjected to surface mechanical attrition treatment (SMAT) with simultaneous ultrahigh strength and good ductility. Their yield strength is increased by fold, while still accompanied by acceptable elongation. The excellent mechanical properties primarily result from the twin structure evolution caused by plastic deformation. This new type of nanostructured TWIP steel with good combination of strength and ductility shows great potential in energy saving and lightweight engineering in automobile industry.

**Shear-Induced Nanostructured Zirconium with Unique Mechanical Properties:** *Srinivasa Rao Bonta*<sup>1</sup>; Alexander Zhyliaev<sup>2</sup>; María Teresa Pérez Prado<sup>1</sup>; <sup>1</sup>IMDEA Materials; <sup>2</sup>National Center for Metals Research

Pure Zr undergoes a wide range of phase transformations when subjected to high temperatures or high pressures. Under ambient conditions, the stable phase (alpha) has a hexagonal close packed structure. At temperatures higher than 1135 K it transforms into a bcc phase (beta). When the alpha phase is subjected to hydrostatic pressure it transforms into a simple hexagonal structure (omega) at applied pressures ranging from 2 to 6 GPa and, finally, to the bcc (beta) phase when the applied pressure exceeds 30 GPa. It has recently been discovered that pure omega plus beta nanostructured Zirconium can be stabilized at room temperature and atmospheric pressure by the application of shear under pressure. The properties of omega plus beta Zirconium have not been investigated yet, as these two phases could previously only be stabilized under very extreme conditions. Here the mechanical behavior of these novel nanostructured Zr phases will be investigated.

**Industrial Potential of Bulk Nanostructured Metals:** *Malgorzata Lewandowska*<sup>1</sup>; Halina Garbac<sup>1</sup>; Krzysztof Kurzydowski<sup>1</sup>; <sup>1</sup>Warsaw University of Technology

Nano-metals have been a subject of extensive research which resulted in the development of a number of fabrication routes, among others utilizing methods of severe plastic deformation. One of such methods is hydrostatic extrusion, which can be used to produce relatively long products, in the form of rods and wires. Such rods and wires allow for better characterization of the mechanical properties of SPD nano-metals and alloys. They also lead to new applications, in particular as components of the more complex structures. In this paper, three possible fields of application, namely Al-based lightweight structures for transport related industry, biomedical applications of nano-Ti and nano-steels for advanced energy power systems, will be described in more detail. These three examples address the major global challenges - reduction in CO2 emission, life quality of ageing society, efficient and clear energy production - indicating that nanometals may contribute to solving world's problems.

**Progress and Potential of Free Pressure-less Spark Plasma Sintering (FPSPS) Processing:** *William Bradbury*<sup>1</sup>; Ridvan Yamanoglu<sup>2</sup>; Wei Li<sup>1</sup>; Randall German<sup>1</sup>; Eugene Olevsky<sup>1</sup>; <sup>1</sup>San Diego State University; <sup>2</sup>Kocaeli University

Experimental aspects of recently developed free pressure-less spark plasma sintering (FPSPS) processing of powder based materials provides encouraging potential for nano-scale structural integration of porous components, nano-wire thin film production and rapid consolidation. Current development has encompassed SiC nanowire network synthesis as well as ZnO consolidation, activated carbon production and nanowire thin film deposition. Complete removal of external load applied to the sample during spark plasma sintering allows simple introduction of this rapid sintering technology to 1-D nanostructure development. Partial retention of contact pressure allows utilization of current flow without destruction or distortion of delicate macrostructure under high loading. The FPSPS process can be utilized independently, or as a sample pretreatment for microstructural development, followed by conventional SPS consolidation.

**Microstructure and Mechanical Behavior of Wet-Processed Cu-Zr-Based BMG Composites:** *Jonathan Nguyen*<sup>1</sup>; Sangmin Lee<sup>2</sup>; Zhihui Zhang<sup>1</sup>; Ying Li<sup>1</sup>; Troy Topping<sup>1</sup>; Yizhang Zhou<sup>1</sup>; Akihisa Inoue<sup>2</sup>; Enrique Lavernia<sup>1</sup>; <sup>1</sup>University of California, Davis; <sup>2</sup>Tohoku University

Cu-Zr (CZ) based bulk metallic glasses (BMG) have become a subject of recent interest due to their high strength and enhanced ductility. In this study, wet process dispersion of multi-wall carbon nanotube (CNT) using a zwitterionic surfactant has been used to synthesize CNT reinforced BMG. A fundamental criterion is that the surfactant used must functionalize the CNTs thereby enabling it to attach to metallic powder surfaces. Spark plasma sintering was used to consolidate CZ-CNT composite powders with varying amounts of CNT (0.1 to 1.5 wt%). The microstructural evolution and the interface between the CNT and the BMG matrix was characterized using electron microscopy, DSC, and Zeta potential measurement. Compression tests were carried out to evaluate the mechanical behavior of consolidated bulk samples. Particular emphasis has been placed on establishing the structural and mechanical interaction at the interface between CNT and the BMG matrix.

**Heterogeneity of Microstructure Evolution in NiTi (50 at% Ni) Alloy Severely Deformed by High Pressure Torsion:** *Reeti Singh*<sup>1</sup>; Jochen Fiebig<sup>1</sup>; Stefan Ostendorf<sup>1</sup>; Harald Rösner<sup>1</sup>; E.A. Prokofyev<sup>2</sup>; Ruslan Valiev<sup>2</sup>; Sergiy Divinski<sup>1</sup>; Gerhard Wilde<sup>1</sup>; <sup>1</sup>Institute of Material Physics, Westfälische Wilhelms-University Münster, Germany; <sup>2</sup>Institute of Physics of Advanced Materials, Ufa State Aviation University, Ufa, Russian Federation

A comparative study on slightly Ni-rich NiTi, deformed by high-pressure torsion (HPT) and repeated cold rolling (RCR) was investigated. The development of the microstructure in dependence of deformation was investigated by differential scanning calorimetry (DSC), X-ray diffraction analysis and transmission electron microscopy. The DSC signals observed during continuous heating experiments indicate that RCR is the more efficient deformation route with respect to grain refinement in comparison to HPT. Unusually large separation between crystallization and growth stages of NiTi is observed. A detailed analysis of the evolution of enthalpy release reveals reproducibly non-monotonous trends with annealing temperature that cannot be explained solely with nucleation and growth of crystalline volume fractions. Instead, these results as well as detailed kinetics analyses indicate that a reverse amorphization process occurs during annealing around 523 K. This behavior is discussed with respect to the nanoscale microstructural heterogeneity after initial deformation processing by HPT and RCR.

**Effect of Repetitive Corrugation and Straightening Rolling on Microstructure and Mechanical Behavior of Metallic Materials:** *Arya Mirsepassi*<sup>1</sup>; *Mahmoud Nili-ahmadabadi*<sup>2</sup>; Mohammad Habibi-parsa<sup>1</sup>; <sup>1</sup>University of Tehran

Severe plastic deformation (SPD) is a promising procedure to achieve ultrafine grained (UFG) microstructures in metallic materials. The homogeneity of microstructure, large applied strains, minimum dimensional changes and industrial applicability are the significant issues that should

be taken into consideration in SPD methods. The mostly applied SPD methods despite their widespread use, don't provide all the mentioned issues simultaneously. A new SPD process called repetitive corrugation and straightening rolling (RCSR), has been developed for fabrication of UFG metallic materials to induce high strains after repetitive cycles, more homogenous microstructure with minor dimensional changes and proper potential industrial application. RCSR consists of corrugated rollers and has the capability of changing the position of the specimens during different routes. Fe-Ni-Mn martensitic steel sheets were subjected to RCSR process. Optical and scanning electron microscopy with mechanical testing were used to study the microstructure and mechanical properties of the specimens.

**Deformation Behavior of Bulk Nanostructured Copper and Copper Alloys Processed by Ball Milling and High Pressure Torsion:** *Hamed Bahmanpour*<sup>1</sup>; Jelena Horky<sup>2</sup>; Sladjana Kahofer<sup>2</sup>; Ronald O. Scattergood<sup>1</sup>; Carl C. Koch<sup>1</sup>; Michael Zehetbauer<sup>2</sup>; <sup>1</sup>North Carolina State University; <sup>2</sup>Research Group Physics of Nanostructured Materials, University of Vienna

Nanostructured copper and copper alloys were produced by high energy ball milling. Powders were consolidated by applying high-pressure torsion (HPT) on cold compacted samples. With HPT pressures < 6 GPa and cyclically applied shear strains > 50 fully dense samples were achieved which showed microhardness values up to 2.8 GPa. These values markedly exceed any strength data reported in literature from in-situ consolidated ball milled or SPD processed Cu. The results are related to the very small crystallite size, as well as high densities of deformation induced defects like dislocations and vacancy agglomerates as being determined by X-ray profile analysis and DSC. Additional investigations of the mechanical behavior of nanostructured copper and copper alloys were done by means of stress relaxation tests in order to clarify the basic deformation mechanisms in the regime of very small grain size.

**Synthesis of High Strength Nano-Structured Alpha and Beta Tantalum:** *Anahita Navid*<sup>1</sup>; Andrea Hodge<sup>1</sup>; <sup>1</sup>University of southern california

High strength nano-structured (d = 50 nm) alpha and beta tantalum films (H=10-17 GPa) were synthesized at room temperature using DC magnetron sputtering. The variations in hardness values are related to phase formation, texture and residual stresses of the film. Several studies combining XRD, surface morphology evaluation and resistivity tests are utilized to verify the formation of alpha tantalum. The role of the substrate/film interface, underlayer materials, grain size and film texture were also investigated. In addition, the phase formation as a function of sputtering pressure is correlated to the effect of impurities and ion energy applied to the film during deposition.

**Ultra-high-Strength Nano-Grained Composites Produced by High-Pressure Torsion:** *Kaveh Edalati*<sup>1</sup>; Zenji Horita<sup>1</sup>; <sup>1</sup>Kyushu University

Processing of pure aluminum, titanium and nickel through the application of high-pressure torsion (HPT) results in a grain refinement at the sub-micrometer level (> 100 nm). In this paper, different fractions of Al, Ti and Ni powders are mixed and subjected to HPT. A significant grain refinement at the nanometer level (<30 nm) and high hardness (>500 Hv) are achieved following the HPT. The hardness values are much higher than 32, 265 and 308 Hv of the bulk form of the HPT-processed Al, Ti and Ni, respectively. High resolution electron microscopy is conducted to analyze the microstructures.

**Dry Sliding Wear and Corrosion Behavior of Ultrafine-Grained HSLA Steel Processed Using Multi Axial Forging:** *Aditya Padap*<sup>1</sup>; G Chaudhari<sup>1</sup>; S. Nath<sup>1</sup>; <sup>1</sup>Indian Institute of Technology Roorkee

A number of studies have been carried out in recent past years to optimize the relationship between mechanical properties and microstructure of steels processed by severe plastic deformation (SPD) techniques. Very few studies are available that correlate the microstructural changes and the mechanical properties of ultrafine grained (UFG) steels obtained by SPD, to the degradation phenomena such as wear and corrosion. In present study HSLA steel was severely deformed by warm (500°C) multiaxial forging (MAF) technique using up to nine strain steps. Submicron sized grain size was obtained after warm MAF. The hardness and strength properties

improved significantly, with adequate ductility. UFG steel obtained from warm MAF processing did not show any improvement in wear resistance. Low pull-off-work and fragmented nano sized pearlitic cementite particles were the two factors found responsible for lower wear resistance of UFG steel. The corrosion resistance of HSLA steel after warm MAF remained largely unaffected.

**Effects of Boron Carbide Additions on Kinetics of Grain Refinement in Cryomilled Al Powders:** *Yuzheng Zhang*<sup>1</sup>; Byungmin Ahn<sup>1</sup>; Rustin Vogt<sup>2</sup>; Zhihui Zhang<sup>2</sup>; Julie Schoenung<sup>2</sup>; Enrique Lavernia<sup>2</sup>; Steven Nutt<sup>1</sup>; <sup>1</sup>University of Southern California; <sup>2</sup>University of California, Davis

Al powders were blended with B4C particles and cryomilled in liquid nitrogen. Microstructural evolution as a function of milling time was investigated via transmission and scanning electron microscopy, and X-ray diffractometry. Al grain size distributions and grain refinement kinetics were determined by analysis of SEM images, and the effects of B4C addition (14.3 wt. %) were revealed by comparisons with unblended powders. The morphology and size of the milled powders and the size distribution of B4C particles were also determined. The grain refinement was achieved by repeated fracture and cold-welded processes. The grain size decreased with the increasing milling time, as did the variance in grain size. The addition of B4C particles facilitated the grain refinement process, and smaller grain sizes were observed in regions with high concentrations of B4C particles.

**Effect of Precipitation on the Mechanical Properties of Hot Extruded Nanostructured Aluminum Powder Alloys:** *Claudemiro Bolfini*<sup>1</sup>; Mauricio Peres<sup>1</sup>; Joao Fogagnolo<sup>2</sup>; Claudio Kiminami<sup>1</sup>; Walter Botta<sup>1</sup>; Alberto MoreiraJorge<sup>1</sup>; <sup>1</sup>Universidade Federal de São Carlos; <sup>2</sup>Universidade Estadual de Campinas

The effect of the extrusion temperature and ram speed during consolidation by hot extrusion of mechanical-alloyed Al-4.5%Cu alloy and Al6061 matrix reinforced with Si3N4 particle composite is discussed. Pre-existent precipitates in Al-Si3N4 alloy were very effective to control grain growth and to promote good mechanical properties on the consolidated alloys. Precipitation of Al2Cu was observed when extruding the mechanical-alloyed Al-4.5%Cu alloy at 375°C and 400°C, but no precipitation was observed in the material extruded at 425°C. The mechanical properties of the consolidated alloys were found to be strongly dependent on the extrusion conditions and this behavior is discussed in association with the original and modified microstructures, which increased with decreasing temperature and increasing ram speed.

**Mechanical Behavior of Cryomilled Al-B<sub>2</sub>C Ultrafine-Grained Metal Matrix Composite Extrusions Attributed to Stress Assisted Grain Growth and Particulate Reinforcement:** *Troy Topping*<sup>1</sup>; Cory Smith<sup>2</sup>; Ying Li<sup>1</sup>; Zhihui Zhang<sup>1</sup>; Bhaskar Majumdar<sup>3</sup>; Kyu Cho<sup>4</sup>; Mark van den Bergh<sup>2</sup>; Julie Schoenung<sup>1</sup>; Enrique Lavernia<sup>1</sup>; <sup>1</sup>University of California, Davis; <sup>2</sup>DWA Aluminum Composites; <sup>3</sup>New Mexico Tech University; <sup>4</sup>U.S. Army Research Laboratory

Aluminum based cryomilled ultrafine-grained metal matrix composites (UFG-MMCs) are of interest for their high specific strength when compared to conventional Al alloys – sometimes in excess of three times the strength on an unreinforced conventional alloy. These MMCs present unique challenges to understanding the effect of thermomechanical processing on microstructure, which is essential to maintaining desirable mechanical properties in the UFG-MMC. Trimodal UFG-MMCs, consisting of cryomilled Al 5083, B<sub>2</sub>C, and unmilled Al 5083, were vacuum hot pressed and extruded for this investigation. Extrusions at various temperatures and ratios were studied, with powders cryomilled at different times to change the contribution of nitrogen to strength. Microstructural evidence reveals a change in grain size scaled with extrusion ratio attributed to stress assisted grain growth, and wet chemical analysis shows variations in the nitrogen content that scale directly with strength. Zener-Holloman and Hall-Petch parameters of the UFG-MMCs are discussed.

**Basal-Plane Stacking-Fault Energies of Mg: A First-Principles Study of Li- And Al-Alloying Effects:** Zhao-Hui Jin<sup>1</sup>; Jian Han<sup>1</sup>; X.-M. Su<sup>1</sup>; Y.T. Zhu<sup>2</sup>; <sup>1</sup>Shanghai Jiao Tong University; <sup>2</sup>North Carolina State University

The understanding of physical mechanisms associated with particular deformation modes helps to develop materials with improved strength and ductility. For design purpose, it is necessary to understand various possible slip pathways associated with basal planes in hcp metals and how alloying effects may influence such pathways. With prototypical hcp metal Mg, we aimed to calculate the generalized stacking fault energies (GSFEs) associated with basal-plane slip pathways. In particular, we focused on to reveal the so-called sequential faulting mechanism in hcp metals, a deformation process quite similar to mechanical twinning in fcc metals. The GSFE profiles were obtained using first-principles technique in combination with climbing-image nudged elastic band methods. Our results show that Li-alloying can facilitate dislocation-mediated process, while with Al-alloying the sequential faulting across basal planes becomes favorable. Such difference is attributed to that the two alloying elements tend to form different types of bond critical points in Mg.

**Effect of Reinforcement Volume Fraction on the Properties of Nanocrystalline Mg Matrix Composite Reinforced with Ti<sub>2</sub>AlC:** Babak Anasori<sup>1</sup>; Shahram Amini<sup>1</sup>; Volker Presser<sup>1</sup>; Michel Barsoum<sup>1</sup>; <sup>1</sup>Drexel University

Herein we report on the effect of the reinforcement volume fraction on the mechanical properties of a novel nanocrystalline magnesium, Mg, matrix composite reinforced with Ti<sub>2</sub>AlC. Increasing the volume fraction of the reinforcement reduced the average size of Mg nanograins. Both Mg and Ti<sub>2</sub>AlC have been classified as kinking nonlinear elastic (KNE) solids. KNE solids trace fully reversible, reproducible, hysteretic stress-strain loops that can be characterized by three independent parameters: stress,  $\sigma$ , nonlinear strain,  $\epsilon_{NL}$ , and energy dissipated per cycle per unit volume,  $W_d$ , all of which can be obtained from the stress-strain loops. The results are in excellent agreement with our incipient kink band (IKB) based model. The Mg nanograins are also extraordinarily thermally stable; heating the composite three times to temperatures 50 °C above the melting point of Mg did not lead to coarsening of the nanograins.

**Effect of the Second Phase Particles on the Grain Refinement of an Al-Si-Mg Alloy Processed by ECAP:** Edgar Garcia-Sanchez<sup>1</sup>; Edgar Lopez-Chipres<sup>2</sup>; Rafael Colás-Ortiz<sup>1</sup>; <sup>1</sup>FIME-UANL; <sup>2</sup>UJED

Three initial microstructural conditions were considered with the aim to study the second phase particles effect on the grain refinement and mechanical properties in an aluminum alloy. In this work a commercial Al-Mg-Si alloy under various initial microstructural conditions has been deformed at room temperature by multi-pass 90° equal channel angular pressing (ECAP). The alloy after ECAP was aging under different conditions. The post ECAP annealing heat treatments in some cases promote high strengths and relatively high ductility; these were evaluated by means of tensile tests carried out at room temperature. The grain refinement was promoted by the presence of particles as observed by SEM and TEM. With this work was possible to obtain the optimal conditions for processing an Aluminum alloy under SPD and post aging heat treatments improving the mechanical properties and obtaining an ultrafine grained microstructure.

**Alumina and Bauxite: Alternative Alumina Sources**

**Adsorption of Polyethylene Glycol at the Interface of Dicalcium Silicate – Sodium Aluminate Solution:** Yu Haiyan<sup>1</sup>; Xiaolin Pan<sup>1</sup>; Zhongke Lu<sup>2</sup>; Tingting Ding<sup>1</sup>; <sup>1</sup>Northeastern University; <sup>2</sup>Shandong Branch, Chalco

Surfactants, such as polyethylene glycol (PEG), are widely used to inhibit the secondary reaction of dicalcium silicate ( $\beta$ -CaO•SiO<sub>2</sub>) in sodium aluminate solution. The adsorption isotherm of PEG on  $\beta$ -CaO•SiO<sub>2</sub> in sodium aluminate solution at 80°C was researched in this paper. It was found that the type of surface adsorption of PEG is saturated adsorption, and the adsorption behavior belongs to “S”-type, according with the multi-molecular layer adsorption model of the Freundlich Equation. The surface coverage of PEG close to saturated adsorption derived from the specific surface area of  $\beta$ -CaO•SiO<sub>2</sub> is 0.723 mol/μm<sup>2</sup>. The relation curves between the surface pressure and the molecular area of adsorption film were obtained according to the adsorption results at the solid-liquid interface by Gibbs formula. The variation of interfacial energy caused by adsorption, as well as the relationship between the relation curves and the type of adsorption was also discussed.

**The Effect of Cooling Rate on the Leachability of Calcium Aluminate Slags:** Wang Bo<sup>1</sup>; Sun Huilan<sup>1</sup>; Zhang Xuezheng<sup>1</sup>; Bi Shiwen<sup>2</sup>; <sup>1</sup>Hebei University of Science and Technology; <sup>2</sup>Northeastern University

The calcium aluminate slag was synthesized by CaCO<sub>3</sub>, SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub> under the conditions of 1500°C for 1h. The effect of cooling rate on alumina leaching property and self-disintegrating property of calcium aluminate slag were studied, and the effect mechanism was discussed by the method of XRD, SEM, and laser particle size analyzer. The results indicated that the phase components, alumina leaching property and self-disintegrating property of calcium aluminate slag were better when cooling rate was lower than 20°C•min<sup>-1</sup>. The formation of 2CaO•Al<sub>2</sub>O<sub>3</sub>•SiO<sub>2</sub> and 3CaO•Al<sub>2</sub>O<sub>3</sub> would decrease alumina leaching rate and self-disintegrating rate obviously when cooling rate was higher than 20°C•min<sup>-1</sup>. The crystal conversion rate from  $\beta$ -2CaO•SiO<sub>2</sub> to  $\gamma$ -2CaO•SiO<sub>2</sub> was still high when cooling rate was between 20°C•min<sup>-1</sup> and 50°C•min<sup>-1</sup>. Therefore, the main reason of the decrease of self-disintegrating rate was the formation of 2CaO•Al<sub>2</sub>O<sub>3</sub>•SiO<sub>2</sub>.

**The Effect of Ultrasonic Treatment on Alumina Leaching from Calcium Aluminate Slag:** Sun Huilan<sup>1</sup>; Wang Bo<sup>1</sup>; Guo Dong<sup>1</sup>; Zhang Xuezheng<sup>1</sup>; Bi Shiwen<sup>2</sup>; <sup>1</sup>Hebei University of Science and Technology; <sup>2</sup>Northeastern University

The effect of ultrasonic on alumina leaching property of calcium aluminate slag was investigated. The effects of the main leaching parameters such as ultrasonic power, leaching time, leaching temperature, and the concentration of sodium carbonate on alumina leaching rate were determined. The effect mechanism of ultrasonic was also discussed. It was found that the increase of leaching rate was slight, but leaching conditions were improved obviously when ultrasonic was used in leaching process. Leaching temperature and sodium carbonate concentration decreased by 30°C and 60g•L<sup>-1</sup> when there was ultrasonic wave. Ultrasonic would not promote the decomposition of  $\gamma$ -2CaO•SiO<sub>2</sub>. The agglomeration of leaching residue was prevented by the cavitation and mechanical effect of ultrasonic.

**Preparing Polymerized Aluminum-Ferrum Chloride with Red Mud:** *Lu Guilin*<sup>1</sup>; Yu Haiyan<sup>1</sup>; Bi Shiwen<sup>1</sup>; <sup>1</sup>School of Sciences; Shenyang University of Technology

Put forward a new method to prepare polyaluminium ferric chloride(PAFC) with red mud. Discuss the effect of pH of PAFC on basicity, study the difference of products in the process of red mud hydrolyzing from products in the process of sodium hydroxide hydrolyzing. The results show that basicity increases with the increases of pH, the prefer pH value is 3.5, and basicity is up to 85.55%. Comparing appearance of PAFC with that of crystal aluminium chloride, polyaluminium chloride by SEM can indicate that distribution of materials is not uniform on the surface of PAFC. Energy chromatogram analysis indicate that content of aluminum, iron, oxygen elements accounts for 60.73% in the white areas, 43.95% in the black areas in process of red mud hydrolyzing; the content of aluminum, iron, oxygen elements in white areas is 49.74% , 23.45% in black areas in process of sodium hydroxide hydrolyzing.

**Production of Hematite Ore from Red Mud:** *Puliyur Krishnaswamy Narasimha Raghavan*<sup>1</sup>; Nand Kumar Kshatriya<sup>1</sup>; <sup>1</sup>Bharat Aluminium Co. Ltd., (A Unit of Vedanta Resources Plc.), BALCO Nagar, Korba

Red Mud generated as a waste material in the Bayer process is a potential source of metal values. Disposal and storage problems will prevail due to the leachable soda content and the bulk to be handled. Jarosite is a waste of Zinc refinery and is both difficult and costly to manage and to dispose safely. Jarosite is normally associated with sulphuric acid and Ferric iron which produce additional acid on hydrolysis. Reaction between red mud and jarosite is expected to produce a liquid phase containing and a solid phase dominated by iron hydroxide. A precipitated Solid (Sodium Sulphate) is obtained from the Liquid Phase and the solid phase was calcined to produce ferruginous solid that could be used as an iron ore. In this paper an attempt is made to evaluate procedure for the preparation of iron ore and marketable salts by reacting the Red Mud and Jarosite.

**Extraction of Alumina from Red Mud by Divalent Alkaline Earth Metal Soda Ash Sinter Process:** *Shib Narayan Meher*<sup>1</sup>; Ashok Kumar Rout<sup>1</sup>; Balakrushna Padhi<sup>2</sup>; <sup>1</sup>Kiit University; <sup>2</sup>National Aluminum Company Limited

A novel method for extraction of alumina from red mud using divalent alkaline earth metal oxide soda ash sinter process followed by thermo chemical leaching in suitable caustic concentration at 105°C for different time is presented in this paper. During sintering Sodalite / Cancrinite , Gibbsite and Boehmite in red mud is converted to sodium aluminate as well as stable phases of divalent alkaline earth metal ferrite, titanate and silicate. In the above novel economic process the extraction of alumina from red mud is achieved 97.64% , 98.7% and 99.5 % by using CaO, MgO and BaO respectively. The morphological study of sinter product as well as leached residue was studied by SEM and XRD . Key Word-Red Mud, Sintering, Leaching and Divalent alkaline earth metal oxide.

**Study on the Strength of Powders Seed-Precipitated from Sodium Aluminate Solutions:** *Gang Xie*<sup>1</sup>; Yu Xiaohua<sup>1</sup>; <sup>1</sup>Technology Center of Yunnan Metallurgy Group Co.Ltd.

The mechanical strength of alumina powders from sintering and precipitation of sodium aluminate solutions were investigated in bench scale studies. The experimental results show that the mechanical strength of the alumina powders increases with increased precipitating temperature and appropriate times of seeds. A higher strength of alumina powders can be obtained as the strength of Al(OH)<sub>3</sub> powders brings to higher.

**The Role of Quasi Web Structure of Nano SiC Whiskers on Strengthen and Density in Bauxite Based Composite Materials:** *Ebrahim Karamian*<sup>1</sup>; Ehsan Mohammadi Zahrani<sup>2</sup>; <sup>1</sup>Isfahan University of Technology; <sup>2</sup>Department of Materials Engineering, University of British Columbia

This study describes the role of quasi web structure of nano β-SiC whiskers on cold crushing strength (CCS) and bulk density in Bauxite based composite materials. SiC whisker is excellent in characteristics (specific strength, specific modulus) and its usefulness as a composite reinforcing

material. Nano β-SiC whiskers can synthesize by the VLS mechanism and using of Fe catalyst at different temperatures. Specimens were composed of a blend of 65 wt.% Chinese bauxite aggregate, 15 wt.% SiC containing material, 10 wt.% coke, 10 wt.% resole and different quantities of silicon compounds carbonized at 800 °C (2 h). The process is consist of a heating at 200 °C (2 h) followed by firing at 1100 °C or 1400 °C (2 h). The web structure formed at 1400 °C and CCS values improved by almost 3-4 times. But they did not fully form at 1100 °C, so that CCS decreased.

**Theory and Experiment on Cooling Strategy during Seeded Precipitation:** *Zhanwei Liu*<sup>1</sup>; Wenmi Chen<sup>1</sup>; Wangxing Li<sup>2</sup>; <sup>1</sup>Central South University; <sup>2</sup>Zhengzhou Research Institute of Chalco

The η-t curve is derived from the dynamical equation of seeded precipitation. The curve has the characteristic of hyperbolic function and the experimental results conform to the characteristic of the curve. The η-t curve indicates that the precipitation ratio rise rapidly at the preliminary stage of precipitation, the precipitation ratio ascend slowly at middle stage of precipitation and the precipitation ratio increase slower and slower at final stage of precipitation. On the basis of this character of the η-t curve and the technology feature of seeded precipitation of producing sandy alumina in Chinese alumina plant, various parameters are determined in precipitation process with intermediate lowering temperature.

**Dissolution Kinetics of Silicon from Sintering Red Mud in Pure Water:** *Xiaohui Li*<sup>1</sup>; Kai Huang<sup>1</sup>; *Hongmin Zhu*<sup>1</sup>; <sup>1</sup>University of Science & Technology Beijing

In the present study, the dissolution kinetics of silicon from sintering red mud in pure water was studied. The different experimental conditions such as liquid-solid ratio (0.3g/L, 0.5g/L, 1.0g/L), particle size (74~185μm, 39~46μm), stirring speed (80r/min, 160r/min, 300r/min), temperature (20°, 40°, 60°) were evaluated. It was found that the silicon extraction increases with temperature, liquid-solid ratio, stirring speed and decreasing in the particle size of red mud. A simple dissolution model, i.e., external film diffusion was determined to be the main step to control the whole dissolution process. The expression of the diffusion model is as follows:  $\ln(C_s/(C_s-C)) = (DA/d) \times t$  The apparent activation energy was correspondingly determined to be 8.67 kJ/mol.

**Human Factors in Operational and Control Decision Making in Aluminium Smelters:** *Yashuang Gao*<sup>1</sup>; Mark Taylor<sup>1</sup>; John Chen<sup>1</sup>; Michael Hautaus<sup>1</sup>; <sup>1</sup>University of Auckland

The aluminium smelting process involves highly complex mechanisms, has rich information but low observability. To operate such a process at maximum current efficiency while striving for continual improvement requires a set of scientific and systematic approaches to problem solving and decision making along with constant human intervention and interaction with the process. Understanding the influence of human factors on the process is important to the improvement of the performance of the operational staff and enhancement of positive impact while minimising negative effects on the process. This poster explains the human factors and decision making involved in the smelting reduction operations and control process, which includes sensing and monitoring signals, identifying abnormalities and implementing appropriate response to not only correct the immediate causes

of the identified problems but also to reduce the variation and continuous improvement of the process over time.

### An Identification Scheme of Grain Boundaries and Construction of Grain Boundary Energy Database: *Byeong-Joo Lee*<sup>1</sup>; <sup>1</sup>Pohang University of Science and Technology

As there exists no systematic way to identify grain boundaries between two grains with arbitrary misorientation relationships, we have developed a systematic scheme to uniquely define individual grain boundaries in polycrystalline materials. This allows us to construct a grain boundary energy database for body-centered-cubic (bcc) Fe in a suitable form for implementation on grain growth simulations. The scheme can be equally applied to identify grain boundaries for different structures and/or individual interfaces between two different phase grains, and enables realistic simulations of phase transformations as well as grain growth assigning real crystallographic orientations to individual grains.

### Computing Thermodynamic Properties of FeCr Alloys by Path Sampling Simulations: *Gilles Adjanor*<sup>1</sup>; Manuel Athènes<sup>2</sup>; <sup>1</sup>EDF R&D; <sup>2</sup>CEA-Saclay

For the prediction of thermal ageing of austeno-ferritic elbows of nuclear reactors primary circuit, as well as to propose candidate chromium ferritic/martensitic steels for Generation IV reactors, the phase diagram of the FeCr system is of primary importance. As ab initio results predict that the mixing enthalpy changes its sign at low temperature due to magnetism, this phase diagram has been recently revised. We report on the application to this system of a path-sampling method, which can be seen as a combination of thermodynamic integration and semi-grand canonical ensemble methods, allowing to alleviate their respective limitations by tuning paths length. As it consists in sampling multiple thermodynamic integrations, the method naturally takes into account both configurational and vibrational contributions to the chemical potential, which can be evaluated separately. In addition, the analysis of path histograms yields a built-in criterion for diagnosing the convergence of chemical potential estimates.

### Identification of Phase Transformation Using Optical Emission Spectroscopy for Direct Metal Deposition Process: *Lijun Song*<sup>1</sup>; Jyoti Mazumder<sup>1</sup>; <sup>1</sup>University of Michigan

The microstructure of an alloy, which is related to the characteristics of its phase diagram, is strongly correlated to its mechanical properties. However, the analysis of microstructure of an alloy has been limited to the postmortem analysis such as optical or scanning electron microscopes. Real time microstructure diagnosis during processing is still not possible. Here we report an in-situ identification of phase transformation by diagnosing the laser induced plasma during direct metal deposition process. Within the same microstructure range, the spectral line intensity ratio is proportional to the composition ratio; however, when there is a phase change, the linear relationship is broken and another linear relationship within the range of the new phase is formed. This phase related plasma change reflects the initial nucleation of the crystallography of the alloy in early stage and will be applicable for in-situ phase transformation identification during any process where plasma is generated.

### Study of the Interaction of Solutes with Interfaces in Iron Using Density-Functional Theory: *Hao Jin*<sup>1</sup>; Ilya Elfimov<sup>1</sup>; Matthias Militzer<sup>1</sup>; <sup>1</sup>The University of British Columbia

Substitutional alloying elements significantly affect the austenite-ferrite phase transformation rates in steels. However, the detailed mechanisms of their interaction with the moving interfaces are not fully understood. To gain insight into the solute-interface interaction density functional studies have been carried using VASP. Simulations have been performed for a Sigma 5 tilt grain boundary in bcc-Fe containing commonly used alloying elements, e.g. Mn, Mo, Nb and V, to determine the binding energies of these solutes to the grain boundary and their activation energies for diffusion along and across the boundary. Further, the interactions of different solutes at the grain boundary have been investigated. This study confirms the strong interaction of Nb with interfaces that is consistent with experimental observations of the effects of Nb in solution in delaying the austenite-to-ferrite transformation.

### Biological Materials Science: Poster Session

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division, TMS: Biomaterials Committee  
*Program Organizers:* Jamie Kruzic, Oregon State University; Nima Rahbar, University of Massachusetts, Dartmouth; Po-Yu Chen, University of California, San Diego; Candan Tamerler, University of Washington

Sun PM-Thurs AM  
Feb 27-Mar 3, 2011

Room: 15A  
Location: San Diego Conv. Ctr

### A Crystallographic and Textural Perspective of Aging and Diagenetic Degradation of Mechanical Properties on Hard Malacological Paleo-Tissues: *Raúl Bolmaro*<sup>1</sup>; María Bayer<sup>2</sup>; Gonzalo Duarte<sup>1</sup>; Natalia De Vincentis<sup>1</sup>; Sandra Gordillo<sup>2</sup>; <sup>1</sup>IFIR; <sup>2</sup>Universidad Nacional de Córdoba

Sea shells of different species are characterized by X-ray diffraction, micro-indentation tests and electron scanning microscopy. A few samples of Amiantis and Prototaca collected on holocene and pleistocene deposits on the Argentine sea coasts were tested in search of crystallographic modifications and mechanical strength degradation in comparison with identical species modern individuals. X ray diffraction was used to look for aragonite replacement by its more stable calcite structure and possible variations on the known highly oriented orientation distribution. On the same samples the strength was evaluated by micro-indentation and the results were correlated with the microscopic observations.

### Antibacterial Microporous Coating Formation on Ti6Al4V Alloy via Micro Arc Oxidation Process: *Faiz Muhaffel*<sup>1</sup>; Eyüp Kayali<sup>1</sup>; Hüseyin Çimenoglu<sup>1</sup>; <sup>1</sup>Istanbul Technical University

Titanium and its alloys have high mechanical properties, superior corrosion resistance, low elasticity module, low density and high biocompatibility. In order to provide the bio-active surface in medical titanium alloys, a hydroxyapatite layer can be developed over the titanium oxide layer by micro-arc oxidation method in recent days. In micro-arc oxidation, an electrolytic solution containing calcium and phosphorus ions, the oxide layer is formed on the anode material. In the micro-arc oxidation of titanium and its alloys, microporous and rough titanium oxide layer containing hydroxyapatite precipitates formed on the surface and it is bonded firmly to the implant surface. The aim of this study is to develop a microporous, rough and antibacterial surface over Ti6Al4V alloy via micro arc oxidation process. Different amount of silver added to micro arc oxidation solution and examined the antibacterial effect of silver concentration.

### Bactericidal Effect of Silver Reinforced Hydroxyapatite and Carbon Nanotubes: *Atif Faiz Mohammed*<sup>1</sup>; Pallavi Kesarwani<sup>2</sup>; Kantesh Balani<sup>1</sup>; <sup>1</sup>Indian Institute of Technology; <sup>2</sup>Visvesvaraya National Institute of Technology

Bacterial infection remains an important risk factor in orthopedic surgery. Present work aims at the synthesis of silver reinforced hydroxyapatite

(HAp-Ag) and carbon nanotube (CNT-Ag) via spark plasma sintering (SPS) processing route. Phase analysis from X-ray diffraction and Raman spectroscopy confirmed the retention of initial phases even after SPS. Energy dispersive spectroscopy of the spark plasma sintered samples elicited the uniform distribution of silver. Antibacterial test with *Escherichia coli* showed significant difference in number of bacterial colonies in HA-Ag and CNT-Ag w.r.t. HA and CNT. Silver reinforcement depicted an increase in hardness (from 7.754 to 8.966 GPa) and elastic modulus (from 119.98 to 125.31 GPa) for HA sintered sample, whereas a decrease in the hardness (from 0.370 to 0.238 GPa) and modulus (from 5.06 to 3.65 GPa) was observed for CNT sintered sample. Silver reinforcement has shown to influence mechanical properties while rendering bactericidal effect in HA and CNT biocomposites.

**Characteristics and Wear Performance of Nitrided Ti6Al7Nb:** *Farid Siyahjani*<sup>1</sup>; Huseyin Cimenoglu<sup>1</sup>; <sup>1</sup>Istanbul Technical University

Samples of a Ti6Al7Nb were treated by thermochemical gas nitriding for 5 h at 1120 °C. X-ray diffraction analysis of the samples was carried out to identify new phases of chemical compounds in the Ti6Al7Nb. Microstructures were analysed using scanning electron microscopy. The hardness of the nitride layer was over 1800 HV. Cross-sectional microhardness profiles of the samples were obtained using a mikro hardness. The titanium nitride layer exhibited excellent wear resistance along with a lower coefficient of friction against sapphire ball under dry lubricated sliding conditions when compared to the as-received state and measured average friction coefficient of nitride layer.

**Development of Hydroxyapatite and Silicon Carbide Composites via Thermal Plasma Route:** *Atif Faiz Mohammed*<sup>1</sup>; Saroj K Singh<sup>2</sup>; <sup>1</sup>Indian Institute of Technology Kanpur; <sup>2</sup>Institute of Materials and Minerals Technology

Hydroxyapatite (HA) and Silicon Carbide are known to be excellent biocompatible materials. In this study composites of Hydroxyapatite and Silicon carbide have been prepared to enhance mechanical properties. The composites were processed via thermal plasma sintering route. In this technique sintering time is the most important parameter. An optimized sintering time was tried to achieve where no HA phase dissociation and no reaction between HA and SiC is observed. Samples were sintered for four different time durations of 15, 30, 45 and 60 seconds. Also no Silicon dioxide formation took place, which could be attributed to the rapid sintering. In 60 seconds, formation of other phases was observed. Phase analysis was studied using Raman spectroscopy and X-ray diffractometry. Microstructural analysis was done by FESEM and EDX. The results for 45 seconds show homogenous distribution of SiC, no reaction between HA and SiC or any formation of Tricalcium phosphates were observed.

**Fatigue and Mechanical Properties of Co-Cr Alloy Tube for Stents after Ultrasonic Nanocrystal Surface Modification:** *Young Sik Pyun*<sup>1</sup>; Auezhan Amanov<sup>1</sup>; Jun Hyong Kim<sup>1</sup>; Sang Ho Kim<sup>2</sup>; Chae Jong Park<sup>2</sup>; <sup>1</sup>Sun Moon University; <sup>2</sup>M.I.Tech Co., Ltd.

The stent made of Co-Cr alloy tube is widely using for treating peripheral artery disease, including the superficial femoral, carotid, and renal arteries. However, fracture occurrences of up to 50% have been reported in some stents after one year. These stent fractures are likely due to in vivo cyclic displacements. Since Ultrasonic Nanocrystal Surface Modification (UNSM) treatment improves surface integrity, surface hardness, and induces compressive residual stress in surface layers, it was applied to stent tube which was made of Co-Cr alloy in order to prevent these stent fractures and to improve its fatigue life and mechanical properties. In this study, the effects of the UNSM treatment on mechanical characteristics and fatigue life of Co-Cr alloy tube are investigated and compared to untreated one. The experiment results show that UNSM-treated specimen has provided good long-term fatigue life than untreated one.

**Improvement of Mechanical Properties of Ti-6Al-4V after EDM Surface Treatment for Biomedical Applications:** Josef Stráský<sup>1</sup>; Miloš Janeček<sup>1</sup>; Petr Harcuba<sup>1</sup>; Jitka Vrátná<sup>1</sup>; Lothar Wagner<sup>2</sup>; Lucie Bacakova<sup>3</sup>; <sup>1</sup>Charles University; <sup>2</sup>Clausthal University of Technology; <sup>3</sup>Institute of Physiology, Academy of Sciences

EDM (electric discharge machining, spark erosion, electro-erosion) was performed to prepare the surface of the Ti-6Al-4V alloy for biomedical application, namely for optimum bone cell ingrowth into orthopaedic implant. Positive bone cells reaction to surface treated by EDM has been analyzed. However, mechanical properties were found to markedly suffer from this treatment making the implant material unacceptable for biomedical applications. Poor properties are not sufficiently improved by simple annealing or variations in original structure (globular, bimodal etc.). This is due to persisting cracks and voids in the surface and subsurface layers. Therefore subsequent shot peening was performed to reduce the detrimental effect of EDM surface treatment. Mechanical properties were finally evaluated and correlated with modifications in microstructure as observed by SEM.

**Investigation of Incorporating Zirconia Particles into Titanium Oxide Coated by Plasma Electrolytic Oxidation:** *Ki Ryong Shin*<sup>1</sup>; Kang Min Lee<sup>1</sup>; Young Gun Ko<sup>2</sup>; Dong H. Shin<sup>1</sup>; <sup>1</sup>Hanyang University; <sup>2</sup>Yeungnam University

The present study investigated the incorporation of zirconia particles into titanium oxide via plasma electrolytic oxidation (PEO) coating with an AC current density of 200 mA/cm<sup>2</sup>. After PEO coating, a number of fine zirconia particles were uniformly distributed throughout the oxide layer. Based on microstructural observation, it was suggested that mechanisms for the incorporation of zirconia particles were electrophoresis, sintering, and melting in series during coating. In addition, zirconia particles incorporated into the oxide layer played an important role in accelerating the occurrence of biomimetic apatite in a simulated body fluid solution.

**Laser Hardening of Beta Titanium Alloy (Ti-23Nb-0.7Ta-2Zr-1O) for Biomedical Applications:** *Velayutham Nainar*<sup>1</sup>; Geetha Manivasagam<sup>1</sup>; Nandy<sup>2</sup>; Asokamani<sup>1</sup>; <sup>1</sup>VIT University; <sup>2</sup>Defence Metallurgical Research Laboratory

Gum metal (Ti-23Nb-0.7Ta-2Zr-1O) is a new beta titanium alloy possessing ultra- low elastic modulus and high strength to weight ratio. As titanium alloys generally suffer from poor tribological properties an attempt is being made to modify the surface of the samples using Nd-YAG pulsed laser by varying its processing parameters. The phases formed and the microstructures of the laser hardened samples were characterized using X-ray diffraction and scanning electron microscopy. The change in the hardness due to laser hardening treatment was also measured using Vicker hardness tester. Apart from the above, corrosion and the sliding wear behavior of the laser hardened and un-modified gum metal were investigated in simulated body fluid (Hank's solution). The results of the above studies will be discussed in detail.

**Microwave Augmented Fabrication and Evaluation of CNT-Reinforced Nanohydroxyapatite:** M Bilal Khan<sup>1</sup>; Rafaqat Hussain<sup>2</sup>; *Muhammad Aftab Akram*<sup>1</sup>; <sup>1</sup>National University of Sciences and Technology (NUST), SCME; <sup>2</sup>COMSATS

Bioactive CNT reinforced hydroxyapatite nano-composite is synthesized by in-situ precipitation for use in load bearing orthopedic applications. Microwaves augment the synthesis, enhance the reaction rate, and institute energy savings. Heat and acid treated purified CNTs in microwaves are functionalized and dispersed in calcium nitrate tetrahydrate. Diammonium hydrogen phosphate is incorporated in calcium ion solution to furnish the required Ca:P ratio. Refluxing of the precursor solution is accomplished under microwaves. XRD shows the phase purity and crystallinity, FTIR spectroscopy indicates the functionalization of CNTs and SEM analysis depicts the nanoporous nanomorphology of synthesized powder. TGA measures the thermal endurance of product, showing good CNTs retention at high temperatures (1100°C) in nitrogen ambient, otherwise they get oxidized in air in that temperature range. CNT reinforced sintered biomaterial exhibits

excellent consolidation and a Vicker hardness increment of 30%. The relation of between mechanical properties and sintering time is correlated by SEM.

**Multifunctional Nanowire Systems for Drug Delivery:** *Karla Brammer*<sup>1</sup>; Chulmin Choi<sup>1</sup>; Sungho Jin<sup>1</sup>; <sup>1</sup>UC San Diego

Nanostructured materials as drug delivery devices can play a key role in localization and controlled/sustained release of therapeutic drugs within the body. We have prepared vertically aligned silicon nanowire (SiNW) arrays, with a 10-40 nm diameter, by chemical etching and utilized them as novel nanostructures for mediating drug delivery. Here we report antibiotic drug release kinetics from SiNW array "motherships", which are desirably anti-biofouling, as well as capable of storing a relatively large amount of drug which allows for a sustained, therapeutic drug release level and longevity for 42 days. Such antibiotic release from this nanostructured surface can provide more reliable antibiotic protection at a targeted implantation or biosensor site with a low probability of biofouling or clogged pores due to the foreign body response. Furthermore, the bio-degradable nature of these nanowires can eventually allow natural disintegration and removal of the drug delivery vehicles.

**Surface Modification of Bio-implantable Ti-alloy by Hybrid Laser-Arc Processes:** *Soundarapandian Santhanakrishnan*<sup>1</sup>; Mehdi Asgharifar<sup>1</sup>; Radovan Kovacevic<sup>1</sup>; <sup>1</sup>Southern Methodist University

In this study, a new hybrid laser-arc process is proposed to modify the surface texture and mechanical properties of the bio-implantable Ti-alloy. A 2-kW high power diode laser (HPDDL) of 808 nm in wavelength with uniform distribution (top-hat) of laser power coupled with an atmospheric DC arc discharge is used to carry out the experiments. The effect of process parameters such as laser power, scanning speeds, and the current on the variation of surface texture and mechanical properties are studied. The study of microstructure, energy dispersive X-ray spectroscopy (EDX), and hardness measurements are performed to quantify the effect of process parameters on the variation of surface texture and the change of mechanical properties.

**Enhanced Functions of Osteoblasts on Nanophase Titania-Coated Nanostructured Austenitic Stainless Steel:** *Pavan Challa*<sup>1</sup>; Devesh Misra<sup>1</sup>; <sup>1</sup>University of Louisiana at Lafayette

We describe here the significance of electrocrystallized nanonodular titania-coated nanogained/ultrafine grained (NG/UFG) austenitic stainless steel in comparison to bare NG/UFG substrate. The study demonstrates that nanophase titania-coated substrate exhibited higher degree of cell attachment and proliferation which are regulated via cellular and molecular interactions with proteins, actin and vinculin. An accompanying objective is to study the antimicrobial activity. The antimicrobial activity associated with the photocatalytic property of titania was assessed in terms of degradation of methyl orange and effectiveness in killing E Coli.

**Design Considerations for Developing Biodegradable Magnesium Implants:** *Harpreet Brar*<sup>1</sup>; Benjamin Keselowsky<sup>1</sup>; Malisa Sarntinoranont<sup>1</sup>; Michele Manuel<sup>1</sup>; <sup>1</sup>University of Florida

The integration of biodegradable and bioabsorbable magnesium implants into the human body is a complex undertaking that faces major challenges. Developing causal relationships between alloy chemistry and microstructure, and its effect on cellular behavior can be a difficult and time intensive process. A systems design approach driven by thermodynamics has the power to provide significant contributions in developing the next generation of magnesium alloy implants with controlled degradability, biocompatibility, and optimized mechanical properties, at reduced time and cost. This approach couples experimental research with theory and mechanistic modeling for the accelerated development of materials. The aim of this article is to enumerate this strategy, design considerations, and hurdles for developing new magnesium alloys for use as biodegradable implant materials [1]. Reference[1] H.S. Brar, B.G. Keselowsky, M. Sarntinoranont, M.V. Manuel, "Design Considerations for Developing Biodegradable Magnesium Implants." JOM 63/4 (2011), to be published.

## Characterization of Minerals, Metals and Materials: Poster Session

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS/ASM: Composite Materials Committee, TMS: Materials Characterization Committee  
*Program Organizer:* Sergio Monteiro, State University of the Northern Rio de Janeiro - UENF

Sun PM-Thurs AM  
Feb 27-Mar 3, 2011

Location: San Diego Conv. Ctr

*Session Chairs:* Sergio Monteiro, UENF; Felipe Perisse Lopes, UENF

**A Method for Measuring the Critical Fracture Strain at Any Temperature during the Quenching of Tool Steels:** *Chao Zheng*<sup>1</sup>; *Daniel Watt*<sup>1</sup>; <sup>1</sup>University of Windsor

A new type of resistance heated tensile specimen allows the measurement of the critical fracture strain at any temperature during the heat treatment of tool steels in a vacuum. It is unique because it controls the temperature variation along the gage length within +/- 8C over a 0-1200C range. The specimen maintains this throughout heating, soaking, and quenching. During quenching, the cooling rate can be varied over a wide range by controlling the heater current decline, combined with an optional nitrogen gas manifold spray. The process can be interrupted at any stage, and held at constant temperature to measure the critical fracture strain. This includes the period when there are austenite-martensite mixtures; the range where quench cracks commonly form. The lack of having these critical fracture strain measurements in this range has hindered existing, but otherwise powerful, FEA simulations to reliably predict quench fractures.

**Effects of Arc Welding Process on Microstructure and Morphology of Flake Graphite in Grey Cast Iron:** *Arash Elhami Khorasani*<sup>1</sup>; Alireza Kiani-Rashid<sup>2</sup>; <sup>1</sup>Ferdowsi University of Mashhad; <sup>2</sup>Associated Professor at Material Science and Engineering Dept., Ferdowsi University of Mashhad

According to the role of factors such as cooling rate, alloying elements and thickness of specimen, in micro-structure of a welded grey cast iron; the effect of these parameters on graphite structure during arc welding process was studied. Results have shown great influence on localized segregation, dendritical structures and the variation of graphite's morphology, even after annealing. It has also been observed that the presence of temperature gradient within the specimen, especially among the welded metal zone, has resulted in a noticeable change of graphite's essence and cast iron's micro-structure in those areas.

**Preparation SCR Catalyst Carrier by Using APCVD and Sol-Gel Technology to Load TiO<sub>2</sub> on Cordierite Ceramic:** *Jian Yang*<sup>1</sup>; Qingcai Liu<sup>1</sup>; Mei Yang<sup>2</sup>; Wei Gao<sup>1</sup>; Wenchang Xi<sup>1</sup>; <sup>1</sup>university of Chongqing; <sup>2</sup>Southwest Petroleum University

TiO<sub>2</sub> has been loaded on cordierite porous ceramic to prepare the SCR catalyst carrier by using both APCVD and sol-gel technology. In APCVD method, TiCl<sub>4</sub> and O<sub>2</sub> were used as reaction precursor. TiCl<sub>4</sub> was gasified by using N<sub>2</sub> as carrier gas which was controlled to 500scm. Its reaction temperature and reaction time were limited to 773K and 30min respectively. The tests showed that TiO<sub>2</sub> loaded by APCVD method were of graininess shape and even accumulation. The loading rate of TiO<sub>2</sub> and the specific area of carrier sample were increased 114% and 21% respectively comparing with sol-gel technology. In the result of sol-gel method, the maximal difference of Ti content was 66.92%, while the result of APCVD method was 18.89%. It demonstrated that TiO<sub>2</sub> was uniformly attached with the cordierite ceramic by using APCVD method, which would ensure the active ingredients well loaded on the cordierite-TiO<sub>2</sub> carrier in the next procedure.

**Pretreatment of Sulfur and Arsenic Containing Gold Concentrate by Double-Layered Ball Solidification Roast:** Jiang Tao<sup>1</sup>; Li Shan<sup>1</sup>; Ge Jie<sup>1</sup>; Qian Li<sup>1</sup>; Yang Bin<sup>1</sup>; <sup>1</sup>Central South University

Sulfur and arsenic containing gold ore is a typical refractory gold ore. In this paper, double-layered ball solidification roast was proposed, which made gold concentrate pellets in the form of small balls and coated the balls with a layer of solidifying reagent in a certain thickness before roasting. As a result, volatilized  $\text{SO}_2$ ,  $\text{As}_2\text{O}_3$  from inner balls were absorbed by the coats and solidified. The results showed that, double-layer ball roast realized not only effective removal of sulfur and arsenic from gold concentrate, but also complete solidification of volatilized  $\text{SO}_2$ ,  $\text{As}_2\text{O}_3$  from inner balls without any emission pollution, showing superiority compared with conventional solidification roast which inevitably has slight amount of emission that failed to be absorbed. In addition, Solidification products were effectively separated from gold ore calcine. The calcine product showed favorable performance in following cyanide leaching and the obtained gold leaching recovery is more than 95%.

**Pullout Tests of Sisal Fibers in Epoxy Matrix for Characterization of Interfacial Shear Stress:** Wellington Inacio<sup>1</sup>; Artur Pereira<sup>1</sup>; Sergio Monteiro<sup>1</sup>; Fernando Wypych<sup>2</sup>; Rafael Marangoni<sup>2</sup>; <sup>1</sup>State University of the Northern Rio de Janeiro - UENF; <sup>2</sup>UFPR

The efficiency by which an applied load is transmitted from the matrix to reinforcing fibers in a composite depends on the fiber/matrix adhesion strength. This is determined as the interfacial shear stress, IFSS, by means of pullout tests that measure the force needed to pull a single fiber out of a block of material simulating the composite matrix. Different techniques are used to perform pullout tests. The objective of this work was to characterize the IFSS of sisal fibers embedded in epoxy matrix through the determination of the critical length pullout curves. As the main results, a relatively small critical length was found for the sisal fiber/epoxy pullout specimens, corresponding to a lower IFSS. This result was compared to others applying different pullout techniques. Scanning electron microscopy observation identified the mechanism responsible for the weak sisal fiber adhesion to the epoxy matrix.

**Shape-Controlled Synthesis of a Novel Precursor for Preparing Rod Silver Powders:** Jing Zhan<sup>1</sup>; Chuanfu Zhang<sup>1</sup>; Weiyan Jiang<sup>1</sup>; <sup>1</sup>Central South University

A novel precursor of rod silver particles have been synthesized by coordination-precipitation process using ammonia as complex agent, silver nitrate and oxalate or ammonia oxalate as starting material. The phase, composition and morphology of the precursor were characterized by XRD and SEM analysis. The influences of various parameters including the pH value, precipitation temperature, reactant concentration, surfactant on the morphology and size of the precursor particles were investigated in detailed. The results show that the precursors obtained in reaction system  $\text{Ag(I)-C}_2\text{O}_4^{2-}\text{-NH}_3\text{-NH}_4\text{+H}_2\text{O}$  is oxalate silver ammonia complex salt, the morphology is rod and the optimum reaction conditions were 3.8~4.8 for pH value, 0.3 mol/L~0.5 mol/L for silver ions concentration, 50~60°C for precipitation temperature and 0.1~0.5% (wt) PVP for surfactant. The rod silver particles with 1.054 m<sup>2</sup>/g for specific surface area can be produced by thermal decomposition of the precursor with rod morphology in mixed atmosphere of nitrogen and carbon dioxide.

**Tensile Behavior of Epoxy Composites Reinforced with Continuous and Thinner Ramie Fibers:** Frederico Margem<sup>1</sup>; Jarbas Bravo<sup>1</sup>; Sergio Monteiro<sup>1</sup>; <sup>1</sup>State University of the Northern Rio de Janeiro - UENF

The mechanical behavior and the fracture characteristics of composites with DGEBA/TETA epoxy matrix reinforced with up to 40% in volume of continuous and thinner ramie fibers were evaluated by tensile tests. Specimens with selected thin fibers aligned along the tensile axis were room temperature tested to rupture. The fracture surface was analyzed by scanning electron microscopy. The results showed significant increase in both the ultimate tensile strength and the elastic modulus. The fracture analysis indicated the possible mechanism for the fiber/matrix interaction, which could be responsible for the composite performance.

**Thermo-Mechanical Properties of Epoxy Diamond Abrasive Composites:** Ruben Jesus Rodriguez<sup>1</sup>; Camila Amaral<sup>1</sup>; <sup>1</sup>Universidade Estadual do Norte Fluminense

Diglycidyl ether of bisphenol A (DGEBA) epoxy resins cured with aliphatic amines present mechanical properties that depend on the amine functionality. In this work an investigation on the thermomechanical behaviour and microstructure of composites with dispersed diamond microparticles in DGEBA resin cured with different functionalities, Tetraethylenetetramine, Tetraethylenepentamine and Jeffamine D230 aliphatic amines was carried out by dynamical mechanical analysis (DMA) and scanning electron microscopy (SEM). The DMA results of the epoxy formulation showed that the storage modulus increases with the amount of diamond particles incorporated into the composite. The composites with epoxy matrix cured with TEPA and D230 aliphatic amines showed distinct mechanical behaviors, mainly as consequence of microstructure difference due to microparticles distribution in epoxy phase. Composites with up to 40 wt. % of diamond microparticles dispersed in epoxy thermosetting matrix DGEBA/TEPA shown better abrasive properties than DGEBA/D230 and DGEBA/TETA formulations.

**Thermodynamic Study on Complex System for Structure-Directed Synthesis of Fibrous Cobalt Powder Precursor:** Jing Zhan<sup>1</sup>; Jianfeng Yue<sup>1</sup>; Chuanfu Zhang<sup>1</sup>; <sup>1</sup>Central South University

Based on the principles of simultaneous equilibrium and mass balance, a series of thermodynamic equilibrium equations of  $\text{Co(II)-C}_2\text{O}_4^{2-}\text{-NH}_3\text{-NH}_4\text{+H}_2\text{O}$  system at ambient temperature are deduced theoretically and the logarithm concentration versus pH (logc-pH) diagrams at different solution compositions are drawn. The results show that when pH is above 8.0, cobalt ions coordinate with ammonia and the precipitation proceeds slowly accompanying with the release of cobalt ions from the multicoordinated  $\text{Co(NH}_3)_n^{2+}$  (n=1, 2, ..., 6), the morphology of cobalt powder precursor is fibrous; when pH is below 8.0, cobalt ions directly react with  $\text{C}_2\text{O}_4^{2-}$ , the morphology of cobalt powder precursor is cubic-shape. According to thermodynamics analysis and calculation, some experiments were done to validate the relation between the total concentration of cobalt ions and pH in this study.

**Chloride 2011: Practice and Theory of Chloride-Based Metallurgy: Poster Session**

**Plutonium Removal from Fluoride Spent Salts:** Jerome Serp<sup>1</sup>; Nathalie Loppinet<sup>1</sup>; Gilles Bourges<sup>1</sup>; <sup>1</sup>CEA

A pyroprocess is developed to remove plutonium from  $\text{CaF}_2$  spent salt in the frame of legacy residues treatment programs. Due to the high melting point of  $\text{CaF}_2$  (mp > 1400°C), the process requires  $\text{CaCl}_2$  addition to the salt residue (60% molar  $\text{CaCl}_2$  – 40%  $\text{CaF}_2$ ) in order to obtain a liquid melt below 700°C. Metallic calcium is used to reduce plutonium species ( $\text{PuO}_2$ ,  $\text{PuF}_4$ ...) into plutonium metal. The obtained metal is recovered after cooling at the bottom of the ceramic crucible used as reaction vessel. In this work, key parameters have been identified in order to optimise the plutonium recovery yield. The shape of the salt to treat (powder or chunks) plays a determining role since  $\text{CaF}_2$  dissolution rate is rather slow. The initial plutonium mass in the spent salt is also important to obtain plutonium metal coalescence as a massive button. Plutonium recovery yield greater than 90% is obtained.

## Computational Thermodynamics and Kinetics: Poster Session

*Sponsored by:* The Minerals, Metals and Materials Society, ASM International, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS: Alloy Phases Committee, TMS: Chemistry and Physics of Materials Committee, TMS/ASM: Computational Materials Science and Engineering Committee, ASM: Alloy Phase Diagrams Committee

### A Heat Management Model for Hardness Uniformity of Multi-Pass Laser Heat Treatment Using Direct Diode Laser: *Soundarapandian Santhanakrishnan*<sup>1</sup>; Radovan Kovacevic<sup>1</sup>; <sup>1</sup>Southern Methodist University

In this study, a cooling rate model coupled the finite element (FE) technique and the thermo-kinetic (TK) equations are developed to predict the temperature history, rates of heating and cooling, phase transformations, and the hardness. As-used boundary conditions, temperature dependent materials properties, and phase change kinetics are adopted in this model. A 2-kW HPDDL of 808 nm in wavelength with the uniform distribution (top-hat) of laser power is used to heat treat the material of tool steel AISI S7. A heat balance between the heat input of HPDDL and the cooling by a cold air jet is established. A number of experiments are carried out by changing the laser power, scanning speeds, and the rate of cooling. Microstructural characterization and hardness measurement are performed to evaluate the effect of cooling by the cold air during heat treatment on the variation of microstructure, and the hardness.

### Critical Temperature for Grain Boundary Unpinning and Subsequent Grain Growth: *Corentin Guebels*<sup>1</sup>; Phi Thanh<sup>1</sup>; Joanna Groza<sup>1</sup>; Elizabeth Holm<sup>2</sup>; Jean-Pierre Delplanque<sup>1</sup>; <sup>1</sup>University of California, Davis; <sup>2</sup>Sandia National Laboratories

The mechanisms of grain boundary pinning and grain growth inhibition by second-phase particles are well known. This investigation extends work done by Holm and co-workers on this topic and focuses on conditions in which some grain boundaries may become unpinning in an otherwise stable, pinned microstructure. The influence of temperature on grain boundary unpinning was investigated numerically using a 3D Monte-Carlo Potts approach. The probability of grain boundaries becoming unpinning as a result of thermally activated microstructural fluctuations increases with temperature while the characteristic time for unpinning decreases. If the probability of grain boundary unpinning is relatively low and the characteristic time for unpinning is not too large, it is possible for a single grain to become unpinning and grow to overtake the microstructure; this is particle assisted abnormal grain growth (PAAGG). The critical values of temperature for the occurrence of PAAGG at prescribed particle volume fractions are characterized.

### Development of Accurate Models for The Microstructure and Properties of Mixed-Oxide Slags: *Angus Gray-Weale*<sup>1</sup>; Patrick Masset<sup>2</sup>; Aurelie Jacob<sup>1</sup>; <sup>1</sup>Monash University; <sup>2</sup>TU Bergakademie Freiberg

Molten oxide slags present in important industrial processes usually have at least three components, for example CaO-SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub>. Useful simulation requires an accurate description of all interactions, at many different compositions. The oxide's high polarisability, and the importance of its higher order deformations, complicates matters further. Any useful model needs a reasonably realistic model of the melt's network structure, and the effect of calcium and aluminium ions on this structure. We report comparisons of the results of simulations and integral-equation calculations

on a selection of molten salts. We show that for all of these, the structures from these two methods of calculation are in good agreement. We also describe the first integral-equation calculation of a molten salt with intermediate-range order based on a realistic interaction potential that includes polarisable ions, and find a structure in good agreement with experiment. This work opens up the possibility that we may use integral-equation methods to predict the structures and thermodynamic properties of complex and ordered molten salt mixtures over a wide range of conditions.

### Domain Structures of Nanoparticles in Magnetic Films: *Jiayang Li*<sup>1</sup>; Yan Yang<sup>1</sup>; Yongmei Jin<sup>1</sup>; <sup>1</sup>Michigan Technological University

Domain structures of nanoparticles in soft magnetic yttrium iron garnet (YIG) and hard magnetic FePt films are studied by using micromagnetic modeling. The two types of magnetic films find important applications in Farady rotator and magnetic storage, respectively, where stable domain structures with high remanent magnetization and large reversal field are required. Computer simulations show details of domain structures and magnetic switching processes in these nanoparticles, and reveal important roles of particle size, shape, and spatial arrangement acting through magnetostatic interactions. It is found that magnetic domain structure largely depends on the particle shape in the soft magnetic YIG, while strongly depends on the particle crystallographic orientation in the hard magnetic FePt. Based on the simulation results and analysis of various energy contributions to domain phenomena, domain mechanisms in YIG and FePt nanoparticle films are explained, which provide insights for nanostructure optimization of magnetic films.

### Engineering Microstructures via General Two-stage Anneals: *Siu Sin Quek*<sup>1</sup>; Marcelo Ciappina<sup>1</sup>; David Wu<sup>1</sup>; <sup>1</sup>Institute of High Performance Computing Singapore

We consider the crystallization of a thin film via interface-/diffusion-limited growth and a nucleation process controlled by general two-stage isothermal anneals. We show that this schedule leads to a two-parameter family of microstructures. The two parameters can be directly related to the annealing temperatures at the two stages and the annealing time for the first stage (we anneal the second stage to a fully transformed microstructure). We use the time-cone method to generate the microstructures, which is subsequently used to compute statistics of various geometrical properties of the crystals. We find that the statistics vary strongly with different combinations of the two parameters. Our results suggest a possible way to easily engineer certain types of microstructures via isothermal annealing stages.

### Entropic Stabilization and Retrograde Solubility in $\beta$ -Zn<sub>4</sub>Sb<sub>3</sub>: *Gregory Pomrehn*<sup>1</sup>; G. Jeffrey Snyder<sup>1</sup>; Axel van de Walle<sup>1</sup>; <sup>1</sup>California Institute of Technology

$\beta$ -Zn<sub>4</sub>Sb<sub>3</sub>, a phase of interest for thermoelectric application, is shown to be entropically stabilized with respect to Zn and ZnSb with significant entropic contributions from both configurational disorder and lattice vibrations. Zn<sub>4</sub>Sb<sub>3</sub> is shown to have retrograde Zn solubility from the ground state stoichiometry of Zn<sub>13</sub>Sb<sub>10</sub> resulting in a p-doped semiconductor. A new phase of interest,  $\beta$ -Zn<sub>3</sub>Sb<sub>3</sub>, is shown to be a potential competing phase on the Zn-deficient side of  $\beta$ -Zn<sub>4</sub>Sb<sub>3</sub>.

### Integrating Finite Temperature Magnetism Into Ab Initio Free Energy Calculations: *Fritz Körmann*<sup>1</sup>; Alexey Dick<sup>1</sup>; Tilmann Hickel<sup>1</sup>; Jörg Neugebauer<sup>1</sup>; <sup>1</sup>Max-Planck-Institut für Eisenforschung

The free energy of a system is a fundamental quantity for predicting phase diagrams, finite temperature materials parameters, or kinetic barriers. An ab initio derivation of it makes a highly accurate evaluation of all excitation processes mandatory. One of the most challenging - but for many engineering materials crucial - contribution is coming from the magnetic degrees of freedom. We have developed an approach that eliminates shortcomings of conventional approaches and that is firmly based on an exact solution of an effective Heisenberg model employing the quantum Monte Carlo approach. We demonstrate the high accuracy achievable by the new approach by computing magnetic heat capacities and free energies for the magnetic pure elements Fe, Co, and Ni, and by extending it to magnetic compounds such

as Cementite (Fe<sub>3</sub>C). Generally, an excellent agreement with experimental data is found.

**Phase Equilibria of the La-Ni-Cu Ternary System at 673 K: Thermodynamic Modeling and Experimental Validation:** *Xuehui An*<sup>1</sup>; Qian Li<sup>1</sup>; Jieyu Zhang<sup>1</sup>; Shuanglin Chen<sup>2</sup>; Ying Yang<sup>2</sup>; <sup>1</sup>Shanghai Key Laboratory of Modern Metallurgy and Materials Processing, Shanghai University; <sup>2</sup>CompuTherm, LLC

Phase equilibria and thermodynamic properties in the La-Ni-Cu ternary system were studied by coupling thermodynamic modeling and experimental validation. A set of self-consistent thermodynamic descriptions for phases in the La-Ni-Cu system were obtained on the basis of those of three constituent binaries and ternary experimental data in literature. The isothermal section at 673 K and the enthalpy of mixing of liquid calculated from the currently established ternary thermodynamic description were compared favorably with available experimental data. Three alloy samples in the La-Ni-Cu system were then selected, synthesized and annealed at 673 K in order to further validate the calculated phase equilibria. These alloys were analyzed with ICP, XRD, OM, SEM/BSE and EDS, and the experimental results agreed well with the calculated phase equilibrium relationships.

**Phase Field Modeling of Static Recrystallization for Deformed Alloys:** *Gao Yingjun*<sup>1</sup>; <sup>1</sup>Guangxi University

Considering characteristics of different deformation region and non-uniform distribution of storage energy in alloy, a multi-state free energy function is proposed to simulate microstructure evolution of static recrystallization for deformation alloy in phase field modeling. The transformation kinetics curve of recrystallization and the time index for Avrami curve are systematic analyzed. The simulation results are well in agreement to other theoretical results and experimental results

**Solubility Modeling of Methanol Aqueous Solutions in Nafion Membrane at 30-60°C:** Hsin-Yi Chen<sup>1</sup>; Shingjiang Jessie Lue<sup>1</sup>; <sup>1</sup>Chang Gung University

The adjective of this study was to establish a mathematical model for predicting liquid sorption levels from binary component systems in Nafion-117 membrane as a function of solvent activities. Flory-Huggins thermodynamic equations were adopted for the solubility modeling. The Flory-Huggins interaction parameters ( $\chi_{im}$ ) between the solvents and membrane were calculated based on the pure solvent solubility results in the membranes. The water-methanol interaction parameter ( $\chi_{12}$ ) was taken from the vapor-liquid equilibrium data and expressed as a function of binary liquid composition. In this modeling procedure, only the interaction parameters between any two components were needed to estimate the sorption levels of water and methanol in the Nafion in a ternary systems. The sorption results of methanol aqueous solutions in Nafion were predicted at temperatures ranging from 30-60 °C. These data are valuable for predicting the methanol permeability in direct methanol fuel cell performance employing Nafion.

**Statistical Model of Precipitation Kinetics for Recycled Commercial Aluminum Alloys:** *Zhenshan Liu*<sup>1</sup>; Volker Mohles<sup>1</sup>; Olaf Engler<sup>2</sup>; Guenter Gottstein<sup>1</sup>; <sup>1</sup>Institut fuer metallkunde und metallphysik; <sup>2</sup>Hydro Aluminium Deutschland GmbH

A thermodynamics based precipitation model for aluminum alloys is presented. The model is capable of describing the simultaneous nucleation, growth and coarsening of all important precipitates in multi-component systems for arbitrary heat treatments. The thermodynamic data required to calculate the nucleation driving force and the equilibrium phase compositions is taken from a database (provided by GTT Technologies, Herzogenrath, Germany) that contains 15 elements (Al, B, C, Cr, Cu, Fe, Mg, Mn, Ni, Si, Sr, Ti, V, Zn, Zr). As a result, the model can be applied on most of commercial aluminum alloys. The model was validated by comparing the simulation with the experiment results of various alloys, such as the precipitate volume fractions and the matrix composition. This validated model was utilized to predict the precipitation kinetics of recycled commercial alloys. In particular, the sensitivity of precipitation on composition fluctuations, which are inherent with recycled materials, is evaluated.

**Surface Prefreezing and Its Effect on Surface Tension of AuSi Nanoparticles:** *Moneesh Upmanyu*<sup>1</sup>; Hailong Wang<sup>1</sup>; <sup>1</sup>Northeastern University

AuSi nanoparticles have emerged as the catalysts of choice for growth of high density silicon nanowire (SiNW) arrays. The surface tension is a critical parameter which is implicated in both direction selection and morphological evolution, yet quantitative understanding remains elusive. In this talk, we use atomistic simulations based on angular EAM classical potential to investigate the interplay between surface structure and surface tension in near-eutectic AuSi liquid alloys. Semi-grancanonical Monte-Carlo simulations reveal a pre-frozen surface structure, consistent with experiments. A combination of surface capillary fluctuation method and surface virial calculations allows us to map the effect of temperature and composition in thin films, while Laplace pressure is exploited to extract the size effect down to 10 nm diameter particles. The implications for morphological and composition growth are discussed.

**The Application of Thermodynamic Analysis In Preparing the MnZn Ferrites Precursor:** *Xue Ping*<sup>1</sup>; Yuan Yaohua<sup>1</sup>; Zhao Peiyu<sup>1</sup>; Chen Xiaofang<sup>1</sup>; <sup>1</sup>Jiangnan University

The thermodynamic analysis on the system of Me(II)-NH<sub>3</sub>-C<sub>2</sub>O<sub>4</sub>-2-(HCO<sub>3</sub>)<sub>2</sub>-H<sub>2</sub>O (Me represents Fe, Mn, Zn) is carried out. The relationship between pH and the total concentration of Me(II) is determined, and the field of coprecipitation is included in the preparing MnZn Ferrites, it shows the thermodynamic analysis coincides with experimental results. The mean diameter of the powder is 2.0 μm after calcination, the sintering temperature is about 40°C lower than that by ordinary dry method. The initial permeability of thermoresponsive MnZn Ferrites is around 4550, the Sensitivity-temperature is less than 1.5°C, and there is good application in the Temperature-Sensitive Sensor.

**The Effect of Nb on the Amount of Retained Austenite and Strengthening in Cold-Rolled TRIP Steels:** *Jong Min Choi*<sup>1</sup>; Bong June Park<sup>1</sup>; Chang Yeon Lee<sup>1</sup>; Seong Ho Han<sup>2</sup>; Kyung Jong Lee<sup>1</sup>; <sup>1</sup>Hanyang University; <sup>2</sup>Automotive Steel Products Research Group, POSCO

The microalloyed TRIP (transformation induced plasticity) steels has been widely studied with the demand of the weight reduction and the safety requirement of vehicle in automotive industry in order to develop high strength and good formability steels. TRIP steels with Nb addition had a potential for 1 GPa grade by grain refinement and precipitation strengthening. However, with increasing Nb contents, the fraction of retained austenite and carbon contents were decreased. In this study, the cold-rolled process was simulated and the predicted microstructures were compared with the measured. The model was mainly focused on the role of Nb on the retained austenite by the carbon redistribution and the bainite and martensite formation. The optimum Nb contents based on strength and formability was also suggested.

**Thermodynamic Modeling of LiNO<sub>3</sub>-NaNO<sub>3</sub>-KNO<sub>3</sub> Ternary Salt for Solar Energy Storage:** *Divakar Mantha*<sup>1</sup>; Ramana Reddy<sup>1</sup>; <sup>1</sup>The University of Alabama

Thermodynamic modeling of the LiNO<sub>3</sub>-NaNO<sub>3</sub>-KNO<sub>3</sub> ternary salt was carried out to predict the eutectic composition and melting point. The predicted salt composition was synthesized and its melting point and heat capacity were experimentally determined using DSC technique. The experimental melting point showed an excellent agreement with the calculated melting point data and was also comparable with the existing literature data. New specific heat capacity of the ternary salt was determined as a function of temperature. Application of these ternary salts for solar energy storage was discussed.

**Thermodynamic Modeling of S-M (M=Al, Zr, Ti and La) Systems Supported by First-Principles Calculations:** *Rongxiang Hu*<sup>1</sup>; Michael Gao<sup>1</sup>; Ömer Dogan<sup>2</sup>; <sup>1</sup>URS at National Energy Technology Laboratory; <sup>2</sup>National Energy Technology Laboratory

CuPd alloys have been widely investigated as promising hydrogen separation membranes and membrane reactors due to their high hydrogen selectivity and permeability. In order to reduce the cost and enhance

hydrogen permeability, NETL has developed CuPd-based ternary alloys using first-principles calculations and CALPHAD modeling. However, sulfur poisoning seriously affects hydrogen permeability of Pd alloys and is a major hurdle for their commercial applications. Although the mechanisms for sulfur poisoning are not well understood, it is worth studying the bulk thermodynamics of these alloys in presence of sulfur. In this study, a series of S-M (M=Al, Zr, Ti and La) binary systems are thermodynamically assessed using CALPHAD method based on available experimental phase equilibria and thermochemistry data. First-principles calculations are used to provide enthalpy formation data when experimental data are not available. Alloying elements that reduce the propensity of sulfur poisoning will be assessed and discussed.

**Thermodynamics Calculation of CuO-NH<sub>3</sub>+NH<sub>4</sub>Cl Solution System:** Weilian Zheng<sup>1</sup>; Dan Li<sup>2</sup>; *Zhongliang Xiao*<sup>1</sup>; Qiyuan Chen<sup>2</sup>; Haixia Tong<sup>1</sup>; <sup>1</sup>Changsha University of Science and Technology; <sup>2</sup>Central South University

A thermodynamic model of dissolution equilibrium process of CuO in NH<sub>3</sub>-NH<sub>4</sub>Cl solution is built according to thermodynamic data, mass action law and the mass conservation principle. Using couple-solving results, a equilibrium surface figure between CuO solid phase and solution-phase, and a overlay figure of the curve of CuO and the leaching solution at simultaneous equilibrium and the curve of Cu(OH)<sub>2</sub>·5Cu<sub>2</sub>O and the solution at precipitation reaction equilibrium attained in this paper.

**A Phase-Field Model with a Novel Way of Coupling to Multi Component Thermodynamic Data:** *Nils Warnken*<sup>1</sup>; <sup>1</sup>University of Birmingham

Phase-field models are remarkable. They are nowadays widely used in materials science and engineering to simulate microstructure evolution in two and three dimensions. Some models are capable to perform simulations for multi component alloys, which is of special interest for alloy development and other engineering applications. However, the coupling of phase-field models with multi component thermodynamics is still quite complicated and not straight forward. In this work a phase-field model for binary and higher order systems is presented, which uses a novel and simple way of incorporating thermodynamic alloy data. This allows for straight forward coupling to CALPHAD type software packages. Alternatively ideal or regular solution descriptions can be used. The model does not assume local equilibrium assumption at the moving interface. Simulations of diffusion controlled phase transformation in binary and multi component systems are shown.

**A Hybrid MD-kMC Algorithm to Study Diffusion in the Presence of Fields: Effect of Coherent Interfaces:** *Enrique Martinez Saez*<sup>1</sup>; Alfredo Caro<sup>1</sup>; <sup>1</sup>LANL

A new hybrid Molecular Dynamics-kinetic Monte Carlo algorithm has been developed in order to study the basic mechanisms taking place in diffusion in concentrated alloys under the action of chemical and stress fields. Parallel implementation of the k-MC part based on a recently developed synchronous algorithm [J. Comp. Phys. 227 (2008) 3804-3823] resorting on the introduction of a set of null events aiming at synchronizing the time for the different subdomains, added to the parallel efficiency of MD, provides the computer power required to evaluate jump rates 'on the flight', incorporating in this way the actual driving force emerging from chemical potential gradients, and the actual environment-dependent jump rates. The time gain has been analyzed and the parallel performance reported. The algorithm is tested on a simple coherent interface sink strength calculation analyzing the bias between vacancies and self-interstitial atoms depending on the character of the interface.

**A Phenomenological Model for Prediction of the Martensite Start Temperature in Steels:** *Albin Stormvinter*<sup>1</sup>; Annika Borgenstam<sup>1</sup>; <sup>1</sup>KTH Royal Inst. of Technology

A phenomenological model for prediction of the martensite start temperature (Ms) in steels has been developed. The model was based on experimental data on Ms from rapid cooling experiments together with a new thermodynamic description. The effects of important alloying elements in steels, such as C, Mn, Cr and Ni on Ms were taken into account. An important

aspect was to describe the different Ms for the formation of lath and plate martensite respectively, based on the experimental results. The modeling work has been assisted by experimental characterization to strengthen the metallographic evidence on how the transition from lath to plate martensite takes place.

**New Approach in Simulating Anisotropy in Thin Film Growth:** *Solmaz Torabi*<sup>1</sup>; John Lowengrub<sup>1</sup>; <sup>1</sup>University of California Irvine

We study the influence of surface and strain energies on heteroepitaxial thin-film growth. We propose an alternate way of simulating anisotropy for the surface energy by using the higher order terms in the free energy. To the second order, the system only has isotropic properties. We can produce different equilibrium shapes by adding higher order terms to the energy. By choosing diamond-cubic-symmetry, we can study the behavior of SiGe/Si thin-films. For this case, we need to add 4th and 6th order terms in the extended-Cahn-Hilliard model. One advantage of this method is its intrinsic regularized behavior. As a result we are able to utilize the energy-stable-scheme in order to have large time steps without losing accuracy. We present numerical results using an adaptive, nonlinear, multigrid finite-difference method. Finally, we add the elastic energy to our diffuse model to predict different Qdot shapes, such as pyramids and domes.

**First Principles Calculation of the  $\alpha$ -ZrO<sub>2</sub>-X, 0 < X < 1 Phase Diagram:** *Benjamin Burton*<sup>1</sup>; A. Van De Walle<sup>2</sup>; <sup>1</sup>NIST; <sup>2</sup>Caltech

Octahedral-interstitial order-disorder in hcp-based ZrO<sub>2</sub>-X suboxides, 0 < X < 1, promotes stress corrosion cracking in Zircalloy cladding on UO<sub>2</sub> fuel rods. A first principles based phase diagram calculation was performed for the  $\alpha$ -ZrO<sub>2</sub>-X solid solution. Planewave pseudopotential calculations of formation energies were used as a basis for fitting a cluster expansion Hamiltonian. As expected near neighbor O-O pairwise interactions are strongly repulsive, but further neighbor interactions are small. The calculated phase diagram has four ordered ground-states, three of which are predicted to be ground-states of the Zr-O binary system.

**Phase Field Crystal Study of Alloys under Irradiation:** *Nana Ofori-Opoku*<sup>1</sup>; Jeffrey Hoyt<sup>1</sup>; Nikolas Provatas<sup>1</sup>; <sup>1</sup>McMaster University

This paper outlines an extension of the Phase Field Crystal (PFC) method in examining the evolution of materials under irradiation. Bombarding highly energetic particles often have deleterious effects on alloys due to this type of athermal ballistic mixing. We incorporate a mesoscopic model of radiation into the atomistic level phase field crystal model. To demonstrate the equilibrium properties, the model is examined in the long wavelength limit, where the equilibrium contributions to the free energy are attained. Radiation effects are determined on an equilibrium basis by considering changes arising in the phase diagrams. The evolution of defect microstructure and the composition field are then modeled and discussed under the application of: grain growth and coarsening kinetics, radiation induced segregation and effects on phase transformations in a eutectic alloy.

**A Novel Approach to Modeling Phase Transformations Free of Numerical Anisotropy:** *Klemens Reuther*<sup>1</sup>; Markus Rettenmayr<sup>1</sup>; <sup>1</sup>Friedrich-Schiller-University Jena

An approach to model phase transformations without any grid anisotropy is presented. The advantageous combination of three main elements allows for a distinct reduction of artificial anisotropy: (1) The governing partial differential equation is solved using the meshless Diffuse Approximation Method with a variety of boundary conditions. (2) The meshless method is applied on a fully amorphous grid which is isotropic on both a mesoscopic and macroscopic scale. (3) The migrating phase interface is tracked precisely by a Moving Particle Method where the tracking particles are directly connected to the grid. The method is at present applied on two-dimensional problems. It combines the precision of regular grids with the isotropy of the moving particle method on an amorphous grid. The opportunities of this method are demonstrated using simulation results on solidification processes that correspond to different practical cases. The further prospects of the method are discussed in detail.

## Electrode Technology for Aluminium Production: Light Metals Poster Session

### Cold Water Model Simulation of Aluminum Liquid Fluctuations Induced by Anodic Gas in New Tape of Cathode Structure Aluminum Electrolytic Cell: Yan Liu<sup>1</sup>; Ting'an Zhang<sup>1</sup>; Zhihe Dou<sup>1</sup>; Hongxing Wang<sup>1</sup>; Guozhi Lv<sup>1</sup>; Qiuyue Zhao<sup>1</sup>; Naixiang Feng<sup>1</sup>; Jicheng He<sup>1</sup>; <sup>1</sup>Key Laboratory of Ecological Utilization of Multi-metal Intergrown Ores of Ministry of Education & School of Materials and Metallurgy, Northeastern University

Compared to conventional cathode structure electrolytic cell, the new tape of cathode structure electrolytic cell can effectively inhibit the fluctuation of liquid aluminum, which can reduce the polar distance, decrease cell voltage, save energy. Cold water model was designed according to scale of 1:3 with 160KA industrial electrolytic cell to examine aluminum liquid fluctuation induced by anodic gas in new tape of cathode structure electrolytic cell. By means of high-speed photography, shooting liquid interface wave in different anode-cathode distance, electrolyte level, aluminum liquid level, and gas flow rate under different factors such as the cathode structure model of the aluminum electrolytic cells water interface wave image. Study shows that in the new tape of cathode structure electrolytic cell, the largest interface wave height will be reduced significantly along with the increase of the anode cathode distance.

### Influence of Ultrafine Powder on the Properties of Carbon Anode Used in Aluminum Electrolysis: Xiao Jin<sup>1</sup>; Deng Songyun<sup>1</sup>; Li Jie<sup>1</sup>; Lai Yanqing<sup>1</sup>; Liu Yexiang<sup>1</sup>; <sup>1</sup>Central South University

The ultrafine powder (<400 mesh) content of ball milling powder has a great influence on the carbon anode quality. Experiment was set on the base of the formula and raw material of an aluminum carbon anode plant in China. The ultrafine powder was separated from ball milling powder by screening method. On the premise of unchanged powder purity and content, anode samples with different ultrafine powder content were prepared and analyzed on their properties. Powder material was characterized by Blaine Number and BET specific area. Results showed that good electrical conductivity, thermal conductivity and air/CO<sub>2</sub> reactivity behavior could be obtained with low ultrafine powder content (3100~4000 Blaine, 2.510~3.734 m<sup>2</sup>/g specific area). Anode properties such as baked density and air permeability were closely related with the ultrafine powder content and Blaine value of powder material. The results have positive meaning on optimizing the properties of carbon anode.

### Preparation NiFe<sub>2</sub>O<sub>4</sub> Matrix Inert Anode Used in Aluminum Electrolysis by Adding Nanopowder: Zhigang Zhang<sup>1</sup>; Guangchun Yao<sup>1</sup>; Yihan Liu<sup>1</sup>; Xiao Zhang<sup>1</sup>; <sup>1</sup>Northeastern University

Two-step sintering process was adopted to prepare NiFe<sub>2</sub>O<sub>4</sub> matrix inert anode in this research. In the process of synthesizing NiFe<sub>2</sub>O<sub>4</sub> spinel, Fe<sub>2</sub>O<sub>3</sub> and NiO powders as raw materials added additives were synthesized at 1000°C. Through crushing and screening, adding NiFe<sub>2</sub>O<sub>4</sub> nanopowder, particle gradation and compression molding, the nickel ferrite matrix ceramic inert anode was sintered secondarily at 1250°C for 6h. The effect of addition level of nanopowder on the density and porosity, bending strength and impact toughness was investigated emphatically. The results showed the addition of NiFe<sub>2</sub>O<sub>4</sub> nanopowder had significantly increased the bending strength and impact toughness of NiFe<sub>2</sub>O<sub>4</sub> matrix ceramic inert anode. Inert anodes had the best comprehensive properties while adding 60wt% nanopowder. The values of density and porosity were 4.62g/cm<sup>3</sup> and 5.2% respectively, the value of bending strength was 53.39MPa and the value of impact toughness was 3.19J/cm<sup>2</sup>.

### Effects of Physical Properties of Anode Raw Materials on the Paste Compaction Behavior: Kamran Azari Dorcheh<sup>1</sup>; Hany Ammar<sup>1</sup>; Houshang Alamdari<sup>1</sup>; Donald Picard<sup>1</sup>; Mario Fafard<sup>1</sup>; Donald Ziegler<sup>2</sup>; <sup>1</sup>Université Laval; <sup>2</sup>Alcoa

The current study investigates the effects of coke particle characteristics and paste formulation on the flowability and the compression behavior of anode pastes. Shape factor and texture of different fractions of cokes were characterized using an image analysis system where the characteristics of each coke were correlated to its vibrated bulk density (VBD). A compression test was designed to study the effects of particle characteristics and paste recipe on the compactability of pastes. The test was applied on four anode pastes, prepared from different coke types, particle size distributions and pitch contents. It was observed that the compression test is significantly sensitive to any changes in raw materials characteristics and formulations. Consequently, the compression test may be used as a tool for evaluating anode quality in relation with material variations.

### A Numerical Benchmark on the Prediction of Macroregregation in Binary Alloys: Hervé Combeau<sup>1</sup>; Michel Bellet<sup>2</sup>; Yves Fautrelle<sup>3</sup>; Dominique Gobin<sup>4</sup>; Eric Arquis<sup>5</sup>; Olga Budenkova<sup>3</sup>; Bernard Dussoubs<sup>1</sup>; Yves Duterrail<sup>3</sup>; Arvind Kumar<sup>1</sup>; Benoît Goyeau<sup>6</sup>; Salem Mosbah<sup>2</sup>; Thibault Quatravaux<sup>1</sup>; Mohamed Rady<sup>5</sup>; Charles-André Gandin<sup>2</sup>; Miha Založnik<sup>1</sup>; <sup>1</sup>Institut Jean Lamour, CNRS – Nancy-Université – UPV-Metz; <sup>2</sup>CEMEF, CNRS – Mines-ParisTech; <sup>3</sup>SIMAP, CNRS – INPG – Université Joseph Fourier; <sup>4</sup>FAST, CNRS – Université Pierre et Marie Curie; <sup>5</sup>TREFLE, CNRS – Université de Bordeaux – ENSAM-ParisTech – ENSCPB; <sup>6</sup>EM2C, CNRS – Ecole Centrale Paris

During the solidification of metal alloys, chemical heterogeneities at the product scale (macroregregation) develop. Numerical simulation tools are beginning to appear in the industry, however their predictive capabilities are still limited. We present a numerical benchmark exercise treating the performance of models in the prediction of macroregregation. In a first stage we defined a “minimal” (i.e. maximally simplified) solidification model describing the coupling of the solidification of a binary alloy and of the transport phenomena (heat, solute transport and fluid flow) that lead to macroregregation in a fully columnar ingot with a fixed solid phase. This model is solved by six different numerical codes, employing different numerical methods (FV and FE) and various solution schemes. We compare the predictions of the evolution of macroregregation in small (10x6 cm) ingots of Pb-18wt%Sn and Sn-10wt%Pb alloys. Further, we present the sensitivities concerning the prediction of instabilities leading to banded channel mesosegregations.

### Binary Alloy Solidification at 35 Tesla: Jason Cooley<sup>1</sup>; Thomas Ott<sup>1</sup>; Sally Tracy<sup>2</sup>; Tim Tucker<sup>1</sup>; Kristen Collar<sup>3</sup>; Scott Lillard<sup>1</sup>; James Foley<sup>1</sup>; Tyler Wheeler<sup>1</sup>; John Balog<sup>1</sup>; Andrew Duffield<sup>1</sup>; Bobby Pullum<sup>3</sup>; <sup>1</sup>Los Alamos National Laboratory; <sup>2</sup>California Institute of Technology; <sup>3</sup>National High Magnetic Field Laboratory

S. Chandrasekar showed in 1954 that the viscosity of a metallic liquid increases quadratically perpendicular to an applied magnetic field. At tens of tesla, this increase in viscosity can be by orders of magnitude, resulting in very anisotropic diffusion constants. Also, the field can orient paramagnetic crystallites in the liquid. Our work is focused on identifying alloys in which an applied field has an effect on the solidification microstructure,

determining its magnitude, and understanding why it occurs. Because the field is an external parameter independent of temperature, composition, and pressure, its ability to effect solidification microstructures has profound implications for the development of engineered microstructures. We report on the solidification microstructures of binary alloys at and near eutectic compositions in 0 and 35 Tesla fields. In Al-Ni and Mg-Sb alloys the microstructures are layered perpendicular to the applied field, while those in the Al-Cu and Ag-Ge systems are parallel.

**Dendritic Growth: Phase Field Crystal Vs. Phase Field Simulations:** *Tamás Pusztai*<sup>1</sup>; Gyula Tóth<sup>1</sup>; György Tegze<sup>1</sup>; László Gránásy<sup>1</sup>; <sup>1</sup>Research Institute for Solid State Physics and Optics

In colloidal systems the particle density relaxes diffusively. As in other systems, the associated Mullins-Sekerka type diffusional instability leads to the formation of dendritic crystals. A simple dynamical density functional theory termed as the phase field crystal (PFC) model has recently been successfully applied to model solidification and pattern formation in colloidal systems. Herein, we demonstrate that large-scale PFC simulations that inherently incorporate elasticity, the anisotropies of the interfacial free energy and kinetic coefficient, surface reconstruction, and surface roughening predict complex dendritic forms of BCC structure in 3D, which vary from faceted dendrites to compact growth forms of rounded shape as the thermodynamic driving force increases. Next, we investigate how far these predictions can be recovered within the framework of a conventional phase-field (PF) model that relies on a Ginzburg-Landau free energy with model parameters (driving force, interface free energy, and kinetic anisotropy) deduced from the PFC model.

**High Speed Synchrotron Tomography for the *In Situ* Quantification of Pore Evolution during the Solidification of Al-Si-Cu-Fe Alloys:** *Chedha Puncreobutr*<sup>1</sup>; Junsheng Wang<sup>2</sup>; Thomas Connolley<sup>3</sup>; Robert Atwood<sup>3</sup>; Peter Lee<sup>1</sup>; <sup>1</sup>Imperial College London; <sup>2</sup>Ford Research and Advanced Engineering Lab; <sup>3</sup>Diamond Light Source Ltd

The presence of pores in aluminum alloy cast components can often limit final fatigue life. In this study we use high speed synchrotron tomography (one scan every 6 s) to quantify the three dimensional evolution of porosity. The alloy studied was W319, Al-7.5Si-3.5Cu-1.2Fe (wt.%). Three different cooling rates were used, comparing the temperature at which the pores formed, as well as quantifying their change in morphology and growth rate. The interaction of the pores with the developing iron intermetallics is also examined. The results are compared to predictions using the  $\mu$ matIC microstructural model.

**In Situ Observations of Rapid Solidification of Metal Thin Films:** *Andreas Kulovits*<sup>1</sup>; Jorg Wiezorek<sup>1</sup>; Thomas LaGrange<sup>2</sup>; Bryan Reed<sup>2</sup>; Geoffrey Campbell<sup>2</sup>; <sup>1</sup>University of Pittsburgh; <sup>2</sup>Lawrence Livermore National Laboratory

We study rapid solidification of metal alloy thin films using the Dynamic Transmission Electron Microscope at Lawrence Livermore National Laboratory. The DTEM combines a conventional TEM with two lasers and provides unprecedented spatio-temporal resolution of about 10 nanometers and 12 nanoseconds facilitating in-situ study of rapid solidification. We used electron diffraction to establish complete melting of the thin films in the illuminated area and imaging mode to monitor the morphology of the liquid-solid interface with nanometer resolution. We determined the interfacial velocity and document morphological evolution during solidification, providing experimental data for validation and verification of theoretical models and computer simulations. The Work was performed under the auspices of the U.S. Department of Energy by the Lawrence Livermore National Laboratory and supported by the Office of Science, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, of the U.S. Department of Energy under contract No. DE-AC52-07NA27344.

**Measurement of the Minimum-Undercooling Spacing of In-In<sub>2</sub>Bi Eutectic Alloys Using Real-Time Videomicroscopy in Thin-Sample Directional Solidification:** *Sabine Bottin-Rousseau*<sup>1</sup>; Silvère Akamatsu<sup>2</sup>; Gabriel Faivre<sup>2</sup>; <sup>1</sup>UPMC / CNRS; <sup>2</sup>INSP

We present an experimental study of the dynamics of lamellar eutectic patterns in directional solidification of In-In<sub>2</sub>Bi alloys in 12- $\mu$ m thick glass-wall samples. The solidification front is observed in real time using reflected-light videomicroscopy. We checked the 1D character of the pattern post-mortem using transverse metallographic sectioning. We focus on the time evolution of patterns that initially contained a smooth spatial modulation of the interlamellar spacing  $\lambda$  about an average value  $\langle \lambda \rangle$ . The spacing distributions obeyed a diffusion-like equation with a  $\lambda$ -dependent coefficient. We determined a threshold spacing value  $\lambda_E$  (where the subscript E stands for « Eckhaus instability »), above which  $\lambda$  modulations relax towards uniformity, and below which they amplify, eventually leading to lamella elimination. Using the semi-empirical corrections to Langer's approximate formula for  $\lambda_E$  [Akamatsu et al. Metall. Mater. Trans. 35A 1815 (2004)], we estimated the material constant  $\lambda_{min}^2 V$  for In-In<sub>2</sub>Bi alloys ( $\lambda_{min}$ : minimum-undercooling spacing).

**Morphology of Graphite Formation from Melt:** *Shaahin Amini*<sup>1</sup>; Haamun Kalaantari<sup>1</sup>; Reza Abbaschian<sup>1</sup>; <sup>1</sup>University of California Riverside

The morphology of graphite and/or graphene layers grown from molten hypereutectic Ni-, Cu- and Fe-c alloys has been investigated. The process involved dissolving carbon in the melt using induction and arc melting processes, followed by cooling to allow the saturated carbon to nucleate and grow as graphite. Experiments showed graphite morphology would depend on the type of metal, nucleation sites, amount of carbon and cooling rate. The optical and scanning electron microscopy as well as Raman spectroscopy showed the thickness of graphite formed on the surface ranged from nanometer to bulk graphite, and were bounded by triangular cross section ridges. The ridge formation is believed to be due to the accommodation of thermal expansion coefficient mismatch between the metal substrate and graphite layer. The morphology of surface graphite was compared with those grown inside the melt and graphite formed as secondary phase on surface of metal dendrite in hypoeutectic alloys.

**Multicomponent Segregation Path with Solid and Liquid Diffusion Coupled with Thermodynamic Equilibrium Calculations:** *Charles-Andre Gandin*<sup>1</sup>; Haithem Ben Hamouda<sup>1</sup>; Hongwei Zhang<sup>2</sup>; Damien Tournet<sup>1</sup>; <sup>1</sup>MINES-ParisTech; <sup>2</sup>Northeastern University

A microsegregation model for the solidification of multicomponent alloys is presented. It couples the volume-averaged conservation equations for total mass, solute mass and energy assuming a uniform temperature. The model includes the effect of diffusion in the liquid and solid phases, the growth kinetics of the solidifying microstructure and the velocity of the solid/liquid interface. Equilibrium between phases is taken into account and computed using a thermodynamic software. Illustration is provided by the solidification of a Fe-1wt%Cr-10wt%Ni alloy. Predictions include the occurrence of a recalescence due to the growth of the microstructure and the progress of solidification. Results are compared with previous works, including Rappaz and Boettinger (Acta materialia 47 (1999) 3205) and Chen and Sundman (Materials Transactions 43 (2002) 551).

**Solidification Processing via Contactless Electromagnetic Acoustic Transmission (EMAT) Driven by High Magnetic Fields:** *Orlando Rios*<sup>1</sup>; John Wilgen<sup>1</sup>; Roger Kisner<sup>1</sup>; Gerard Ludtka<sup>1</sup>; Gail Mackiewicz Ludtka<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

When induction heating is applied in a high magnetic field environment, the induction heating coil is typically configured in such a way that a high intensity ultrasonic signal is superimposed. The resulting non-contact electromagnetic acoustical transducer (EMAT) dramatically impacts nucleation and growth by fundamentally altering the solid/liquid interfaces. The current study examines the microstructure of three materials consisting of pure Mg, a commercial Mg alloy and a commercial cast iron. Solidification experiments were conducted at the NHMFL using a custom sample environment and instrumentation developed by the magnetic processing

team at ORNL. Each material was induction melted by conventional means and parallel samples solidified under EMAT near 10 kHz driven by magnetic fields up to 20 Tesla under a controlled atmosphere in custom cylindrical crucibles. A comparison to the conventionally solidified material reveals that the high intensity acoustic frequency EMAT promotes a finer scale microstructure and uniquely interesting morphological features.

**Three-Dimensional Characterization and Modeling of Solidified Microstructures of Magnesium-Based Alloys:** *Mingyue Wang*<sup>1</sup>; Tao Jing<sup>1</sup>; Nikhilesh Chawla<sup>2</sup>; <sup>1</sup>Tsinghua University; <sup>2</sup>Arizona State University

Microstructural features of most of engineering materials involved solidification processes are typically three-dimensional and polycrystalline network structure geometrically. The importance of the full three-dimensional characterization including morphologies selection, microstructures evolution, and growth mechanism, and modeling of microstructures and how to bridge that is being realized. Here we demonstrate the use of dual-beam focused ion beam-scanning electron microscopy (DB FIB-SEM) to make a complete three-dimensional reconstruction of the solidified microstructures of magnesium-based alloys, further, on the basis of that, the three-dimensional phase field model derived directly from thermodynamic theory is improved and modified by experimental observations and correlated simulations were conducted. The combined description of three-dimensional microstructural characterization and modeling has important potential applications to the understanding of interaction relationship model of processing-microstructures-properties which is the foundation of modern materials science.

**Theoretical and Computational Study of Lamellar Three-Phase Patterns in a Model Ternary Eutectic System:** *Abhik Choudhury*<sup>1</sup>; Mathis Plapp<sup>2</sup>; Britta Nestler<sup>1</sup>; <sup>1</sup>Institute of Materials and Processes; <sup>2</sup>Ecole Polytechnique

We investigate lamellar three-phase patterns that form during the directional solidification of ternary eutectic alloys in thin samples. A distinctive feature of this system is that many different geometric arrangements of the three phases are possible, contrary to the widely studied two-phase patterns in binary eutectics. Here, we first analyse the case of stable lamellar coupled growth of a symmetric model ternary eutectic alloy, using a Jackson-Hunt type calculation in thin film morphology, for arbitrary configurations, and derive expressions for the front undercooling as a function of velocity and spacing. Next, we carry out phase-field simulations to study the instabilities of the simplest periodic lamellar arrays. For large spacings, we observe different oscillatory modes that are similar to those found previously for binary eutectics and that can be classified using the symmetry elements of the steady pattern. For small spacings, we observe a new instability that leads to a change in the sequence of the phases. Its onset can be well predicted by our analytic calculations. Finally, some preliminary phase-field simulations of three-dimensional patterns are presented.

## Magnesium Technology 2011: Poster Session

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Magnesium Committee

Program Organizers: Wim Sillekens, TNO Science and Industry; Sean Agnew, University of Virginia; Suveen Mathaudhu, US Army Research Laboratory; Neale Neelameggham, US Magnesium LLC

Sun PM-Thurs PM  
Feb 27-Mar 3, 2011

Room: 6F  
Location: San Diego Conv. Ctr

Session Chair: Eric Nyberg, Pacific Northwest National Laboratory

## Interdiffusion in the Mg-Al System and Intrinsic Diffusion in $\beta$ (Al<sub>3</sub>Mg<sub>2</sub>)

**Phase:** *Sarah Brennan*<sup>1</sup>; Katrina Bermudez<sup>1</sup>; Nagraj Kulkarni<sup>2</sup>; Yongho Sohn<sup>1</sup>; <sup>1</sup>University of Central Florida; <sup>2</sup>Oak Ridge National Laboratory

Intrinsic and interdiffusion between pure Mg (99.9%) and pure Al (99.999%) was examined using three solid-to-solid diffusion couples. The couples were annealed at 300°, 350° and 400°C for 30, 15 and 10 days,

respectively. The interaction layers that developed were examined by optical and scanning electron microscopy. Concentration profiles were determined by energy dispersive spectroscopy and electron microprobe analysis. A thick layer of  $\beta$  (Al<sub>3</sub>Mg<sub>2</sub>) and a thin layer of  $\beta$  (Al<sub>12</sub>Mg<sub>17</sub>), both with measurable concentration gradients, formed in all three couples. However, the  $\epsilon$ -phase was not observed at any temperature studied. The marker plane was identified within the  $\beta$ -phase, close to the Al/ $\beta$  interface. Interdiffusion coefficients in Mg- and Al-solid solution,  $\beta$ -phase,  $\gamma$ -phase, and intrinsic diffusion coefficients within  $\beta$  (Al<sub>3</sub>Mg<sub>2</sub>) are reported and discussed.

**High Strain-Rate Behaviour of Die Casting Magnesium-Aluminium Alloys:** N.V. Dudamell<sup>1</sup>; F. Gálvez<sup>2</sup>; M.T. Pérez-Prado<sup>1</sup>; <sup>1</sup>Madrid Institute for Advanced Studies in Materials (IMDEA Materials); <sup>2</sup>ETS Ingenieros de Caminos

Magnesium alloys, due to their relative low density, are considered as very attractive candidates to be used in the transportation industry where weight saving entails a drop of fuel consumption and, therefore, a reduction of CO<sub>2</sub> emissions. Die casting is the most extended technique used in the fabrication of magnesium components because it allows high productivity and good mechanical properties, being the automotive industry one of the main customers. To increase the application of magnesium components in the automotive industry it is extremely necessary to understand the deformation mechanisms that take place during dynamic straining of die casting magnesium alloys, which are nowadays widely unknown. This investigation is focused on the analysis of the high-strain-rate mechanical behavior of Mg-Al die casting alloys. With this purpose, tests have been performed in a Hopkinson bar, in tension and in compression, at temperatures between 25°C and 400°C.

**High-Temperature Elastic Properties of Two Wrought Magnesium Alloys:** *Matt Freels*<sup>1</sup>; Elena Garlea<sup>2</sup>; Jonathan Morrell<sup>2</sup>; Miladin Radovic<sup>3</sup>; Peter Liaw<sup>1</sup>; <sup>1</sup>Department of Materials Science and Engineering, University of Tennessee; <sup>2</sup>Applied Technologies Division, Y-12 National Security Complex; <sup>3</sup>Department of Mechanical Engineering, Texas A&M University

The elastic constants of the hexagonal close-packed (hcp) wrought magnesium alloys, ZK60A and AZ31B, were measured by dynamic and static methods from room temperature to 450°C. The ZK60A and AZ31B alloys exhibit two different crystallographic textures, respectively, typical for extrusion and rolling. The dynamic resonant ultrasound spectroscopy (RUS) method was selected to investigate the effects of crystallographic texture on the elastic mechanical properties in three directions (extruded or rolled, transverse, and normal). The results from RUS were compared to those from static mechanical testing. From RUS measurements, the Young's, shear, and bulk moduli were found to decrease with temperature, while the Poisson's ratio increased with temperature. At lower temperatures the Young's moduli obtained from mechanical testing agreed well with the RUS measurements. However, at higher temperatures, the Young's moduli from mechanical testing were significantly lower when compared to those from RUS.

## Development and Characterization of New AZ41 and AZ51 Magnesium

**Alloys:** *Md Ershadul Alam*<sup>1</sup>; Han Samson<sup>2</sup>; Abdelmagid Hamouda<sup>1</sup>; Quy Nguyen<sup>2</sup>; Manoj Gupta<sup>2</sup>; <sup>1</sup>Qatar University; <sup>2</sup>National University of Singapore

In the present study, new AZ41 and AZ51 magnesium alloys were successfully synthesized by adding 1 wt. % and 2 wt. % aluminum into AZ31B matrix, respectively, using an innovative disintegrated melt deposition technique followed by hot extrusion. Microstructural characterization studies revealed equiaxed grain morphology, reasonably uniform distribution of intermetallics in the matrix and minimal porosity. Physical properties characterization revealed that addition of Al reduced the coefficient of thermal expansion (CTE) of monolithic AZ31B. The presence of higher percentage of aluminum also assisted in improving overall mechanical properties including microhardness, modulus of elasticity, 0.2% yield strength, ultimate tensile strength, and work of fracture of AZ31. The results suggest that these newly developed AZ magnesium alloys have significant potential in diverse engineering applications when compared to AZ31 alloy.

**Edge-Wise Determination of Compression Strength in Magnesium Alloy Sheet:** *Eric Nyberg*<sup>1</sup>; Curt Lavender<sup>1</sup>; Elizabeth Stephens<sup>1</sup>; Richard Davies<sup>1</sup>; Robert Klingensmith<sup>2</sup>; <sup>1</sup>Pacific Northwest National Laboratory; <sup>2</sup>DOE Academies Creating Teacher Scientists

Quantifying the anisotropic properties in bulk HCP metals is common; however, determining the inhomogeneous properties is inherently more difficult with sheet products. To compare the edge-wise compressive strength of magnesium sheet to standard tensile tests, the compression samples were oriented in the rolling direction, accounting for their tendency to buckle. The edge-wise compressive strength is compared to the tensile yield strength of AZ31 sheet. The compressive strength is determined using a test fixture to prevent buckling, identified for use in ASTM D-695, Standard Test Method for Compressive Properties of Rigid Plastics. The testing was followed according to ASTM E9-09, Standard Test Methods of Compression Testing of Metallic Materials at Room Temperature. The in-situ strain evolution is captured optically using speckle pattern strain imaging. Comparison is made of the anisotropy in fine grained, friction stir processed material versus coarse grained sheet. The compressive strength is compared to bulk compression properties.

**The Grain-Size Dependence of Fatigue Failure Mechanism in Tension Cycles in AZ31 Mg Alloys:** *Daisuke Ando*<sup>1</sup>; Junichi Koike<sup>1</sup>; Yuji Sutou<sup>1</sup>; <sup>1</sup>Tohoku University

The mechanisms of fatigue deformation and failure were studied in rolled AZ31 sheets having a grain size of 5 and 220  $\mu\text{m}$ . Tensile cycle tests were carried out at room temperature to investigate the effects of {10-12} twinning and dislocation slip on cyclic deformation behavior. Fatigue tests were also performed in tension cycle at 10 Hz and  $R = 0.1$ . Deformation twinning of {10-12} type was observed both below and above the fatigue limit. Prismatic slip was observed only above the fatigue limit. They indicated the fatigue limit coincides with the stress required to activate cross-slipping of prismatic slip. In the coarse grain, {10-11}-{10-12} double twinning gave rise to the formation of surface steps and subsequent fatigue cracks. In contrast, the fine grain sample showed neither surface steps nor deformation twinning. Fatigue failure occurred in an intra-granular manner. The failure was probably caused by work hardening with cross-slipping.

**Effect of 15kHz Ultrasonic Treatment on Purification of Magnesium Alloy Melts:** *Qichi Le*<sup>1</sup>; <sup>1</sup>Northeastern University

The effective substitution methods of fluxing processing for magnesium melt purification are paid more attention recent years in order to avoid the risk of flux inclusions and alleviate environmental pressure. The former research in our group had showed the 20kHz ultrasonic treatment could promote and accelerate the separation of oxidation inclusions from magnesium melt by its conglomeration effect. In this research, 15kHz ultrasonic treatments on AZ80 and GW103K magnesium melts were also investigated and the similar results were achieved. The results show that the metal temperature, the ultrasonic power, treating time, and holding time all influent the purification degree, and the over 80% and over 70% of inclusions in AZ80 and GW103K melts could settle into the bottom layer at the optimum treating condition, respectively. In addition, the electrical conductivity study of ingot showed that the electrical conductivity of ingot could characteristic its purification degree commendably.

**The Effect of Different Physical Fields on the Process of Direct Chill Casting for AZ80 Magnesium Alloy Billets:** *Zhiqiang Zhang*<sup>1</sup>; Qichi Le<sup>1</sup>; Jianzhong Cui<sup>1</sup>; <sup>1</sup>Northeastern University

On the basis of conventional direct chill (DC) casting, different physical fields are applied during DC casting of F165mm AZ80 magnesium alloy billets. The effects of low frequency electromagnetic field (LFEC) and ultrasonic field (US) on microstructures, macrosegregation of alloying elements and mechanical properties of AZ80 billets was investigated. The results show that microstructures of DC casting AZ80 billets under different physical fields are significantly refined. Mechanical properties are increased and alloying element distribution are also very uniform. The effective refinement takes place in the edge of AZ80 billets cast by LFEC. However, the effective refinement takes place in the center of AZ80 billets cast by US.

A new process for DC casting of magnesium alloy billets was developed by application of combining LFEC with US which can significantly refine the microstructures in the entire cross section of the billets, and the mechanical properties of the billets were improved.

**Extrusion-Processed Mg-Zn-Al-(Y) Base Alloys with Dispersion of Quasicrystal Phase:** *Guangyin Yuan*<sup>1</sup>; Jian Tong<sup>1</sup>; Hua Huang<sup>1</sup>; Wenjiang Ding<sup>1</sup>; <sup>1</sup>Shanghai Jiao Tong University

The structure and mechanical properties of extrusion-processed Mg-Zn-Al-(Y) base alloys containing an icosahedral quasicrystal phase (i-phase) as a main strengthening phase were investigated. Mg-8Zn-4Al-xY ( $x=0,1$ ) base alloys containing the i-phase were prepared by casting into a permanent mold at moderate cooling rates and then extruding at 598K with the extrusion ratio of 9. The Y addition was effective for decreasing the size of the i-phase and the increasing the homogeneity of its dispersed state. This Mg-Zn-Al-(Y) alloys reinforced with quasicrystal and related phase particles showed high strength and ductility balance, which was superior to that of the well-known quasicrystal phase dispersed in Mg-Zn-RE alloys.

**Engineering a More Efficient Zirconium Grain Refiner For Magnesium:** *Srinath Viswanathan*<sup>1</sup>; Partha Saha<sup>1</sup>; David Foley<sup>2</sup>; K. Ted Hartwig<sup>2</sup>; <sup>1</sup>University of Alabama; <sup>2</sup>Texas A&M University

A systematic study of the grain refinement of magnesium by zirconium was conducted: variables included the amount of zirconium, the pouring temperature, and the settling time prior to casting. Optical microscopy was utilized to measure the grain size. Sample dissolution followed by SEM was used to characterize particle size and morphology both in the master alloy and grain refined samples. It was apparent that only 1 to 3% of the total particles serve as nucleation sites, but a comparison of the grain density vs. faceted particle density showed close agreement, suggesting that only faceted particles were likely nucleation sites. ECAE processing of the magnesium-15wt% zirconium master alloy to increase the number of faceted particles resulted in improved grain refinement efficacy.

**Severe Plastic Deformation Temperature Influences on Texture Development in AZ31B Magnesium:** *David Foley*<sup>1</sup>; Sonia Modarres Razavi<sup>1</sup>; K.T. Hartwig<sup>1</sup>; Laszlo Kecskes<sup>2</sup>; Ibrahim Karaman<sup>1</sup>; Suveen Mathaudhu<sup>2</sup>; <sup>1</sup>Texas A&M University; <sup>2</sup>U.S. Army Research Lab

Depending on the route and "class" of alloy, Equal Channel Angular Extrusion of Mg alloys produces several archetypal textures. However, these textures are the result of "warm" deformation, on the order of 200C. In an effort to obtain high strength through grain refinement, several groups have explored lower temperature deformation where dynamic recrystallization does not limit grain refinement. The authors have found that when AZ31 is deformed at sufficiently low temperature in a preferentially basal slip route, non-basal slip seems to be completely inactive. This generates a closely oriented texture and ultra-fine grain size. The typical ECAE textures for AZ31 have either a split or spread peak character, making it difficult to isolate grain size effects on specific deformation modes. In this case, comparison with coarse-grain material is straightforward. The effect of grain size on the yield strength under various deformation modes will be discussed.

**Microstructure and Mechanical Properties of Mg-1.7Y-1.2Zn Sheet Processed by Hot Rolling and Friction Stir Processing:** *V. Jain*<sup>1</sup>; J.Q. Su<sup>2</sup>; R.S. Mishra<sup>2</sup>; R. Verma<sup>3</sup>; A. Javaid<sup>4</sup>; M. Aljarrah<sup>4</sup>; E. Essadiqi<sup>1</sup>; <sup>1</sup>Division of Engineering Materials, National Physical Laboratory, CSIR; Center for Friction Stir Processing and Department of Materials Science and Engineering, Missouri University of Science and Technology, Rolla; <sup>2</sup>Center for Friction Stir Processing and Department of Materials Science and Engineering, Missouri University of Science and Technology, Rolla; <sup>3</sup>General Motors R&D Center; <sup>4</sup>Materials Technology Laboratory-CANMET, Ottawa

The use of lightweight structural materials is an integral part of mass reduction strategy in transportation applications. Magnesium based sheet products have gained significant interest in the automobile industry. Newer magnesium alloys such as Mg-Y-Zn have potential to develop sheet products with superior mechanical properties owing to improved precipitation hardening response. In the present work, rolled sheet of an Mg-1.7Y-1.2Zn

alloy containing small amounts of Al and Ce was investigated. Microstructure and mechanical properties were examined in as-rolled, rolled+aged, friction stir processed (FSP) and FSP+aged conditions. Mechanical properties (YS, UTS and %El) of the sheet showed certain anisotropy in rolling and transverse directions, which was marginally reduced upon ageing. However, FSP led to a significant range of mechanical properties depending on the test direction. Ageing of FSPed sheet showed improvement in mechanical properties and reduced anisotropy in the two directions. The static recrystallization due to ageing caused reduced anisotropy in FSP treated sheet. The overall strength-ductility variation is discussed in terms of relative contributions of grain boundary strengthening, texture and precipitation strengthening.

**Texture Evolution in Large Strain Extrusion Machining of Magnesium Alloy AZ31B:** *Dinakar Sagapuram*<sup>1</sup>; Mert Efe<sup>1</sup>; Wilfredo Moscoso<sup>1</sup>; Kevin Trumble<sup>1</sup>; Srinivasan Chandrasekar<sup>1</sup>; <sup>1</sup>Purdue University

Large Strain Extrusion Machining, a single-cut, constrained machining process efficient in introducing large shear strains (1-10) is used to produce magnesium alloy AZ31B strip. By exploiting the heat that is inherently generated, this process proves to be capable of producing high quality thin strip (~200 \956m thick) from a workpiece starting at ambient temperature. The texture analysis using two-dimensional XRD on the strips produced from unheated workpiece showed strong non-basal textures, with the c-axes of the grains inclined towards the cutting direction. In contrast, strips produced from a preheated workpiece (200°C) showed splitting of the basal pole in the transverse direction, consistent with the increased prismatic slip activity. The process also yields a fine equiaxed grain structure (~2-6 \956m). The influence of the resulted texture and microstructure on the mechanical properties, and the implications of scaling up the process to produce wider and thicker sheets will be addressed.

**The Microstructure and Mechanical Properties of Cast Mg-5Sn Based Alloys:** Mahsa Keyvani<sup>1</sup>; Reza Mahmudi<sup>1</sup>; *Ghazal Nayyeri*<sup>1</sup>; <sup>1</sup>University of Tehran

The effects of 1 wt.% Ce-rich misch-metal, 3 wt.% Bi, 0.4 wt.% Sb, and 2 wt.% Ca additions on the microstructure, mechanical properties, and creep resistance of a cast Mg-5Sn alloy were studied. Impression creep tests were carried out at 150 and 225 oC under constant stresses of 300 and 175 MPa. The results showed that creep resistance, hardness, and shear strength of the base alloy were significantly enhanced with the addition of ternary alloying elements. This was attributed to the concurrent formation of Mg<sub>2</sub>Sn particles with the more thermally stable CaMgSn, Mg<sub>3</sub>Sb<sub>2</sub>, Mg<sub>3</sub>Bi<sub>2</sub> and MgSnRE phases which strengthen both matrix and grain boundaries during deformation in the investigated system. Among all tested materials, the Mg-5Sn-2Ca alloy indicated the highest mechanical properties and creep resistance due to the refined microstructure as well as the type and volume fraction of the intermetallic phases present in this alloy.

**Effects of Misch Metal on Microstructure and Mechanical Properties of Mg-Nd Alloys:** *Bo Keon Kwon*<sup>1</sup>; Il Hwan Choi<sup>1</sup>; Kwang Seon Shin<sup>1</sup>; <sup>1</sup>Magnesium Technology Innovation Center / Seoul National University

In recent years, there have been efforts to develop gravity casting magnesium alloys for automobile engine applications. In order to achieve high temperature mechanical properties required for engine blocks, precipitation hardenable Mg-Nd-Y alloys have been developed. For elevated temperature strength, it is necessary to add considerable amounts of rare earth (RE) elements such as Nd, Y, etc. to magnesium alloys, because these RE elements form thermally stable precipitates which are essential for high temperature strength. However, the amounts of RE elements should be minimized to reduce the cost of alloy ingots. In the present study, it was attempted to utilize misch metal in order to reduce the amounts of expensive alloying elements in Mg-Nd alloys. All specimens were produced by the gravity casting process. The microstructures of the as-cast and the heat-treated specimens were examined by optical and scanning electron microscopy. Mechanical properties were examined both at room and elevated temperatures.

**A Study on Combined Effect of Forging and Ageing in Mg-Y-RE Magnesium Alloy:** *S. K. Panigrahi*<sup>1</sup>; R.S. Mishra<sup>1</sup>; K. Kumar<sup>1</sup>; R. DeLorme<sup>2</sup>; B. Davies<sup>2</sup>; R. A. Howell<sup>3</sup>; K. Cho<sup>3</sup>; <sup>1</sup>Centre for Friction Stir Welding and Material science and Engineering; <sup>2</sup>Magnesium Elektron North America Inc.; <sup>3</sup>Manufacturing and Materials Technology Branch, Army Research Laboratory

The recent thrust for weight reduction in aircraft, automobiles and other transportation vehicles have made magnesium-rare earth (Mg-RE) alloys very attractive as structural materials. Among various Mg-RE alloys, WE43 is one of the most promising candidates due to the remarkable age hardening response, good thermal stability, corrosion resistance, and creep resistance up to relatively high temperatures. The increased usage of these alloys depends on enhancing their mechanical properties by implementing a combination of strain hardening, grain refinement and age hardening. The present work explores forging of F temper plate and subsequent ageing to maximize the strength-ductility combination of a WE43 alloy. The forged samples with peak ageing treatment (64 hours at 180 oC) showed a significant enhancement of both strength and ductility as compared to previous reported values. These results are discussed in the framework of grain boundary and precipitate strengthening mechanisms.

**Effect of Cooling Rate and Chemical Modification on the Tensile Properties of Mg-5wt. % Si Alloy:** F. Mirshahi<sup>1</sup>; M. Meratian<sup>1</sup>; *M. Mohammadi Zahrani*<sup>1</sup>; E. Zahrani<sup>1</sup>; <sup>1</sup>Isfahan University of Technology

Hypereutectic Mg-Si alloys are suitable candidates to replace Al-Si alloys used in aerospace and engine applications. In this study the effects of both cooling rate and bismuth addition on the microstructure and tensile properties of Mg-5wt% Si alloy were investigated. It was found that the addition of 0.5%Bi, altered the morphology of primary Mg<sub>2</sub>Si precipitate from dendritic to polygonal shape and reduced their size from ~20 to ~8 μm. The tensile strength and elongation of the modified alloy increased at ambient and elevated temperatures, which should ascribed to the modification of Mg<sub>2</sub>Si morphology and more uniform distribution of the particles. Adding Bi also reduced the number of decohered particles observed in fracture surfaces thereby increasing the alloy ductility. Increase in both tensile strength and elongation values with increase in cooling rate were observed witch is attributed to polygonal morphology of Mg<sub>2</sub>Si precipitates in higher cooling rates.

**On Predicting the Channel Die Compression Behavior of HCP Magnesium AM30 using Crystal Plasticity FEM:** *Q. Ma*<sup>1</sup>; E.B. Marin<sup>1</sup>; A. Antonyraj<sup>1</sup>; Y. Hammi<sup>1</sup>; H. El Kadiri<sup>1</sup>; P.T. Wang<sup>1</sup>; M.F. Horstemeyer<sup>1</sup>; <sup>1</sup>Mississippi State University

Deformation of polycrystalline aggregates of HCP crystals was investigated by employing crystal plasticity and finite element simulations. Results were validated using channel die compression tests. The three dimensional polycrystal, represented by Voronoi techniques, was assigned an initial distribution of crystallographic orientations determined from X-Ray Diffraction. The mechanical properties from the channel die compression tests were used to correlate the material parameters of the crystal plasticity model. Simulations predicted grain-to-grain interactions and the resulting texture evolution under channel die compression. The inhomogeneous deformation among grains was mapped by a stress and a strain distribution and grain orientation spread. The simulation results were compared with experimental observations of an HCP polycrystal subjected to channel die compression.

**Hardening of Pure Magnesium Due to Higher Order Deformation Twins:** *Fumiaki Hiura*<sup>1</sup>; Marek Niewczas<sup>1</sup>; <sup>1</sup>McMaster University

Hardening effect due to {10-12} deformation twins was studied in magnesium single crystals, by means of a latent hardening experiments. Large parent single crystals oriented for tensile twinning were deformed up to 10% of strain. Subsequently, the secondary samples with the tensile axis oriented 90o to the tensile axis of the parent samples were cut and deformed to evaluate the work-hardening behavior of secondary samples. The microstructure and micro-texture observations of secondary samples by SEM/EBSD technique revealed formation of higher order {10-12} twins

inside the primary twin regions. The secondary samples showed enhanced work hardening, influenced by the density of higher order {10-12} twins. The mechanical properties and the work hardening behavior of secondary samples are interpreted in terms of a dynamical Hall-Petch effect arising from the grain refinement and the reduction of the dislocation mean free path due to formation of higher order twins.

**Slip and Twin Behavior in Magnesium Single Crystals:** *Ming Zhe Bian*<sup>1</sup>; Kwang Seon Shin<sup>1</sup>; <sup>1</sup>Seoul National University

Deformation behavior of magnesium single crystals was investigated by compression tests parallel or perpendicular to the c-axis between room temperature and 623K. {10-12} tensile twin and {10-11} compression twin, as well as {10-11}-{10-12} double twins, were observed during compression tests as reported earlier. In addition, {10-13} twins and {10-13}-{10-12} double twins were also observed at low temperatures. Electron backscattered diffraction (EBSD) data revealed that shear bands developed from compression twins and localized recrystallization in twins took place at 473K. Twin induced dynamic recrystallization (DRX) during compression tests was systematically investigated by optical microscopy (OM) and EBSD technique.

**Investigation of Microhardness and Microstructure of AZ31 Alloy after High-Pressure Torsion (HPT):** *Jitka Vrátná*<sup>1</sup>; Miloš Janeček<sup>1</sup>; Petr Hrcubá<sup>1</sup>; Robert Král<sup>1</sup>; Hyoung Seop Kim<sup>2</sup>; <sup>1</sup>Charles University; <sup>2</sup>Chungnam National University

Cast commercial magnesium alloy AZ31 was processed by high pressure torsion (HPT) at room temperature for 1, 3, 5 and 15 rotations. Texture and microstructure evolutions were observed using electron backscatter diffraction (EBSD). Lattice defects formed during HPT straining were determined by positron annihilation spectroscopy (PAS). Mechanical properties were revealed by detailed 2-D microhardness measurements. The variations of microstructure, defects structure and microhardness were observed along the diameter of particular specimen since deformation energy differs between the centre and the periphery of the disc. The differences between specimens strained by different number of rotations were also analyzed.

**Plastic Deformation of Magnesium Alloy Subjected to Compression-First Cyclic Loading:** *Soo Yeol Lee*<sup>1</sup>; Michael A. Gharghour<sup>2</sup>; John H. Root<sup>2</sup>; <sup>1</sup>The University of British Columbia; <sup>2</sup>National Research Council Canada

In-situ neutron diffraction has been employed to study the deformation mechanisms in a precipitation-hardened and extruded Mg-8.5wt.% Al alloy subjected to compression followed by reverse tension. The starting texture is such that the basal poles of most grains are oriented normal to the extrusion axis and a small portion of grains are oriented with the basal pole parallel to the extrusion axis. Diffraction peak intensities for several grain orientations monitored in-situ during deformation show that deformation twinning plays an important role in the elastic-plastic transition and subsequent plastic deformation behavior. Significant non-linear behavior is observed during unloading after compression and appears to be due to detwinning. This effect is much stronger after compressive loading than after tensile loading.

**Dislocation Slip and Stacking Fault Formation during Cold Deformation of Mg and Mg-Y Alloys:** *Stefanie Sandlöbes*<sup>1</sup>; Stefan Zaeferrer<sup>1</sup>; Igor Schestakow<sup>1</sup>; Sangbong Yi<sup>2</sup>; <sup>1</sup>Max-Planck-Institut für Eisenforschung GmbH; <sup>2</sup>GKSS-Forschungszentrum Geesthacht GmbH

Solid solution Mg-Y alloys show a significantly increased room temperature ductility compared to pure Mg and commercial wrought Mg alloys. It was shown before that this ductility improvement is caused by enhanced activity of deformation mechanisms on pyramidal planes, as {10-11}<10-12> compression and {10-11}{10-12} secondary twinning and pyramidal dislocation slip. It is assumed that the higher activation of these deformation modes is caused by a change in the stacking fault energies by solid solution of Y. The present study focuses on identification of the Burgers vectors of activated perfect and partial dislocations in Mg-Y alloys and determination of the kind of stacking faults and their frequency by transmission electron

microscopy (TEM). Complementary ab initio calculations on Mg and Mg-Y alloys are performed. Based on these results assumptions about the magnitude of the corresponding stacking fault energies are given and their relevance for the activation of different deformation modes is discussed.

**Investigation of Dynamic Recrystallization Mechanisms during Hot Deformation of a Mg Alloy:** *Zhenzhen Yu*<sup>1</sup>; Hahn Choo<sup>1</sup>; Tamás Ungár<sup>2</sup>; Levente Balogh<sup>2</sup>; Edward Kenik<sup>3</sup>; <sup>1</sup>University of Tennessee; <sup>2</sup>Eötvös University; <sup>3</sup>Oak Ridge National Laboratory

The deformation and recrystallization mechanisms of AZ31B Mg wrought plate were investigated using x-ray line profile analysis (XLP) and electron back-scatter diffraction (EBSD) techniques. First, a series of through-thickness (TT) compression tests were performed at a wide range of temperatures and strain rates for various strain levels. A relationship was established between the final recrystallized grain size and deformation conditions represented by Zener-Hollomon parameter (Z). The results show a transition of dynamic recrystallization (DRX) mechanism as Z was increased. At high Z values, twinning preceded the DRX and resulted in dramatic changes in the texture as well as the grain refinement process. The XLP and EBSD results provide further insights to the evolution of deformation microstructure including the dominant deformation mechanisms, and the influence of twinning on DRX and micro-texture distribution. Finally, compression tests were also performed along in-plane direction to compare the DRX processes observed along the TT direction.

**High Strain-Rate Behaviour in a Weakly Textured Extruded Mg-Mn-Nd (MN11) Alloy:** *N.V. Dudamell*<sup>1</sup>; F. Gálvez<sup>2</sup>; S. Yi<sup>3</sup>; J. Bohlen<sup>3</sup>; D. Letzig<sup>3</sup>; M.T. Pérez-Prado<sup>1</sup>; <sup>1</sup>Madrid Institute for Advanced Studies in Materials (IMDEA Materials); <sup>2</sup>Universidad Politécnica de Madrid; <sup>3</sup>GKSS Research Center

Magnesium alloys, due to their relative low density (1.74 g cm<sup>-3</sup>), are considered as potential materials to be used in components in which weight reduction is desired. Manganese and Neodymium have received special attention as alloying elements. Manganese, due to its effect in the enhancement of corrosion resistance and in the prevention of hot-cracking at high extrusion speeds and neodymium, due to its effect on the dynamic recrystallization during hot extrusion, leading to the formation of a weak texture. The mechanical behaviour of Mg-Mn-Nd alloys at high strain-rate has not been investigated yet. The main purpose of this contribution is to characterize the mechanical behaviour of an Mg-Mn-Nd alloy tested in tension and in compression at high strain-rate and to establish the deformation mechanisms activated under the dynamic straining. Tests will be carried out in tension and in compression in a Hopkinson bar at temperatures between 25°C and 400°C.

**The Effect of Strain Rate on Flow Behavior and Microstructure Evolution of AZ31 Mg Alloys:** *Mehdi Sanjari*<sup>1</sup>; S.A. Farzadfar<sup>1</sup>; S. Yue<sup>1</sup>; E. Essadiqi<sup>2</sup>; <sup>1</sup>McGill University, Department of Materials Engineering; <sup>2</sup>CANMET - Materials Technology Laboratory

In this work, the effects of strain rate on the flow behaviour and microstructure evolution on AZ31 Mg alloy were studied by compression testing over a wide range of strain rates (0.01-1000 s<sup>-1</sup>). The results showed that the recrystallization mechanism changed with increasing strain rate at a constant temperature. Also, the recrystallized volume fraction increased significantly with strain rate. Two types of constitutive equations were used to analyze the flow behaviour. Average activation energies of 162 kJ/mol and 135 kJ/mol were obtained for the peak and steady-state strain, respectively.

**Microstructure and Texture Effects on the Deformation Behaviors of the Statically Recrystallized Mg-Zn-MM Alloy Sheets:** *Heon Kang*<sup>1</sup>; Beomsoo Shin<sup>1</sup>; Donghyun Bae<sup>1</sup>; <sup>1</sup>yonsei university

The Mg-Zn-MM alloy sheets were annealed at two different temperatures and mechanical properties and texture effect were evaluated. Few grains were observed in as-rolled sheets and the different grains size and orientations were analyzed in annealed sheets at 220 °C, 380°C for 5min by using Electron back scattering diffraction (EBSD). Tensile tests were performed at a strain rate of 10<sup>-4</sup>s<sup>-1</sup> at room temperature in three directions ; RD, 45°, TD.

The sheets annealed at 220°C exhibited superior elongations (higher than 30%) and similar elongations in three tensile directions at room temperature. 10~50nm sizes of the nano twins were observed in the deformed region. The alloy sheets were deformed by not only the activation of non-basal slips which caused by the presence of refined grains, but also formation of the nano twins. The details of texture effect of the alloy will be also presented.

**The Mechanical Response of a Magnesium Alloy under a Range of Biaxial Loading Conditions:** *Philip Tomlinson*<sup>1</sup>; Warren Poole<sup>1</sup>; Chad Sinclair<sup>1</sup>; <sup>1</sup>University of British Columbia

Owing to the strong mechanical anisotropy of magnesium alloys, simple uniaxial testing is insufficient for complete mechanical performance characterization. The fact that deformation mechanisms in magnesium alloys are very sensitive to external testing conditions as well as microstructural and compositional modifications means that one expects strong variations in the anisotropy as indicated, for example, by the yield surface and its expansion. Despite the practical and theoretical importance of understanding the stress state/strain path dependence of the yielding, work hardening and fracture, few studies have been reported in the literature for magnesium alloys. A testing solution that allows for experiments where a range of biaxial stress states can be accessed has been developed. In this talk this facility will be described and experimental results from testing of an AM30 alloy will be presented. These results will be discussed in relation to the expected path dependence of various deformation modes.

**Microstructural Investigations into Novel Alloys Based on The Mg-Y-Nd System:** *Andy Williams*<sup>1</sup>; Mark Rainforth<sup>1</sup>; Brad Wynne<sup>1</sup>; Bruce Davis<sup>2</sup>; <sup>1</sup>University of Sheffield; <sup>2</sup>Magnesium Elektron USA

Three novel Mg-Y-Nd based alloys have been produced, containing reduced levels of Y as compared to the current Mg-RE systems, and are intended, in particular, as potential cost effective option for the automotive industry. Hot axisymmetric compression tests are employed on these alloys to investigate their deformation behaviour at raised temperatures, with the resulting data used to develop constitutive equations to describe flow behaviour as a function of temperature, strain and strain rate. A complimentary TEM and EBSD study is conducted to examine the active deformation mechanisms during hot working. The relationship between the slip, twinning, dynamic recrystallisation and flow behaviour will be considered with the aim being to isolate a viable processing window for the hot rolling of these new alloys, potentially widening their applications range.

**Deformation Behavior and Microstructure Evolution during the Hot Compression of AM50 Mg Alloy by Cooling Slope:** *Dae-Hwan Kim*<sup>1</sup>; Seung-Hwa Choi<sup>1</sup>; Hee-Kyeong Kim<sup>1</sup>; Su-Gun Lim<sup>1</sup>; <sup>1</sup>i-Cube Center, Engineering Research Institute, Gyeongsang National University

For the hot forming of Mg alloy such as hot extrusion and forging, it is important to have knowledge on the deformation behavior of the material with the variation of temperature. Therefore, the deformation behavior and microstructure variation of Mg alloy by cooling slope during the hot compression with different deformation temperature in this study was investigated. The material used for this experiment was AM50A Mg alloy used for production of automotive wheels and other parts. And the experiments for deformation behavior of the alloy were conducted at deformation temperatures of 300°C, 350°C and 400°C under Ar gas atmosphere. AM50A alloy by cooling slope was composed with equiaxed grains. The microstructure of the alloy during the hot compression test varied more finely than that of as-cast. Also, with increasing deformation temperature, the compression stress of AM50A alloy decreased.

**Deformation Characteristics of Thixo-processed Mg Sheet Alloy:** *Muammer Koc*<sup>1</sup>; Ryan Snell<sup>1</sup>; Omer Cora<sup>1</sup>; John Cheng<sup>2</sup>; <sup>1</sup>Virginia Commonwealth University; <sup>2</sup>Thixomat

This study was conducted to understand the material behavior and formability limits of thixo-cast Mg alloy sheets at elevated temperature as well as room temperature conditions. Uniaxial tensile and hydraulic bulge tests were conducted to investigate the material behavior at different temperatures (25°C -300°C) and strain rates (0.0013, 0.013, and 0.13 s<sup>-1</sup>).

Based on the test results, flow stress and the maximum plastic strain were found to increase with increasing temperature and decreasing strain rate. Effect of test technique (tensile or bulge tests) on the results (strain, strength levels). Apart from tensile and bulge tests, closed die hydroforming tests were conducted to evaluate the formability of the alloy. Die filling and thinning of the sheet blanks were measured with non-contact optical photogrammetry. Results showed that slower strain rates and higher temperatures increase formability, with benefits from lower strain rates being more dominant at temperatures over 200°C.

**Texture Evolution in As-Cast AZ31 Magnesium Alloy Sheet under Various Rolling and Annealing Conditions:** *Jun-ho Park*<sup>1</sup>; Hyun-Sik Choi<sup>1</sup>; Ju-Heon Kim<sup>2</sup>; Dong-Ik Kim<sup>2</sup>; Kyu Hwan Oh<sup>1</sup>; Heung Nam Han<sup>1</sup>; <sup>1</sup>Seoul National University; <sup>2</sup>Korea Institute of Science and Technology

Wrought magnesium alloys show poor formability at room temperature due to the shortage of independent slip systems. Thus hot rolling method is generally used for manufacturing the magnesium alloy sheets. In this study, in order to observe the deformation and annealing texture of the rolled Mg alloy sheet, the multi-pass cold and 1-pass hot rolling was adopted in as-cast AZ31 magnesium alloys. Subsequently, some of the cold-rolled sheets were annealed under various time period and temperature conditions to observe the recrystallization texture. Then, the analysis of microstructure and texture evolution with depth of the rolled sheet was performed with Optical Microscope (OM), X-Ray Diffractometer (XRD) and Electron Back-Scattered Diffraction (EBSD). As a result, the rolled Mg sheets revealed the texture with basal poles tilted about ±15° up to ±25° from the normal direction towards the rolling direction. After the recrystallization, it was observed that the basal texture became strong.

**Texture Development in Rolled Mg Alloy Sheets:** *Hyun-Sik Choi*<sup>1</sup>; Jun-Ho Park<sup>1</sup>; Se-Jong Kim<sup>1</sup>; Dong Nyung Lee<sup>1</sup>; Heung Nam Han<sup>1</sup>; <sup>1</sup>Seoul National University

In this study, in order to observe experimentally the texture development after rolling and annealing of the Mg alloy sheet, an AZ31 magnesium alloy was used. Microstructure and texture evolution in the rolled Mg sheets was observed with optical microscope, X-ray diffractometer and electron back-scattered diffraction. It was found that the rolled Mg sheets revealed the texture with basal poles tilted about ±20° from the normal direction towards the rolling direction. After the recrystallization, it was observed that the basal texture became strong. To analyze the deformation texture during rolling, a visco-plastic self-consistent polycrystal model was employed. As for the calculation of annealing texture, the concept of Strain-Energy-Release-Maximization proposed by D.N. Lee [Philos. Mag. 85 (2005), pp. 297–322], in which the texture evolves to maximize the mechanical internal energy release during recrystallization, was generalized. The calculated results were compared with the experiments.

**Effect of Differential Speed Rolling on Texture Evolution of Mg-4Zn-1Gd Alloy:** *Myeong-shik Shim*<sup>1</sup>; Jun ho Bae<sup>1</sup>; Dong-wook Kim<sup>1</sup>; Byeong-chan Suh<sup>1</sup>; Sunghak Lee<sup>1</sup>; Nack Joon Kim<sup>1</sup>; <sup>1</sup>POSTECH

Mg alloys generally have low ductility and formability at room temperature because of the strong basal texture developed during conventional symmetric rolling. It has been recently shown that the differential speed rolling (DSR) utilizing the different rotation speeds for upper and lower rolls introduces intense shear deformation, which might lead to the development of weaker basal texture than the conventional rolling process. In the present study, twin-roll cast Mg-4Zn-1Gd alloy sheet was subjected to high speed-ratio DSR to modify its texture and microstructure. It shows that there is a development of deformation bands by DSR and dynamic recrystallization occurs along the deformation bands. In addition to such microstructural changes, the DSR sheet has a texture characterized by the basal pole tilted from the normal direction (ND) towards the rolling direction (RD). However, the maximum intensity of basal texture is quite similar between the DSR sheet and the conventionally rolled sheet.

**Texture and Microstructure Control of AZ91 Mg Alloy Sheet by High Speed Rolling:** Akinori Hashimoto<sup>1</sup>; Tetsuo Sakai<sup>1</sup>; Hiroshi Utsunomiya<sup>1</sup>; <sup>1</sup>Osaka University

The present authors succeeded in single pass large draught rolling of AZ31 magnesium alloy sheets below 473K without heating rolls by rolling at the speed higher than 250m/min. The rolled and quenched sheets had fine recrystallized microstructure and exhibited excellent mechanical properties. It remains uncertain whether the high limiting reduction by high speed rolling can be attained in other magnesium alloys. In this study, we tried to roll the sheet of AZ91 magnesium alloy at 1000m/min below 473K. Rollability of AZ91 sheet is improved, and the maximum reduction in thickness of 50% is obtained. However, rollability of AZ91 is lower than that of AZ31. The sheets rolled show fine recrystallized grains with the average diameter of 3 $\mu$ m. Basal texture with double peaks is formed. The best result shows the tensile strength of 350MPa and the elongation of 29%, which is an excellent strength-ductility balance.

**Cavitation Behavior of AZ31 Sheet during Gas Blow Forming:** Yong-Nam Kwon<sup>1</sup>; Wonkyu Bang<sup>2</sup>; <sup>1</sup>Korea Institute of Materials Science; <sup>2</sup>RIST

Superplastic behavior of fine grained AZ31 sheet has been reported to occur in the temperature over 400°C and the strain rate of 10-4/s order. Cavitations usually bring out as result of poor accommodation of grain boundary sliding in the AZ31 sheet. As well known in superplastic Al alloys, it was reasonable to assume that back pressure could prohibit cavitations effectively in AZ31 sheet. In the present study, blow forming behavior was measured with the variation of back pressure. Especially, cavitation behavior was characterized in terms of strain, strain rate and temperature. Particles sitting along rolling direction would be the preferable sites for cavity opening in microstructure observation. However, results showed that back pressure did not influence the overall blow forming characteristics in AZ31 system as much as in superplastic Al alloys. This tendency might be originated from a limited accommodation system for grain boundary sliding of AZ31.

**Mechanical and Terminal Ballistic Properties of Magnesium Yttrium Rare Earth WE43 Alloy Rolled Plate:** Richard DeLorme<sup>1</sup>; Bruce Davis<sup>1</sup>; Jonathan Montgomery<sup>2</sup>; Tyrone Jones<sup>2</sup>; Kyu Cho<sup>2</sup>; <sup>1</sup>Magnesium Elektron North America; <sup>2</sup>U.S. Army Research Laboratory

The publication of MIL-DTL-32333(MR) in July 2009 represents the first magnesium alloy armor plate specification published. While the current scope of MIL-DTL-32333(MR) is limited to AZ31B (H24) rolled plate, higher performance nonflammable magnesium alloy classes are being considered as potential inclusion candidates to this specification. Magnesium Elektron North America (MENA) and U.S. Army Research Laboratory have collaborated in the research, development, manufacturing, testing, and evaluation of one such candidate magnesium alloy WE43. The present work summarizes the mechanical and terminal ballistic properties of the WE43 rolled plate. The results are also compared with those reported from other nonferrous light alloy armor plates.

**A Development of Mg Alloy Reinforced by Quasicrystalline Phase:** J.S. Kyeong<sup>1</sup>; Won Tae Kim<sup>2</sup>; D.H. Kim<sup>1</sup>; <sup>1</sup>Yonsei University; <sup>2</sup>Cheongju University

Mg-Zn-Y based alloys, reinforced by icosahedral quasicrystalline phase (I-phase) have been developed by ingot casting, followed by thermomechanical treatment and post heat treatment. Microstructure and mechanical properties of the resulting specimens were characterized by using optical microscopy, scanning electron microscopy, transmission electron microscopy, electron backscatter diffraction, X-ray diffractometry and tensile test. The alloys show relatively homogeneous distribution of I-phase particle in an alpha Mg matrix. The alloys exhibited high strength and good formability, due to high thermal stability and symmetry of I phase and stable interface formation with matrix. With increasing the volume fraction of the I-phase, tensile strength of the specimens increased. Also the small addition of Ca was very effective to weakening the basal texture in statically recrystallized specimen as well as hot-rolled specimen. The effect of Ca on texture evolution will be discussed in terms of enhanced particle stimulated nucleation during the process of recrystallization.

**Nano-Structured Mg-Al-Zn Alloy via Cryomilling and Spark Plasma Sintering:** Baolong Zheng<sup>1</sup>; Osman Ertoer<sup>1</sup>; Ying Li<sup>1</sup>; Troy Topping<sup>1</sup>; Yizhang Zhou<sup>1</sup>; Chi Tsao<sup>2</sup>; Enrique Lavernia<sup>1</sup>; <sup>1</sup>University of California, Davis; <sup>2</sup>National Cheng Kung University

Nanostructured Mg alloys have become of interest in various engineering applications due to their high specific strength. The mechanical behavior and microstructure of nanocrystalline (nc) Mg AZ80 alloy, synthesized via a cryomilling (mechanical milling under cryogenic temperature) and spark plasma sintering (SPS) approach are herein reported. First, Mg-based AZ80 powders, with an average grain size of 40 nm were synthesized via cryomilling for 8 hours. Second, the cryomilled AZ80 powder was subsequently consolidated using SPS at 300, 350, 400 and 450°C. SEM and TEM analysis shows that the SPS'ed Mg AZ80 consists of a bimodal microstructure with nc grains and coarse grains. The underlying mechanisms for the formation of bimodal microstructure during SPS sintering and the effect of bimodal microstructure to properties are discussed. A microhardness of 140 HV and a compressive strength of 546 MPa are achieved in the SPS'ed Mg AZ80.

**Microstructure Evolution in AZ61L During TTMP and Subsequent Annealing Treatments:** Tracy Berman<sup>1</sup>; William Donlon<sup>1</sup>; Raymond Decker<sup>2</sup>; Jack Huang<sup>2</sup>; Tresa Pollock<sup>3</sup>; J. Wayne Jones<sup>1</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>nanoMAG, LLC.; <sup>3</sup>University of California, Santa Barbara

Microstructure evolution is studied in Thixomolded Thermomechanical Processed (TTMP) AZ61L sheet at various stages of processing. Transmission electron microscopy (TEM) is utilized to examine (1) grain refinement and recrystallization and (2) refinement and re-distribution of the  $\beta$ -Mg<sub>17</sub>Al<sub>12</sub> phase in the as-Thixomolded, as-TTMP, and annealed conditions. Electron backscatter diffraction (EBSD) is used to study texture evolution through the TTMP and annealing process. The influence of microstructure by the TTMP and annealing on the mechanical properties will be presented.

**Fine Scale Microstructure and Deformation Behavior of AZ61L:** Ramasis Goswami<sup>1</sup>; Khershed Cooper<sup>2</sup>; Ray Decker<sup>3</sup>; Steve LeBeau<sup>3</sup>; <sup>1</sup>SAIC/Naval Research Laboratory; <sup>2</sup>Naval Research Laboratory; <sup>3</sup>nanoMAG LLC

The effect of size and distribution of Al<sub>12</sub>Mg<sub>17</sub> precipitate in hcp  $\alpha$ -Mg matrix on deformation behavior was studied in Mg alloys produced by the thixomolded thermomechanical processing (TTMP) route. Precipitate size and distribution were controlled by varying process parameters at a given Al content. The strength and ductility were enhanced by TTMP as a result of grain and particle size refinement, and an increase in dislocation density. The Al<sub>12</sub>Mg<sub>17</sub> particles were divided by this process into smaller particles. Also, some particles were found to have dissolved and reprecipitated as nano-scale precipitates during thermomechanical processing. The nucleation and growth of the Al<sub>12</sub>Mg<sub>17</sub> particles within the grain will be discussed.

**Role of Secondary phases for Improved Plasticity in Mg-based Bulk Metallic Glass Composites:** Je-In Lee<sup>1</sup>; Eun Soo Park<sup>1</sup>; <sup>1</sup>Seoul National University

Considerable demands for new low-cost and light-weight structural materials have prompted a wide variety of research on Mg-based bulk metallic glasses (BMGs). Despite their high strength and large elastic limit, Mg-based BMGs confront a serious problem that they exhibit brittle fracture by the formation of localized shear bands. In the present study, we reported a series of in-situ composites with different scales and fractions of secondary phases in Mg-Cu-Zn-Gd BMG-forming alloy systems. When the Mg contents increased, the density of the alloys decreased and a fully amorphous phase of the alloys was transformed into a combination of a partial amorphous phase and relatively small secondary phases. In comparison with monolithic Mg-based BMGs, the in-situ composites definitely exhibited enhanced plasticity, which was obtained by preventing propagation of localized shear bands during deformation. The effect of both scales and fractions of secondary phases by controlling alloy composition will be systematically reported.

**Microstructural Characteristics and Charge-Discharge Behavior of Mg-Li-C System Materials:** *Hung Fei-Yi*<sup>1</sup>; <sup>1</sup>Institute of Nanotechnology and Microsystems Engineering, Center for Micro/Nano Science and Technology, National Cheng Kung University

Magnesium-carbon powders and Magnesium-lithium powders were used as the anode materials for lithium ion batteries to investigate the structure and electrochemical behavior in room temperature. The composition of Mg-C powders contained 1:1 and 9:1. The powders and the thermal coated films of Mg-10Li were compared with the Mg-C systems. In addition, the Mg-10Li thermal evaporated film was used as the experimental materials to process the post-treatment. The results show that Mg-C powders system had an interface effect of Cu foil to reduce the electrochemical reaction. With increasing the carbon content, the charge-discharge characteristics of Mg-C powders had raised. Notably, the Mg-10Li specimen had better cycling properties than that of Mg-50C. After annealing at 200 °C, it was found that the Mg-10Li film not only increased the capacity, but also improved the charge-discharge cyclability.

**Modeling the Corrosive Effects of Various Magnesium Alloys Exposed to Two Saltwater Environments:** *Holly Martin*<sup>1</sup>; M. Horstemeyer<sup>1</sup>; Paul Wang<sup>1</sup>; <sup>1</sup>Center for Advanced Vehicular Systems, Mississippi State University

The use of magnesium within the automotive industry is limited by its corrosion rate in the presence of saltwater. By adding various elements, the magnesium microstructure and corrosion rate can be altered. In the Center for Advanced Vehicular Systems at Mississippi State University, a model is being developed to elucidate the total corrosion of magnesium alloys and is comprised of general corrosion and pitting corrosion, respectively:

$\phi = \phi_{GC} + \phi_{IC}$  where pitting corrosion is based on the pit number density, pit surface area, and a nearest neighbor distance function, respectively:  
 $\phi_{IC} = \eta_p v_p c^p$  The exposure environment resulted in differences in the amount of pit nucleation, in the size of the pits formed, and in the rate of coalescence. Time also affected the surface characteristics, as general corrosion began to degrade the number and size of the pits. The research presented here will cover the model development, calibration, and validation.

**Corrosion Performance of Mg-Ti Alloys Synthesized By Magnetron Sputtering:** *Zhenqing Xu*<sup>1</sup>; *Guang-Ling Song*<sup>2</sup>; *Daad Haddad*<sup>1</sup>; <sup>1</sup>MEDA engineering and technical services; <sup>2</sup>GM Global Research & Development

Mg if alloyed with Ti may become corrosion resistant. This hypothesis is verified in this study. Mg<sub>1-x</sub>Ti<sub>x</sub> alloy thin films (with x=0, 0.2, 0.4, 0.6, 0.8 and 1) were deposited by dc magnetron sputtering onto glass substrate. Film compositions were identified by electron probe micro-analyzer (EPMA). The corrosion properties of these alloys were characterized in saturated Mg(OH)<sub>2</sub> solutions with and without 0.1 M NaCl. The morphology of the thin film alloys was compared before and after polarization and immersion test. Polarization results showed that the corrosion resistance of the alloy was improved with increasing Ti content. No material loss and corrosion damage was observed for alloys with 80% or more Ti content in both solutions.

**Structure and Mechanical Properties of Magnesium-Titanium Solid Solution Thin Film Alloys Prepared by Magnetron-Sputter Deposition:** *Daad Haddad*<sup>1</sup>; *Guang-Ling Song*<sup>2</sup>; *Yang-Tse Cheng*<sup>3</sup>; <sup>1</sup>MEDA Engineering and Technical Services LLC; <sup>2</sup>GM Global Research & Development; <sup>3</sup>Chemical and Materials Engineering, University of Kentucky

The mechanical properties of Mg<sub>1-x</sub>Ti<sub>x</sub> thin film alloys, with x=0, 0.2, 0.4, 0.6, 0.8 and 1, were obtained using nanoindentation. The Mg-Ti alloys were deposited by dc magnetron sputtering on Si substrates. EPMA was used to determine the film compositions. XRD measurements showed that single phase magnesium-titanium solid solutions were obtained across the full range of magnesium and titanium mixtures. The topography and the rms roughness of the different alloys were studied using AFM. The mechanical properties of the Mg<sub>1-x</sub>Ti<sub>x</sub> thin films were determined by analyzing the load-displacement traces based on the Oliver-Pharr method. The nanoindentation results show that both the elastic modulus and hardness of the Mg<sub>1-x</sub>Ti<sub>x</sub> alloy thin films are higher than those of conventional Mg alloys.

**The Influence of Sol-Gel Coatings on the Corrosion Resistance of Magnesium and AZ91D:** *Daniela Zander*<sup>1</sup>; *Anna Pipetz*<sup>1</sup>; <sup>1</sup>TU Dortmund

The low corrosion resistance of magnesium alloys is known to limit significantly the application area. Among others the sol-gel process is a promising coating method to improve the corrosion of magnesium alloys. The aim of the present study is to investigate the influence of surface pre-treatments and subsequent sol-gel processing on the corrosion resistance of magnesium and die-cast AZ91D. The sol-gel coating was prepared by an acid catalyzed sol-gel process using Methyltriethoxysilan as a major compound. Various etching procedures were used to improve the adhesion between material and coating. The corrosion resistance was investigated by immersion tests and electrochemical methods in pH7 without and with NaCl. The etching and coating procedure was characterized by SEM and TEM. A strong influence of the microstructure on the etching procedure and on the adhesion of the coating was observed. A significant decrease of the corrosion rate was obtained by applying the sol-gel coating.

**Effect of Adding SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub> Sol into Anodizing Bath on Corrosion Resistance of Oxidation Film on Magnesium Alloy:** *Huicong Liu*<sup>1</sup>; *Liqun Zhu*<sup>1</sup>; *Weiping Li*<sup>1</sup>; <sup>1</sup>Beihang University, Key Laboratory of Aerospace Materials and Performance (Ministry of Education), School of Materials Science and Engineering

In order to extend the application area of magnesium alloy, many methods such as sol-gel, anodic oxidation, plating, micro-arc oxidation have been researched, each method has its own specialties and disadvantages. In this paper, three kinds of films were made on magnesium alloy by anodic oxidation together with sol-gel method. The first one named as anodic oxidation film was prepared by anodic oxidation in the usual alkaline solution, the second one named as multiple film was prepared by coating SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub> sol on the samples and heat-treating before anodic oxidation, the third one named as modified oxidation film was prepared by anodic oxidation in the usual alkaline solution added by 5%(vol) SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub> sol. Corrosion resistance, thickness, surface morphologies of the films were studied. The results showed that, compared with anodic oxidation film and multiple film, the modified oxidation film has the biggest thickness, has the most even and compact configuration, and thus it owns best corrosion resistance. Silicon and aluminum in the sol acted in the process of forming the modified oxidation film, and resulted in improving of comprehensive abilities of magnesium alloy samples.

**Effect of Zirconium Oxide on Corrosion Properties of Mg Alloy Subjected to Plasma Electrolytic Oxidation:** *In Jun Hwang*<sup>1</sup>; *Byung Uk Lee*<sup>1</sup>; *Young Gun Ko*<sup>2</sup>; *Dong H. Shin*<sup>1</sup>; <sup>1</sup>Hanyang University; <sup>2</sup>Yeungnam University

In current automobile and electronic industries, the use of magnesium alloys where energy and weight saving are attainable is increasing. Despite their light weight, there has been an inherent drawback arising from the surface vulnerable to be oxidized with ease, specifically under corrosive environments. To protect magnesium alloys from corrosion, the present work deals with the electrochemical response of the oxide layer on magnesium alloy specimen prepared by plasma electrolytic oxidation (PEO) method in an electrolyte containing zirconia powder. Surface observation evidences that a number of zirconia particles are effectively incorporated into oxide layer, resulting in higher oxidation resistance. This is a result of micro-arc during PEO treatment in spite of no polarization of zirconia. From the results of potentiodynamic tests in 3.5% NaCl solution whose pH is 7.8, corrosion behavior of the PEO-treated magnesium alloy is also discussed in relation to Stern-Geary equation.

**Weight Function and Stress Intensity Factors of Friction Stir Spot Welds of Magnesium AZ31 Alloy:** *Tian Tang*<sup>1</sup>; *Mark F. Horstemeyer*<sup>2</sup>; *Brian Jordan*<sup>2</sup>; *Paul Wang*<sup>2</sup>; <sup>1</sup>Mississippi State University; <sup>2</sup>National Chung Hsing University

Weight functions were derived for the critical points of friction stir spot welds. Both cases, namely, infinitesimal kinked crack and finite kinked crack were considered. These weight functions were developed based on the general format proposed by Fett et al. (2004). The unknown constants in these

equations were determined from reference stress intensity factors obtained from the three dimensional finite element computations. The accuracy and validity of these equations were verified using finite element results.

**Friction Stir Welding of Magnesium Alloy AZ31B-H24 Rolled Plate:** Richard DeLorme<sup>1</sup>; Jonathan Perrett<sup>2</sup>; Bruce Davis<sup>1</sup>; Kyu Cho<sup>3</sup>; <sup>1</sup>Magnesium Elektron North America; <sup>2</sup>TWI; <sup>3</sup>Army Research Laboratory

Magnesium Elektron North America (MENA) produces AZ31B-H24 rolled plate for many different applications. Although alloy AZ31B is weldable by traditional fusion welding methods, optimal friction stir welding (FSW) parameters for the required thickness of some applications have not been previously published. As such, MENA enlisted TWI to develop tooling and optimal FSW parameters for producing single-pass butt joints on MENA's 1.5 inch thick AZ31B-H24 plate. TWI also produced and delivered butt-jointed panels representing the optimal process; and, MENA and US Army Research Laboratory (ARL) have tested and evaluated the plate for strength and terminal ballistic performance. The present work describes the process and resulting optimal parameters developed by TWI and the MENA/ARL testing and evaluation results.

**Monotonic and Fatigue Behavior of Mg AZ31 in Friction Stir Spot Welds: An International Benchmark Test in the "Magnesium Front End Research and Development" Project:** B Badarinarayan<sup>1</sup>; S Behraves<sup>2</sup>; S Bhole<sup>3</sup>; D Chen<sup>3</sup>; H Patel<sup>3</sup>; M Horstemeyer<sup>4</sup>; H Jahed<sup>2</sup>; J Jordan<sup>5</sup>; S Lambert<sup>2</sup>; X Su<sup>6</sup>; Y Yang<sup>7</sup>; <sup>1</sup>Hitachi America Limited; <sup>2</sup>University of Waterloo; <sup>3</sup>Ryerson University; <sup>4</sup>Mississippi State University; <sup>5</sup>The University of Alabama; <sup>6</sup>Ford Motor Co; <sup>7</sup>Institute for Metals Research

This paper presents the experimental results of benchmark coupon testing of monotonic and cyclic conditions on friction stir spot welded coupons of Mg AZ31 alloy. The results presented here are a product of a collaborative multinational research effort involving research teams from Canada, China, and the United States. Fatigue tests were conducted in load control at R=0.1 at two different maximum loads: 1kN and 3kN. Good agreement was found between the participating labs regarding the number of cycles to failure. Differences in the failure modes were observed for the two different loading conditions tested. At the higher load, fatigue failure was caused by interfacial fracture. However, at the lower load, fatigue cracks formed perpendicular to the loading direction, which led to full width separation. For additional comparison, the monotonic and cyclic results of the friction stir spot welds are compared to resistance spot welded coupons of similar nugget size.

## Materials Processing Fundamentals: Poster Session

**Change of Iron Content in Metal Pad and Potling Failure during Start-up Period of Aluminum Reduction Cells:** Yongliang Wang<sup>1</sup>; Jilai Xue<sup>1</sup>; Jun TIE<sup>1</sup>; <sup>1</sup>University of Science and Technology Beijing

Iron content in metal pad in aluminum reduction cell is very important indication for pot lining failure during cell start-up period. Usually, higher iron content may indicate a leakage occurring in the potlining. If the lining failure could be detected in its early time, it might be possible to take action to limit further damage. In this paper, the change of the iron content in metal pad in aluminum reduction cell has been investigated to develop a method for possible early detection of potlining failure. It is found that the dispersed

degree of the iron content' fluctuation in the cell start-up of period can reflect potlining leakage in the future to some extent. For instance, when seven consecutive measurements of iron content above the center line(CL), or six consecutive measurements showing a rise trend, or the measurements beyond the upper center line(UCL), the cell is going to break down.

**Preparation and Characterization of Porous Ni-Ti Alloys:** Luxing Feng<sup>1</sup>; Jilai Xue<sup>1</sup>; Jun Zhu<sup>1</sup>; Yuanling Gao<sup>1</sup>; Chen Dong<sup>1</sup>; <sup>1</sup>University of Science and Technology Beijing

Porous Ni-Ti alloy has many applications in a wide range of engineering areas. The porous NiTi alloys were prepared from Al and Ni powders in sintering process under argon atmosphere. The major chemical compositions of the sintered Ni-Ti body were NiTi, Ni<sub>2</sub>Ti<sub>4</sub>O and Ni<sub>2</sub>Ti, respectively. The internal pore structures were characterized by image analysis technique, which were dependent on various processing parameters such as sintering temperature, amount of pore-forming agent, forming pressure, etc. The results show that the porous alloy samples had the characteristics of uniform pore and high open porosity; pore-forming agent and sintering temperature are important factors in porous; pressure affected the sintered products' pore, by affecting the combination of alloy powder with pore-forming agent.

**Production Technology of Cored Wire Used For Liquid Metal Treatment in Steel Plants (Part-I):** Pradeep Kumar Maitra<sup>1</sup>; <sup>1</sup>Dipaly Consultants

Structurally the CW is made up of two components only i.e. a steel jacket and an additive core. CW is produced by roll forming the steel strip into a tube (9 to 13mm diameter) which is simultaneously filled with additives and sealed longitudinally and wound on a cable drum, CW is used for metal cleaning, alloying, inoculating, nodularizing etc. The performance of the CW depends on its quality and method of its application. For quality assessments the CW users have to get familiarized with CW metallurgy, chemistry of additive-metal inter-action, etc to develop their internal standards. In this context following matter has been discussed in this presentation. Liquid metal chemistry, genesis of CW, morphology of CW, quality of steel strip and additives, mill configuration, CW manufacturing process, quality of CW and recommendations. Hope the article will be useful for both users and producers of CW.

**Recent Improvements at Mount Isa Copper Smelter:** Pengfu Tan<sup>1</sup>; <sup>1</sup>Xstrata Copper

Xstrata Copper Smelter at Mount Isa in Australia has operated one copper Isasmelt furnace, two Rotary Holding Furnaces (RHF), four Peirce-Smith P-S converters, two anode furnaces, one casting wheel, slag crushing and screening plant, and ESP dust recovery plant. Some recent technical improvements have been presented in this paper: 1) Development of smelting and converting process models, slag chemistry models and slag viscosity model 2) Reduction of copper loss in RHF slag 3) Reduction of converter foamover frequency 4) Improvements of smelter reporting system 5) Development of throughput model 6) Improvement of yields and throughput 7) Lab test works for ESP dust recovery process 8) ESP dust recovery plant trials, commissioning and operations 9) Slag slow cooling trial and improvement of slag milling recovery 10) Improvement of Isasmelt brick campaign life 11) Improvement of separation efficiency of Slag Crushing and Screening Plant

**Surface Treatment of Aluminum Alloys by Atmospheric Plasma Arc Discharge:** Mehdi Asgharifar<sup>1</sup>; Rouzbeh Sarrafi<sup>1</sup>; Radovan Kovacevic<sup>1</sup>; <sup>1</sup>Research Center for Advanced Manufacturing, Southern Methodist University

The surface treatment of aluminum alloys using atmospheric-pressure low intensity DC plasma arc discharge is investigated in terms of surface properties. Despite the conventional surface treatment process for aluminum alloys based on chemical process, this process is very environmental-friendly and economic. The effect of two processing parameters, the current and the plasma torch scanning speed, on the surface morphology was studied by using scanning electron microscope. The effects of cathode spots within the tested range of process parameters were determined, and the limiting factors of the process (such as surface cracking) were discussed. The topographical

studies of the treated surfaces have suggested potential enhancement of surface properties in different applications.

**Ultrasound-Assisted Electrolysis in NaOH Solution for Hydrogen Generation:** Jigang Li<sup>1</sup>; Jilai Xue<sup>1</sup>; Zhenjun Chen<sup>1</sup>; Lei Zhang<sup>1</sup>; Yifang Zheng<sup>1</sup>; Jun Zhu<sup>1</sup>; <sup>1</sup>University of Science and Technology Beijing

Water electrolysis in 0.4 M NaOH solution for hydrogen generation was carried out with ultrasound introduced through the anode. It was found that the cell voltage reduced by 150-250 mV in the current range of 20 mA to 40 mA with ultrasound frequency at 25.3 Hz. The cell operation became unstable when the cell current was larger than 75 mA with ultrasound. This reduction in cell voltage was due to removal of the gas bubbles on the electrode surface, which can be directly observed in the see-through cell of water electrolysis. Ultrasound with frequency of 33.3 Hz was also tried, but no better effect was obtained. The results suggest that ultrasound assisted water electrolysis can have potential in energy savings for hydrogen production.

## Microstructural Processes in Irradiated Materials: Poster Session

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Nuclear Materials Committee

*Program Organizers:* Gary Was, University of Michigan; Thak Sang Byun, Oak Ridge National Laboratory; Shenyang Hu, Pacific Northwest National Laboratory; Dane Morgan, UW Madison; Yasuyoshi Nagai, Tohoku University

Sun PM-Thurs PM  
Feb 27-Mar 3, 2011

Room: 3  
Location: San Diego Conv. Ctr

*Session Chairs:* Dane Morgan, University of Wisconsin; Yasuyoshi Nagai, Tohoku University; Shenyang Hu, Pacific Northwest National Laboratory

**Characterization of Swift Heavy Ion and Proton Damage in CeO<sub>2</sub>:** Peng Xu<sup>1</sup>; Tony Schulte<sup>1</sup>; Todd Allen<sup>1</sup>; <sup>1</sup>University of Wisconsin

The material response to irradiation is of prime importance for fuel property prediction. The focus in this study is to investigate radiation damage in CeO<sub>2</sub>, a fluorite type material which serves as a surrogate for UO<sub>2</sub>. Due to the similarities in their structures and physical properties, the knowledge learned in CeO<sub>2</sub> is of value for understanding the radiation damage mechanisms in fluorite type compounds such as UO<sub>2</sub>. To simulate fission fragments damage, 300 and 1000 MeV Au ions were used to irradiate CeO<sub>2</sub> to fluences from 1010 to 5x10<sup>12</sup> /cm<sup>2</sup> as well as 2.6 MeV protons to doses up to 1 dpa. The structure and microstructure evolution of the irradiated CeO<sub>2</sub> as a function of ion fluences was characterized using Raman spectroscopy, glancing angle XRD and HRTEM. The chemistry of the tracks was studied using local electrode atom probe. Structure recovery under thermal annealing will be discussed.

**Growth Behavior of Dislocation Loops in CeO<sub>2</sub> Irradiated with Krypton:** Bei Ye<sup>1</sup>; Jeffrey Rest<sup>2</sup>; Jerome Jonnet<sup>3</sup>; Wei-Ying Chen<sup>1</sup>; Mark Kirk<sup>2</sup>; Abdellatif Yacout<sup>2</sup>; James F. Stubbins<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign; <sup>2</sup>Argonne National Laboratory; <sup>3</sup>Delft University of Technology

Irradiation damage processes in UO<sub>2</sub> are studied by simulation of ion irradiation of CeO<sub>2</sub>, which shares the same fluorite structure. *In-situ* transmission electron microscopy is performed on a single crystal CeO<sub>2</sub> thin foil bombarded with 1MeV Kr at 800°C to an accumulated dose of 5x10<sup>15</sup> ions/cm<sup>2</sup>. Sequential change of defect microstructure is recorded as a function of dose. Qualitative assessment of dislocation loop growth is achieved by measuring loop diameter and density at varied dose levels. In order to interpret the combined effects of irradiation-induced re-resolution and coalescence on the kinetics of loop growth, a chemical rate theory based model is employed to calculate the evolution of the dislocation loop size distribution. In addition, the contribution of the evolving interstitial loop population to the change in CeO<sub>2</sub> lattice parameter is assessed, and estimates

of loop coalescence and re-resolution rates based on *in-situ* observation are discussed.

**Stoichiometric Dependence of Oxygen Diffusivity in La<sub>x</sub>Ce<sub>1-x</sub>O<sub>2-x/2</sub>:** Aaron Oaks<sup>1</sup>; Di Yun<sup>1</sup>; Bei Ye<sup>1</sup>; Wei-Ying Chen<sup>1</sup>; James Stubbins<sup>1</sup>; <sup>1</sup>University of Illinois, Urbana-Champaign

To study the stoichiometric dependence of oxygen diffusivity in fluorite-type mixed oxide nuclear fuels (UPuO<sub>2</sub>), a generalized Kinetic Monte Carlo code was developed and demonstrated on the surrogate material La<sub>x</sub>Ce<sub>1-x</sub>O<sub>2-x/2</sub>. Molecular Statics simulations were performed using interatomic potentials for cerium oxide provided by Gotte et al., Minervini et al. and Sayle et al. to calculate local configuration-dependent oxygen vacancy migration energies. Kinetic Monte Carlo simulations of oxygen vacancy diffusion were performed at varying lanthanum dopant concentrations (x=0 to x=0.33) using the developed generalized Kinetic Monte Carlo code and the calculated configuration-dependent migration energies. All three interatomic potentials were found to confirm the lanthanum trapping effect. The results of the simulations were compared with experimental data and the Gotte potential was concluded to yield the most realistic diffusivity curve.

**Irradiation Behavior of the Interaction Product of U-Mo Fuel Particle Dispersion in an Al Matrix:** Yeon Soo Kim<sup>1</sup>; Gerard Hofman<sup>1</sup>; <sup>1</sup>Argonne National Laboratory

The irradiation behavior of the interaction product in U-Mo fuel particle dispersion in an Al matrix is that of a typical amorphous material. At high burnup, large-scale pores form in the interaction layer, which can lead to a potential fuel failure. Addition of a small amount of Si in the matrix Al was shown to be effective to suppress the interaction layer growth and pore formation in the interaction layer. Analyses of microstructures of the irradiated samples with and without a Si addition are presented. A comparison with other dispersion fuel systems such as U-Si intermetallic particles in an Al matrix and U-Al intermetallic particles in an Al matrix, the interaction layers of which are also amorphous, is provided.

**Atomistic Validation of Kinetic Methodology via Multiscale Simulation of Nuclear Fuels:** Z. Insepov<sup>1</sup>; J. Rest<sup>1</sup>; G. Hofman<sup>1</sup>; A. Yacout<sup>1</sup>; A.Yu. Kuskun<sup>2</sup>; G.E. Norman<sup>2</sup>; S.V. Starikov<sup>2</sup>; V.V. Stegailov<sup>2</sup>; A.V. Yanilkin<sup>2</sup>; <sup>1</sup>Argonne National Laboratory; <sup>2</sup>Joint Institute for High Temperatures

A new approach for gas-driven swelling of fuels is under development based on the kinetic theory of defect accumulation, interaction, and growth of cavities during irradiation. This multiscale formulation will be used to assess the impact of elemental defect kinetics on important nuclear fuel performance parameters. Our new concept introduces an Ab-initio force matching method combined with atomistic molecular dynamics (MD) simulation for calculation of the defect energies, atomistic configurations, interatomic potentials, the elemental processes and reactions, and the kinetic coefficients that are applicable to high burn-up nuclear materials. The models include the interaction of the fission gas and gas filled bubbles with irradiation-induced dislocation loops. The equations describing the evolution of the vacancy, interstitial, interstitial loop and, fission gas concentrations contain materials dependent parameters such as the rate coefficients for radiation defects and gas atoms. This approach allows direct comparison of the analysis to in-reactor experimental data.

**Application of Phase-Field Method in Predicting the Kinetics of Microstructure Evolution in Irradiated Materials:** Yulan Li<sup>1</sup>; Shenyang Hu<sup>1</sup>; Chuck H. Henager Jr<sup>1</sup>; Fei Gao<sup>1</sup>; Xin Sun<sup>1</sup>; Mohammad A. Khaleel<sup>1</sup>; <sup>1</sup>Pacific Northwest National Laboratory

There are multiple microstructural processes taking place in fuel and cladding materials including generation/migration of defects and fission products, defect recombination/annihilation and emission/resolution, nucleation/growth/coalescence of gas bubbles and voids, precipitation of second-phase particles, and grain growth. These processes lead to structural instability such as swelling and cracking as well as mass/heat transport and thermo-mechanical property changes. A fundamental understanding of these processes and developing the capability to predict microstructure evolution in three-dimensions (3D) and property evolution are critical to the design of

nuclear reactor components as well as the optimization of nuclear reactor operation. The phase-field method based on the fundamental thermodynamic and kinetic information is a powerfully computational approach at the meso-scale for predicting phase stability and microstructural evolution kinetics. This talk will discuss the application of the phase-field approach coupling atomic mechanisms in predicting the microstructure evolution in irradiated materials that are far from equilibrium. Some results on volume swelling, void migration, void lattice formation, gas bubble nucleation and evolution will be presented to demonstrate the successful applications.

**Atomic-Scale Modeling of the Sliding Behavior of {110} Twist Grain Boundaries in Alpha-Iron:** *Jinbo Yang*<sup>1</sup>; Yuri Osetsyki<sup>1</sup>; Roger Stoller<sup>1</sup>; <sup>1</sup>ORNL

Grain boundary sliding (GBS) plays an important role in the plastic deformation and fracture of polycrystalline materials used in nuclear applications. Great attention is therefore paid to understanding factors affecting GB sliding such as segregation, modification under irradiation etc. In this paper we present first results on atomic-scale properties of twist grain boundaries (TGB) in iron. Molecular statics was applied to study structure and sliding TGB of different twist angles  $T$  at zero temperature. The structure of TGB in {110} plane with  $T < 120^\circ$  presents a network of intersecting screw dislocations segments with Burgers vectors  $\frac{1}{2}\langle 111 \rangle$  and  $\langle 100 \rangle$ . The resolved stress for sliding depends on the twist angle and can drop down to the value below the Peierls stress for an edge dislocation. The results are compared with available experimental observations. This work will be continued to investigate the effect of radiation induced defects and impurity segregation on sliding process.

**Helium Sequestration in Oxide Dispersion Strengthened Steels from First-Principles:** *Paul Erhart*<sup>1</sup>; Jaime Marian<sup>1</sup>; <sup>1</sup>Lawrence Livermore National Laboratory

Oxide dispersion strengthened steels have been proposed for structural components in next generation nuclear reactors in part thanks to their larger tolerance to He induced swelling than their oxide-free counterparts. Here, we explore this behavior by means of quantum-mechanical calculations. To this end, we have studied the properties of He-related point defects in several characteristic oxides within density functional theory using both conventional and hybrid exchange-correlation functionals. We find that He interstitials have very low formation energies compared to Fe, and He does not bind to intrinsic vacancies. Our results indicate that there is a strong thermodynamic driving force for storing He inside the oxide particles that should thus serve as volumetric sinks. We discuss the effect of the formation of a metal-oxide interface on the thermodynamic properties of the oxide particles and their ability to store helium.

**Small Scale Mechanical Testing and Atom Probe Analysis on New Materials for Nuclear Applications:** *E. Stergar*<sup>1</sup>; P. Hosemann<sup>1</sup>; A.T. Nelson<sup>2</sup>; Y.Q. Wang<sup>2</sup>; S.A. Maloy<sup>2</sup>; <sup>1</sup>UC Berkeley; <sup>2</sup>Los Alamos National Laboratory

Nanostructured alloys like ODS steels contain a high density of (oxide) precipitates providing outstanding high temperature properties and remarkable radiation tolerance. It has been shown that proper heat treatment of specialized tool steels (maraging steels) lead to the formation of coherent nm sized fine dispersed intermetallic precipitates with a number density of  $10^{23}$ - $10^{24}$  m<sup>-3</sup>. These precipitates are formed by solution annealing and a subsequent heat treatment. Therefore the formation of nm sized precipitates does not require a mechanical alloying step. In this work the concept of utilizing intermetallic precipitates and their effectiveness as defect sinks or He traps is explored. In this study Ion beam irradiations were performed to cause significant radiation damage and He implantation. High resolution post irradiation examination (nano indentation, TEM, atom probe) was used to assess the materials properties and micro structural changes on two commercially available maraging steels.

**TEM Characterization of the Structure and Composition of Nanofeatures and Oxides in Nanostructured Ferritic Alloys:** *Yuan Wu*<sup>1</sup>; Nicholas Cunningham<sup>1</sup>; George Odette<sup>1</sup>; Erich Stergar<sup>1</sup>; Auriane Etienne<sup>1</sup>; Erin Haney<sup>1</sup>; <sup>1</sup>UCSB

The structure and composition of the complex Ti-Y oxides in the nanostructure ferrite alloys (NFA) MA957 and model NFA 14YWT were characterized by high-resolution transmission electron/scanning electron microscopy (HRTEM/STEM) and energy dispersive X-ray (EDX). HRTEM fast Fourier transform diffraction show that some of the intermediate sized precipitates (5 to 15 nm) are consistent with orthorhombic Y<sub>2</sub>TiO<sub>5</sub>, while other vary from any known Y-Ti oxides. The EDX compositions of these features range from about 0.4 to 2, and differ slightly between French and US heats of MA957. About 20% of oxides in the 14YWT alloy show Y/Ti greater than 2, while about 80% show Y/Ti less than 2.0. FFT and powder diffraction measurements show that the smaller precipitates are generally consistent with cubic Y<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>, with EDX Y/Ti ~ 1.0. Results of high angle annular dark field (HAADF) TEM measurements of the size distribution and morphology of phases in NFA are also described.

**Effect of Grain Size and Grain Boundaries on the Proton Irradiation Response of Nanostructured Austenitic Model Alloy:** *Yong Yang*<sup>1</sup>; Cheng Sun<sup>2</sup>; Xinghang Zhang<sup>2</sup>; Allen Todd<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison; <sup>2</sup>Texas A&M University

A steel with nanometer-sized grain structure has the possibility to provide radiation resistance by increasing the grain boundary length and subsequently providing a greater amount sinks for absorbing mobile defect. Optimizing the type of boundary to include a greater number of sinks might further improve the radiation resistance. A model austenitic alloy was processed using the equal channel angular pressing (ECAP) method for eight passes at 500 °C to obtain an average grain size of ~360 nm. Grain boundary engineering (GBE) was then applied to optimize the grain boundary character distribution (GBCD) by promoting a higher population of low  $S$  grain boundaries. The effect of grain refinement and GBE on the radiation response was studied using a 2 MeV proton irradiation at 400 °C to dose up to 3 dpa. The irradiated microstructures was examined using transmission electron microscopy (TEM), and irradiation induced hardening was studied using Vickers hardness test.

**Friction Stir Welding and Irradiation Effects of Oxide Dispersion Strengthened Alloys:** *Chun-Liang Chen*<sup>1</sup>; Asta Richter<sup>2</sup>; R. Kögler<sup>3</sup>; L.T. Wu<sup>4</sup>; <sup>1</sup>Department of Materials Science and Engineering, I-Shou University, Kaohsiung 840, Taiwan; <sup>2</sup>Department of Engineering, Technical University of Applied Sciences Wildau, Bahnhofstrasse 1, 15745 Wildau, Germany; <sup>3</sup>Institute of Ion Beam Physics and Materials Research, Research Center Dresden-Rossendorf (FZD), Bautzner Landstraße 400, 01328 Dresden, Germany; <sup>4</sup>Met Ind Res & Dev Ctr, Kaohsiung 811, Taiwan

Nanostructured oxide dispersion strengthened (ODS) Fe-based alloys have potential for application in fission/fusion power plant materials, particularly in the use of a first-wall and blanket structure of a next generation reactor. These steels usually contain a high density of Y-Al-O nanoparticles. Structural analysis including HRTEM shows the chemical composition of the Y-Al-O oxides. Friction stir welding (FSW) is a very promising technique for the joining of ODS materials without oxide particle agglomeration and loss in mechanical properties in the weld zone. In this study, irradiation of these alloys was performed with a Fe+/He+ dual beam irradiation. Irradiation causes atomic displacements resulting in vacancy and self-interstitial lattice defects and dislocation loops. SRIM calculations for ODS steel indicate a clear separation between the vacancy distribution close to the surface and the interstitials in deeper layers of the material surface. The helium atoms will mainly accumulate in the vacancies.

**Stress Relaxation Behavior of Ferritic ODS Alloys:** *Jeoung Han Kim*<sup>1</sup>; Thak Sang Byun<sup>1</sup>; David T. Hoelzer<sup>1</sup>; <sup>1</sup>Oak Ridge National Lab

Stress relaxation (SR) has been investigated for the particle-strengthened steels including nanostructured ferritic alloy 14YWT(SM10), ODS Eurofer97, and commercial PM2000. The SR tests were carried out at temperatures ranging from 600 to 1000°C. The relaxation rates of 14YWT

and ODS Eurofer97 were lower than that of PM2000. Up to 700°C the activation energies of the three alloys were in a narrow range of 35 ~ 40 b<sup>3</sup>. Above 700°C, however, the activation energy of PM2000 and ODS Eurofer97 increased abruptly with test temperature while that of 14YWT showed relatively lower temperature dependence. To analyze the strain rate sensitivity of the alloys, the load drop-time curves were converted to the stress-strain rate curves. In the log-log plots of these curves no significant change in slope was observed in the strain rate range of 2×10<sup>-5</sup> ~ 10<sup>-3</sup>/sec. Rate-controlling mechanism for the three alloys was dislocation glide and climb process.

**Role of Microstructural Defect on Radiation Hardening of Ion Irradiated Fe-Cr Binary Alloys:** *Hyung-Ha Jin*<sup>1</sup>; Chansun Shin<sup>1</sup>; Junhyun Kwon<sup>1</sup>; <sup>1</sup>Korea Atomic Energy Research Institute

The role of microstructural defects on radiation hardening of Fe-Cr binary alloys was investigated using transmission electron microscopy. The experimental specimens were irradiated with 8MeV Fe ions at room temperature up to 5.8E14 ion/cm<sup>2</sup> (~1dpa at peak damage depth). Nano indentation result showed that radiation hardening of Fe-15Cr alloy was significantly larger than that of Fe-5Cr alloy. TEM observation showed that nanometer sized black dots were observed in both Fe-5Cr and Fe-15Cr alloy. On the other hands, some coffee bean contrasts were observed under the 020 reflection in only Fe-15Cr alloy, which were identified with <100> dislocation loops. By means of in-situ strain TEM technique, we will analyze the change of defects in ion irradiated Fe-Cr alloys during interaction with moving dislocation to understand radiation hardening behavior in Fe-Cr binary alloys.

**Nanoindentation at Elevated Temperature on Ion Beam Irradiated Advanced Structural Alloys for Nuclear Applications:** *Peter Hosemann*<sup>1</sup>; Adrian Harris<sup>2</sup>; Yongqiang Wang<sup>3</sup>; Stuart Maloy<sup>3</sup>; <sup>1</sup>UC Berkeley; <sup>2</sup>Micro Materials; <sup>3</sup>Los Alamos National Laboratory

In the past several years small scale material testing methodologies have been developed to investigate mechanical property changes as a result of ion irradiation. Specifically, micro hardness, nano indentation, micro and nano compression measurements were performed to investigate the basic processes of materials deformation and the effects of ion irradiation upon these processes. In this work we applied nano indentation experiments on ion beam irradiated samples at room temperature and elevated temperatures. Besides simple indentation also indentation creep experiments were performed. We learned that the irradiation significantly increased near-surface indentation creep rates and hardness of the selected oxide dispersion strengthened alloys studied here. While long term high temperature behavior was not measured, this study gives us an important insight into how defect mobility supports dislocation movement in the alloy of interest.

**Ab Initio Calculations on FeNiCr Model Austenitic Alloys: Chemical and Magnetic Disorder Treatment:** *Jean-Baptiste Piochaud*<sup>1</sup>; Charlotte Becquart<sup>1</sup>; Christophe Domain<sup>2</sup>; <sup>1</sup>CNRS; <sup>2</sup>EDF-R&D

Under irradiation, in austenitic steels, the microstructure and microchemistry evolution due to radiation induced segregation (RIS) can lead to a degradation of the mechanical properties. In order to better predict this evolution, a multiscale modelling approach is developed within the PERFORM60 project. The objective of our work is to simulate RIS at the atomic level in model FeNiCr alloys by an Atomic Kinetic Monte Carlo (AKMC) approach. For this purpose a suitable set of data is needed to build a cohesive model in the AKMC for both configurational and migration energies. We use Density Functional Theory which allows to determine accurate input interaction and migration energies. The FeNiCr paramagnetic alloys are modelled by considering both structural and magnetic disorder based on quasi-random structures. Their stability and magnetic ground state will be analysed and discussed. Some elementary properties (defect formation energies) will also be presented.

**Response of 321 Analog Austenitic Stainless Steel Microstructure of Reactor Core Internals to Neutron Irradiation in VVER-440:** *Jan Michalicka*<sup>1</sup>; <sup>1</sup>Nuclear Research Institute Rez plc.

This paper surveys analysis of radiation-induced microstructure defects in reactor core internals of VVER-440 Greifswald's reactor, decommissioned after 15 years of service. Studied material was irradiated to 2.4, 5.2 and 11.4 dpa and irradiation temperatures was between 270-400°C, and depended on the location of the particular component, namely the core barrel, core shroud basket, baffle and baffle bolts. Each of the components was made of Ti-stabilized austenitic stainless steel 08Ch18N10T. The irradiated microstructure revealed characteristic radiation defects: Frank loops, cavities and precipitates. Frank loops were saturated in all cases, excepting the core barrel. Cavities density and size distribution revealed strong dependence on temperature. Nano-cavities appeared at 270°C already and relatively significant cavities formation revealed at higher temperatures. Precipitates were minor, in form of G-phase. A baffle bolt was investigated along its longitudinal axis to assess the dependence of temperature gradient on radiation defects. Microhardness was measured in the same direction.

**Evolution of Radiation-induced Precipitates in Proton-irradiated HCM12A:** *Zhijie Jiao*<sup>1</sup>; Gary Was<sup>1</sup>; <sup>1</sup>University of Michigan

Ferritic-martensitic (F-M) alloy HCM12A is one of the candidates for cladding and structural materials in fast fission and fusion reactors. However, radiation-induced precipitates may cause serious hardening and embrittlement in this alloy. In this study, HCM12A was irradiated to 3, 7 and 10 dpa at 400 and 500/176C using 2 MeV protons. Radiation-induced precipitates were characterized using atom probe tomography. Preliminary results have showed that Ni/Si/Mn-rich, Cu-rich and Cr-rich precipitates form under irradiation and they are temperature dependent. The evolution of radiation-induced precipitates with irradiation dose and temperature in HCM12A will be presented and discussed.

**Examination of Precipitates in T91 and HCM12A Alloy by the Replica Extraction Technique:** *Liang Chen*<sup>1</sup>; Vani Shankar<sup>1</sup>; Zhijie Jiao<sup>1</sup>; Lumin Wang<sup>1</sup>; Gary Was<sup>1</sup>; <sup>1</sup>University of Michigan

Replica extraction of precipitates has been done on T91 and HCM12A alloys for analytical TEM examination. Precipitates are found to be of several different morphologies, ranging from rectangle to sphere. Three different types of precipitates have been observed in the replica obtained from the T91 alloy. The larger and most abundant of these precipitates are the M<sub>23</sub>C<sub>6</sub> type, accompanied by a small fraction of V-rich and Nb-rich precipitates in smaller size (<100 nm). Only M<sub>23</sub>C<sub>6</sub> precipitates are found in the HCM12A replica. The compositions of different precipitates are analyzed in detail using energy dispersive x-ray spectroscopy (EDS). Results from proton irradiated T91 samples with irradiation doses up to 100 dpa will be presented and compared with that from the unirradiated samples. The radiation effects on the evolution of precipitate size and composition will be discussed.

**Effects of Irradiation Dose on Microstructural Evolution and Hardening of High- and Low-Cu Reactor Pressure Vessel Steels:** *Akira Kuramoto*<sup>1</sup>; Tomoaki Takeuchi<sup>2</sup>; Takeshi Toyama<sup>1</sup>; Yasuyoshi Nagai<sup>1</sup>; Masayuki Hasegawa<sup>3</sup>; Toshimasa Yoshiie<sup>4</sup>; Nishiyama Yutaka<sup>2</sup>; <sup>1</sup>International Research Center for Nuclear Materials Science, Institute for Materials Research, Tohoku University; <sup>2</sup>Japan Atomic Energy Agency; <sup>3</sup>Institute for Materials Research, Tohoku University; <sup>4</sup>Research Reactor Institute, Kyoto University

Microstructural evolution and mechanical property change of A533B-1 steel with high and low Cu impurity subjected to well-controlled neutron irradiation (temperature: 563±2 K; flux: 1.7×10<sup>13</sup> n/cm<sup>2</sup>/s) in a wide range of dose from 0.32 to 9.9×10<sup>19</sup> n/cm<sup>2</sup> using JMTR have been investigated using atom probe tomography (APT), positron annihilation technique and Vickers micro-hardness test. The hardening rate of the steels was steep up to 0.59×10<sup>19</sup> n/cm<sup>2</sup> and gradual with further doses regardless of Cu composition. These hardness changes were consistent with the dose dependence of positron lifetime and coincidence Doppler broadening spectra, implying that the hardening in the lower doses was mainly caused by irradiation-induced defects for both high and low Cu steels. On the other hand, the contribution of the solute clusters to irradiation hardening, estimated using APT data

based on the Russell and Brown model, was consistent with the gradual hardening in the higher doses.

**Mechanical Properties and Radiation Response of Ultra-Fine Grained Stainless Steels:** *J. Gonzalez<sup>1</sup>; C. Sun<sup>1</sup>; K.T. Hartwig<sup>1</sup>; Y. Yang<sup>2</sup>; T. R. Allen<sup>2</sup>; S. A. Maloy<sup>3</sup>; X. Zhang<sup>1</sup>;* <sup>1</sup>Texas A&M University; <sup>2</sup>University of Wisconsin-Madison; <sup>3</sup>Los Alamos National Laboratory

We present microstructure and mechanical properties of 304L and 316L austenitic stainless steels and a model Fe-Cr-Ni alloy, processed by equal channel angular pressing (ECAP). The average grain size of ECAPed alloy is on the order of a few hundred nm. Helium ion irradiations to a dose of a few dpa are performed on these alloys with ultra-fine grains. The evolution of microstructure, defect density, and mechanical properties of alloys are investigated.

**Microstructural Evolution of Cu based Complex Alloys Under Prolonged Particle Irradiation:** *Rannesh Lokesh<sup>1</sup>;* Pascal Bellon<sup>1</sup>; Robert Averback<sup>1</sup>; <sup>1</sup>University of Illinois Urbana Champaign

Nanostructured materials are believed to be resistant to radiation damage due to the presence of large concentration of defect sinks which prevent large super-saturations of point defects. However, such far-from-equilibrium microstructures coarsen when exposed to high temperature and particle irradiation. A stabilized microstructure having radiation resistance can be obtained by exploiting the concepts of self organization. This paper investigates the effect of borides in copper based alloys under the conditions of ion irradiation and elevated temperature. Borides are extremely hard compounds with high melting point making it an interesting system. Various analytical techniques such as X-ray diffraction, Transmission electron microscopy were employed to characterize the microstructure. It was found that macroscopic coarsening was suppressed at high temperatures and irradiation doses due to the formation of precipitates which pin the grain boundaries. The Copper grain size remained stabilized at around 28 nm even at 0.65 of the melting temperature of Copper.

**Evolution of Microstructures in Helium Ion Irradiated MgO/W Multilayers:** *Engang Fu<sup>1</sup>;* Yongqiang Wang<sup>1</sup>; Amit Misra<sup>1</sup>; Michael Nastasi<sup>1</sup>; <sup>1</sup>LANL

MgO/W multilayer films were deposited on Si (100) substrates by magnetron sputtering technique with individual layer thickness (h) of 2 to 100 nm. Helium (He) ion irradiations on MgO/W multilayers were performed to study the effect of interfaces as defects sinks on reducing radiation induced defects. The influence of size dependence (different individual layer thickness) of MgO/W multilayers on ion irradiation tolerance is investigated. X-ray diffraction (XRD) and transmission electron microscopy (TEM) were used to characterize the microstructure change of the MgO/W multilayers before and after ion irradiation. The interfacial stability of the MgO/W multilayers upon ion irradiation was examined by scanning transmission electron microscopy (STEM). The potential mechanisms of interface-defect (induced by radiations) interactions under the context of length scale and growth of He bubbles will be discussed.

**The Response of Polycrystalline Tungsten to 30keV Helium Ion Implantation at High Temperatures and Its Dependence on the Angle of Incidence:** *Samuel Zenobia<sup>1</sup>;* *Lauren Garrison<sup>1</sup>;* Gerald Kulcinski<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison

Twelve polycrystalline tungsten samples were irradiated with 30keV helium ions in the Materials Irradiation Experiment (MITE-E). Samples were held at temperatures between 500–900 °C while irradiated to fluences of  $\sim 6 \times 10^{16}$ – $\sim 4 \times 10^{19}$  He/cm<sup>2</sup>. Severe changes to the surface morphology were observed at implant doses exceeding  $\sim 1 \times 10^{18}$  He/cm<sup>2</sup> and classified as blisters, pitting, or a highly directional surface structure dubbed “grass.” Morphological details of the grass structure depended on the crystal orientation of the grains to the sample surface. A sub-surface semi-porous layer was formed during irradiation, and post-implantation analysis revealed that this layer extended up to  $\sim 1000$  nm below the surface in the highest fluence cases. Specimens irradiated to fluences of  $\sim 1 \times 10^{18}$  He/cm<sup>2</sup> and greater experienced statistically significant mass loss which increased with higher implant dose. Implications

of this mass loss are discussed for the plasma facing components of both magnetic and inertial fusion reactors.

**Precipitation in Irradiated W Alloys:** *Emmanuelle Marquis<sup>1</sup>;* Colin English<sup>2</sup>; Samuel Humphry-Baker<sup>3</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>University of Oxford; <sup>3</sup>Massachusetts Institute of Technology

Tungsten is being considered for plasma facing and diverter components in future fusion reactors. A major issue for the use of tungsten is the transmutation of W into Re and Os under neutron irradiation, and current neutronic calculations (Cottrell, J. Nucl. Mater. 2004) predict that pure tungsten would transform into W-13%Re-12%Os after just five years of service. As demonstrated in past studies by Seidman et al. (acta Metall. 1984) and Williams et al. (Metall. Trans. A 1983), irradiated W-Re alloys exhibit precipitation of Re-rich phases even in undersaturated solid-solutions. The precipitation mechanisms are unclear and understanding the kinetics of precipitation is a necessary step towards establishing predictive tools for the structural and mechanical integrity of the reactor components during service, thereby ensuring reactor safety and optimizing reactor efficiency. We report on a systematic series of atomic scale investigations on W alloys implanted using 2MeV W<sup>+</sup> ions. The formation of solute-rich clusters and the kinetics of precipitation will be discussed.

**In-Situ Transmission Electron Microscopic Study of the E-Beam Damage Process in the Next Generation Nuclear Graphites:** *Karthik Chinnathambi<sup>1</sup>;* Josh Kane<sup>1</sup>; Darryl Butt<sup>1</sup>; Rick Ubic<sup>1</sup>; <sup>1</sup>Boise State University

Under irradiation, graphite is known to undergo changes in its thermo-mechanical properties, especially via irradiation-induced creep. Developing an understanding of these life-limiting phenomena is very important for the development of new grades of nuclear graphite. We have in-situ observed the atomic level processes involved in the swelling of the nuclear graphites (IG-110, NBG-18, PCEA and PGX) under e-beam irradiation using high resolution electron microscopy (HREM) and electron energy loss spectroscopy (EELS). Under e-beam irradiation, the structural ordering parallel to the basal plane gradually deteriorated because of the appearance of dislocation loops, bending and fragmentation of the basal planes in addition to a dilation in the lattice parameter along the c-axis causing the swelling and closing of the micro cracks. EELS studies showed that the p bonding in the basal plane was retained. Preliminary results on the structural changes associated with thermal creep using HREM and EELS will also be discussed.

**Experimental Study of <c> Component Loops Nucleation and Growth under Charged Particles Irradiation in Recrystallized Zircaloy-4:** *Lea Tournadre<sup>1</sup>;* F. Onimus<sup>1</sup>; D. Gilbon<sup>1</sup>; J.-M. Cloue<sup>2</sup>; J.-P. Mardon<sup>2</sup>; X. Feaugas<sup>3</sup>; O. Toader<sup>4</sup>; C. Bachelet<sup>5</sup>; <sup>1</sup>Commissariat à l’Energie Atomique (CEA); <sup>2</sup>AREVA AREVA NP Fuel BusinessUnit10; <sup>3</sup>Laboratoire d’Etude des Matériaux en Milieux Agressifs (LEMMA), Université de La Rochelle; <sup>4</sup>Michigan Ion Beam Laboratory (MIBL), University of Michigan; <sup>5</sup>Centre de Spectrométrie Nucléaire et de Spectroscopie de Masse (CSNSM), Université Paris-sud 11

Recrystallized zirconium alloys, used as structure materials for the Pressurised Water Reactor fuel assembly, undergo under neutron irradiation stress free growth which accelerates for high irradiation doses. This acceleration is correlated to the formation of <c> component vacancy dislocation loops in the basal plane. In the present work, two types of charged particle irradiations have been conducted on recrystallized Zircaloy-4. A 2MeV proton irradiation was performed on the Tandatron in the MIBL up to  $1.2 \times 10^{19}$  protons/cm<sup>2</sup> at 350°C, and 600keV Zr ion irradiations were carried out on the ARAMIS facility (CSNSM/IN2P3) at 300°C up to  $9.5 \times 10^{14}$  ions/cm<sup>2</sup>. For the first time after such irradiations, <c> loops have been observed by Transmission Electron Microscopy. It has been shown that using ions, they start to nucleate and grow beyond a threshold dose. Irradiated microstructures – loop diameter and density – will be discussed for both proton and ion irradiations and compared to the neutron irradiated one.

**FIM of Defects in Pt Induced by Neutron Irradiation:** *Elena Medvedeva<sup>1</sup>; Elena Kalinina; Mihail Ivchenko<sup>1</sup>; <sup>1</sup>Institute of Electrophysics, Urals Division of Russian Academy of Sciences*

The aim of report is to analyze, using FIM, the structure of radiation-induced defects in the platinum bulk, which were formed by radiation effects of low-temperature bombardment by fast neutrons ( $E > 0.1$  MeV). The neutron bombardment of platinum up to a fluency of  $6.7 \times 10^{17} \text{ cm}^{-2}$  led to the formation of a defect structure in platinum, which is characterized by the high concentration of single point defects and their complexes whose dimensions are comparable with the inter atomic distance. As the fluency is increased up to  $3.5 \times 10^{18} \text{ cm}^{-2}$ , radiation-induced clusters whose average size was 3.2 nm, were observed in the irradiated plate. The experimental concentration of radiation-induced clusters in platinum was  $9 \times 10^{22} \text{ m}^{-3}$ . Work is executed with support of the federal target program «Scientific and scientific and pedagogical cadres of innovative Russia» for 2009-2013 (N 831).

**Evolution of the Residual Stresses in Zirconium Nitride Films Irradiated by High-Energy Xe Ions:** *Vladimir Uglov<sup>1</sup>; Sergey Zlotski<sup>1</sup>; Vladimir Skuratov<sup>2</sup>; Aleksandr Sohatsky<sup>2</sup>; Alina Shashok<sup>1</sup>; <sup>1</sup>Belorussian State University; <sup>2</sup>Joint institute for nuclear research*

Ceramics (different transition metals nitrides) due to their high radiation stability under neutron and alpha-particle irradiation and additional thermal and corrosion stability are the best candidates as the inert matrix for nuclear fuel. The radiation effects of zirconium nitride films with different thickness (0.1 and 3  $\mu\text{m}$ ) are investigated. The films were deposited by vacuum arc evaporation in nanocrystalline state (average size of crystallites in order to 4 nm). Irradiation was carried out at the cyclotron by Xe ions with energy 167 MeV and dose from  $3 \cdot 10^{12}$  to  $5 \cdot 10^{14} \text{ cm}^{-2}$ . Post-irradiated TEM and XRD investigations revealed that microstructure and phase composition of nanocrystalline films are stable. It is established that change of the macrostresses type occurs for the thick coatings with an increase in the radiation dose: from tensile to compressive. The mechanisms of the evolution of residual stresses in ZrN films during the high-energy ion irradiation are discussed.

**Chemically Bonded Phosphate Ceramics Composites Response to Irradiation:** *H. A. Colorado<sup>1</sup>; C. Hiel<sup>2</sup>; J. M. Yang<sup>1</sup>; H. T. Hahn<sup>1</sup>; J. Pleitt<sup>3</sup>; C. H. Castano<sup>3</sup>; <sup>1</sup>University of California, Los Angeles; <sup>2</sup>Composites Support and Solutions Inc.; <sup>3</sup>Missouri University of Science and Technology, Nuclear Engineering Department*

The effect of gamma rays and neutron radiation on chemically bonded phosphate ceramics (CBPC) composites have been investigated. The effect of lead concentration incorporated into the CBPC is presented. CBPC has been proved to be good structural material [1] and some research already showed their potential for radiation shielding applications [2]. CBPC is a composite material itself, with several crystalline and amorphous phases [1]. In addition, irradiation experiments were also conducted on different CBPCs with reinforcements as well as wollastonite powders (raw material). CBPC samples were irradiated at room temperature up to 6.5 MRad in the Missouri S&T nuclear reactor (MSTR). Preliminary simulation study of the materials effects as well as radiation shielding potential and attenuation coefficients in a broad range of energies pertinent to engineering applications are also included. Microstructure was identified by using optical and scanning electron microscopes, X-ray diffraction and Raman Spectroscopy.

**Defect Structures before Steady Void Growth in Austenitic Stainless Steels:** *Toshimsa Yoshie<sup>1</sup>; Koichi Sato<sup>1</sup>; Xingzhong Cao<sup>1</sup>; Qiu Xu<sup>1</sup>; Troyo Troev<sup>2</sup>; <sup>1</sup>Kyoto University; <sup>2</sup>Bulgarian Academy of Sciences*

The existence of a transient stage before steady void growth in austenitic stainless steels is well known. The incubation period depends on alloy compositions remarkably. As most of experimental studies have been performed by transmission electron microscopy, point defects and their clusters under the resolution limits are impossible to detect. In this study, defect structures during the incubation period in austenitic stainless steels, both practical alloys such as SUS316 and their model alloys such as Fe-Cr-Ni were studied by using positron annihilation lifetime measurement. Large

vacancy clusters were formed in model alloys, while only life times smaller than 150 ps, which is smaller than that of single vacancies of 180 ps were detected in practical alloys with neutron irradiation to 0.2dpa at 573 K. The defect evolution in the incubation period will be discussed based on results of electron irradiation and neutron irradiation.

**Ab Initio Calculations of Point Defects in Tungsten:** *Lisa Ventelon<sup>1</sup>; François Willaime<sup>1</sup>; Mihai-Cosmin Marinica<sup>1</sup>; Chu Chun Fu<sup>1</sup>; <sup>1</sup>CEA*

The development of plasma facing components is one of the critical issues to realize next generation fusion devices. Tungsten has the highest melting point of all the non-alloyed metals and is the only material, with carbon composites, that can resist to high heat fluxes, which the divertor is subject to from the plasma. Ab initio calculations have revealed unexpected behaviors of radiation point defects in tungsten. The vacancy-vacancy interaction is not attractive and an intermediate configuration between the  $\langle 111 \rangle$  and  $\langle 110 \rangle$  dumbbells has been proposed for the self-interstitial. We have confirmed these results and investigated the effects of electronic entropy and cell geometry. Empirical potentials for tungsten have been developed, including in their fitted properties, besides the experimental values of the bulk properties, the ab initio formation energies of several self-interstitial configurations. They have been tested on gamma-surfaces and properties of screw dislocations: core structure, Peierls barrier and glide plane.

**Benchmarking of Structural Materials Pre-Selected for Advanced Nuclear Reactors:** *P. Salame<sup>1</sup>; A Zeman<sup>1</sup>; V. Inozemtsev<sup>1</sup>; A. Stanculescu<sup>1</sup>; <sup>1</sup>International Atomic Energy Agency*

Advanced materials capable of operation over a wide range of elevated temperatures to high radiation damage levels are highly required for the innovative nuclear reactor concepts. Newly developed ferritic/martensitic steels with oxide dispersion strengthened (ODS) features is a very unique and promising candidate material qualified for both fission and fusion applications. Nevertheless, there are several issues to be addressed, specifically (1) Microstructure optimisation (size and distribution of oxide particles, etc.), (2) Larger scale fabrication process and (3) technological aspects. New IAEA coordinated research project will help to optimise the recent class of ODS steels, as well as detailed mechanical and microstructural characterisation. It is expected, this initiative will speed up R&D activities and pre-normative research of such materials through comprehensive Round Robin testing.

## Neutron and X-Ray Studies of Advanced Materials IV: Poster Session

*Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Chemistry and Physics of Materials Committee*

*Program Organizers: Rozaliya Barabash, Oak Ridge National Laboratory; Xun-Li Wang, Oak Ridge National Laboratory; Jaimie Tiley, Air Force Research Laboratory; Peter Liaw, The University of Tennessee; Erica Lilleodden, GKSS Research Center; Brent Fultz, California Institute of Technology; Y-D Wang, Northeastern University*

Sun PM-Thurs AM  
Feb 27-Mar 3, 2011

Location: San Diego Conv. Ctr

**Probing Li-Ni Cation Disorder in  $\text{Li}_{1-x}\text{Ni}_{1-x-y}\text{Al}_y\text{O}_2$  Cathode Materials by Neutron Diffraction:** *Lu Cai<sup>1</sup>; Zengcai Liu<sup>1</sup>; Ke An<sup>1</sup>; Chengdu Liang<sup>1</sup>; Xun-Li Wang<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory*

Neutron diffraction is unique in the studies of Li-ion batteries: its power to detect lithium ions provides ways to accurately determine the positions of lithium ions; and its ability of differentiating cations via coherent scattering lengths of metal ions enables the probing of cation disorder. The rich structure information provided by neutron diffraction is essential for understanding the subtle structure/property relationships of metal oxides and phosphates, which are the active cathode materials in lithium-ion batteries. In this study, we will present the research on probing the cation mixing of

LiNiO<sub>2</sub> with and without Al<sup>3+</sup> substitution. LiNi<sup>3+</sup>O<sub>2</sub> is an attractive cathode material for lithium-ion batteries, but the cycling properties has been greatly depressed by the Ni<sup>2+</sup> ions entering into Li<sup>+</sup> sites. The appearance of Ni<sup>2+</sup> in the Li<sup>+</sup> sites obstructs Li<sup>+</sup> diffusion and causes irreversible capacity loss. Al<sup>3+</sup> substitution of Ni<sup>3+</sup> stabilizes the structure of lithium nickelate (LiNi<sub>1-y</sub>Al<sub>y</sub>O<sub>2</sub>) and reduces the formation of Ni<sup>2+</sup>, therefore mitigating the migration of Ni<sup>2+</sup> into the Li<sup>+</sup> sites. The Rietveld refinement of the powder neutron diffraction patterns will be used to determine the cation disorder of Li and Ni in samples synthesized at different conditions. The correlation of structure with synthesis conditions will be discussed in details. We expect the results will provide guidance on the development of new materials to meet the needs of lithium-ion batteries.

**Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Poster Session**

 Feb 27-Mar 3, 2011 Location: San Diego Conv. Ctr

**Oxidation Behavior of ENIG and ENEPIG Surface Finish:** C. Li<sup>1</sup>; H. Chuang<sup>1</sup>; C. Chung<sup>1</sup>; C. Kao<sup>1</sup>; <sup>1</sup>National Taiwan University

In this study, two commonly used surface finishes, electroless Ni immersion Au (ENIG) and electroless Ni electroless Pd immersion Au (ENEPIG) were investigated on their resistance to oxidation. AES and SIMS analysis were carried out to reveal oxide species and estimate their relative thickness after an isothermal aging at 150°C for 200 hours. Elemental mapping revealed that the oxide formed as a continuous layer on the surface of ENIG and ENEPIG. NiO and NiO<sub>2</sub> were detected on the surface of ENIG, but the oxide thickness of ENEPIG is much thinner than that of ENIG according to the depth profiling examination. This result that ENEPIG exhibits better oxidation resistance and Pd suppresses the growth of Ni oxides on surface.

**Bond Strengths of Au Stud Bumps Joined with Pb-Free Solders:** Young-Kyu Lee<sup>1</sup>; Chang-Woo Lee<sup>2</sup>; Sehoon Yoo<sup>2</sup>; <sup>1</sup>University of Science & Technology; <sup>2</sup>Korea Institute of Industrial Technology

Joining properties of Au stud bumps joined with Pb-free solders were investigated in this study. A conventional wire bonding process was used to form the Au studs. The Au stud bumps were bonded on the solder bumps on the substrate with flip chip bonder. After bonding, intermetallic compound (IMC), AuSn and AuSn<sub>2</sub> was formed at the interface of Au and Sn. An aging test was performed, and the IMC thickness increased as the aging time increased. The joint strength and microstructure of stud bumps were evaluated by scanning electron microscope (SEM), energy dispersive spectroscopy (EDS), and shear tester as well.

**Joule Heating Effect in Microbumps for 3D IC Packaging:** Yu-Chun Liang<sup>1</sup>; Chih Chen<sup>1</sup>; <sup>1</sup>National Chiao Tung University

For high-capability packaging, the flip-chip bump is a well-known technology. To accommodate the performance requirement of portable devices, the size of bumps continuously shrinks. This trend accounts for increasing chip temperature and current density in each solder bump called Joule-heating effect and current-crowding effect. Recently, the dimensions of flip-chip bumps reduce to 20-30 micrometers known as "microbumps" sandwiched between two Si chips. In this study, the temperature distribution during current-stressing in microbumps is directly examined by using infrared microscopy. The Joule-heating effect in microbumps is less serious

than those in flip-chip bumps on polymer substrates. The temperature increase is only few degrees when the current density is 1.06x10<sup>5</sup> A/cm<sup>2</sup>. In addition, the temperature in the aluminum trace of top die is lower than that in the aluminum trace of bottom die. That is, the direction of thermal gradient in microbumps is opposite from that in the traditional solder bumps.

**Distribution of Pd within Solder Joints in the Reaction between SAC305 and ENEPIG Surface Finish:** H. Chuang<sup>1</sup>; J. Ke<sup>1</sup>; C. Chung<sup>1</sup>; C. Li<sup>1</sup>; C. Kao<sup>1</sup>; <sup>1</sup>National Taiwan University

The interfacial reaction between electroless Ni, electroless Pd, immersion Au (ENEPIG) surface finish and the SAC305 lead-free solder is investigated. The microstructure analysis reveals no detectable Pd content in either IMCs or in the solder region after multiple reflows. However, after high temperature storage at 150°C for 500 h, a Sn-Ni-Au-Pd-Cu compound is observed both within the solder region and in the vicinity of the interface. The composition of this compound is 80.2Sn-11Ni-4.4Au-3.8Pd-0.6Cu (at.%), which likely corresponds to (Au<sub>0.22</sub>Pd<sub>0.2</sub>Ni<sub>0.55</sub>Cu<sub>0.03</sub>)Sn<sub>4</sub>. This stoichiometry suggests that this compound is related to AuSn<sub>4</sub>, which tends to induce the well-known Au embrittlement phenomenon if its amount is large enough. This result suggests that the amount of Au and Pd should be considered together when establishing the safe upper limit for these two elements.

**Effect of SnAg Solder Height on Metallurgical Reaction in Microbumps for 3D IC Packaging:** Wei-Chi Sung<sup>1</sup>; Chih Chen<sup>1</sup>; <sup>1</sup>National Chiao Tung University

The shrinkage of bump size for better performance has become a trend on the electronic packaging industry. Microbumps have been adopted as interconnects between chips in 3D IC packaging. So far the bumps size decreases dramatically to 20 microns and thus the bump height may range from 10 microns to 20 microns. As the bump size decrease, the volume of solder decreases. Thus, the formation of intermetallic compounds (IMCs) play crucial role on the joint performance. In this study, we use different heights of SnAg<sub>2.6</sub> solders, including 5µm, 10µm, and 20µm to analyze microstructure evolution in the microbumps during reflowing at 260°C and solid state aging at 150°C on both Cu and Ni metallization. Cross-sectional and plan-view SEM images are employed to observe the morphology of Ag<sub>3</sub>Sn, Cu<sub>6</sub>Sn<sub>5</sub>, and Ni<sub>3</sub>Sn<sub>4</sub> IMCs. The effect of solder volume on IMC formation will be presented.

**Preferred Crystal Orientations of Cu<sub>6</sub>Sn<sub>5</sub> Formed on Ni Substrate:** W. M. Chen<sup>1</sup>; C. R. Kao<sup>1</sup>; <sup>1</sup>National Taiwan University

Texture as well as epitaxial growth of intermetallic compounds (IMCs) has become an important issue due to the increasing IMCs to solder ratio in micro-bumps under development today. The existence of preferred orientations of Cu<sub>6</sub>Sn<sub>5</sub> formed over Cu substrates had been reported by several research groups and was a well-established fact. In this study, we show for the first time that Cu<sub>6</sub>Sn<sub>5</sub> formed over Ni substrate also exhibits preferred crystal orientations. In this study, solders doped with Cu are reacted with large grain, annealed Ni substrate to induce the formation of Cu<sub>6</sub>Sn<sub>5</sub>. It is demonstrate that Cu<sub>6</sub>Sn<sub>5</sub> has the following orientation relationship with Ni: (1-20)Cu<sub>6</sub>Sn<sub>5</sub>II(1-11)Ni and [001]Cu<sub>6</sub>Sn<sub>5</sub>II[110]Ni.

**Correlation between Elemental Distribution and Shear Impact Resistance in Sn-3.0Ag-0.5Cu Solder Alloy Joints before and after Board Assembly:** Chi-Yang Yu<sup>1</sup>; Jenq-Gong Duh<sup>1</sup>; Tae-Kyu Lee<sup>2</sup>; Michael Tsai<sup>2</sup>; Kuo-Chuan Liu<sup>2</sup>; <sup>1</sup>National Tsing Hua University; <sup>2</sup>Cisco Systems, Inc.

Elemental distribution in the solder joints affects the reliability of the device with ball grid array package, and the distribution is continuously changing based on the assembly process. The mechanical stability change is identified based on these elemental distribution changes. The shear impact performances for each process steps are observed. During first step reflow process, components with Ni/Au surface finish are attached with Sn-3.0Ag-0.5Cu solder balls. An additional second step reflow process connects the component solder joints with Cu pads on the printed circuit board. Each reflow process produced a different compound layer structure and elemental re-distribution. The quantitative analysis reveals the Cu and Ni distribution near the Ni/Au substrate for each step and the impact resistance is measured

using a high speed shear tester. The results show the correlation between elemental distribution and impact resistance in stand alone solder joints right after ball attached components and after board assembled.

**Investigation of Stress Evolution Induced by High Current Density in Lead-Free Solder Joints Based on X-Ray Diffraction Technique:** *Guangchen Xu<sup>1</sup>; Fu Guo<sup>1</sup>; Hongwen He<sup>2</sup>; Haiyan Zhao<sup>2</sup>; <sup>1</sup>Beijing University of Technology; <sup>2</sup>Tsinghua University*

The lifetime of solder joints under high current density is associated with the interactions among electrical field, thermal field, and stress field. Effects of electrical field and thermal field on microstructural evolution of various solder alloys have been investigated by many researchers. Accordingly, critical current density and endured temperature at solder joints are identified as the most important two parameters to determine the occurrence of EM. However, the directional movement of metal atoms/ions during current stressing can induce obvious stress concentration at the anode and cathode interfaces. In order to evaluate the stress evolution of lead-free solder joints during the current stressing, nondestructive X-ray diffraction technique was employed, in which the strain in the crystal lattice was measured, and residual stress producing the strain was calculated. Moreover, different lead-free solder alloys, i.e. eutectic SnAgCu, SnBi, are used to demonstrate their distinct stress evolution under high current density.

**Electromigration Reliability of Sn-Ag-Cu Solder Joints Containing Various Ag Contents:** *Bo-Zung Chen<sup>1</sup>; Chih-Nan Chen<sup>1</sup>; Cheng-En Ho<sup>1</sup>; <sup>1</sup>Yuan Ze University*

The influence of Ag content on the electromigration reliability of Sn-Ag-Cu solder joints was systematically investigated in this study. The joints had a typical line-to-bump geometry with the Cu/Sn-Ag-Cu/Cu configuration, and the Ag contents of the Sn-Ag-Cu were 0, 1, 2, 3, 3.5, 4 wt.%, respectively. Electromigration tests were carried out at an ambient temperature (25 degree Celsius) with a fixed 9600 A/cm<sup>2</sup> at the contact of the Cu/Sn-Ag-Cu. After the tests, a SEM, FIB (focused ion beam), and CLSM (confocal laser scanning microscopy) were employed to observe the microstructure evolution with current stressing time. Research showed doping an adequate Ag to the Sn-Cu alloy significantly increased resistance to electromigration. This diminished the electromigration-induced Sn-Cu alloy deformations and Cu metallization consumption, extending the lifetime of solder joints. More details about the Ag effect on the electromigration reliability of solder joints will be presented in this talk.

**Solder Thickness Effect on Mechanical and Electrical Reliabilities of Cu Pillar/ Sn-3.5Ag Bump:** *Byung-Hyun Kwak<sup>1</sup>; Myeong-Hyeok Jeong<sup>1</sup>; Byoung-Joon Kim<sup>2</sup>; Kiwook Lee<sup>2</sup>; Jaedong Kim<sup>3</sup>; Young-Chang Joo<sup>2</sup>; Young-Bae Park<sup>1</sup>; <sup>1</sup>Andong National University; <sup>2</sup>Seoul National University; <sup>3</sup>Amkor Technology Korea, Inc.*

Cu pillar/Sn-3.5Ag bump is widely adopted as chip-to-substrate interconnect in TSV stack as well as flip chip package because it provides the finer pitch and uniform current distribution. However, Cu pillar bump makes large amount of IMC and Kirkendall void at Cu/solder interface under current stressing conditions, which can degrade electrical and mechanical reliability. In this work, solder thickness effects on the IMC growth kinetics in Cu pillar/solder bump with pure Sn or Sn-3.5Ag were quantitatively evaluated by using in-situ annealing and electromigration test in a SEM chamber during pure annealing or current stressing conditions with current density of 3.5 x 10<sup>4</sup> A/cm<sup>2</sup> at 120 ~ 175°C. IMC growth was significantly enhanced by current stressing where the growth rate follows a linear relationship with stressing time. Also, their effect on the mechanical and electrical reliability of Cu pillar/Sn-3.5Ag bump will be discussed in detail.

**Supersaturation and Recrystallization in Solder Alloys Induced by Current Stressing:** *Kwang-Lung Lin<sup>1</sup>; Ying-Ta Chiu<sup>1</sup>; Shi-Min Kuo<sup>1</sup>; Chia-Hao Liu<sup>1</sup>; Yi-Shao Lai<sup>2</sup>; <sup>1</sup>National Cheng Kung University; <sup>2</sup>Advanced Semiconductor Engineering, Inc.*

Current stressing is known to induce electromigration in solder joints. This present study reports that current stressing will also induce supersaturation and the subsequent recrystallization in solder alloys. An in-situ SEM-EDS

investigation shows that the Sn rich phase of the 95Pb-5Sn solder disappears upon current stressing. The Sn concentration in the Pb matrix increases and reaches a maximum value after long time current stressing. The maximum Sn concentration achievable exceeds the thermal equilibrium magnitude as described by phase diagram. The maximum supersaturation concentration of Sn increases with current density increase in 5 x 10<sup>3</sup> ~ 1 x 10<sup>4</sup> A/cm<sup>2</sup>. The Zn rich phase of Sn-9Zn solder and the Sn rich phase in 95Pb-5Sn show recrystallization behavior after current stressing. The recrystallization forms one dimensional nano crystals of Sn in the Pb matrix while forms nano sheet Zn crystal in the Sn-9Zn solder. The nano crystals will appear only after the current stops.

**The Control Tin Whisker Growth by Lithography Process:** *Chien-Hao Su<sup>1</sup>; Li-Wei Zou<sup>1</sup>; Hao Chen<sup>1</sup>; Albert T. Wu<sup>1</sup>; <sup>1</sup>National Central University*

The growth of tin whiskers on lead-free finishes coated on the leadframes is spontaneous and contributed by stress generation and relaxation. A protective layer of tin oxide that grown on the surfaces is required for the formation of tin whiskers. Cracks on the oxide served as weak spots that are essential for the protrusion of whiskers to release the stresses. This paper presents a new approach to control the grown positions of tin whiskers. The original tin oxide was removed by etchant and polishing. The lithography process was used immediately after surface treatments to define the pattern on tin oxide thin film that was deposited by sputter. The purpose of the pattern is to intentionally form weak oxide spots for stress relaxation. The results suggested that hillocks or whiskers would grow in these pre-defined areas. The location of tin whiskers can thus be well predicted by this approach.

**Simulation on Current Density Distribution in Micro-Bumps with Various UBM and Solder Structures:** *Chung Kuang Lin<sup>1</sup>; Chih Chen<sup>1</sup>; <sup>1</sup>National Chiao Tung University*

Three-dimensional simulations on current-density distribution in solder joints of micro-bumps under 30 mA current stressing were carried out by finite element method. The current density in solder joints will reach to 10<sup>4</sup> A/cm<sup>2</sup> which will induce electromigration damage in SnAg solder joints. The different UBM structures could change the maximum current density in solder joints. Six micro-bump structures were simulated, including different thickness SnAg solder joints and Cu / Ni UBM in chip side and board side. The maximum current density occurred at the entrance of Cu trace into UBM and current crowding effect took place within 3 μm of current entrance, while there was the uniform current density distribution in the solder joints. The thickness of UBM layer played important role in current density distribution. Therefore, the micro-bumps with 10 μm Cu UBM on both sides had the lowest maximum current density in solder layer.

**Phase-Field Simulations of Microstructure and Crystal Orientation Evolution of Intermetallic Compound (Cu<sub>6</sub>Sn<sub>5</sub>) during Early Stages of Lead-Free Soldering:** *Min Soo Park<sup>1</sup>; Colton Shannon<sup>1</sup>; Raymundo Arroyave<sup>1</sup>; <sup>1</sup>Texas A&M University*

We present phase-field simulations of the evolution of crystallographic orientation and morphology (including precipitation) of intermetallic compound (IMC) during early stages of soldering. We focus on the interactions between liquid Sn-based solder (L) and copper substrate (α) in a Cu/Sn system. It is assumed that IMC (Cu<sub>6</sub>Sn<sub>5</sub>, η) grains precipitate at the L/α interface with its own crystallographic orientation. Classical nucleation theory is used to model the precipitation of IMC grains. A crystalline-field model considering grain's misorientation is included in the formulation. CALPHAD models are used to define the bulk thermodynamics of the phases. The simulations will show the evolution of the morphology and kinetics of IMC growth with different grain boundary diffusion and L/η interface energies. The effects of considering nucleation and crystal orientation on the resulting morphology of the IMC layer will be explored. Experimental investigations will be used to validate the models developed in this work.

**Mechanisms of Deformation in Cerium (Ce)-Containing Pb-Free Solders:** *Huxiao Xie*<sup>1</sup>; Nikhilesh Chawla<sup>1</sup>; Kabir Mirpuri<sup>2</sup>; Aleks Aleksov<sup>2</sup>; <sup>1</sup>Arizona State University; <sup>2</sup>Intel Corp

Traditional Pb-free solders such as Sn-Ag-Cu (SAC) show relatively low ductility and poor damage tolerance. Our research has shown that SAC-alloy doped with trace amounts of Ce exhibits a substantial improvement in ductility, with a relatively small decrease in strength. These alloys also have better oxidation resistance than other rare earth-containing solders such as Lanthanum and Yttrium. In addition to the beneficial bulk and surface properties, it is imperative to understand the mechanisms for enhanced mechanical properties in Ce-containing SAC solders. Using interrupted experiments in a scanning electron microscope, we have been able to elucidate the relevant deformation mechanisms in these materials. We will discuss the influence of CeSn<sub>3</sub> particle fracture and interfacial debonding on enhanced macroscopic ductility.

**Electromigration Failure in Micro-Bumps for 3D IC Packaging:** *Hsiang-Yao Hsiao*<sup>1</sup>; Chih Chen<sup>1</sup>; <sup>1</sup>National Chiao Tung University

The three-dimensional chip stacking technology with fine-pitch and high input/output interconnects has emerged due to the requirements of multi-function and high performance in electronic devices. When the electronic packaging technology develops toward the miniaturization trend, the reliability of the fine-pitch-solder bump interconnections will become a critical issue in advanced 3D chip stacking technology. With the joint size becoming small and the increasing current in each solder bump, the current density flowing in each individual bump continues to increase. Therefore, electromigration has become a major reliability issue in microelectronic devices. In this study, electromigration in SnAg solder micro-bump with a pitch of 20- $\mu$ m was investigated under current stressing at hot stage. Ni/Cu under-bump-metallurgy layer was selected on both top and bottom chips. Kelvin-probes are employed to monitor the bump resistance during current stressing. Electromigration characteristics of fine pitch micro-bump will be discussed with the microstructure evolution of micro-bump during current stressing.

**Interfacial Reactions at Pogo Probe Pins/Sn-Ag-Cu Solder Interfaces:** *Mao Gao*<sup>1</sup>; Eric Cotts<sup>1</sup>; <sup>1</sup>Binghamton University

Au and PdCo plated, 0.32mm diameter pogo probe pins were used for the repeated functional testing of printed circuit boards. For repeated test insertions into PbSn solder, these pins were found to be highly reliable. However, very early failures, due to increased contact resistance, were experienced when these pins were used with Pb free, Sn-Ag-Cu solder alloys. This study focused on an examination of contamination of the surfaces of probe pins, including failed probe pins. These devices were cold mounted in epoxy and careful cross sections were produced. Optical microscopy, and field-emission scanning electron microscopy equipped with energy dispersive X-ray spectroscopy, were used to investigate the Sn contamination and intermetallic compounds at the surface of pins. Correlations with failures are reported.

**Electro-Migration Behavior of 3-D Flip Chip Packaging by Thermal Compression Bonding with Pb-Free Solder:** *Jong-Gun Lee*<sup>1</sup>; Jong-Bum Lee<sup>1</sup>; Jae-Hyun Yoon<sup>1</sup>; Sang-Su Ha<sup>1</sup>; Seung-Boo Jung<sup>1</sup>; <sup>1</sup>Sungkyunkwan University

The electro-migration of solder joints under high current stressing is an important concern for the solder joint system's reliability, especially with the increase in the required device density and power of 3-D flip chip packages. In this study, the electro-migration phenomena in Sn-3.0Ag-0.5Cu (in wt.%) solder bumps was investigated for application in the flip chip structure. Flip chip samples were cross-sectioned and polished to observe the electro-migration behavior under high current stressing. The electro-migration behavior was characterized by measuring the failure time at high current density and temperature. Current stressing was carried out in an ambient temperature of 120°C. A current was passed through the six solder joints, producing a nominal current density of  $2.0 \times 10^4$  A/cm<sup>2</sup>. The microstructure of the solder bumps at the cathode and anode sides were compared before

and after current stressing. Cross-sectional studies were conducted with scanning electron microscopy (SEM).

**Interfacial Reaction Comparison between Sn-3.0Ag-0.5Cu Solder Joint Attached to ENIG and ENEPIG Surface Finishes:** *Chien-Fu Tseng*<sup>1</sup>; Jenq-Gong Duh<sup>1</sup>; Tae-Kyu Lee<sup>2</sup>; Kuo-Chuan Liu<sup>2</sup>; <sup>1</sup>National Tsing Hua University; <sup>2</sup>Cisco Systems, Inc.

Solid-state interfacial reactions of Sn-3.0Ag-0.5Cu solder joint with ENIG and ENEPIG surface finish are investigated in this study. For the ENIG solder joint, two kinds of voids are observed at the interface, i.e. columnar voids in the P-rich layer and nano-voids among IMC. These two kinds of voids are believed to deteriorate the reliability of lead free solder joint. Therefore, retarding the formation of these two kinds of voids is a critical issue in the microelectronic packaging. Interestingly, only columnar voids were observed in the ENEPIG solder joint. Also, the grow rate of (Cu, Ni)<sub>6</sub>Sn<sub>5</sub> was found to be slower in the ENEPIG solder joint. Thus, the insertion of Pd layer seemed to improve the interfacial reaction which might improve the mechanical reliability. The detailed mechanism of microstructure variation for solder joint with different surface finish will be addressed with a discussion about the mechanism in this alloy system.

**High Bump Resistance of Ultra-Fine-Pitch Microbumps for Three-Dimensional Integrate Circuits Packaging:** *Yuan-wei Chang*<sup>1</sup>; Chih Chen<sup>1</sup>; <sup>1</sup>National Chiao Tung University

In decades, the technological improvement follows the Moore's law; the size of devices shrinks and the I/O number increases dramatically. In order to continually increase the I/O number, the three-dimensional integrate circuits (3D-IC) package is needed. In 3D-IC packaging, ultra-fine-pitch microbumps have been adopted to achieve the goal. Ultra-fine-pitch microbumps of 30  $\mu$ m were fabricated in this study. The bump resistance of the microbumps is obtained with the Kelvin-bump-structures. The bump resistance is approximate a hundred milliohms, much higher than that of a flip-chip bump. The unexpected high bump resistance causes high circuit inductance and RC delay. A finite-element-model (FEM) was also built to analyze the high bump resistance. The FEM shows the high resistance is caused by the current crowding. Increasing the trace thickness is an effective way to reduce the bump resistance. When the trace thickness increases from 0.8 to 3.0  $\mu$ m, the resistance reduces to a third.

**Joint Properties of Cu-Solder-Cu for Fine Pitch 3D Packaging:** *Min-Kyu Han*<sup>1</sup>; Se-Min Park<sup>2</sup>; Sehoon Yoo<sup>1</sup>; Chang-Woo Lee<sup>1</sup>; <sup>1</sup>Korea Institute of Industrial Technology; <sup>2</sup>Chosun University

Cu pillar has been received great attention in ultra fine pitch 3D packaging. In this study, Sn-Bi capped Cu pillars were bonded to Cu pads at 150~200°C. After bonding, the specimens were aged at 150°C up to 400 hrs to study on the microstructure of intermetallic compounds. Before aging, Cu<sub>6</sub>Sn<sub>5</sub> intermetallic compounds (IMCs) were observed at the Cu-SnBi interface. As aging time increased, the Cu<sub>6</sub>Sn<sub>5</sub> IMC thickness increased and Cu<sub>3</sub>Sn was formed below the Cu<sub>6</sub>Sn<sub>5</sub>. After 400hrs of aging, Bi was separated from the IMC interface. Continuous Kirkendall voids were also observed at the Cu<sub>6</sub>Sn<sub>5</sub>/Cu<sub>3</sub>Sn interfaces after 400 hr aging. Such void formation decreased the shear strength of the Cu pillar bumps.

**In-Situ Synchrotron Characterization of Melting, Dissolution and Resolidification in Lead-Free Solder Joints:** *Bite Zhou*<sup>1</sup>; Thomas Bieler<sup>1</sup>; Tae-Kyu Lee<sup>2</sup>; Kuo-Chuan Liu<sup>2</sup>; <sup>1</sup>Michigan State University; <sup>2</sup>Cisco Systems, Inc.

Melting and solidification of SAC 305 and 405 lead-free solders in a Wafer-Level-Chip-Scale package were examined in-situ with synchrotron x-ray diffraction. The chips with balls attached (but not assembled to a board) were reflowed 1-3 times. The temperature and time history was similar to an industrial reflow process. Laue patterns were collected every half second during the melting and solidification process. The melting and solidification of the Sn in the solder joint occurred in about 0.5-1 second, whereas it takes several 10's of seconds for some diffraction peaks from Cu<sub>6</sub>Sn<sub>5</sub> and Ni<sub>3</sub>Sn<sub>4</sub> precipitates to disappear as they dissolve in molten Sn. Some intermetallic peaks were persistent and did not change throughout

the melting and solidification process. The crystal orientation of tin and thermal strains were analyzed after each reflow. Different orientations of Sn always developed upon resolidification. Supported by NSF GOALI research contract DMR-1006656 with Cisco Systems.

**Joint Properties of Pb-Free Solder Bumps on Flexible Board:** *Won-Myoung Ki*<sup>1</sup>; *Sehoon Yoo*<sup>1</sup>; *Chang-Woo Lee*<sup>1</sup>; <sup>1</sup>Korea Institute of Industrial Technology

The aim of this study is to investigate mechanical properties and reliability according to changing process variables on mounting components by a roll-to-roll (R2R) process. The R2R process is an important method to improve productivity, especially for the packaging of flexible electronic modules. The R2R process was composed of underfill dispensing, chip mounting and thermal compression. Si chip with Pb-free solder bumps were joined on polyimide substrate by R2R process. Solder bumps to interconnect between chips and flexible substrates were made by electroplating. The microstructure and mechanical properties of the solder bump were evaluated by SEM, EDS and shear tester. Also the bumps were aged up to 400 hours at 100°C for estimation of its reliability.

**Effect of Zn Content on the Electrification-Fusion and Failure Behaviors of Sn-xZn Alloys:** *Gong-An Lan*<sup>1</sup>; *Chung-Wei Yang*<sup>2</sup>; *Truan-Sheng Lui*<sup>1</sup>; *Li-Hui Chen*<sup>1</sup>; <sup>1</sup>National Cheng Kung University; <sup>2</sup>National Formosa University

Microstructural features of Sn-xZn alloys with varying Zn content of 7, 9, 20, 30 wt.% on the electrification-fusion phenomenon was investigated in this study. Experimental results showed that the critical fusion current density (CFCD) of Sn-xZn alloys increased with increasing Zn content. The enrichment of Zn-rich phase was the main factor in the improvement of electrical conductivity and the required electrical current density for triggering microstructural evolution for the hypereutectic Sn-30Zn alloy was much higher than the hypoeutectic Sn-7Zn alloy. The increasing rate of CFCD has an obvious variation at the transition from the hypoeutectic composition (Sn-7Zn) to the eutectic composition (Sn-9Zn) due to the microstructural change caused by Zn content. The in-situ examination of microstructural evolution provided a constructive method for ascertaining the relationship between each individual phase, the CFCD and the fusion-induced failure mechanism of Sn-xZn alloys.

**High Temperature Gold Based Lead Free Solder:** *Heiner Lichtenberger*<sup>1</sup>; <sup>1</sup>Williams Advanced Materials

With the conversion to lead free solders, and their higher processing temperatures, a need has arisen for a Gold Tin solder with a higher melting point than the conventional 278C, 80Au 20Sn eutectic electronic solder. In this work we examine the effects of minor Germanium or Indium additions to the 80Au20Sn composition in an effort to raise its Liquidus and Solidus to 300C. In order to study the AuGeSn and AuInSn ternary phase diagrams, we made a series of ternary alloys to map out the Au20Sn area, with up to 6% Ge or 6% Sn, compositions of the diagrams. We found that additions of Germanium increased the Liquidus, but decreased the Solidus, leaving these ternary alloys vulnerable to reflow during subsequent lead free SAC alloy soldering. Successful alloys were created by adding Indium to the Au Sn binary system, generating a ternary eutectic solder with a melting point of 300C.

**Study of Interfacial Morphology in Flip Chip Solder Joints under Extra-High Current Density with Local Temperature Control:** *Ting-Li Yang*<sup>1</sup>; *Jia-Hong Ke*<sup>1</sup>; *C. Robert Kao*<sup>1</sup>; <sup>1</sup>National Taiwan University

Temperature and current density are two key factors in electromigration behaviors. A temperature control device, employing forced fluid convection, was used to de-couple the chip temperature from the applied current density. With this temperature control, the electromigration effect on UBM consumption and interfacial reactions in Cu/Sn2.6Ag/Cu flip chip solder joints was investigated under varied extra-high current densities of  $3.5 \times 10^4$  A/cm<sup>2</sup> and  $4.5 \times 10^4$  A/cm<sup>2</sup> at the chip temperature of 50 °C. A unique sawtooth-type Cu UBM morphology was observed at the cathode/chip and cathode/substrate side under extra-high current stressing. In this study, the possible mechanism for this sawtooth-type morphology resulting from the

particular condition of low temperature and extra-high current density will be discussed.

**Study of PCB Dynamics and Reliability Assessment of BGA's under Shock and Vibration Loading:** *Pradosh Guruprasad*<sup>1</sup>; *Brian Roggeman*<sup>2</sup>; *James Pitarresi*<sup>1</sup>; <sup>1</sup>Binghamton University; <sup>2</sup>Universal Instruments

Traditional electronics reliability testing centers around thermal cycling lifetimes, however with the transition to Pb-free soldering and the popularity prevalence of portable and handheld devices, mechanical loading is many times of much greater concern. Even those high reliability industries that are exempt from RoHS and still using SnPb soldering, shock and vibration loading is many times a greater risk for failure than thermal cycling. Unlike thermal cycling, test parameters in shock and vibration are not general but very specific to the test vehicle. The shock and vibration responses of a PCB are highly sensitive to the geometry, construction boundary conditions, and test inputs, which all need to be considered to run a relevant reliability test. This paper intends to discuss the dynamic factors of the printed circuit board under shock and vibration loading, the use of these as reliability tools, and the consequences in terms of failures modes and lifetimes.

**Shear Strength and the Weibull Failure Analysis of Sn-Ag-Cu Solder Ball Joints with Different Reflow Processes:** *Chung-Wei Yang*<sup>1</sup>; *Truan-Sheng Lui*<sup>2</sup>; *Li-Hui Chen*<sup>2</sup>; <sup>1</sup>National Formosa University; <sup>2</sup>National Cheng Kung University

This study evaluated the shear strength of Sn-3Ag-0.5Cu (SAC305) and Sn-4Ag-0.5Cu (SAC405) solder balls on Cu/Ni/Au substrate after reflow soldering. The failures of joints were evaluated by the Weibull model. Experimental results show the shear strength increased with increasing ball sizes after 245°C reflow. However, shear strength was decreased for applying reflow at 235 and 255°C. Fracture morphologies displayed the failure of joints was occurred within solder balls. It represented the solder/substrate interface was bonded for 245°C reflow. The strength of joints was not related to the thickness of interfacial intermetallic compounds (IMCs). The minimum shear strength of joints was increased and data fluctuation was decreased with applying an aging at 105°C for 8 h after 245°C reflow. The Weibull analysis showed SAC305 and SAC405 were reliable joints with a wear-out failure model. The knowledge of minimum shear strength is helpful for understanding the joint reliability of electronic packaging applications.

**Interfacial Reaction and Elemental Redistribution in Sn3.0Ag0.5Cu-xPd/ENIG Solder Joints after Aging:** *I-Tai Wang*<sup>1</sup>; *Jenq-Gong Duh*<sup>1</sup>; *Chin-Yuan Cheng*<sup>2</sup>; *Jim Wang*<sup>2</sup>; <sup>1</sup>National Tsing Hua University; <sup>2</sup>Shenmao Technology Inc.

Electroless Nickel/Electroless Palladium/Immersion Gold (ENEPIG) surface finish has been developed to overcome the "black pad" issue of Electroless Nickel/Immersion Gold (ENIG). After reflow, the electroless Pd layer of ENEPIG would dissolve in Cu6Sn5, which might reduce the growth of IMC and P-rich layer. Moreover, the solderability and reliability of ENEPIG are superior to those of ENIG. However, the Pd distribution in solder joint is not yet clear. In this study, the Sn3.0Ag0.5Cu solder was doped with 100~500ppm Pd, and then was reflowed with ENIG. Afterward, the Sn3.0Ag0.5Cu-xPd/ENIG solder joints were aged at 150 deg-C for various periods of time. The Pd distribution in solder and IMCs was systematically analyzed by a field emission electron probe microanalyzer. The correlation between Pd distribution and interfacial reaction of Sn3.0Ag0.5Cu-xPd/ENIG solder joints was probed and discussed. In addition, the role of Pd in the solder joint reliability was also addressed.

**Microstructure and Brazing Performance of Spray-Formed Si-40Al Alloy Used for Electronic Packaging:** *Bin Yang*<sup>1</sup>; <sup>1</sup>University of Science and Technology Beijing

The experimental results have shown that the wettability between spray-formed Si-40Al alloy and Sn-3.0Ag-0.5Cu solder was very poor. The high frequency impulse electro-deposition technique is beneficial to form a fine and sound nano-nickel coating on the surface of Si-40Al sample, which can effectively improve the brazing performance of the alloy. A new galvanized method to prepare nano-nickel coating on the surface of Si-Al alloys was

proposed. The brazing performance of spray-deposited Si-Al alloys with Ni coating was improved effectively. It is found that the galvanized surface of spray-formed Si-40Al alloy was activated for succeeding impulse electro-deposition nano-nickel coating. The brazing performance of plated Si-40Al alloy with Ni coating was tested again. It is found that certain element diffusion was carried out between the coating and weld layer, the weld layer and bond Cu, showing that the interface strength was fairly good.

**Interfacial Reactions and Physical Properties of the Sn-Cu-Based Lead-Free Solder Joints:** Petr Harcuba<sup>1</sup>; Miloš Janeček<sup>1</sup>; <sup>1</sup>Charles University in Prague

In this study the influence of Cu content and minor Ni addition on the growth kinetic and morphology of the layers of intermetallic compound was study during the reaction of liquid solder and Cu substrate and subsequent ageing. The strength and electric resistance of simulated solder joints were also investigated. The reaction of a Sn-0.7Cu alloy with the substrate leads to the formation of a thin layer of Cu<sub>6</sub>Sn<sub>5</sub> ( $\eta$ -phase) of typical scallop morphology, which does not grow with longer reaction time. Higher Cu content in Sn-1.4Cu alloy leads to the extensive growth with reaction time and at long reaction times, a Cu<sub>3</sub>Sn ( $\epsilon$ -phase) was observed at the interface between the Cu substrate and the Cu<sub>6</sub>Sn<sub>5</sub> layer. A small nickel addition to a Sn-0.7Cu alloy significantly changes the IMC morphology, accelerates its growth kinetics, prevents the formation of the Cu<sub>3</sub>Sn layer and reduces the rate of substrate dissolution.

**Effect of Multiple Reflow Processes on the Reliability and Microstructure of Sn-Ag-Cu-In Solder Joint:** A-Mi Yu<sup>1</sup>; Jae-Won Jang<sup>1</sup>; Mok-Soon Kim<sup>1</sup>; Jong-Hyun Lee<sup>2</sup>; Jun-Ki Kim<sup>3</sup>; <sup>1</sup>Inha University; <sup>2</sup>Seoul National University of Technology; <sup>3</sup>Korea Institute of Industrial Technology

The authors have previously reported that the quaternary Sn-1.2Ag-0.7Cu-0.4In(wt%) alloy showed excellent wettability and mechanical reliability. Moreover, the addition of small amount of Pd or Mn was considered to improve its reliability to a greater extent especially in drop impact condition. In this study, the effect of multiple reflow processes on the drop impact reliability and microstructure of Sn-1.2Ag-0.7Cu-0.4In-X solder joints was investigated. The test package was prepared with OSP (organic solderability preservative)/Cu finished FR-4 PCB and ENIG finished BGA package. After the first reflow, the samples were repeated reflow of 3 and 5 cycles. The drop impact reliability tests were performed in a various ways and the results were compared with those of Sn-1.0Ag-0.5Cu and Sn-3.0Ag-0.5Cu alloys. The microstructure and partitioning of alloying elements in the solder joint were analyzed using SEM, EDS, XRD, EPMA and XPS.

**In Situ Stress Measurement by Synchrotron Radiation X-Ray in Pure Tin Stripes and Flip Chip with Microbumps on Silicon Substrates:** Hsueh-Hsien Hsu<sup>1</sup>; Chun-Yang Tsai<sup>1</sup>; Hsin-Yi Lee<sup>2</sup>; Ching-Shun Ku<sup>2</sup>; Albert T. Wu<sup>1</sup>; <sup>1</sup>National Central University; <sup>2</sup>National Synchrotron Research Center

The first part of the talk emphasizes the electromigration induced stress in pure tin stripes measured by Synchrotron radiation X-ray. Tin stripes were current stressed by  $5 \times 10^3$  A/cm<sup>2</sup> at 100°C while in situ detecting the diffraction signals. Both  $\theta$  and  $\Psi$  angles varied to measure the stresses at the cathode and the anode by  $\sin^2\Psi$  method. The transient changes in stress gradient provide the kinetics information of tin atoms under current. The  $DZ^*$  was calculated to be about  $2.6 \times 10^{-12}$  m<sup>2</sup>/s under electromigration. The second part focuses on in situ analyze the stress in silicon of flip chips with microbumps that were assembled on Si substrates. Each microbump was stressed with an average current density of  $1 \times 10^4$  A/cm<sup>2</sup>. Comparing to the conventional FR-4 substrates, the chips with silicon substrates showed less deformation. However, the results suggested that the deformation of the chips were greatly affected by underfill.

**Microstructure and Native Oxide Scale Characteristics of a Cu-9at.%La Alloy:** Bilge Senturk<sup>1</sup>; Yong Liu<sup>1</sup>; Joseph Mantese<sup>2</sup>; Pamir Alpay<sup>1</sup>; Mark Aindow<sup>1</sup>; <sup>1</sup>University of Connecticut; <sup>2</sup>United Technologies Research Center

Copper is used widely for electrical contacts due to its high electrical conductivity, ease of fabrication and low cost. The main drawback is

that copper forms a low-conductivity native oxide scale resulting in the development of high contact resistance. To overcome this, copper-based alloys that form inherently conductive native oxide scales are being developed. Here we present a study of the microstructure and electrical contact resistance behavior of a Cu-9 at.%La alloy to demonstrate the viability of this approach. The alloy has a uniform eutectic microstructure with rods of Cu in a Cu<sub>6</sub>La matrix. The oxide scale formed in air on the rods comprises a thin layer of pure Cu<sub>2</sub>O on the Cu rods and a thicker La-doped Cu<sub>2</sub>O layer on the Cu<sub>6</sub>La matrix. Although the scale is thicker than that formed on pure Cu, the contact resistance is lower and the mechanisms for this effect will be discussed.

**Electromigration Behavior of Sn-In Lead-Free Solder Alloy Under High Current Stress:** Kiju Lee<sup>1</sup>; Keun-Soo Kim<sup>1</sup>; Katsuaki Sukanuma<sup>1</sup>; <sup>1</sup>Osaka University

The electromigration behaviors of Cu/Sn-In/Cu solder strip models were examined under high electrical current density (10 kA/cm<sup>2</sup>) at high temperature (140 °C). The composition of Indium was 0, 4, 8 and 16 in wt%. The Sn-In solder interconnection with bare Cu substrate was prepared by reflow soldering up to 250°C. As a result of microstructural analysis, primary intermetallic compounds formed at the interface of Cu/Sn-In was confirmed as Cu<sub>6</sub>(In, Sn)<sub>5</sub> with various indium composition. After current stressing, voids and cracks formed at the cathode side and intermetallic compounds formed at the anode side. The addition of indium effectively reduces the grain size and forms an intermetallic compound network along grain boundaries of Sn. In the case of the Sn-8-16wt%In solder, migration of Cu and Sn atoms can be effectively suppressed.

**Multiscale Simulation of Fracture in Lead-Free Solder Joints:** Huiyang Fei<sup>1</sup>; Kyle Yazzie<sup>1</sup>; Nikhilesh Chawla<sup>1</sup>; Hanqing Jiang<sup>1</sup>; <sup>1</sup>Arizona State University

The structural reliability of lead-free solder joint is of great interest in both academic and industrial societies. In this talk, a combination of fracture models has been used to study the fracture mechanism of lead-free solder joint with a Cu-Sn-Cu bar structure. In our analysis, Copper is considered as isotropic elastic-plastic and the intermetallic compound (IMC) fails by brittle fracture. The key contribution of our work is that we developed a stochastic enhancement for the Modified Gursion Model, and have applied it to lead-free solder alloys. This stochastic enhancement method better characterizes the real distribution of microvoids in porous metals, and better predicts the failure than non-randomized Modified Gursion Model. The simulation was conducted in the FEA package ABAQUS with our enhancement. This work gives a reasonable explanation for the fracture mechanism of lead-free solder joint, and furthermore points out a way to improve the structural reliability of the joint.

**Thermomigration of Al in Flip-Chip Solder Joints:** Hsiao-Yun Chen<sup>1</sup>; Chih Chen<sup>1</sup>; <sup>1</sup>National Chiao Tung University

The electromigration and thermomigration behaviors of lead-free solders have been investigated under a current density of  $9 \times 10^3$  A/cm<sup>2</sup> at 150°C. It is found that voids not only formed inside solder bumps with and without current stressing, but also formed inside the upper Al trace, which was without current passing through. Theoretical calculation indicates that the thermomigration force under this condition is large enough to push Al atoms migrate from upper chip side to the cold end on substrate side. Moreover, the original Ti layer between Al trace and Cu UBM was vanished and Cu-Al intermetallic compounds (IMCs) can also be found. The results here inferred that thermomigration of Al itself can induce deterioration of Al trace and therefore followed by resistance increase and greater Joule heating effect. This study can provide us a new insight in understanding the deterioration of Al trace under a thermal gradient during the electromigration test.

**Calculation of Ni/Cu<sub>6</sub>Sn<sub>5</sub> Inter-Diffusion Coefficient and Activation Energy by Using Bulk Cu<sub>6</sub>Sn<sub>5</sub> Substrate:** *Kuan Chih Huang*<sup>1</sup>; Yu Hsiang Hsiao<sup>2</sup>; Cheng Yi Liu<sup>2</sup>; Fuh Sheng Shieue<sup>1</sup>; <sup>1</sup>National Chung Hsing University; <sup>2</sup>National Central University

Ni layer is usually introduced as a diffusion barrier layer at Cu/Sn interface for Flip-Chip and ball-grid array (BGA) solder bumps. The diffusion of Ni atoms in Cu/Sn intermetallic compound (IMC) and activation energy of compound growth is studied. Ni thin film was deposited on bulk Cu<sub>6</sub>Sn<sub>5</sub> and annealed for 2 hours in vacuum. The Ni atomic depth profiles would be detected by electron spectroscopy for chemical analysis (ESCA). We can calculate the Ni inter-diffusion coefficient "D" by Matano method. In our study, the annealing temperatures are 120°C, 160°C, 200°C, 255°C, 290°C, and 320°C. From six Ni atomic depth profiles, the activation energy Q (based on Cu<sub>6</sub>Sn<sub>5</sub> and Ni<sub>3</sub>Sn<sub>4</sub> crystal structure) for different atomic percentage of Ni atoms were determined by using Arrhenius plot based upon the equation:  $\ln D = -Q/kT + \ln D_0$ .

**Effects of the Substrate Topography on the Black Pad Formation after Electroless Nickel Immersion Gold (ENIG) Process:** *Ji Hee Kim*<sup>1</sup>; Jin Yu<sup>1</sup>; <sup>1</sup>Korea Advanced Institute of Science and Technology

Black Pad phenomenon reported to occur in the ENIG UBM (under bump metallurgy) seriously damages the wetting property of the solder and thereby degrades the solder joint reliability. Black pad is known to be caused by the hypercorrosion of Ni in the IG solution, however a thorough understanding on the phenomenon has not been procured yet due to the difficulty of the sample reproducibility. At EPL (electronics packaging laboratory) of KAIST, black pad was reproduced using standard chemicals, and a systematic work has been carried out. Most recently, a corrosion couple made of two electroless nickel films with different P content demonstrated the occurrence of black pad on the low P side (Scripta Materialia 2010). Here, three specimens with different substrate topography; Cu block, rolled Cu foil and sputter deposited Cu film underwent the same ENIG process; thereby the same P content in the EN film, and characteristics of the black pad formation were analyzed. Using AFM, SEM, XRD and TEM. All the specimens showed preferential corrosion along the nodule boundaries after the IG process, however, there were large variations in the corrosion susceptibility, which was ascribed to surface roughness, texture and others.

## Physical and Mechanical Metallurgy of Shape Memory Alloys for Actuator Applications: Poster Session

*Sponsored by:* The Minerals, Metals and Materials Society  
*Program Organizers:* S. Raj, NASA Glenn Research Center; Raj Vaidyanathan, University of Central Florida; Ibrahim Karaman, Texas A&M University; Ronald Noebe, NASA Glenn Research Center; Frederick Calkins, The Boeing Company; Shuichi Miyazaki, Institute of Materials Science, University of Tsukuba

Sun PM-Thurs AM  
Feb 27-Mar 3, 2011

Room: 11B  
Location: San Diego Conv. Ctr

**Adaptive Shape Memory Actuator Systems for Applications at Varying Boundary Conditions:** Horst Meier<sup>1</sup>; Alexander Czechowicz<sup>1</sup>; Sven Langbein<sup>1</sup>; <sup>1</sup>Ruhr-University Bochum

Due to their possibility to recover an imprinted shape by thermal or electrical activation, shape memory alloys (SMA) are suitable for actuator applications. Their dynamical behavior depends inter alia on the boundary conditions, exemplary the thermally field. Therefore the wide range of possible applications is today reduced to systems with slight thermal variations, and to temperatures which are less than the retransformation temperature (Mf). In order to design systems which adapt automatically to these changes, various experiments with SMA-alloys have been made, which are presented in this paper. The solutions to the boundary condition problem can be subdivided into active and passive approaches, which are presented as automotive applications in this elaboration.

**Effect of H in Metals and Alloys: An Application to bcc W and NiTi Alloy:** *Amitava Moitra*<sup>1</sup>; Kiran Solanki<sup>1</sup>; <sup>1</sup>Center for Advanced Vehicular Systems

Strengthening and embrittlement are controlled by the interactions between lattice defects and hydrogen induced defect structures that can inversely affect the deformation mechanisms in materials. These interactions depend on the character of the defects, the nature of the material, and the impurity. To understand environmental effects on the damage of materials, we performed first principles density functional theory based study in a pure bcc W, and NiTi shape memory alloy. Local distortions due to interstitial H are examined along with the diffusion barrier for an H atom from one interstitial to another. Finally H adsorption and penetration through the surface to the bulk has been analyzed.

**Growth of Oriented Nickel Manganese Gallium Single Crystals via the Bridgman Method:** *Douglas Kellis*<sup>1</sup>; K. Ullakko<sup>1</sup>; P. Müllner<sup>1</sup>; <sup>1</sup>Boise State University

Magnetic shape memory alloys such as nickel manganese gallium show great promise as actuating and sensing applications due a strong coupling between magnetic and crystallographic domains (twins) leading to magnetic-field-induced strains of up to 10%. Fabrication of Ni-Mn-Ga single crystals is hampered by strong chemical segregation during crystal growth and material losses resulting from the off-axis orientation of crystals grown by the Bridgman method. We built a single crystal growth furnace with a temperature gradient of 20 K/mm capable of growing crystals from an oriented seed. Systematic crystal growth experiments were performed by varying the growth velocity and the seed temperature. At a growth velocity of 0.08 mm/min, oriented single crystals were obtained with a constant composition over 60% of the crystal. With increasing growth velocity, the tendency for nucleation increases, resulting in off-axis oriented crystals and elongated grains. This technique provides a method for the rapid and efficient production of Ni-Mn-Ga single crystals.

**Mechanism of Artifact Formation on NiTi Alloy during Metallographic Preparation:** *Andreas Undisz*<sup>1</sup>; Klemens Reuther<sup>2</sup>; Helfried Reuther<sup>2</sup>; Markus Rettenmayr<sup>2</sup>; <sup>1</sup>University of Jena; <sup>2</sup>Friedrich-Schiller-University; <sup>3</sup>Research Center Dresden-Rossendorf

Statements on the structure/property relationship of NiTi via structure characterization based on metallographic preparation have been shown to be ambiguous. In the literature, acicular structures on NiTi after metallographic preparation are often interpreted as martensite or martensitic surface relief. The composition of the acicular structures cannot be distinguished from the bulk material by standard analysis, e.g. EDX or AES. However, these structures were recently identified as artifacts. NiTi samples were observed at different stages of preparation using SEM, EDX and AES. Rod-like crystals were detected on the NiTi surface. The crystals form during etching with solutions containing hydrofluoric acid and were identified as NiTiF<sub>6</sub>·6H<sub>2</sub>O by XRD. During etching, the crystals locally prevent contact of etching solution and NiTi. Further etching solely removes NiTi at adjacent uncovered areas. During cleaning with water the crystals dissolve and the surface relief with a shape according to that of the dissolved crystals remains.

**Microstructure and Martensitic Transformation Characteristics of CoNiGa High Temperature Shape Memory Alloys:** *Ebubekir Dogan*<sup>1</sup>; Ibrahim Karaman<sup>1</sup>; Zhiping Luo<sup>1</sup>; Yuriy Chumlyakov<sup>2</sup>; <sup>1</sup>Texas A&M University; <sup>2</sup>Siberian Physical Technical Institute

Microstructure and martensitic transformation characteristics of Co<sub>46</sub>Ni<sub>27</sub>Ga<sub>27</sub> and Co<sub>44</sub>Ni<sub>26</sub>Ga<sub>30</sub> high temperature shape memory alloys were investigated as a function of heat treatment. Heat treatments were selected to introduce single, two, and three phase structures, where the precipitate phases don't martensitically transform. The effects of these precipitates, and associated compositional changes, on transformation temperatures and microstructural evolution during thermal cycling were revealed. The most cyclically stable compositions with narrow hysteresis (<40 °C) were identified. It was also found that Ms temperature linearly depends on the valence electron concentration (e/a) of the matrix, if the Ga content is constant. For a given e/a, the higher the Ga content is, the higher

the transformation temperatures become. The samples with narrow hysteresis demonstrate reversible martensitic transformation in constant-stress thermal cycling experiments. However, their crystallographic texture should be engineered to increase the transformation strain, and ductile  $\gamma$ -phase content should be reduced to improve cyclic reversibility.

**Microstructure and Shape Memory Characteristics of Powder Metallurgical Processed TiNiCu Alloys:** *Yeon-wook Kim*<sup>1</sup>; Young-soo Chung<sup>2</sup>; Eunsoo Choi Choi<sup>3</sup>; Tae-hyun Nam Nam<sup>4</sup>; <sup>1</sup>Keimyung University; <sup>2</sup>Chungang University; <sup>3</sup>Hongik University; <sup>4</sup>Gyeongsang National University

Although Ti-Ni-Cu alloys have attracted a lot of attention due to their high performance of shape memory effect and decrease of thermal and stress hysteresis in comparison with Ti-Ni binary alloys, their poor workability restrains the practical applications of Ti-Ni-Cu shape memory alloys. Consolidation of TiNiCu alloy powders is very useful for the fabrication of bulk near-net-shape shape memory alloy. Ti50Ni30Cu20 shape memory alloy powders were prepared by gas atomization, and the dense cylindrical bulk was prepared from the powders by spark plasma sintering. Single step martensitic transformation of B2-B19' was observed for both powders and bulk. Ms of the 10-20  $\mu\text{m}$  powders was 30°C and continued to decrease inconsiderably with increasing powder size. The difference of Ms between 10-20  $\mu\text{m}$  powders and 150-200  $\mu\text{m}$  powders is only 2°C. However, Ms of bulk samples was lower than those of as-atomized powders because of microstructural changes during SPS sintering.

**Origin of Non Recoverable Strain in NiTi and NiTiFe Shape Memory Alloys on Thermal Cycling:** *Ritwik Basu*<sup>1</sup>; Bikas Maji<sup>2</sup>; Prita Pant<sup>1</sup>; Indradev Samajdar<sup>1</sup>; Madangopal Krishnan<sup>2</sup>; <sup>1</sup>Indian Institute of Technology Bombay; <sup>2</sup>Bhabha Atomic Research Centre, Mumbai

The aim of this work is to study the effect of thermal cycling on the non-recoverable strain for alloys of two different compositions, NiTi and NiTiFe. We started with three different microstructures for each of these alloy composition. The major results of this work concern the microstructure of these alloys and distribution of fine grains. We have shown that the microstructure which shows largest clustering of fine grains exhibits the largest non recoverable strains after a few thermal cycles. Finally we have shown that the main condition for the martensite to revert back to austenite is to obey an orientation relationship which in successive thermal cycle is violated and therefore the fraction of retained martensite increases after every cycle which is the key factor for the non recoverable strain. The micro texture and microstructure have been studied using electron backscattering diffraction and orientation imaging mapping (EBSD-OIM).

**Oxidation Behavior of Sputter-Deposited TiNiPd Sharp Memory Films:** *Shiqiang Qian*<sup>1</sup>; <sup>1</sup>School of Materials Engineering, Shanghai University of Engineering Science

Using TGA and AES the oxidation dynamics of sputter-deposited TiNiPd films and the contents of oxygen and other elements in surface layer of the films were investigated. It was found that TiNiPd films are oxidizable more than TiNi films and their short time oxidation character accords with linearity-parabola law. The results showed oxygenizing activation energy of amorphous films is almost equal to that of titanium dioxide (TiO<sub>2</sub>) but that of crystal films is less than the half of titanium dioxide. This is one reason that TiNiPd films are oxidizable easily. The research attested that the Pd atom promoted the combine of O atom and Ti atom and excluded Ti atom of oxide at interface, therefore, led the Ti atom in the film to diffuse out through oxide interface, which is the principal reason that TiNiPd films is more oxidizable than that of TiNi films.

**Phase Transformations in Sputtered NiMnGa Thin Films:** Nishitha Jetta<sup>1</sup>; Steven Rios<sup>1</sup>; Nevin Ozdemir<sup>1</sup>; Ibrahim Karaman<sup>1</sup>; *Xinghang Zhang*<sup>1</sup>; <sup>1</sup>Texas A&M University

NiMnGa films have been prepared by the DC magnetron sputtering technique on partially oxidized Si (100) substrates. As-deposited films show a quasi-amorphous structure that crystallize on heating to ~ 230°C. Crystallization study using Kissinger's analysis reveals a relatively low activation energy indicating partial crystallinity in the films. Phase transformations studied

using in-situ and ex-situ XRD and TEM techniques show reversible transitions between martensite and austenite phases, and phase segregation to non-transforming L12 precipitates at higher temperatures. It was observed that phase segregation can be suppressed by proper heat treatment.

**Powder Metallurgy Processing of Replicated Ni-Mn-Ga Foams:** *Peiqi Zheng*<sup>1</sup>; Bing Ye<sup>1</sup>; Cassie Witherspoon<sup>2</sup>; Peter Müllner<sup>2</sup>; David Dunand<sup>1</sup>; <sup>1</sup>Northwestern University; <sup>2</sup>Boise State University

Previously, we demonstrated very large magnetic-field induced strain (MFIS) of up to ~8.7% in replication-cast Ni-Mn-Ga foams, where the molten alloy infiltrates a bed of space-holder which is subsequently dissolved to create porosity. This casting process requires a space-holder with very high melting point (NaAlO<sub>2</sub>) which is difficult to remove. Here, we apply the powder metallurgy replication method to produce a Ni-Mn-Ga foam by densifying Ni-Mn-Ga and BaCl<sub>2</sub> (melting point of 965 °C) blend powders and then dissolving BaCl<sub>2</sub>. Vacuum hot pressing at 930 °C under a 30 MPa pressure results in densified Ni-Mn-Ga/BaCl<sub>2</sub> composites. The high solubility of BaCl<sub>2</sub> in water permits a rapid removal while the powder metallurgy route opens the door to easy manipulation of pore size, shape and connectivity. We compare architecture, microstructure, magnetic properties, and MFIS of the present hot-pressed Ni-Mn-Ga foams with those of the previous cast foams.

**Relationship between Orientation and Strain of Polycrystalline Ni<sub>50</sub>Mn<sub>20</sub>Ga<sub>21</sub> Samples:** *Claudia Hürrieh*<sup>1</sup>; Martin Pötschke<sup>1</sup>; Stefan Roth<sup>1</sup>; Bernd Rellinghaus<sup>1</sup>; Ludwig Schultz<sup>1</sup>; <sup>1</sup>IFW Dresden

The Ni-Mn-Ga magnetic shape memory alloy provokes plenty of interest for application because of the effect that twin variants reorient by the action of an external magnetic field. Most of the experiments were concentrated on single crystals. But, this effect can also be realized in polycrystals which can be prepared much more efficiently. Here, polycrystalline samples were prepared by directional solidification with a <100> fibre texture of the high temperature cubic phase parallel to the heat flow. A heat treatment was applied for chemical homogenisation and stress relaxation. Samples were heated up to the austenitic state and cooled down under load. The microstructure was analyzed by EBSD before and after that treatment. Stress-strain curves were measured at room temperature and at 40°C. As a result of such treatment the twinning stress is reduced and the twinning strain is maximized. This work is supported by DFG within SPP 1239.

**Standardized Shape Memory Actuators for Axis Drives in Modular Machine Tools:** Horst Meier<sup>1</sup>; *Alexander Czechowicz*<sup>1</sup>; Sven Langbein<sup>1</sup>; <sup>1</sup>Ruhr-University Bochum

Shape memory alloys (SMA) are materials which are able to generate high forces and adaptive strokes in actuator applications. It is remarkable that available systems using shape memory drives are commonly individual designs done by system developers. The SMA-development process is complicated due to underestimation of the complex material behavior and there is no wide field of SMA-development experience in medium-sized enterprises. Therefore standardized systems are essential to invent new products with SMA. As an example, an axis drive for a modular machine tool is presented, using standardized shape memory actuators. Because of the unique properties of SMA, this machine can move a slide precisely and with a minimum of effort. This paper contains the approaches towards the development of standardized systems and the experimental results of their combination to positioning modules.

**Study of Magnetic Domain Structures in a Ni-Mn-Ga Alloy by Aberration Corrected Lorentz Transmission Electron Microscopy:** *Abhijeet Budruk*<sup>1</sup>; Marc De Graef<sup>1</sup>; <sup>1</sup>Carnegie Mellon University

Magnetic shape memory alloys (MSMAs) have a large magnetic field induced strain (up to 9.5% in non-stoichiometric Ni-Mn-Ga alloys). These large strains are thought to result from a rearrangement of martensite twin variants under the influence of a magnetic field. The Lorentz TEM observation mode is used regularly to study the magnetic domain structure in thin foils of ferromagnetic materials. Until recently, the spatial resolution for such magnetic imaging was limited by objective lens aberrations. In

this study, we have employed an aberration corrected Lorentz TEM to image the magnetic domain structures associated with lattice defects in a  $\text{Ni}_{49.9}\text{Mn}_{28.3}\text{Ga}_{21.8}$  alloy. Anti-phase boundaries and twin boundaries were found to interact strongly with magnetic domain walls, whereas dislocations do not show significant interactions. Depending on the orientation of the magnetic easy axis, the twin variants displayed either a maze like domain structure or a 180 degree domain wall pattern.

**The Effect of Composition on the Shape Memory and Super Elasticity Effect of Nano-Structured Ni-Ti Thin Films:** Maryam Mohri<sup>1</sup>; *Mahmoud Nili-Ahmadabadi*<sup>1</sup>; Hamidreza Rezaeean<sup>1</sup>; <sup>1</sup>university of Tehran

Shape memory thin films formed by sputtering are attractive candidates for micro actuators owing to their large deformation and strong recovery force. In this study three types of Ni-Ti thin films have been deposited on polyimide substrates by dc magnetron sputtering source fitted with an alloy target. Ti and Ni-rich thin films were separately deposited on polyimide substrate. And also a composite layer of Ti and Ni-rich. In order to obtain a variety of film compositions, several discs of alloy target were used. The as deposited Ni-Ti thin films were crystallized at different temperatures and times to change the amorphous structure to a nano-structured material. The effect of composition on film structure, transformation temperature and mechanical behavior was studied by using energy dispersive X-ray spectroscopy, X-ray diffraction (XRD), atomic force microscope (AFM), electrical resistivity and nanoindentation. Superelasticity effect and transformation temperatures of thin films have been compared to each other.

**Thermomechanical Treatment Effects on Two-Way Shape Memory in Ti-49.2%Ni Alloy:** Fatemeh Daei<sup>1</sup>; *Mahmoud Nili-Ahmadabadi*<sup>1</sup>; <sup>1</sup>University of Tehran

In this research, the effect of thermomechanical treatment (cold working + annealing) and number of training cycles was investigated on two-way shape memory effect (TWSME) in a Ti-49.2at.%Ni alloy. The ingot was prepared in a vacuum arc remelting furnace with non-consumable electrode followed by forging, homogenization at 1000°C and water quenching. The samples prepared from the homogenized ingot were cold rolled to induce different cold workings. Annealing treatment was performed at 450°C for 30 and 60 min after 10, 20 and 25% cold working. The samples were trained in martensitic state in order to investigate the two-way shape memory effect by bending deformation. Results indicate that the optimum recovery was obtained after 25% cold working followed by annealing at 450°C for 60 min. Also, the TWSME recovery increases by increasing the training cycles and finally reaches to steady state.

**Turning of NiTi Based Shape Memory Alloy Using Ultrasonic Vibration:** Amir Chegini<sup>1</sup>; *Saeed Tamimi*<sup>2</sup>; Zahra Chegini<sup>1</sup>; Hang Baharuddin<sup>1</sup>; Mehdi Sanjari<sup>3</sup>; <sup>1</sup>Department of Mechanical Engineering; <sup>2</sup>TEMA; <sup>3</sup>Department of Material Science

In this study, vibration cutting has been applied to machining of NiTi based shape memory alloy (SMA), using a commercial ultrasonic piezoelectric transducer to vibrate a standard insert geometry cutting tool. The effect of vibration in turning process was characterized by investigating the surface roughness of work piece and surface quality assessment of machined surface using Light microscopy. Turning was conducted by ultrasonic cutting vibration applied in the direction of feed using auto-resonant control software. The surface roughness of the conventionally and ultrasonically machined work pieces are measured. The intend of the current research is to make a facility of ultrasonic-assisted turning (UAT) to machining NiTi based SMA and to guess the potential improvements in surface quality, using commercial transducers and standard insert cutting tool. The results indicate that the use of ultrasonic vibration can significantly get better the surface quality of NiTi based alloy up to 30%.

## Polycrystal Modelling with Experimental Integration: A Symposium Honoring Carlos Tome: Poster Session

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Materials Processing and Manufacturing Division, ASM-MSCTS: Texture and Anisotropy Committee, TMS/ASM: Mechanical Behavior of Materials Committee, TMS/ASM: Computational Materials Science and Engineering Committee

*Program Organizers:* Ricardo Lebensohn, Los Alamos National Laboratory; Sean Agnew, University of Virginia; Mark Daymond, Queens's University

Sun PM-Thurs AM  
Feb 27-Mar 3, 2011

Room: 6C  
Location: San Diego Conv. Ctr

*Session Chairs:* Carlos Tome, Los Alamos National Laboratory; Ricardo Lebensohn, Los Alamos National Laboratory

**An Electron Microscopy Study of the Intermetallic Phases in a Hot Dip Galvanize Coating on IF Steel:** *Md Zakaria Quadir*<sup>1</sup>; Syahbuddin Syahbuddin<sup>1</sup>; Karen Privat<sup>1</sup>; Charlie Kong<sup>1</sup>; Paul Munroe<sup>1</sup>; <sup>1</sup>University of New South Wales

The quantitative distribution of structural morphology and crystallography of a hot dipped galvanized zinc coating on an interstitial free steel has been investigated. After 5 to 60 seconds dipping the gamma, delta, zeta and eata-Zn phases were found to be organized sequentially in the coating on the steel surface. The interfaces between the phases are irregular and the interface between zeta and eata-Zn phases was much diffused. The eata-Zn phase was also found to be trapped in the zeta phase and the spatial distribution of the eata-Zn in the zeta (FeZn13) is correlated to the interface profile between the zeta and delta (FeZn10) phases. The presence of compositional variation within zeta phases indicates the occurrence of spinodal decomposition along <110> monoclinic direction as proved by TEM diffraction analysis. The growth of the zeta phase is highly textured along [100] and [001] crystallographic directions of their monoclinic lattice.

**Deformation Behavior of Steel Alloys under Combined Axial-Torsional Loading:** *Dayakar Penumadu*<sup>1</sup>; Akawat Siriruk<sup>1</sup>; Elena Garlea<sup>2</sup>; <sup>1</sup>University of Tennessee; <sup>2</sup>B&W Y-12, L.L.C.

Using hollow cylinder samples with suitable geometry obtained from round bar stock and flat dog-bone samples from sheets, the deformation behavior of bcc alloys is evaluated under multi-axial conditions. A strain gage rosette mounted at the mid height of the specimen provided strain tensor as a function of applied stress for pure tensile and torsion tests prior to yielding. Flat specimens are not ideal for use in experiments which involves varying rotation of principal stress, but are quite practical to study the behavior in the limit (pure tension versus torsion) for sheet metals. To study the elastic and yield behavior as a function of microstructure, hollow cylinder shape (tubes) with small wall thickness and relatively (to its thickness) large inner diameter was used. The variation of observed yield surface in deviatoric plane and the effect on mode of deformation (tension versus torsion and their combination) on texture is discussed.

**Deformation Localization in Two-Dimensional Single Crystals:** *M. Arulkumar*<sup>1</sup>; Sivasambu Mahesh<sup>1</sup>; P. Venkitanarayanan<sup>1</sup>; <sup>1</sup>Indian Institute of Technology, Kanpur

A novel methodology to predict localization of deformation in single crystals is developed. This approach regards the single crystal as a stack of sub-granular rate-independent rigid-plastic domains separated by parallel dislocation walls. Traction and velocity continuity are enforced across the dislocation walls. If dislocation wall mobility and dynamic recrystallization induced reduction in the hardening rate are suitably incorporated, small initial lattice perturbation across the walls can develop into large intragranular misorientations for suitably oriented single crystals. The present methodology is used to map out regions of deformation localization

in the lattice orientation and slip system hardening spaces of ideal two dimensional single crystals endowed with two slip systems (Asaro 1979). It also successfully predicts deformation localization in several experimentally well studied fcc single crystal orientations.

**Development of an In-Situ Experimental Technique for Characterizing Strain Localization in Polycrystalline Ni-Base Superalloys:** *Jennifer Walley*<sup>1</sup>; Robert Wheeler<sup>2</sup>; Michael Uchic<sup>3</sup>; Michael Mills<sup>1</sup>; <sup>1</sup>The Ohio State University; <sup>2</sup>UES; <sup>3</sup>Air Force Research Laboratory

An in-situ experimental methodology is being developed to characterize local strain heterogeneities in polycrystalline nickel-based superalloys. The data collected is directly applicable towards validating crystal plasticity models. Initial work was conducted on Rene 104 that was heat treated to produce two sets of samples with similar grain size distributions but different  $\square$ ' distributions and grain boundary morphologies. This talk will focus on the technical issues associated with performing quasi-isostatic tensile tests at elevated temperature in a scanning electron microscope (SEM). Electron beam lithography techniques were developed to produce a suitable speckle pattern on the surface to facilitate full field strain analysis. The speckle pattern and microscope magnification were optimized to obtain the resolution necessary to discern strain localizations within grain interiors and along grain boundaries using Correlated Solutions VIC-2D strain mapping software. Limitations due to SEM image distortions and the in-situ tensile stage and heating element will be discussed.

**Evolution of Dislocation Density and Burgers Vector Types with Annealing Temperature in Compressed Texture-Free and Compressed Rolled Beryllium Samples Determined by Diffraction Line Profile Analysis:** *Levente Balogh*<sup>1</sup>; Donald Brown<sup>1</sup>; Bjorn Clausen<sup>2</sup>; Diana Donati<sup>2</sup>; Thomas Sisneros<sup>1</sup>; <sup>1</sup>Materials Science and Technology Division, Los Alamos National Laboratory; <sup>2</sup>Los Alamos Neutron Science Center, Los Alamos National Laboratory

Texture-free and rolling induced textured pure beryllium samples were deformed to 20% by compression and then annealed on temperatures between 100 and 550 degrees Celsius with steps of 50 degrees. In situ neutron diffraction measurements have been conducted during the annealing process using the Neutron Powder Diffractometer (NPDF) instrument located at the Lujan Neutron Scattering Center (LANSCE), Los Alamos National Laboratory. The powder diffraction patterns were evaluated by the Diffraction Line Profile Analysis method (DLPA). The DLPA procedure is able to provide the sub-grain size distribution and the characteristic parameters of the dislocation structure for a variety of crystal structures. When used on hexagonal powder diffraction patterns, besides the sub-grain size distribution and total dislocation density, DLPA is able to determine the ratio of the partial densities consisting of dislocations with  $\langle a \rangle$ ,  $\langle c+a \rangle$  and  $\langle c \rangle$  Burgers vector types. Results show, that the recovery rate of the dislocation density depends on the relative orientation of the compression axis to the rolling induced texture. The evolution of the partial dislocation densities consisting of the different Burgers vector types show, that dislocations with  $\langle a \rangle$  type Burgers vectors recover faster, than  $\langle c+a \rangle$  type dislocations.

**EBSD Measurement of Deformation Behavior and Orientation Change in Dual Phase Steel Sheet during Equi-Biaxial Tension:** *Do Hyun Kim*<sup>1</sup>; Se-Jong Kim<sup>1</sup>; Anthony Rollett<sup>2</sup>; Heung Nam Han<sup>1</sup>; Kyu Hwan Oh<sup>1</sup>; <sup>1</sup>Seoul National University; <sup>2</sup>Carnegie-Mellon University

Modern steels rely on a two-phase microstructure with soft ferrite and hard martensite. This dual phase microstructure leads to an excellent combination of tensile strength and elongation. A novel experimental setting for electron backscattering diffraction was developed to characterize equi-biaxial tensile tests. To measure the orientation change in the same area on the specimen during equi-biaxial deformation, four micro-indentation marks were placed on the center top of the surface before loading. The distribution and amount of martensite before loading were derived from the band contrast map. The local misorientation change in each ferrite grain was measured as a function of strain. The effect of the hard martensite on local misorientation change in soft ferrite grains was analyzed, as well as interactions between adjacent ferrite grains. Surface topography was also measured before and after

the equi-biaxial deformation by Atomic Force Microscope to investigate 3-dimensional strain character.

**Experimental and Simulation Studies on the Texture Evolution during Deformation of ARB Processed Cu-Cu Multilayer:** *Suresh Santharam*<sup>1</sup>; Satyam Suwas<sup>1</sup>; Anthony Rollett<sup>2</sup>; <sup>1</sup>Indian Institute of Science; <sup>2</sup>Carnegie Mellon University

Texture evolution during large strain deformation of a Cu-Cu multilayer is investigated. The Cu-Cu multilayer was produced by the Accumulative Roll Bonding (ARB) technique and then further rolled to 93% reduction at room temperature. The 8-pass ARB processed material was, in effect, the initial material for deformation, which consisted of grains with an average aspect ratio of 1:10. After 93% rolling reduction the aspect ratio decreased to 1:2.5. The bulk X-ray texture measurement showed a stronger Brass  $\{011\}\langle 211 \rangle$  component evolution compared to that of the Copper  $\{112\}\langle 111 \rangle$  component. The texture strength stabilizes after 87% reduction. Texture evolution was simulated using the ViscoPlastic Self-Consistent (VPSC) code. The slip systems, work hardening behavior, grain aspect ratio, initial texture and shear strain arising from surface friction were considered for texture simulation. The addition of shear strain leads to reduced texture sharpening. The simulated texture is in good agreement with the experimental measurements.

**Full Field Study of Local Interactions between Twin and Its Parent Grain:** *Anand Kanjarla*<sup>1</sup>; Irene Beyerlein<sup>1</sup>; Carlos Tomé<sup>1</sup>; Ricardo Lebensohn<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

In the present study, we use a full field method, namely the Fast Fourier Transform Technique (FFT), to study the interaction of an existing twin with its parent grain in Zirconium. Both compressive and tensile twins are considered. By allowing the development of spatially resolved heterogeneous micromechanical fields inside a parent and a twin, accurate estimates of the interaction between them can be obtained. By altering the twin volume fraction and the surrounding local neighborhood grains, one can obtain realistic trends about local fields and localization criteria that can, in turn, be used to improve the assumptions made about these interactions in Homogenized Effective Media (HEM) models, such as the Visco-plastic and Elasto-plastic self consistent models.

**Investigation of Texturing and Bending during Asymmetric Rolling of AZ31B:** *Jaehyung Cho*<sup>1</sup>; SukBong Kang<sup>1</sup>; <sup>1</sup>Korea Institute of Materials Science

Asymmetric deformation generated by differential speed rolling produced bending of AZ31 magnesium alloy sheets. Bending curvature and texture and microstructure evolution of the AZ31 magnesium alloys were investigated and compared with model predictions. Modeling asymmetric rolling process was carried out using finite element approaches and obtained deformation gradients were used to predict texture evolution. Texturing was predicted based on a visco-plastic self consistent (VPSC) model. Asymmetric rolling was carried out with various roll speed ratios and reduction area. Bending curvatures were predicted to dynamically depend on ratio of the roll speeds, reduction area and friction. AZ31B alloy sheets initially had some texture gradient along the thickness direction. Top and bottom surface showed the similar basal texture and the center had elongated basal fiber along the transverse direction. The overall feature of the texture gradient remained after 10% and 20% reduction area.

**Modelling the Mechanical Behavior of Dual-Phase Steels under Strain Reversal:** *Smritikana Dutta*<sup>1</sup>; <sup>1</sup>University of Aveiro

In this work we analyze the mechanical behavior of dual-phase steels under strain reversal with the previous proposed Phi-Model. In this model the proposed interaction law is based on a new non-linear intermediate approach. In the formulation, it is proposed to minimize an error function which combines the deviations of the local fields from the corresponding macroscopic ones. A scalar weight parameter was introduced to span the entire solution domain between the upper and lower bound approaches. The model takes into account the texture evolution and micro structural features

related with changes in strain path. A comparison between the self-consistent model (VPSC code) and the Phi-model is also considered.

**Phase Field Simulation of Static Recrystallization for AZ31 Mg Alloy:** Gao Yingjun<sup>1</sup>; <sup>1</sup>Guangxi University

In order to obtain the deformation grain structure for static recrystallization, an initial grain structure for deformation grain structure are produced by lattice deformation model; aiming at characteristics of different deformation regions and non-uniform distribution of the stored energy in deformed alloy, a multi-state free energy (MSFE) function are proposed by introducing a weight factor for the stored energy and a characteristics state factor for different deformation regions. Based on these models, the microstructure evolutions of static recrystallization for deformation Mg alloys are simulated by phase field model. The transformation dynamic curve of recrystallization and the time index for Avrami curve, and the stored energy released regularity and distribution of grain size in recrystallization process are systematic analyzed. Based on our established MSFE model, the simulation results here are well in accordance with the other theoretical results and experimental results.

**Physical Parameters Determination from 3D Phase Field Simulations of Martensitic Transformations in Steels:** Hemantha Yeddu<sup>1</sup>; John Ågren<sup>1</sup>; Annika Borgenstam<sup>1</sup>; <sup>1</sup>Royal Institute of Technology (KTH)

Typically Phase Field Modeling (PFM) is applied to simulate microstructure evolution in order to understand the physical phenomena involved in the phase transformations, viz. solidification, martensitic transformations, spinodal decomposition etc. In the present work the limits of applicability of PFM are extended to determine various process as well as material parameters that control the martensitic transformation in steels apart from the above mentioned typical application. Plastic relaxation rate, i.e. the rapidity of the response by the material to accommodate the elastic stresses by means of plastic deformation, and the driving forces needed for nucleation as well as growth of martensite are calculated from the simulations. Usage of anisotropic physical parameters, acquired from experimental works performed on different Fe-C alloys, as the simulation parameters has yielded the simulation results as close to reality as possible.

**Residual Stress Concentration and Distribution in Polycrystalline Ceramic Materials Using a 3D Fast Fourier Transform Thermoelastic Method:** Benjamin Anglin<sup>1</sup>; R Hay<sup>2</sup>; T. A. Parthasarathy<sup>3</sup>; R.A. Lebensohn<sup>4</sup>; A.D. Rollett<sup>1</sup>; <sup>1</sup>Carnegie Mellon University; <sup>2</sup>Air Force Research Laboratory; <sup>3</sup>UES, Inc.; <sup>4</sup>Los Alamos National Laboratory

Residual stresses develop in non-cubic polycrystalline materials with anisotropic thermal expansivity. These can lead to microcracking and/or can reduce the mechanical properties of the bulk solid. These stresses are difficult to experimentally measure in 3D and numerical methods have attempted to model them. A common numerical method for modeling residual stresses is finite element; previous studies have used 2D models to show that residual stresses in ceramic polycrystals are distributed over tens of grains. Extending this to 3D is complicated since this method requires a mesh for the microstructure and requires large computation time for realistic polygrain arrangements. A computationally more efficient method is the FFT thermoelastic method which uses a periodic mesh independent of grain geometry. In this work, the thermoelastic FFT method is used to determine the residual stress concentration and distribution within a polycrystalline ceramic material in 3D; the results will be presented and their implications discussed.

**The Texture Evolution of Interstitial-Free Steel Processed by Different Speed Rolling:** Jordan Suharto<sup>1</sup>; Jae Sik Lee<sup>1</sup>; Yeon Jin Gil<sup>1</sup>; Young Gun Ko<sup>1</sup>; <sup>1</sup>Yeungnam University

The texture evolution of the interstitial free steel sheets severely deformed at room temperature using differential speed rolling (DSR) method was investigated in which the variation of roll speed ratio from 1:2 to 1:4. The effects of speed ratio in texture evolution and grain boundary orientation of IF steel were analyzed by electron back scattered diffraction and TEM interpretation. With the increasing of rolls speed ratio, the textures were

transformed which were affected by misorientations on grain boundary during deformation. As compared to initial stage, the presence of fine ferrite grain has increased and microstructure homogeneity increased. The stress-strain curve of rolled specimen will be discussed in relation to the degree of formability in this study.

**Processing and Properties of Powder-Based Materials: Poster Session**

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Powder Materials Committee

*Program Organizers:* K. Morsi, San Diego State University; Ahmed El-Desouky, San Diego State University

Sun PM-Wed PM  
Feb 27-Mar 2, 2011

Room: 33A  
Location: San Diego Conv. Ctr

**High Temperature Oxidation Behaviors of Fe-Cr-Al Bulk and Powder Sintered Materials:** Kee-Ahn Lee<sup>1</sup>; Song-Yi Kim<sup>1</sup>; Sung-Hwan Choi<sup>1</sup>; Jung-Yeol Yun<sup>2</sup>; Hye-Moon Lee<sup>2</sup>; Byung-Kee Kim; <sup>1</sup>Andong National University; <sup>2</sup>Korea Institute of Machinery and Materials

Bulk specimens and powder sintered specimens were each produced from Fe-22%Cr-5.8% Al alloy and the high-temperature oxidation behaviors of the specimens were compared and analyzed. Temperatures of 900°, 1000°, and 1100° (24 hours) and gas atmosphere of 79%N<sub>2</sub>+ 21%O<sub>2</sub> were set as testing conditions. The results of the oxidation testing showed that both bulk and powder sintered specimens gained weight as the temperature increased, with the powder sintered specimens exhibiting far more weight gain than the bulk specimens. In the powder sintered specimens, the internal diffusion of O<sub>2</sub> toward the powder interfaces easily took place due to weak binding between powder particles constituting the microstructure. The Fe-Cr-Al alloy bulk and powder sintered specimens' oxidation behaviors and mechanism of microstructures were further discussed in relation to temperature rise. [supported by the Fundamental R&D program for Core technology of Materials funded by the Ministry of Knowledge Economy, Republic of Korea]

**Investigation of Engineered Pore Structures in Powdered Metals by Means of Freeze Tape Casting:** David Driscoll<sup>1</sup>; Adam Weisenstein<sup>1</sup>; Stephen Sofie<sup>1</sup>; <sup>1</sup>Montana State University

Engineered metal foams have strong potential in applications such as fuel cell electrodes, sensors, differential springs, filtering media, and composite structures. In this study the variation in mechanical and electrical properties were characterized in engineered porous metal foams with aligned porosity. Utilizing freeze tape casting, aqueous 440SS metal powder suspensions were drawn onto a freeze bed. After directional solidification, the solvent was sublimed from the ~1mm thick tapes, yielding porous green metal compacts which were sintered in a vacuum furnace from 900 – 1100C. Densification was shown to begin at 1000C yielding shrinkage variations relative to pore alignment. The resulting disks exhibit highly ordered acicular pores with substantial anisotropy in the mechanical and electrical properties. DC conductivity revealed up to 62% variation depending on direction of measurement relative to the alignment of pores. The affects of rigidity and tensile strength in relation to pore orientation will also be reported.

## Silicon Production, Purification and Recycling for Photovoltaic Cells: Poster Session

## Parallel Developments of a Cellular Automaton - Finite Element Model for the Prediction of Grain Structure in Casting: *Tommy Carozzani*<sup>1</sup>; Charles-André Gandin<sup>2</sup>; Hugues Dignonnet<sup>2</sup>; <sup>1</sup>MINES - Paristech; <sup>2</sup>MINES ParisTech

A coupled Cellular Automaton (CA) - Finite Element (FE) model is developed to predict grain structure in casting. The model tracks the nucleation and growth of each grain. The outputs are the final grain structure and texture. Macroscopic equations are solved on the FE mesh, while grain structure is described on the CA grid. Coupling of heat and mass transfers are set up between the two modeling scales. Grains are typically represented with a 100 microns resolution (cell size), in a 15x15x100 cm quarter of ingot. The huge amount of data involved (22.5 10<sup>9</sup> cells) cannot be processed on a single computer. The present implementation uses massive parallel computation to solve the industrial scale problem. Developments have been done to balance the load between processors, the only limitation of the domain size being the computing resources available.

## Study of Pellets and Lumps as Raw Material for Silicon Production: *Elena Dal Martello*<sup>1</sup>; Gabriella Tranell<sup>1</sup>; Sean Gaal<sup>2</sup>; Ola Raanes<sup>2</sup>; Merete Tangstad<sup>1</sup>; Lars Arnborg<sup>1</sup>; Rune Larsen<sup>1</sup>; <sup>1</sup>Norwegian University of Science and Technology; <sup>2</sup>SINTEF

The aim of this paper is twofold: to compare the behaviour of pellets and lumps and to compare the properties of two hydrothermal quartzes during carbothermic reduction. Small scale carbothermic reduction experiments have been carried out in an induction furnace. High purity silicon carbide and two different high purity hydrothermal quartzes were charged as raw materials at different molar ratios, either in the form of lumps (size 2-5 mm), or as powder, mixed and agglomerated as pellets (size 1-3 mm) and reacted at 2000°C. The high temperature properties of the two quartzes were also investigated in a sessile drop experimental set-up. A quantitative XRD-based method has been tested in order to estimate the reaction products between quartz and silicon carbide at 2000°C.

## Surfaces and Heterostructures at Nano- or Micro-Scale and Their Characterization, Properties, and Applications: Poster Session

*Sponsored by:* TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS: Nanomaterials Committee, TMS: Surface Engineering Committee

*Program Organizers:* Nitin Chopra, The University of Alabama; Ramana Reddy, The University of Alabama; Jiyoung Kim, Univ of Texas; Arvind Agarwal, Florida International Univ; Sandip Harimkar, Oklahoma State University

Sun PM-Wed AM  
Feb 27-Mar 2, 2011

Room: 31B  
Location: San Diego Conv. Ctr

## Novel Carbon Nanotubes-Nanoparticle Heterostructures and Their Utilization in Soft Nanocomposite Fabrication: Adrika Venkatanarayan<sup>1</sup>; Wenwu Shi<sup>1</sup>; *Nitin Chopra*<sup>1</sup>; <sup>1</sup>The University of Alabama

Development of multi-functional and multi-component carbon nanotube-nanoparticle heterostructures is critical for future analytical platforms and biosensors. In this, we demonstrate here a unique approach to fabricate carbon nanotube-multiple nanoparticle heterostructures in a single step facile synthetic approach. These heterostructures were understood by SEM, TEM, UV-vis, and EDS studies. It was observed that uniform coating of nanoparticles on carbon nanotubes could be formed and there was no free nanoparticle formation in the solution, thus indicating the importance to carbon nanotube surface characteristics and dimensionality. These heterostructures are further incorporated into a stimuli-responsive hydrogels to result in a smart, hybrid, and soft nanocomposites. These nanocomposites will be useful for developing novel chemical and biological sensors.

## Effect of Pulsed Electrodeposition Conditions and Reinforcement Content on Microstructure and Tribological Properties of Nickel Composite Coatings: *Tushar Borkar*<sup>1</sup>; Sandip Harimkar<sup>1</sup>; <sup>1</sup>Oklahoma State University

Pure nickel and nickel composite coatings (Ni-Al<sub>2</sub>O<sub>3</sub>, Ni-SiC, and Ni-ZrO<sub>2</sub>) were deposited from Watts bath using direct current (DC), pulsed current (PC), and pulsed reverse current (PRC) deposition conditions. Detailed investigations on the effect of deposition conditions on the evolution of surface microstructure, crystallographic micro-texture, microhardness, and sliding wear behavior of pure nickel and nickel composite coatings are presented. Coatings deposited by PC and PRC techniques resulted in more random crystallographic texture. The composite coatings deposited using PC and PRC deposition also exhibited significant improvement in microhardness and wear resistance. Also, the effect of nanoparticle content of the electrolyte bath on the surface microstructure, tribological properties, and level of reinforcement in the Ni-Al<sub>2</sub>O<sub>3</sub> composite coating is investigated. The reinforcement of nanoparticles as well as microhardness and wear resistance of Ni-Al<sub>2</sub>O<sub>3</sub> composite coatings increased linearly with the amount of nanoparticle loading in the electrolyte bath.

## Spark Plasma Sintering of Amorphous-Crystalline Laminated Composites: *Tushar Borkar*<sup>1</sup>; *Ashish Singh*<sup>1</sup>; Sandip Harimkar<sup>1</sup>; <sup>1</sup>Oklahoma State University

In this paper, a novel approach involving pulsed electrodeposition (PED) and spark plasma sintering (SPS) of Fe-B-Si amorphous ribbons is presented for the processing of amorphous-crystalline laminated composites. The PED allowed the deposition of nanocrystalline Ni or Cu layers (thickness: <3 μm) on the Fe-B-Si amorphous ribbons (thickness: <25 μm). The coated ribbons were subsequently stacked and SPS sintered under the influence of pulsed direct current and uniaxial pressure. The SPS sintered amorphous ribbons (uncoated) and amorphous-Ni laminates exhibited partial crystallization of the ribbons and poor lamellar bonding in the composites. With the similar SPS sintering parameters (temperature: 450°C; pressure: 350 MPa; sintering

time: 20 min), the amorphous-Ni-Cu laminates were sintered to full densification without undesirable crystallization of the amorphous ribbons.

**Mechanical Properties of Grain Boundary-Containing Al Nano-Pillars:** Allison Kunz<sup>1</sup>; Siddhartha Pathak<sup>1</sup>; Andrew Jennings<sup>1</sup>; Julia Greer<sup>1</sup>; <sup>1</sup>Caltech

Mechanical behavior of bi-crystalline aluminum nano-pillars under uniaxial compression reveals size effects, stochastic stress-strain signature, and strain-hardening. Pillar diameters range from 400nm to 2 microns and contain a single high-angle grain boundary oriented parallel to pillar axes. Loading-unloading cycles reveal no Bauschinger effect, suggesting that the native oxide does not trap mobile dislocations. Our results indicate that these bi-crystalline pillars are characterized by intermittent strain bursts and exhibit an identical size effect to their single crystalline counterparts. Further, we find that the presence of the grain boundary generally decreased the degree of work hardening relative to the single-crystalline micro-pillars. These findings suggest that micro-pillar plasticity in the presence of a grain boundary is also dislocation nucleation-controlled and that the grain boundary likely serves as a dislocation sink rather than a dislocation source. Transmission electron microscopy (TEM) analysis provides further insight into dislocation density evolution in these bicrystalline pillars.

**Silicon Nanorod Formation for Solar Absorbers Using Nanosphere Lithography:** Blake Whitley<sup>1</sup>; Faisal Salman<sup>1</sup>; Chris Redden<sup>1</sup>; Anusha Natarajathinam<sup>1</sup>; Alton Highsmith<sup>1</sup>; Subhadra Gupta<sup>1</sup>; <sup>1</sup>The University of Alabama

Solar absorption has been realized through strategically located geometries, including closely spaced nanorods. For this research, polystyrene nanospheres have been used as masking agents in the top-down formation of nanorods through nanosphere lithography (NSL). NSL requires a uniform monolayer of polystyrene spheres on a substrate as the initial step in the formation of nanorods. Monolayers were successfully created over select areas of the wafer through spin-coating. The effects of ashing on polystyrene spheres were then studied in detail. The Bosch process was carried out in an inductively coupled plasma deep reactive ion etcher (ICP-DRIE) to etch several microns into the silicon substrate, producing nanorods of aspect ratios exceeding 50. A statistical design of experiments was carried out to optimize the absorption of the etched silicon as a function of nanorod aspect ratio and spacing, which was optimized as a function of the etch parameters.

**Development and Mechanical Characterization of Novel Alumina Based Composites for Reduced Friction and Wear Applications:** Rajeshwari Paluri<sup>1</sup>; Sudeep Ingole<sup>1</sup>; <sup>1</sup>Texas A&M University

Self-lubricating materials with superior surface properties for reduced friction and wear application are always a point of attention for surface scientists, tribologists and lubrication engineers. Alumina is one such material which is a merit choice for wear resistance applications like pump bearings, piston components, etc. We attempt to develop a novel alumina based ceramic composite to further enhance its surface properties. This presentation will focus on mechanical and surface characterization of alumina under influence of varying percentages of boron as friction modifier. The results of XRD, optical microscopy and ESEM will be presented along with hardness and fracture toughness. Effect of sintering temperature and percentage of boron on mechanical properties, density, porosity and grain size will be presented. Preliminary results show that increasing percent of boron resulted in grain boundary diffusion and high sintering temperatures resulted in low porosity. X-ray diffractograms confirm formation of aluminum diboride and aluminum borate.

**Data Transmission Performance of Graphene Interconnects:** Cengiz Ozkan<sup>1</sup>; <sup>1</sup>University of California

This poster describes our recent work on emerging interconnect technologies based on graphene layers and on the materials processing challenges for large scale applications. Interconnects fabricated from graphene layers could serve as a future replacement for metal interconnects. An attractive aspect of using graphene interconnects is the potential dual-functionality where they could also serve as thermal spreaders given their excellent thermal conductivity characteristics. We present results on digital data transmission performance

of graphene interconnects grown by chemical vapor deposition, and the initial studies demonstrated that they can sustain data rates up to 90 megabits per second. Graphene interconnects behave as RLC lines and the bandwidth is inversely proportional to resistance caused by defects in the synthesized graphene layers and the inductance and capacitance of the interconnect lines. We are continuously improving the quality of CVD grown graphene layers to improve the bandwidth of transmission beyond the gigabits per second level.

## The Second Symposium on the Recycling of Electronic Wastes: Poster Session

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Extraction and Processing Division, TMS Light Metals Division, TMS: Electronic Packaging and Interconnection Materials Committee, TMS: Recycling and Environmental Technologies Committee  
*Program Organizers:* Lifeng Zhang, Missouri University of Science and Technology; Gregory Krumdick, Argonne National Laboratory; Jaan Kers, Tallinn University of Technology; Thomas P. Schuman, Missouri University of Science and Technology (Missouri S&T); Markus Reuter, Ausmelt Limited

Sun PM-Mon PM  
Feb 27-28, 2011

Room: 15B  
Location: San Diego Conv. Ctr

**A Novel Process for Foam Glass Preparation from Waste CRT Panel Glass:** Mengjun Chen<sup>1</sup>; Fu-shen Zhang<sup>2</sup>; Jianxin Zhu<sup>2</sup>; <sup>1</sup>Southwest University of Science and Technology (SWUST); <sup>2</sup>Chinese Academy of Sciences

A novel approach for foam glass preparation, namely vacuum-aided powder sintering technique, was preliminarily investigated in the present study. The key point of this approach was to prepare foam glass at a negative pressure. Compared to normal powder sintering process, the new approach could benefit the foaming process by shorting the holding time, reducing the amount of foaming agent and especially decreasing relative density of the product. Optimum conditions were 750 °C, 1000 Pa, 5 min and 1 wt.% foaming agent, respectively.

**Development of Reproduction of Glass Substrate from Old TFT-LCD Panel:** Sung-Jei Hong<sup>1</sup>; Jong-Woong Kim<sup>1</sup>; Min-Sun Kim<sup>1</sup>; Tae-Whan Hong<sup>2</sup>; Young-Sung Kim<sup>3</sup>; Nam-Ki Kang<sup>1</sup>; <sup>1</sup>Korea Electronics Technology Institute; <sup>2</sup>Chungju National University; <sup>3</sup>Seoul National University of Science and Technology

The glass substrate is one of important parts of TFT-LCD panel. In general, most of the glass substrates included in old TFT-LCD panel is crashed and melt into the furnace with high temperature to recycle it. However, the complex recycling process uses lots of harmful chemicals and high electrical power, and waste water and CO<sub>2</sub> gas are generated during the process. Therefore, in this work, the new reproduction of glass substrate from old TFT-LCD panel was attempted without any crashing and melting process. The front-plane panel was used for the reproduction of glass substrate. As a result, ITO layer on the glass substrate were clearly separated using the newly attempted process. No damage was given to the glass during the process, and surface roughness was less than 1 nm. Also, the good optical transmittance more than 90% was achieved from the reproduced glass because the reproduced state was clear.

**Environmental Leaching Characteristics and Bioavailabilities of Waste Cathode Ray Tube Glass:** Mengjun Chen<sup>1</sup>; Fu-Shen Zhang<sup>2</sup>; Jianxin Zhu<sup>2</sup>; <sup>1</sup>Southwest University of Science and Technology (SWUST); <sup>2</sup>Chinese Academy of Sciences

In China hazardous e-waste, cathode ray tube (CRT) glass, is usually left around and it is likely to contact with water resources directly. To identify the real leaching characteristics and bioavailabilities of heavy metals Pb and Ba contained in CRT glass in the nature environment, experiments were carried out by simulating the nature environment. The results indicated that Pb and Ba contained in CRT glass were stable in most conditions, which only showed obvious leaching toxicities in strong acidic/alkali conditions. EDTA

and DTPA extractable Pb and Ba amounts were extremely high, e.g., EDTA extractable Pb of color funnel glass was up to 1960.07  $\mu\text{g}/\text{kg}$ , indicating that the potential bioavailability of waste CRT glass is very high.

**Leaching Toxicity of Pb and Ba Containing in Cathode Ray Tube Glasses by SEP-TCLP:** Mengjun Chen<sup>1</sup>; Fu-Shen Zhang<sup>2</sup>; Jianxin Zhu<sup>2</sup>; <sup>1</sup>Southwest University of Science and Technology (SWUST); <sup>2</sup>Chinese Academy of Sciences

In the present study, different types of cathode ray tube (CRT) glasses were examined by sequential extraction, combined with TCLP, to provide possible explanations for how Pb and Ba leach out from the waste CRT glasses. Sequential extraction results showed that Pb and Ba in the CRT glasses dominantly presented as the residual fraction. The exchangeable fractions of Pb and Ba were extremely low, less than 0.01 % of the total content, but they were higher than those required by the regulation limits, 5 and 100 mg/L for Pb and Ba, respectively. TCLP tests of the original CRT glasses, and their residue after each step of sequential extraction, demonstrated that the extremely high leaching toxicity of CRT glasses was mainly caused by its exchangeable and carbonate fractions of Pb and Ba.

**Recovery of Copper from Printed Circuit Boards Waste by Bioleaching:** Luciana Yamane<sup>1</sup>; Denise Espinosa<sup>1</sup>; Jorge Tenório<sup>1</sup>; <sup>1</sup>Polytechnic School of São Paulo University

The present work investigated the influence of Fe+2 initial concentrations in the bioleaching of copper from printed circuit board using *Acidithiobacillus ferrooxidans*-LR. Printed circuit boards were collected from obsolete computers and mechanically processed through size reduction followed by magnetic separation. The bacteria *Acidithiobacillus ferrooxidans*-LR were grown and adapted in presence of printed circuit boards. A shake flask study was carried out on the printed circuit boards samples (non-magnetic fraction) using a rotary shaker under the following fixed conditions (185 rpm, 30°C). The bioleaching efficiency was evaluated by comparison between the concentration in the initial sample and in the leached liquor, pH of the medium and concentration of ferrous iron produced. Inductively coupled plasma optical emission spectrometry (ICP-OES) was used to determine the metals concentration. The results showed that *Acidithiobacillus ferrooxidans*-LR leached 63% copper from printed circuit boards using supplemented medium with Fe+2.

**Recovery of Nickel from Leaching Liquor of Printed Circuit Board by Solvent Extraction:** Adriana Santanilla<sup>1</sup>; Beatriz Campos<sup>1</sup>; Jorge Tenório<sup>1</sup>; Denise Espinosa<sup>1</sup>; <sup>1</sup>Polytechnic School of University of São Paulo

The aim of the present work is to investigate the recovery of nickel from obsolete cell phones. Printed circuit boards from cell phone scrap was submitted prior to a grinding process and then leached in sulfuric acid. Nickel was extracted from aqueous solution using Cyanex 272. Aqueous/organic ratio was set equal to 1. The effect of both pH and temperature on selectivity was investigated.

# NOTES

## 2011 Aluminum Plenary Symposium: The 125th Anniversary of the Hall-Héroult Process

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee  
Program Organizer: John Johnson, JCG

Monday AM Room: 6B  
February 28, 2011 Location: San Diego Conv. Ctr

Session Chair: John Johnson, Johnson's Consulting Group

### 8:30 AM Plenary

**Paul Héroult: The Early Days of the European Aluminium Industry:** Claude Vanvoren<sup>1</sup>; <sup>1</sup>Rio Tinto Alcan

Paul Héroult story is indistinguishable from the early days of the European aluminium industry in France and Switzerland. The personal engagement of the co-inventor of the electrolytic process, a true entrepreneur, tells a lot about his conviction on the bright future of the light metal. The lecture will come back on those adventurous early days and illustrate how they gave birth to an industry which since, relentlessly, devoted effort to innovate and facilitate access to a material which developed from semi-precious to commodity status in less than 125 years.

### 9:05 AM Plenary

**Charles Martin Hall and Warren Haupin: Over 100 Years of Technical Innovation:** Gary Tarcy<sup>1</sup>; <sup>1</sup>Alcoa

Two scientists at Alcoa stand above all others. The first, of course is Charles Martin Hall, one of the co-inventors of the electrolysis process that is still used today. C. M. Hall was also one of the co-founders of what was originally the Pittsburgh Reduction Company that later became the Aluminum Company of America (ALCOA). Looking back on some of his early work and in particular his invention one only wonders what he would think of what became a worldwide metals industry that in volume is only surpassed by steel. Although the process is essentially the same as it was invented 125 years ago. A second Alcoa scientist, Warren Haupin, was one of the essential people to increase the understanding of the process that has led to a multitude of incremental improvements over the last 60 years. The lecture will discuss the contributions and some antidotal information about both of these scientists.

### 9:40 AM Plenary

**The Rise and Fall of the Knowledge Base for Aluminium Smelting – The Last 50 Years:** Barry Welch<sup>1</sup>; <sup>1</sup>University of New South Wales- Australia, and Welbank Consulting Ltd - New Zealand

In the second half of the 1950's the space race was with us. Cheaper more efficient production of light metals (such as titanium, magnesium and aluminium) as well as the refractory metals and materials - including zirconium and titanium diborides for example - that would withstand extremely high temperatures became a major research thrust. As a flow-on from the European and Russian research eminence in these areas during the 1930's and 1940's, a few academic Western-world research "cells" (to pinch a George Bush phrase) specialising in the structure, properties and electro chemistry of molten salts were being established and active. The activities were heavily biased to molten fluorides included research aiming at developing more efficient nuclear reactors (ORNL) and a better understanding of aluminum smelting electrolyte. "Young-bloods" trained in academic institutions (especially the University of Toronto, the Technical University of Norway and Imperial College -London Penn State Univ., and MIT) spearheaded and intense research that developed an excellent understanding of the fundamentals of the properties of molten electrolytes and the electrochemistry. The glowing example was Kai Grjotheim's thesis in 1956. The Symposium on Aluminium organised by TMS in 1962 was the first one that brought together some of the academic understanding and industrial issues associated with aluminium smelting. Inspiring papers by Eric Ransley on titanium diboride (with concepts quite different to those

that are being considered in the decades since), the reactivity and properties of carbon anodes and cathodes, and the options for maximising current efficiency stood alongside one on Bus-bar designs which initiated magnetic modelling of the cells - then computing was in its infancy. From these and other papers presented the growth in design features that enabled an increase in amperage took off. The impact of some of the "characters" who became leaders in the early 1960s, together with their contributions will be traced and highlighted. As also will be the decline that started following the change in emphasis introduced by aluminium industry leaders in the second half of the 1980s, to the point to day where it is harming performance and displaying a greater lack of understanding of core fundamentals than existed 50 years ago!

### 10:20 AM Break

### 10:30 AM Plenary

**The Early Years of Light Metals, TMS:** Nolan Richards<sup>1</sup>; <sup>1</sup>Richards & Associates

The symposium held in New York, 1962, "Extractive Metallurgy of Aluminum", under the auspices of the Metallurgical Society of AIME, was a ground breaking event in the U. S.A. for the entire aluminum industry. As a result of two-years of organizing, fifty five contributors, thirty one embracing the production of aluminum, freely shared results of research done within their companies or universities with this tentative opening up of communication and sharing that had occurred previously only in a few conferences in Europe. The amicable interactions and success of this meeting led to the beginning of annual meetings organized by the Light Metals Committee, the Metallurgical Society (TMS) of the American Institute of Mining Metallurgical and Petroleum Engineers Inc. (AIME). Before this conference, technologists involved in improving the operation, design and safety of alumina reduction cells, apart from their in-house, guarded data, had recourse to the monographs of J.W. Richards (1896), T.G. Pearson 1955), Kai Grjotheim (1956) and excepting the Russian literature, a few papers in The Journal of the Electrochemical and Faraday Societies. While it took a while, the consensus was that sharing non-competitive technical and discovering some of the trends in the strategies of competitors was that these aspects were all conducive to advancing the competitiveness of the whole aluminum industry, raising the awareness of the effectiveness of in-house R&D and enhancing the innovations and creativity of all technologists. Therefore, in 1971, again in New York, now the TMS Light Metal, began its series of annual meetings involving the international aluminum industry and academia. There participation increased to ninety-seven contributors with sixty four concerned with the reduction process. This presentation explores the first eight or nine TMS Light metals symposia with the objective of categorizing the topic fields, the extent to which they were "cutting edge", comments on how they influenced the electrolytic production of aluminum and inspired competitive research with improved funding, the attraction of future technologists into the industry and nurturing of "centers of excellence" for research in the Hall Héroult Process, novel processes and advanced materials.

### 10:55 AM Plenary

**Russian Aluminium Industry:** Peter Polyakov<sup>1</sup>; Victor Mann<sup>2</sup>; <sup>1</sup>Siberian Federal University; <sup>2</sup>Russian Aluminum Industry

1. Prehistory: Professor Fedotyeff's, Professor Pushin's investigations. 2. Soviet Union Early stage: 1932 – Volkov Smelter (PB); 1933 – Zaporozhye Smelter (PB); 1939 – Ural Smelter (HSS). 3. Scientific research: Professor M. Rappoport – Sodium intercalation; Professor A. Belyaev – bath for Al-cells; Professor M. Vetyukov – carbon technology; Professor Korobov – heat transfer; Candidate Science Forsblom A. Tsyplakov – magnetic fields; Professor Kaluzhsky – from VSS to PB; Professor P. Polyakov – Al-cell as a living creature. 4. After WW II. Huge Smelters: 1964 – Krasnoyarsk (VSS); 1966 – Bratsk (VSS); 1985 – Sayanogorsk (PB); 2007 – Khakas (PB). 5. Current scientific investigations: Soderberg technology improvement; PB-cells development; Al laboratory studies.

### 11:35 AM Plenary

#### **Brief Overview of Environmental Control within the Primary Aluminium Industry:** Erik Keul<sup>1</sup>; <sup>1</sup>ALSTOM Environmental Norway

The Aluminium Industry has come a long way with respect to Environmental Control during the 125 years with the Hall-Heroult process. The initial smelters were small and any adverse effects were either of no concern or were not detected. As the smelters grew in size improved potroom ventilation was the major method for reducing exposure of the workers to fumes as well as for protection of equipment. The first noticeable damage to vegetation was detected in St. Jean de Maurienne in 1909. Environmental Control within the industry was basically a voluntary effort and evolved due to concern about worker's health and obvious damage to the local environment, but has been helped along due to legislations. Various types of roof scrubbers were introduced in the 1930's and were applied by some smelters as the only treatment systems until the 1970's. None of these had reached the expected removal efficiencies due to inadequate sampling methods. Hooded cells were also introduced in the 1930's and in the following decades the concentrated fumes were either dispersed by tall stacks or cleaned by cyclones, electrostatic precipitators, wet scrubbers or a combination of these. Since the late 1960s dry scrubbers operating with alumina for removal of gaseous fluorides and particulates have been the state of the art emission control technology. Mega-smelters may introduce local environmental impact from SO<sub>2</sub> which would need to be treated in additional downstream scrubbers such as seawater scrubbers for coastal smelters. As per IAI the reduction in fluoride emission can be divided into three generations: 1st generation plants 1940 – 1955 12 – 15 kg per tonne; 2nd generation plants 1955 – 1975 2 – 6 kg per tonne; 3rd generation plants 1975 – today 0.3 – 1 kg per tonne. Today fluoride emission is not a major concern and due to legislation as well as to potential loss of costly raw materials all new smelters employ efficient pot hooding combined with dry scrubbers at +99% collection efficiencies. The focus today is on SO<sub>2</sub> removal, on greenhouse gases like CF<sub>4</sub>/C<sub>2</sub>F<sub>6</sub> and on PAHs from the green-mills and baking kilns. Future legislation (in EU) will likely enforce reductions in particulate emissions in addition to CO<sub>2</sub> limitations.

### 12:00 PM Plenary

#### **The Future for Aluminium Smelting:** Mark Taylor<sup>1</sup>; J.J.J. Chen<sup>1</sup>; <sup>1</sup>University of Auckland

The future of aluminium smelting is not assured. A primary driver of this situation is that the reasons for continuously reducing real margin for primary aluminium are not openly acknowledged, or even agreed. Is it the total cash cost of production? Or is it the community perception first, which causes a loss of public support for investment in infrastructure and resources to support heavy industries like aluminium smelting? Of course this is not a new question and many countries including USA and Europe have been confronted with the competing requirements of energy or resource intensive industries. In this competition, the wider community must prevail eventually. And as these competitive situations play out in the customary adversarial manner between business and Government, the new question is becoming: Is there another way for the business community to think about the place of energy intensive industries in our interconnected, interdependent societies where energy and other natural resources are apparently in short supply? In this paper we discuss specific energy consumption across the industry, the perceived barrier in reducing it, and enabling factors. Lastly we explore the possibility that aluminium smelters could become an integral part of the network for power supply in the community, and across communities and countries.

### 2011 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: Nanomaterials: General

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Nanomaterials Committee

### 8:30 AM Introductory Comments

#### 8:35 AM Keynote

#### **Materials Research Support at the National Science Foundation:** Alan Ardell<sup>1</sup>; <sup>1</sup>National Science Foundation

The NSF/DMR perspective on materials research and education will be presented. DMR invested ~\$303M in FY10, supporting people, ideas, and instrumentation primarily through awards to the nation's colleges and universities. Apart from DMR, there is also substantial support for materials and materials-related research and education from other programs in NSF. Specific new opportunities – including the 4+ year-old program in biomaterials and the SOLAR and EFRI initiatives – will be discussed. There are also avenues for collaborative research, nationally and internationally, via different types of special funding programs such as the new CEMRI and MIRT, which have replaced the MRSEC program, and the established MWN program. Other The projects supported by the MMN program in FY10 and the budgetary outlook for FY11 will be described. General information on all the programs in DMR can be found on the DMR Web page: <<http://www.nsf.gov/mps/divisions/dmr/>>.

#### 9:05 AM Keynote

#### **Nanostructured Materials Development by the Center for Nanostructured Materials Technology:** Sang-Hee Suh<sup>1</sup>; <sup>1</sup>KIST, Center for Nanostructured Materials Technology

Over the last 10 years Korea has put large effort on nanotechnology development. Since Korean government started Korea Nanotechnology Initiative, we have seen tremendous increase in nanotechnology related publications, patents filed, new venture companies, and commercial products. Sponsored by the Ministry of Education, Science and Technology of Korea, the Center for Nanostructured Materials Technology has been managing one of the biggest programs for developing nanotechnologies in Korea. This Program aims to develop various nanostructured materials with superior properties by creating new materials or by applying nanotechnology to the already existing materials. The R&D areas covered by the Program include nanostructured materials for structural applications, environment and energy applications, and information technology applications. By the program, more than 30 original nanotechnologies have been developed, including 11 platform technologies. 22 technologies have been transferred to industry with many of them commercialized. Commercialized products include cutting tools with nano-layered coating; carbon nanotube/metal nanocomposites; amorphous structured thermal sprayed ceramic coating; nano-membrane with dual functionalities of catalytic reaction; and separation and nano-cathode materials for Li rechargeable batteries. The author will introduce some of the platform and commercialized technologies developed by the program.

**9:35 AM Invited**

**Nanomaterials: Research, Development and Technology (R&D&T) Roadmaps - 2020:** *Marcel Van De Voorde*<sup>1</sup>; <sup>1</sup>TU Delft

An overview will be given of nanomaterials Science and Technology in the world. Fundamental research will be the backbone for future industrial success including new theories, design of third generation nanoMaterials, macro, and micro-nano computer modelling. Potential nanoMaterials will be highlighted. Research-development-technology “nanoMaterials” roadmaps: 2010 - 2025 for: Breakthroughs in communication and information; Grand challenges in life science and medical applications; NanoMaterials with tailored functionalities for new generation energy sources; Role of nanoMaterials in transportation: aeronautics and car industry; Potentials for the chemical industry; NanoConsumer products. Roadmaps 2010 – 2020 for nanoscience environment and climate change and safety; Man-Made environment; Climate Change; Nanopotentials in Safety; (Toxicology) and Security. Guidelines for a prosperous modern university - industry and welfare for the society: Initiate “university – science/technology institutes -industry” partnerships; Create International NanoMaterials R&D&T Centres; Promote Nanoindustrialisation: Technology Parks, nanometrology and standardisation. Initiate International Infrastructures for nanoMaterials R&D&T; and Familiarise the Society with the new Culture of NanoMaterials Technology. Countries and Industries investing in NanoMaterials Science and Technology: Model for a global nanoMaterials landscape: NanoMaterials - science, technology and nanoindustrialisation are complex topics and cannot be subject anymore for one institute or industry, or nation. The success rate will depend on joining brilliancies. Models for research and industrial collaboration will be elaborated and mechanisms for execution proposed.

**10:05 AM Break**

**10:20 AM Invited**

**Nanomaterials Control for Biotech Applications:** *Sungho Jin*<sup>1</sup>; <sup>1</sup>UC San Diego

There has been a strong trend in recent years toward convergence of nanotechnology and biotechnology for advanced biomedical applications. For example, biomagnetics is potentially a huge field for science and applications of magnetism and magnetic materials. Magnetic nanoparticles (e.g., superparamagnetic Fe-oxide) are one of the most versatile nanotech/biotech materials actively investigated for targeted cancer treatment, cell sorting and manipulations, guided drug delivery, bio-imaging and medical diagnosis. Nanowires and nanopore arrays are also useful for a variety of biotech applications. These are all very rapidly advancing fields. For practical applications for biomedical devices, proper engineering of these nanomaterials is essential. In addition, some aspects of nanotoxicity need to be understood for safe bio applications. This talk describes materials science aspects of these nano-biomaterials, their control, and implications for safe, therapeutic applications.

**10:50 AM Invited**

**Can Single-Atom Change Affect Electron Transport Properties of Molecular Nanostructures such as C60 Fullerene?:** *Xiaoliang Zhong*<sup>1</sup>; *Ravindra Pandey*<sup>1</sup>; *Alexandre Rocha*<sup>2</sup>; *Shashi Karna*<sup>3</sup>; <sup>1</sup>Michigan Tech; <sup>2</sup>Universidade Federal do ABC; <sup>3</sup>Army Research Lab

At the nanoscale, even a single atom change in the structure can noticeably alter the properties, and therefore, the application space of materials. We examine this critical behavior of nanomaterials using fullerene as a model structure in (i) endohedral (B@C60 and N@C60), in which the doping atom is encapsulated inside the fullerene cage, and (ii) substitutional (BC59 and NC59), in which the doping atom replaces a C atom on the fullerene cage, configurations. The calculated results reveal that the conductivity for the doped fullerene is higher than that of the pristine fullerene. In the low-bias regime, the current-voltage characteristic of the endohedral as well as the substitutional configurations are very similar. However, as the external bias increases beyond 1.0 V, the substitutional BC59 fullerene exhibits a considerably higher magnitude of current than all other species considered, thus suggesting that it can be an ineffective semiconductor in p-type devices.

**11:20 AM Invited**

**Atomic Layer Deposition - A Modern Tool for Nanoscience:** *Mato Knez*<sup>1</sup>; <sup>1</sup>Max-Planck-Institute MSP

Atomic layer deposition (ALD) is a thin film deposition technique which was developed in the 1970s to meet the needs for processing thin film electroluminescent displays (TFEL). Technically and chemically it is similar to chemical vapor deposition (CVD). However, in contrast to CVD, ALD incorporates as a specific feature the separation of the chemical reaction into two half-reactions. Being a non-line-of-sight deposition technique, ALD allows for good coating conformality even with 3D nanostructured substrates or structures with a high aspect ratio. Our mission is to make use of the precision of ALD for fabrication or functionalization of a variety of nanostructures, optical coatings, encapsulation, replication or even infiltration of soft materials with metals. This talk will step through a selection of strategies on how to modify existing nanostructures or even change some physical properties of the structures making use of ALD for coating and infiltration, respectively.

**11:50 AM**

**Advancing The Science of Nanomanufacturing:** *Khershed Cooper*<sup>1</sup>; <sup>1</sup>Naval Research Laboratory

Nanomanufacturing is the fabrication of materials, components and devices with nano-scale features and their integration into viable engineering systems. A key ingredient is the enhancement or creation of new properties and functions by nano-scale physical phenomena. Nanomaterial building blocks, such as, quantum dots, nanotubes, nanowires, nanopillars and nanoparticles can be manipulated by top-down (e.g., atomic layer deposition) and bottom-up (e.g., self-assembly) processes to build novel nanodevice structures and useful nanosystems. The challenges for nanomanufacturing are achieving functionality, quality, repeatability, scalability and affordability. To address some of these challenges, basic research in areas such as nanoDDM (direct digital manufacturing), massively parallel processing, high-throughput (e.g., roll-to-roll) processing and system-level integration is needed. These concepts will be described in this paper and illustrated with research examples.

**12:20 PM Concluding Comments**

**8:30 AM**

**A Breakthrough Application of Electricity at High Temperature for Steel Production: Molten Oxide Electrolysis:** *Antoine Allanore*<sup>1</sup>; *Luis Ortiz*<sup>1</sup>; *Donald Sadoway*<sup>1</sup>; <sup>1</sup>MIT

In the search for more energy efficient processes together with a mitigation of GHG emissions, the use of a high-temperature electrolytic process to produce iron from its molten oxide is of interest as an alternative to traditional iron making. The intensive use of electricity for a steelmaking process is not new, but its application in electrochemical reactors can lead to a drastic reduction of its emission of pollutants together with the production of a new product: pure liquid iron. A description of the thermodynamics of the iron

oxide conversion to metal will be presented. This approach shows that at high temperature, electricity is a suitable energy vector for both the heat and work required for the reaction. The key physico-chemical parameters that govern the corresponding energy balance of the electrolysis process will then be discussed, to depict the process design conditions for best energetic efficiency.

**8:50 AM**

**Intrinsic Hydrogen Reduction Kinetics of Magnetite Concentrate Particles Relevant to a Novel Green Ironmaking Technology:** Haitao Wang<sup>1</sup>; Moo Eob Choi<sup>1</sup>; Hong Yong Sohn<sup>1</sup>; <sup>1</sup>University of Utah

A novel ironmaking technology is under development at the University of Utah. This technology produces iron directly from iron ore concentrate by gas-solid suspension reduction. Hydrogen is the main reducing agent for high reactivity and for the elimination of carbon dioxide release in this ironmaking process. The direct use of concentrates allowing bypassing the problematic pelletization/sintering and cokemaking steps in the steel industry. Intrinsic kinetics of the suspension reduction of magnetite concentrate particles by hydrogen have been measured. Experiments were carried out in the temperature range of 1423 - 1673 K, other experimental variable being hydrogen partial pressure, the amount of excess hydrogen and particle size. Under most experimental conditions, 95% reduction was attained within several seconds, which presents sufficiently rapid kinetics for a suspension reduction process. The reaction kinetics followed the nucleation-and-growth equation, and a rate equation that contains all the effects of the experimental parameters has been obtained.

**9:10 AM**

**A Laboratory Investigation of the Reduction of the Iron Carbonate Bearing Ore to Iron Nugget by Means of the ITmk3 Technology:** Nikolay Panishev<sup>1</sup>; Rafkat Tahautdinov<sup>1</sup>; Anton Posazhennikov<sup>1</sup>; Vasily Bastrygin<sup>1</sup>; <sup>1</sup>Magnitogorsk Iron & Steel Works

The Bakal (South Ural, Russia) deposit of iron ore bearing iron carbonate with the capacity of more than 1 billion tones belongs to the MMK. This ore cannot be fully processed via blast furnace technology because of high content of MgO. According to the investigations carried out in the USA and Japan in 1999-2004 the ITmk3 RHF technology is a breakthrough in ironmaking technology. Four iron ore types (hematite, magnetite, high and low Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>) were tested. The main objective of the investigation is to establish optimum operation conditions for the production of iron nuggets from iron carbonate bearing ore via the ITmk3 by means of the lab scale testing. Green pellets were processed via a lab tube furnace to simulate RHF conditions. This preliminary test work provides valuable information which may be used for large-scale testing in a commercially sized RHF.

**9:30 AM**

**Prospects of Making Directed Reduction Iron by Microwave Heating:** Linqing Dai<sup>1</sup>; <sup>1</sup>Kunming University of Science and Technology

Based on selectively summarized the characteristics of microwave heating and the research advances on making directed reduction iron by microwave heating. It was pointed out that microwave heating on making directed reduction iron has a good future by analyzing the development direction of directed reduction iron technology

**9:50 AM**

**Behavior of Coal-Based Direct Reduction Reaction of Iron Oxide Pellets by Microwave Heating:** Zhu-cheng Huang<sup>1</sup>; Hua Wang<sup>1</sup>; Bing Hu<sup>1</sup>; Hu Peng<sup>2</sup>; Guang-bin Xia<sup>2</sup>; <sup>1</sup>Central South University; <sup>2</sup>Changsha SYNO-THERM Co., Ltd

The temperature rising characteristics and reaction of the reduction of iron oxide pellets with anthracite fines were studied using a MW-L0316V microwave oven and Leica-DM-RXP polarizing microscope. The results show that iron oxide pellets and anthracite fines have good microwave absorbing properties, and high temperature and reducing atmosphere in a relatively short time for reduction of iron oxide pellets can be achieved. The reduction reaction, which follows the unreacted core model, is rapid and the metallization increases from 13.41% to 56.57% as the reduction end

point temperature increases from 850° to 950°. The iron is formed, fine grain crystals of iron are transferred and the contraction of metal phase occurs firstly at the surface of pellets, which hinders the reduction reaction at the center of pellets. The rate of reduction reaction increases slowly as the reduction end point temperature increases from 950° to 1050°.

**10:10 AM**

**Sustainable Developments in High Temperature Mineral and Metals Extraction and Processing:** Florian Kongoli<sup>1</sup>; Edward O'Brien<sup>1</sup>; S. Llubani<sup>1</sup>; Ian McBow<sup>1</sup>; <sup>1</sup>FLOGEN Technologies Inc

Sustainability has become a more frequent prerequisite for any project in any field of life. Any major development project has started to include sustainability as a criteria in evaluating its objectives and outcome. However for heavy multibillion dollar industries such as high temperature mineral processing and metals extraction, sustainability is a major criteria since the impact this industry has in the world and its sustainable future is much more pronounced than in many other fields. Environment, energy, residues, efficiency, etc are all important factors related to sustainability of high temperature mineral and metals extraction and processes. Improving or updating these characteristics make these industries more sustainable. However high temperature minerals and metal extraction and processing industries face the competition of low temperature minerals extraction and processing such as hydrometallurgical, electrochemical routes. Low temperature processes sometimes look more popular than high temperature ones. The real question is: Which one of these 2 different routes is more sustainable for the future? Are low temperature processes capable of replacing high temperature ones and if yes are they more sustainable? This paper will give an overview of aspects of sustainability of various high and low temperature mineral and metal processing routes in terms of environmental protection and residues, productivity, energy etc. and will offer a glimpse of the future that waits us.

**10:30 AM**

**Carbothermal Reduction of Titanium Concentrate at High Temperature:** Rin Huang<sup>1</sup>; Chenguang Bai<sup>1</sup>; Xuewei Lv<sup>1</sup>; Guibao Qiu<sup>1</sup>; Lei Lei<sup>1</sup>; <sup>1</sup>College of Materials Science and Engineering, Chongqing University

The TiO<sub>2</sub>-rich slag and pig iron can be produced from ilmenite concentrate by the electric furnace process. In this study, ilmenite concentrate was reduced in a vertical furnace equipped with a weighting data acquisition system. The effects of reducing agent (carbon) amount on the iron reduction were studied. The phase transformation, morphology and chemical compositions of reduced samples were investigated by X-ray diffractometry (XRD), scanning electron microscopy (SEM) and energy dispersive spectroscopy (EDS), respectively. It was found that the reductive degree of ilmenite concentrate increased with the increase of reducing time. The phases of reduced samples were mostly iron, rutile, Ti<sub>3</sub>O<sub>5</sub> and Fe<sub>2</sub>TiO<sub>5</sub>. The mass loss percentage increased with increasing the carbon amount from 8% to 12%. When the carbon amount exceeded 12%, the mass loss percentage decreased with the increasing of carbon amount.

**10:50 AM**

**A Simulation Study on Flue Gas Circulating Sintering (FGCS) for Iron Ores:** Tao Jiang<sup>1</sup>; Zhenyu Fan<sup>1</sup>; Yuanbo Zhang<sup>1</sup>; Bin Xu<sup>1</sup>; Guanghui Li<sup>1</sup>; Xiaohui Fan<sup>1</sup>; <sup>1</sup>Central South University

Iron ore sintering process is the main source of SO<sub>2</sub> generated in the steel industry, of which the discharge amount of SO<sub>2</sub> emission accounts for about 60% of the total. Aiming at the features of sintering flue gases and existing problems during the flue gas desulphurization, a technical route of flue gas circulation sintering (FGCS) for iron ores has been put forward. Under the simulated experimental conditions, effects of FGCS process on the main output and quality indexes and SO<sub>2</sub> emission rule are researched using simulating flue gases. Compared the novel FGCS with conventional sintering process, SO<sub>2</sub> in the final sintering flue gas is obviously enriched and the total exhaust gases can be reduced evidently. The decreasing of oxygen content in circulating gases has bad effect on the sintering indexes. Increasing the oxygen potential is beneficial to obtain high quality sinters. This investigation shows that the FGCS process is promising.

11:10 AM

**Energy And Exergy Analysis of Different Technologies of Copper, Zinc and Lead Production – Entropy Generation and Thermoecological Cost:** *Bozena Boryczko*<sup>1</sup>; Adam Holda<sup>1</sup>; Zygmunt Kolenda<sup>1</sup>; <sup>1</sup>AGH University of Science and Technology

Copper, zinc and lead can be produced with different technologies. Most popular copper technologies are shaft furnace and flash smelting. Zinc and lead are produced by shaft furnace or by hydrometallurgical method. Main problem of all metallurgical technologies is the consumption of exergy connected with inevitable depletion of nonrenewable natural resources. One of the most important (from thermodynamic point of view) measure of their depletion is Cumulative Exergy Consumption as the basis of calculation of thermoecological cost (defined as the cumulative exergy consumption of non-renewable natural resources). Difference in exergy consumption is the result of different kinds of driving energy. In shaft furnace technologies, driving energy is the chemical exergy of coke and for flash smelting or hydrometallurgical processes, electric energy plays principal rule. Because of those different exergy sources, the CexC values can differ significantly. The concept of thermoecological cost allows to choose technology with the lowest value of CexC.

11:30 AM

**Optimizations of Preparation for U3O8 by Calcination from Ammonium Durante Using Response Surface Methodology:** *Bingguo Liu*<sup>1</sup>; Jinhui Peng<sup>1</sup>; Daifu Huang<sup>1</sup>; <sup>1</sup>Kunming University of Science and Technology

The conditions of technique to prepare U3O8 by calcinations from ammonium diuranate were optimized, and the response surface design was applied to analyze the influence on the total uranium and of calcination temperature, calcination time mass of sample. A quadratic equation model for the total uranium and of U3O8 was built and effects of main factors and their corresponding relationships were obtained. The analysis of variance shows that calcination temperature and calcination time significantly affected the value of total uranium and of U3O8. The optimal calcination conditions were as follows: calcination temperature 931.83 K, calcination time 24.32min and 43.89 g. Under these conditions the value of total uranium and of U3O8 was 84.78% and 28.02%, respectively. The validity of the model was confirmed experimentally and the results were satisfactory.

11:50 AM

**Microwave Field Attenuation Length and Half-power Depth in Magnetic Materials:** *Zhiwei Peng*<sup>1</sup>; Jiann-Yang Hwang<sup>1</sup>; Xiaodi Huang<sup>1</sup>; Matthew Andriese<sup>1</sup>; Wayne Bell<sup>1</sup>; <sup>1</sup>Michigan Technological University

The equations for determining microwave field attenuation length and half-power depth in magnetic materials were derived from Maxwell's equations. The microwave field attenuation length and the half-power depth for a magnetite concentrate were calculated and the temperature dependence of them was determined. It is demonstrated the microwave field attenuation length and the half-power depth highly depend on temperature and decrease with increasing temperature up to 900 °C. The variations of field attenuation length and the half-power depth with temperature indicate the microwave power attenuates much faster than the field strength in materials. The evaluations of field attenuation length and microwave half-power depth can be used to characterize the microwave dissipation behaviors in the sample and optimize the dimensions of the material in microwave heating.

12:10 PM

**Vanukov Furnace Technology: Application Experience for Processing Different Types of Raw Materials and General Development Trends:** *Valentin Bystrov*<sup>1</sup>; Valery Paretsky<sup>2</sup>; Anton Vernigora<sup>1</sup>; Rostislav Kamkin<sup>1</sup>; *Alexander Mamaev*<sup>1</sup>; Alexander Kuznetsov<sup>1</sup>; <sup>1</sup>National University of Science and Technology (MISIS); <sup>2</sup>State Research Center of Russian Federation "Gintsvetmet" Institute

Vanukov Furnace Technology is an efficient, proven pyrometallurgical injection technology, extensively used in Russia and Kazakhstan for a number of different applications. Technology was most widely adopted for processing copper sulfide concentrates for matte in smelters of Norilsk, Revda (Russia) and Balkhash (Kazakhstan). Also the following applications

were developed and tested in industrial scale: treatment of sulfide lead and lead-zinc concentrates, laterite nickel ore, production of cast iron, treatment of antimony gold-containing ores and municipal solid waste. In this paper, current experience of Vanukov Furnace application to these technologies is described with a number of general development trends and new ways of applications.

## Advances in Science-Based Processing of Superalloys for Cost and Sustainment: Processing Advancements via Modeling and Simulation

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS Structural Materials Division, TMS/ASM: Computational Materials Science and Engineering Committee, TMS: High Temperature Alloys Committee, TMS: Advanced Characterization, Testing, and Simulation Committee

*Program Organizers:* Donna Ballard, US Air Force; David Furrer, Pratt & Whitney; Paul Jablonski, US Department of Energy; Christopher Woodward, Air Force Research Laboratory; Jeff Simmons, AFRL; Mark Blodgett, Wright-Patterson AFB

Monday AM

February 28, 2011

Room: 33B

Location: San Diego Conv. Ctr

*Session Chairs:* Paul Jablonski, US Department of Energy; Lee Semiatin, US Air Force Research Laboratory

## 8:30 AM Introductory Comments

### 8:35 AM Keynote

**Nickel-Based Superalloys: Construction, Use and Validation of Numerical Models:** *Roger Reed*<sup>1</sup>; <sup>1</sup>University of Birmingham

In recent years, the use of numerical modelling in the field of high temperature materials – particularly for the superalloys – has increased markedly. There are now very tangible advantages to be gained from modelling work, e.g. for (i) the invention of new grades of alloy, (ii) the analysis and optimisation of manufacturing processes (casting, welding, heat treatment etc) and (iii) the design of high-integrity components such as turbine blades and discs. In this presentation, examples of successful modelling work in each of these areas will be given. The advantages, limitations and future expectations are given. The overarching observation is that the field has grown from one of mere academic curiosity to one which is of great importance to the viability of businesses operating in the high temperature world.

### 9:15 AM Invited

**Air Force Research Laboratory R&D in Science-Based Superalloy Processing:** *Lee Semiatin*<sup>1</sup>; Donna Ballard<sup>1</sup>; David Mahaffey<sup>1</sup>; Jonathan Miller<sup>1</sup>; Jaimie Tiley<sup>1</sup>; Todd Turner<sup>1</sup>; Donald Weaver<sup>1</sup>; Adam Pilchak<sup>2</sup>; JP Thomas<sup>3</sup>; Kyle McClary<sup>4</sup>; Peter Lee<sup>5</sup>; <sup>1</sup>US Air Force Research Laboratory; <sup>2</sup>UTC, Inc; <sup>3</sup>ATI Allvac; <sup>4</sup>Wright State University; <sup>5</sup>Imperial College London

Basic research at AFRL to develop science-based understanding and predictive models for microstructure evolution during the thermomechanical and solidification processing of superalloys will be summarized. For cast-and-wrought superalloys, the physics of homogenization heat treatment and recrystallization during hot working have been established. These observations have been interpreted using 2D diffusion analysis, crystal-plasticity FEM to quantify deformation nonuniformity, and a mesoscale modeling technique that treats the effects of dislocation generation/annihilation and boundary migration on the kinetics of recrystallization. With respect to powder-metallurgy superalloys, the evolution of grain structure during TMP will be described. Specifically, the effect of hot working/heat treatment conditions and second phases on the final grain size and the status of associated models will be presented. Last, the effect of solidification conditions on the propensity for lateral dendrite growth during directional solidification will be described. Phenomenological (processing-map) and

mesoscale (cellular-automaton) models to describe such phenomena will be briefly reviewed.

**9:45 AM**

**Recrystallization and Grain Growth of a Hot Pack Rolled Nickel-Base Superalloy:** *Adam Pilchak*<sup>1</sup>; *S. Semiatin*<sup>1</sup>; *Donna Ballard*<sup>1</sup>; *Donald Weaver*<sup>1</sup>; <sup>1</sup>Air Force Research Laboratory

Microstructure and texture evolution of a hot pack rolled and annealed Ni-Al-Cr-base superalloy were investigated with electron backscatter diffraction. In the as-rolled condition, the microstructure consisted of elongated, unrecrystallized grains that were in orientations consistent with typical rolling deformation texture components. Subsequent heat treatment recrystallized the microstructure which resulted in an overall decrease in the intensity of the various deformation texture components, but not the development of new orientations. Grain growth kinetics during subsolvus heat treatment were quantified and analyzed on the basis of existing models for grain growth in the presence of second phase pinning particles and texture controlled grain growth. Grain growth behavior during supersolvus heat treatment was also investigated. The results were compared to simulations performed using 3D Monte-Carlo methods incorporating misorientation dependent grain boundary energy and mobility.

**10:05 AM Break**

**10:20 AM**

**HIP of Ni-Base PM Superalloys- Back to the Future:** *Charles Barre*<sup>1</sup>; *Viktor Samarov*<sup>1</sup>; *Dmitry Seliverstov*<sup>1</sup>; <sup>1</sup>Synertech PM Inc.

HIP of complex shape parts from PM superalloys is coming back for critical applications. This comeback is based on a suit of the advanced technologies related to this consolidation process. These technologies include: - Advanced computer process modeling that enables to provide very complex shapes and a significant reduction of development and manufacturing cost. - Enhancement of mechanical properties due to the control of the powder size and inclusions during manufacturing of powder and filling of the HIP capsules - Shape control during HIP due to the adequate design of the HIP tooling and filling procedures - Control of the quality for the net shape surfaces and their enhancement for the environmental compatibility - New technologies of non-destructive testing for the complex shape components. The paper analyses the developed technological tools and numerous applications.

**10:40 AM Invited**

**Microstructural Level Modelling of Freckle Initiation during Directional Solidification:** *Peter D. Lee*<sup>1</sup>; *Lang Yuan*<sup>1</sup>; <sup>1</sup>Imperial College London

Freckles are severe channel-like segregations commonly observed in directionally solidified and single-crystal Ni-base superalloy turbine blade castings, causing part rejection. Freckles arise from the segregation of solute from the solidifying dendrites, altering the density of the interdendritic liquid, causing a Rayleigh instability initiated flow. To predict the on-set of flow the interaction of thermal gradients, microstructure, and permeability all need to be modelled. However, prior work has focused on macrosegregation, with the onset of flow initiated due to numeric noise. In this study, a microstructural model is coupled with a flow solver to provide direct simulation of freckle simulation. The predictions are compared to the extensive prior experimental results in the model binary alloy system, Pb-Sn. Solute channel formation was predicted under different solidification conditions (based on temperature gradient and cooling rate). Using the Rayleigh number, a good correlation between the numerical simulations and experimental was found.

**11:10 AM Invited**

**Heat Extraction and Structure Evolution in LMC Single-Crystal Growth:** *Jonathan Miller*<sup>1</sup>; *Lang Yuan*<sup>2</sup>; *Michael Eisman*<sup>3</sup>; *Peter Lee*<sup>2</sup>; *Tresa Pollock*<sup>4</sup>; <sup>1</sup>AFRL/RXLM; <sup>2</sup>Imperial College; <sup>3</sup>Wright State University; <sup>4</sup>University of California, Santa Barbara

The liquid-metal-cooling (LMC) process for growth of single-crystal superalloys provides enhanced heat extraction, higher cooling rates and refinement of dendritic structure. However, some processing conditions cause substantial lateral heat extraction that promotes lateral growth of

dendrites – the formation of long secondary dendrite arms overgrowing favorably aligned primary dendrites. The conditions under which lateral growth occurs during solidification of alloys CMSX-486 and René N4 have been studied experimentally and with solidification modeling at the macro- and meso-scales. Solidification experiments have been conducted in a LMC furnace that utilizes liquid tin as the cooling medium and a floating ceramic baffle. A mold geometry was designed to evaluate a range of thermal conditions and assess the tendency for lateral growth. Correlations between dendritic structure, solidification-front curvature, solidification rate and thermal gradient will be presented. The presence of lateral growth is strongly dependent on the solidification-front curvature at the casting surface.

**11:40 AM**

**Residual Strain Measurements in a Single-Crystal Nickel-Based Superalloys Turbine Blade using Neutron Diffraction:** *Stephane Pierret*<sup>1</sup>; *Alexander Evans*<sup>1</sup>; *Ania Paradowska*<sup>2</sup>; *Thomas Etter*<sup>3</sup>; *Helena Van Swygenhoven*<sup>1</sup>; <sup>1</sup>Paul Scherrer Institute; <sup>2</sup>ISIS; <sup>3</sup>Alstom

Rafting in nickel-based superalloys describes the directional coarsening of the gamma prime precipitates when subjecting the alloy to high temperature creep deformation. But rafting has also been observed at very localised areas in a non-crept fully heat-treated single-crystal (SX) Ni-based superalloy turbine blade. The influence of macro residual stresses and the associated inhomogeneous plastic strain fields on the rafting of the precipitates has been investigated using neutron diffraction in a 2nd generation SX Ni-based superalloy turbine blade following cooling from the solution heat treatment. A novel approach was used to localise the measurements in the partially hollow blade, by combining a 3D digitisation with a 3D reconstructed image obtained by neutron tomography. Complementary hard energy synchrotron diffraction followed on a cross-section of the blade at the position where the maximum residual strains were determined with neutrons. This revealed the variation of the diffraction peak width and the lattice parameter misfit.

**12:00 PM**

**Numerical Simulation of Directional Solidification of Turbine Blade by LMC Process:** *Ning Tang*<sup>1</sup>; *Qingyan Xu*<sup>1</sup>; *Baicheng Liu*<sup>1</sup>; <sup>1</sup>Tsinghua University

Directionally solidified blade castings are widely used in turbines, because the directional solidified microstructure leads to outstanding high temperature properties. A very strict process control is needed to avoid stray grains. In recent years, liquid metal cooling (LMC) is used as a new process in manufacturing of the blade casting, and it still needs to be improved. Numerical simulation of the LMC process is helpful to optimize the technical parameters and reduce the development cycle and cost. In this paper, a model of a LMC process considering the convection between the shell and the cooling metal was established, which was validated by the experimental results. Different processes of LMC solidification were simulated. The results indicated that higher withdrawal rate or lower cooling liquid metal temperature can obtain higher temperature gradient and lead to thinner mushy zone. However, if the withdrawal rate is too high, the mushy zone becomes more concave.

## Aluminum Alloys: Fabrication, Characterization and Applications: Development and Application

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Processing Committee  
Program Organizers: Subodh Das, Phinix LLC; Zhengdong Long, Kaiser Aluminum; Tongguang Zhai, University of Kentucky

Monday AM Room: 14A  
February 28, 2011 Location: San Diego Conv. Ctr

Session Chair: Zhengdong Long, Kaiser Aluminum

### 8:30 AM

#### Scandium/Zirconium Modified Aluminum Alloys for Improved Mechanical Properties: *Jennifer Gaines*<sup>1</sup>; <sup>1</sup>NSWC Carderock Division

Due to the need for high speed lightweight ships there is an increased use of aluminum alloys in ship construction. These applications require materials with the following combination of properties: high welded strength, ductility and elongation, corrosion resistance, and fatigue and corrosion fatigue resistance. The most commonly used aluminum alloy families in marine applications are the Al-Mg (5XXX series) alloys which derive their strength from work hardening and are not heat-treatable. Reduced as-welded strengths limit their practical structural applications. The high temperatures introduced during the welding process reverse some of the effects of the strengthening mechanisms so aluminum alloys which can retain the greatest amount of post-welded strength are, therefore, greatly desired. Small additions of Sc and Zr have been shown to improve mechanical and corrosion properties of aluminum alloys and their effect as additions to commercial 5XXX alloys are investigated.

### 8:50 AM

#### Continuous Cast Superplastic Grade Aluminum Sheet: *Ravi Verma*<sup>1</sup>; <sup>1</sup>General Motors

Thermo-mechanical processing of a twin-belt continuous cast (CC) Al 5083 slab is investigated with the objective of developing superplastic (SP) grade aluminum sheet. The effect of small variations in the Mn content of the alloy on its SP formability is also investigated. The optimized process is capable of breaking down the as-cast structure of the CC slab to a fine equiaxed microstructure (grain size 7  $\mu\text{m}$ ) suitable for superplastic forming. Compared to the conventional Direct-Chill (DC) process, which uses massive rolling to achieve the necessary grain refinement, the developed process achieves similar level of grain refinement in much less rolling reduction. The SP grade sheet produced with the developed process exhibit tensile ductility of 302% at 500°C and  $10^{-3} \text{ s}^{-1}$  strain rate, which is impressive for this initial material. This work demonstrates the technical feasibility of producing high quality SP grade aluminum sheet based on low-cost, twin-belt continuous cast technology.

### 9:10 AM

#### Study of Aluminum Sensitization at Moderately Elevated Temperatures: *William Golumbskie*<sup>1</sup>; Catherine Wong<sup>2</sup>; <sup>1</sup>Naval Surface Warfare Center, Carderock Division; <sup>2</sup>NAVSEA

Structural aluminum alloys are seeing increased use in marine applications, with the shipbuilding industry looking to reduce weight. The 5xxx series is an ideal candidate, combining high specific strength, corrosion resistance, and weldability. A particular concern is sensitization. Aluminum becomes sensitized when beta phase (Al<sub>3</sub>Mg<sub>2</sub>) is precipitated at grain boundaries, which may lead to stress corrosion cracking. Sensitization is believed to occur when aluminum is exposed to temperatures greater than 50°C. This study will investigate the effects of exposure at lower temperatures (>30°C) on sensitization. Such "moderately" elevated temperatures are of great importance as ship decking and superstructures experience such temperatures while in service. The ASTM G67 mass loss test is being used to quantify the extent of sensitization. The new data will aid in determining the degree

of sensitization for in-service 5xxx alloys and estimate the lifetime until the material has fully sensitized.

### 9:30 AM

#### Forming Limit Diagrams for AA5182 after Preform Annealing: *Jingjing Li*<sup>1</sup>; *John Carsley*<sup>2</sup>; Theresa Lee<sup>2</sup>; S. Jack Hu<sup>1</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>General Motors

Preform Annealing is a process of forming aluminum sheet panels in which a blank is partially stamped, heat treated and then stamped to the final desired shape. Because strain from the first deformation event is recovered by annealing, the process significantly improves product formability. The effects of prestraining along different strain paths and subsequent annealing on the ultimate forming limits of aluminum alloy 5182-O were investigated by determining forming limit diagrams (FLDs) using digital image correlation (DIC) and circle grid analysis (CGA). Aluminum panels were prestrained in uniaxial, equibiaxial and plane strain tension at 15 and 20% equivalent strains, perpendicular to the rolling direction; and annealed at 350°C for short (10 seconds) and long (20 minutes) durations. Calculations of total effective forming limit curves (FLC) were compared to experimental CGA and DIC results. The improvement in FLCs shows the advantage of annealing that can extend the formability of strained materials.

### 9:50 AM

#### A Positron Annihilation Study of Hot Band of a Continuous Cast AA 2037 Al Alloy after Annealing: *Yichu Wu*<sup>1</sup>; *Tongguang Zhai*<sup>2</sup>; <sup>1</sup>University of Wuhan; <sup>2</sup>University of Kentucky

Continuous cast AA 2037 Al alloy hotband was annealed at temperatures ranging from 25 to 500°C for 3h. Vacancy-solute interactions and precipitates in the samples during annealing were investigated using positron annihilation techniques (coincidence Doppler broadening (CDB) and lifetime, respectively) and TEM. It was found that there were vacancy-Cu and vacancy-Cu-Mg complexes at room temperature. Positron mean lifetime peaked at 200°C because of the formation of semicoherent precipitates. The measured CDB ratio curve, characteristic to Mn in shape, indicated the formation of vacancy-Mg-Mn complexes or Mn clusters in these precipitates. Above 250°C, coarsening and dissolution of semicoherent precipitates resulted in decrease in mean lifetime and disappearance of Mn signal, but Cu signal increased clearly with annealing temperature. Over 350°C, Cu signal started to saturate, indicating that Cu dissolved might agglomerate and cluster with vacancies, while new increase in mean lifetime might be attributed to the formation of incoherent phase.

### 10:10 AM Break

### 10:25 AM

#### Aluminium-Titanium Alloys for Thermal Spraying: *Christopher Wheatley*<sup>1</sup>; <sup>1</sup>CJ Wiretech Limited

Arc-spraying using pure aluminium wire (TSA) has been accepted for many years in the oil industry for barrier protection of steel structures in aggressive marine environments. Aluminium-titanium alloys provide an even better physical barrier which exhibits extremely good resistance to erosion and this is achieved with no detrimental affect on corrosion properties. The combination of wear resistance and the macroscopic surface roughness from thermal spraying provides a surface of extremely low slip potential which can remain 'non-slip' for over 20 years at 1000 footfalls per day. Data of slip testing for pedestrians and vehicles is presented and this is supported by case studies in real life situations. Data from corrosion testing in laboratory conditions demonstrates that in some cases the aluminium-titanium alloys sprayed onto steel structures can give improved protection against corrosion in very severe conditions.

### 10:45 AM

#### Hot Tensile Behaviour and Constitutive Analysis of Al-5.5Zn-1.2Mg/Zr Alloys: *Paola Leo*<sup>1</sup>; Emanuela Cerri<sup>1</sup>; Hugh McQueen<sup>2</sup>; <sup>1</sup>Università del Salento; <sup>2</sup>Concordia University

In this study hot tensile behaviour of Al-5.5Zn-1.2Mg and Al-5.5Zn-1.2Mg-0.16Zr alloys deformed in the as-cast state has been analyzed. Tensile tests have been performed in the range 250°C-350°C and 10<sup>-5</sup>s<sup>-1</sup> to 10<sup>-3</sup>s<sup>-1</sup>

1. At the lowest test temperature the stress-strain curves shows a gradual softening after a stress maximum or peak while at the other temperatures a plateau is attained which is lower as temperature T rises and strain rates decrease. For each fixed temperature T, the ductility is almost independent of strain rate for Al-5.5Zn-1.2Mg whereas, for the Zr modified alloy, it decrease slightly with  $\epsilon$ . The constitutive analysis by the sinh equation give  $Q_{HW}=218\text{kJ/mol}$  and  $Q_{HW}=271\text{kJ/mol}$  for unmodified and Zr modified alloys respectively. These values of activation energy are quite high and similar to that of other 7000 alloy containing Cu. The microstructure of all tensioned samples is characterized by cavitation phenomena.

11:05 AM

**Production of Continuous Cast 3105 Coil-Stock for Thin Gauge Roller Shutters:** *Dionisios Spathis*<sup>1</sup>; John Tsiros<sup>1</sup>; <sup>1</sup>Hellenic Aluminium industry (ELVAL SA)

An optimum industrial process was established through trials of continuous cast 3105 alloy for roller shutters. Several thermomechanical processes were investigated regarding final gauge mechanical properties, bendability and surface quality. Softening curves were determined through laboratory annealing trials at intermediate and final gauge in order to choose the proper coil anneal temperature regime.

11:25 AM

**Microstructure Evolution of the Modified AA 5083 Alloy: From the As-Cast State to the Final Product:** *Endre Romhanji*<sup>1</sup>; Miljana Popovic<sup>1</sup>; Tamara Radetic<sup>1</sup>; <sup>1</sup>University of Belgrade

In this work, we characterized the microstructure evolution of industrially processed, commercial AA 5083 with a small Zr addition throughout complete processing route: from the as-cast state to the final hot rolled product. We investigated the effect of multiple stage thermal soaking of the cast alloy and homogenization of the industrially hot-rolled alloy on recrystallization and recovery during the final hot rolling. Microstructural changes during the thermo-mechanical treatments were followed by electrical resistivity measurements, optical and TEM. Two populations of the Mn-based secondary phases were identified in as-cast state. Coarse, eutectic particles containing Fe precipitated at grain boundaries, while finer Mn particles alloyed with Cr formed within grains. Although further processing affected the particle morphology and distribution, both types of precipitates remained distinct and had significant, but different effect on recrystallization process. This work is supported by Ministry of Science and Technological Development, Republic of Serbia under contract number E!4569.

### 8:35 AM Keynote

**Simulation of Particle Effects on Recrystallization in Commercial Al Alloys:** *Günter Gottstein*<sup>1</sup>; Volker Mohles<sup>1</sup>; Carmen Schaefer<sup>1</sup>; <sup>1</sup>RWTH Aachen University

Depending on particle size and precipitation kinetics, second phase particles can affect recrystallization in various ways. Large particles which exist prior to recrystallization can cause particle stimulated nucleation which makes itself felt by an acceleration of recrystallization and a change of the recrystallization texture. A complex case arises when recrystallization and precipitation occur concurrently. This will have a significant influence on

the recrystallization kinetics as well as grain size and texture. By means of finite element modeling and recrystallization simulation with the adaptive cellular automata code CORE the various cases were studied. The results will be discussed with respect the predictive power of recrystallization modeling in such cases.

9:05 AM

**Texture Evolution during Symmetric and Asymmetric Rolling of Al-Si-Mg Alloys Fabricated by Twin Roll Casting:** *Jaehyung Cho*<sup>1</sup>; Hyung Wook Kim<sup>1</sup>; <sup>1</sup>Korea Institute of Materials Science

6K21 aluminum alloys (1%Si-0.6Mg) fabricated by twin roll casting were cold-rolled using differential speed rolls. Effect of speed ratio and reduction in area on texture evolution was examined using XRD. Overall reduction in area was 75%. Loads measured in the rolls were decreased with speed ratio. As-casted alloys had texture gradient from the surface to the center. {111}//ND textures were found in the surface and weak rolling textures were located in the center. The initial textures changed into rotated cube, {100}<011> and rolling textures, a (Goss-Brass) and b (Brass-S-Copper). Shear texture, rotated cube, was found in both symmetric and asymmetric rolling processes. Various rolling parameters were investigated to generate shear texture. Roll speed ratios greater than 1.4 produced shear texture throughout the whole thickness direction.

9:30 AM

**An Investigation of Deformation Behavior of Bimetal Clad Sheets by Asymmetrical Rolling at Room Temperature:** *Li Xiaobing*<sup>1</sup>; Zu Guoyin<sup>1</sup>; Deng Qiang<sup>2</sup>; <sup>1</sup>School of Materials and Metallurgy, Northeastern University; <sup>2</sup>Cold rolling company, Pangang group company LTD.

The different thickness metals mild steel, aluminum and copper were bonded with each other by means of asymmetrical rolling at room temperature. The deformation behaviors, bonding conditions and interfacial layer thickness of the clad sheets were discussed. According to the slab stress in the plastic deformation region at the roll gap, the relations of bonding condition and metal flow were analyzed. The influence of cross shear on the bonding due to the roll speed mismatch is obvious. The large speed mismatch makes a good bonding and drops the critical reduction. The improvement of bonding is achieved with the increase of the total rolling reduction. The reduction of both layers increases in direct proportion with the total reduction, and the difference between hard and soft metals gradually diminishes. The large initial thickness ratio of hard and soft metal is unhelpful for the bonding due to the inconsistent deformation of bimetal.

10:15 AM

**Parameter Study within the Through-Process-Modeling Chain of AA8xxx-Alloys and Its Validation:** *Thiemo Brüggemann*<sup>1</sup>; Volker Mohles<sup>1</sup>; Carmen Schäfer<sup>1</sup>; Günter Gottstein<sup>1</sup>; Kai Karhausen<sup>2</sup>; <sup>1</sup>Institute; <sup>2</sup>Hydro Aluminium Deutschland GmbH

Optimization of alloys and whole process chains for aluminum sheets and foils is a major goal of the aluminum industry. Since experimental methods are cost- and time-intensive, simulation tools are to be used to predict effects of material and process parameter changes on the product. Within this work the behavior of a through-process-modeling-chain is tested for its reaction on various parameter changes within the group of 8xxx-Aluminum alloys. The modeling chain consists of a thermally coupled roll gap model with subsequent simulation of rolling- and recrystallization-texture by grain-interaction and cellular automata models, respectively. Parameter studies will include microchemistry changes such as solute contents and particle sizes and radii. Data from industrial trials and experiments will be used for validation.

10:40 AM

**Coil Build up Compensation during Cold Rolling to Improve Off-Line Flatness:** *Lourival Almeida Neto*<sup>1</sup>; Tuggan Ayhan<sup>2</sup>; <sup>1</sup>Achenbach Buschhütten GmbH; <sup>2</sup>Assan Alüminyum

During rolling, overlaps of material with a convex profile at recoiler cause greater tension in strip center fibers than in fibers of the edges, which is

known as coil build up. The high tension on central area is understood by the automation system as zones tighter than reference commanding its actuators to put back such zones on target, loosening the correspondent strip fibers. The difficulty is that the buckles created by the flatness controller are not seen at operator's screen. A coil build up compensation based on material profile was developed in order to have the cause of center buckles after unwinding reduced to the coiling process. From 24 coils with thickness ranging between 0.7 and 2.0mm, 100% presented better offline flatness. Flatness carpets related to profile suggested a paradigm breaking: perhaps we have to accept rolling with not so good flatness in order to have the desired offline flatness.

#### 11:05 AM

**Through Process Effects on Final Al-Sheet Flatness:** *Stefan Neumann*<sup>1</sup>; Kai Karhausen<sup>1</sup>; <sup>1</sup>Hydro Aluminium Dts. GmbH

In the process of rolled products to achieve a defined flatness of the strip in ever decreasing tolerances becomes more and more a key challenge. The typical process chain of strip material consists of hot rolling, cold rolling, annealing as well as coil winding and unwinding at various stages. Some Aluminium alloys exhibit the strong tendency to reduce internal stresses by creep and relaxation. This transformation of elastic into plastic strains frequently leads to considerable changes of shape and flatness of the product over the different steps of the process chain. This contribution introduces a model based through process analysis with emphasis to the evolution of strip flatness via the most decisive production stages. Case studies from aluminium strip production will be used to illustrate the impact of different process parameters.

#### 11:30 AM Concluding Comments

### Approaches for Investigating Phase Transformations at the Atomic Scale: Transformation Kinetics and Mechanisms

*Sponsored by:* The Minerals, Metals and Materials Society, ASM International, TMS Materials Processing and Manufacturing Division, TMS/ASM: Computational Materials Science and Engineering Committee, TMS/ASM: Phase Transformations Committee

#### 8:30 AM Keynote

**Solid-State Diffusion and Transformation Kinetics:** *Georges Martin*<sup>1</sup>; <sup>1</sup>Retired

The recent dramatic increase in efficiency of atomic scale observation and modeling techniques opens new routes to the understanding of diffusion controlled phase transformations. The kinetic pathway for phase separation in ternary Ni(Cr, Al) supersaturated solid solutions is discussed\*. First principle calculations and empirical fits to simple experiments give the parameters for kinetic Monte Carlo simulations of long sequences of vacancy jumps in the solution. The latter result in the precipitation of the  $\square^{\prime}$  Ni<sub>3</sub>(Al<sub>1-x</sub>, Cr<sub>x</sub>) phase (L12), and perfectly reproduce quantitative and qualitative features revealed in real alloys by 3DAP. The same parameters are also used to measure the Onsager and diffusion matrices in the model solid solutions; several intriguing features of the observed pathways are shown to result from kinetic couplings between the diffusion fluxes of the alloy components, a coupling ignored by existing models. \*Collaboration with David Seidman et al. NWU.

#### 9:10 AM Invited

**Atomistic Modeling of Diffusive Phase Transformations Kinetics by Monte Carlo Simulations:** *Frederic Soisson*<sup>1</sup>; <sup>1</sup>CEA Saclay

The kinetics of diffusive phase transformations are essentially controlled by the concentrations, jump mechanisms and jump frequencies of point defects, and by the way they depend on the local atomic configurations. Atomistic Kinetic Monte Carlo (AKMC) simulations are nowadays one of the most efficient tools for taking into account such details and therefore for predicting the kinetic pathways, especially when associated with ab initio calculations, which provide a reliable way to compute the key physical properties and the corresponding Monte Carlo parameters. We present a few recent AKMC simulations of phase transformations in model systems of industrial interest, especially in iron-based alloys. Comparison with experimental kinetics using 3D atom probe and neutron scattering techniques is emphasized.

#### 9:35 AM Invited

**Chemical Mixing at Hetero-Interfaces Forced by Severe Plastic Deformation:** *Pascal Bellon*<sup>1</sup>; Robert Averback<sup>1</sup>; Nhon Vo<sup>1</sup>; Xuan Zhang<sup>1</sup>; Elvan Ekiz<sup>2</sup>; Yinon Ashkenazy<sup>1</sup>; Daniel Schwen<sup>1</sup>; Mohsen Pouryazdan<sup>2</sup>; Horst Hahn<sup>2</sup>; <sup>1</sup>University of Illinois; <sup>2</sup>Karlsruhe Institute of Technology

Severe plastic deformation (SPD) can lead to the stabilization of supersaturated solid solutions in the case of moderately immiscible elements such as Cu and Ag, and to self-organization into lamellar structures in the case of highly immiscible elements, such as Cu and Nb. In this work, we contrast the different mechanisms operating in Cu-Ag and Cu-Nb alloys subjected to SPD, including high pressure torsion testing and ball milling. Combining experiments and molecular dynamics simulations, we show that the atomic mixing in Cu-Ag, surprisingly, increases linearly with strain as the elements are brought into solution. In contrast, Cu-Nb alloys can either remain phase separated or they can mix, depending on the initial crystallographic orientation of the Cu-Nb interfaces. Special orientations such as Kurdjumov-Sachs, for example, are remarkable stability against mixing, whereas others are not. In these latter cases, local amorphization is often observed at the interfaces.

#### 10:15 AM Keynote

**THE INSTITUTE OF METALS LECTURE AND ROBERT FRANKLIN MEHL AWARD WINNER: The Ubiquitous Interfacial Free Energy in Phase Transformations:** *David Seidman*<sup>1</sup>; <sup>1</sup>Northwestern University

The interfacial free-energy of a grain boundary or a heterophase interface is a ubiquitous and important quantity in all microstructures, and its short and long-term stability or lack of stability is intimately related to this fundamental quantity. Interfacial free energy affects important physical phenomena such as nucleation, growth and coarsening of different phases in multicomponent alloys, which are integral to the decomposition of a single-phase solid-solution. In this talk I focus on the diverse roles played by interfacial free energy in phase transformations in multicomponent metallic alloys, which are studied experimentally by atom-probe tomography and transmission electron microscopy. The results of simulations employing lattice kinetic Monte Carlo, where the phase transformation is mediated by a vacancy mechanism, will be presented and compared in detail with experimental observations. First-principles calculations of interfacial energies in the same metallic alloys will be discussed in terms of their relevance to all of the above.

#### 10:55 AM Invited

**Atomic Scale Investigation of Alpha Nucleation in the Beta Matrix of Titanium Alloys:** Soumya Nag<sup>1</sup>; Robert Williams<sup>2</sup>; Arun Devaraj<sup>1</sup>; Peter Collins<sup>1</sup>; Gopal Viswanathan<sup>3</sup>; Rajarshi Banerjee<sup>1</sup>; *Hamish Fraser*<sup>2</sup>; <sup>1</sup>University of North Texas; <sup>2</sup>The Ohio State University; <sup>3</sup>Air Force Research Laboratory

The solid-state decomposition of the beta phase of titanium alloys, leading to the precipitation of the equilibrium alpha phase, is a rather complex phenomenon involving multiple competing compositional and structural instabilities. The generally accepted mechanism of alpha precipitation

in these alloys is via classical nucleation and growth. Coupling advanced characterization techniques such as synchrotron-based in situ x-ray diffraction, aberration-corrected high-resolution (S)TEM, and atom probe tomography, the early stages of alpha precipitation at the atomic to near-atomic scale have been investigated in two titanium alloys, a commercial beta alloy, Ti-5Al-5Mo-5V-3Cr-0.5Fe (TIMETAL-5553 or Ti-5553), and a model ternary Ti-Mo-Al system. These experimental observations indicate that depending on temperature the decomposition can take place via a novel pseudospinodal mechanism that involves homogeneous alpha precipitation at a composition far-from equilibrium, followed by a continuous change in the compositions of both the parent beta and the product alpha phases towards equilibrium.

**11:20 AM**

**In Situ Studies and Simulations of Rapid, Self-Propagating Phase Transformations in Nanolayer Foils:** *Timothy Weihs*<sup>1</sup>; *Sara Barron*<sup>1</sup>; *Todd Hufnagel*<sup>1</sup>; *Steve Kelly*<sup>1</sup>; *Michael Falk*<sup>1</sup>; *Rong Xu*<sup>1</sup>; *Omar Knio*<sup>1</sup>; *Francesco Rizzi*<sup>1</sup>; *Geoffrey Campbell*<sup>2</sup>; *Judy Kim*<sup>3</sup>; <sup>1</sup>Johns Hopkins University; <sup>2</sup>Lawrence Livermore National Lab; <sup>3</sup>Oxford University

Exothermic formation reactions are known to self-propagate in multilayer foils with nanoscale layers and large, negative heats of mixing, such as Ni/Al, Nb/Si and Ti/B multilayers. The exothermic reactions can travel at velocities greater than 10 m/s and they reach temperatures as high as 3000 K. The combination of rapid propagation and high temperatures produces extremely fast heating rates ( $\sim 10^7$  K/sec) within the reaction front, while the nanoscale layers provide steep chemical gradients. Here we investigate the impact of both extremes (heating rate and chemical gradient) on reaction paths and phase morphologies using in situ X-ray diffraction, Dynamic TEM, Molecular Dynamic Simulations, and numerical modeling. The sequence of phase transformations and the phase morphologies that appear under fast and slow ( $\sim 1$  K/sec) heat rates are shown to be different and the impact of steep chemical gradients is assessed. Work performed under auspices of USDOE OBES by JHU under contract DE-SC0002509 and by LLNL under contract DE-AC52-07NA27344.

**11:35 AM**

**Molecular Dynamics Studies of Phase Transformations during Rapid Heating of Nanolayer Foils:** *Rongguang Xu*<sup>1</sup>; *Michael Falk*<sup>1</sup>; <sup>1</sup>Johns Hopkins University

A series of molecular dynamics studies of multilayer metallic foils undergoing rapid heating due to exothermic reaction reveal a number of salient details regarding the sequence of reaction. In simulations of Ni-Al foils melting is followed by the sequential precipitation of a number of intermetallic phases. The sequence of phase formation is observed to be sensitive to the interlayer mixing prior to the onset of the reaction. In simulations of Ni-Zr foils spontaneous amorphization precedes the formation of an ordered intermetallic. Atomic scale diagnostics are used to quantify the fraction of the material that has undergone phase transformation, identifying both atoms in ordered alloy and solid solution phases. This work was performed under DOE contract DE-FG02-09ER46648.

**11:50 AM**

**Interplay between Interfacial Segregation and Diffusion Shapes the Growth of Gold-Catalyzed Silicon Nanowires:** *Moneesh Upmanyu*<sup>1</sup>; *Hailong Wang*<sup>1</sup>; *Luis Zepeda-Ruiz*<sup>1</sup>; <sup>1</sup>Northeastern University

The vapor-liquid-solid for nanowire synthesis route has gained relevance of late as it in principle allows direct control over nanowire morphology and composition during synthesis. Here, we present classical computations on a small diameter, gold-catalyzed  $\langle 111 \rangle$  silicon nanowire that for the first time allow access to the atomistics underlying the growth process. We find a direct effect of the interfacial segregation, at the catalytic particle surface and at the faceted particle-nanowire interphase, on the diffusive kinetics that builds up the supersaturation necessary for interphase nucleation. The silicon-rich surface layer suppresses diffusion to an extent that the supersaturation is carried by the bulk of the particle. Their key structural aspect is the Au segregation at the interphase. The enhanced undercooling is kinetically offset by Au metastability around nucleated steps that arrests lateral flow

such that the growth is no longer layer-by-layer. We discuss the implications controlled growth of nanowire arrays.

**12:05 PM**

**Ta Clustering and Microstructural Evolution in the A1 to L10 Fe52PtX(Ta1-X) Phase Transformation:** *Diondra Means*<sup>1</sup>; *Billie Wang*<sup>1</sup>; *Gregory Thompson*<sup>1</sup>; <sup>1</sup>University of Alabama

FePt magnetic films have application in ultrahigh magnetic storage media. Their chemical ordering phase transformation and microstructure can be controlled by the addition of ternary elements. Controversy has existed on whether Ta additions promote or hinder the A1 to L10 ordering transformation. A series of Fe52Pt48, Fe52.3Pt46.3Ta1.4 and Fe52Pt40.7Ta7.3 thin films were sputter deposited and subsequently annealed. The as-deposited films had a change from a {111} fiber texture to {002} with the Ta additions. Annealing at 550°C facilitated the L10 order in Fe52Pt48 and Fe52.3Pt46.3Ta1.4 films. Upon annealing at 750°C, all three compositions L10 phase transformed. Atom probe tomography revealed nano-scale clustering in the annealed Ta containing films. The formation of these clusters appeared to be a necessary initial step to allow the L10 ordering reaction to occur. Additionally, clustering at grain boundaries provided a Zener-based pinning mechanism for grain growth measured by TEM.

**Nature-Inspired Hybrid Structural Materials for Bone Repair:** *Antoni Tomsia*<sup>1</sup>; <sup>1</sup>Lawrence Berkeley Lab

While the need for organ repair is being partly addressed by transplantation, the development of a systematic method to generate new organs would transform medicine. So far we have made little progress in engineering bone and cartilage even at relatively small scales. A critical component of this engineering approach is the development of porous 3D structures — scaffolds — that will provide cell support and guide tissue regeneration. Ceramics will play an important role in the development of new scaffolds but this will require materials and structures able to combine the optimum environment for bone formation with the optimized mechanical response. We will describe how new processing techniques can be combined with novel design principles taken, in part, from natural material such as nacre or bone to fabricate ceramic-based scaffolds and composites for bone repair. The critical design and material parameters as well as future research directions will be discussed.

**9:15 AM**

**Bone Regeneration in CaP Scaffolds: The Complementary Roles of BMP-2 and Microporosity:** *Amy Wagoner Johnson*<sup>1</sup>; *Samantha Polak*<sup>1</sup>; *Sheeny Lan Levensgood*<sup>2</sup>; *Aaron Maki*<sup>1</sup>; *Matthew Wheeler*<sup>1</sup>; *Sherrie Clark*<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign; <sup>2</sup>University of Wisconsin, Madison

BMP-2 is a well-known stimulant for bone regeneration. Microporosity ( $< 20\mu\text{m}$ ), has also been shown to influence regeneration in CaP scaffolds

MONDAY AM

that contain both macro (>100µm) and microporosity. This study shows that BMP-2 and microporosity have different, yet complementary, roles in bone regeneration in biphasic calcium phosphate (BCP) scaffolds. Microporosity increases the volume of bone (BV), but does not influence the specific surface area (SSA), in a study using a pig mandible model. In contrast, BMP-2 influences SSA, but not BV. Both make regeneration more uniform throughout scaffolds. Bone concentrates at the defect margin in scaffolds without microporosity or BMP-2. Additionally, BMP-2 and microporosity accelerate healing up to four-fold. Thus, microporosity may be as influential in healing large defects as BMP-2, as demonstrated by rapid and uniform regeneration. Mechanisms controlling regeneration for these two variables will be discussed.

**9:35 AM**

**Enhanced Functions of Osteoblasts on Biomimetic Nanohydroxyapatite-Grafted Chitosan Scaffolds for Bone Tissue Engineering:** *Dilip Depan*<sup>1</sup>; Bhupinder Girase<sup>1</sup>; Pavan Challa<sup>1</sup>; Devesh Misra<sup>1</sup>; <sup>1</sup>University of Louisiana at Lafayette

We describe here three dimensional biodegradable chitosan-nanohydroxyapatite (nHA) composite scaffolds with improved mechanical, physico-chemical, and biological properties compared to pure chitosan scaffolds for bone tissue engineering. High and medium molecular weight chitosan scaffolds with 0.5, 1, and 2 wt % fraction of nHA were fabricated by freezing and lyophilization. The nanocomposite scaffolds were characterized by a highly porous structure with interconnected pores and the pore size was similar for the scaffolds with varying content of nHA. The nanocomposite scaffolds exhibited greater compression modulus, slower biodegradation rate and reduced water uptake, but the water retention ability was similar to pure chitosan scaffolds. Favorable biological response of pre-osteoblast (MC 3T3-E1) on nanocomposite scaffolds includes improved cell adhesion, higher proliferation, and well spreading morphology in relation to pure chitosan scaffold. The study underscores chitosan-nHA composite as a potential scaffold material for bone regeneration.

**9:55 AM**

**Structure and Mechanical Properties of Bioinspired Inorganic/Polymer Multi-Layer Composites:** *Gustavo Hirata*<sup>1</sup>; Sandra Payán<sup>1</sup>; Yu-Chen Chan<sup>2</sup>; Po-Yu Chen<sup>3</sup>; Jenq-Gong Duh<sup>2</sup>; Joanna McKittrick<sup>2</sup>; <sup>1</sup>Centro de Nanociencias y Nanotecnología-UNAM; <sup>2</sup>National Tsing Hua University; <sup>3</sup>University of California, San Diego

Abalone nacre has mechanical properties that are far beyond its constituents, CaCO<sub>3</sub> and biopolymer, due to the well-defined structure at varying hierarchical levels. Abalone-inspired ZrN/PMMA multi-layer composites are synthesized by combining DC-magnetron sputtering and pulsed laser deposition on silicon substrates in a single chamber. SEM and high resolution TEM images show uniform polymeric layers (10-50 nm) sandwiched between nanocrystalline ZrN layers (0.3-0.5 µm). The thickness ratio of the inorganic/polymer layers is the same as that in abalone. Multi-layered ZrN/PMMA thin films with increasing interfacial roughness were also made to mimic the nano-sized asperities and bridges observed in abalone. Nanoindentation and nanoscratch tests are conducted on the synthetic thin films and abalone nacre followed by SEM and AFM characterization. Failure mechanisms are discussed and comparisons are made. This research is supported by the NSF Grant DMR 1006931.

**10:25 AM Invited**

**Mimicking Bone Formation Using Anionic Polymeric Process-Directing Agents:** *Taili Thula*<sup>1</sup>; *Laurie Gower*<sup>1</sup>; <sup>1</sup>University of Florida

Bone is a hierarchically-structured composite which imparts it with unique mechanical properties and bioresorptive potential. These properties are primarily influenced by the underlying nanostructure of bone, which consists of nanocrystals of hydroxyapatite embedded and uniaxially aligned within collagen fibrils. There is also a small fraction of non-collagenous proteins in bone, and these are thought to contribute both to bone's formation as well as its mechanical properties. In our in vitro model system of bone

formation, polyanionic peptides and proteins are used to mimic the role of the non-collagenous proteins. Intrafibrillar mineralization of collagen can be achieved using a polymer-induced liquid-precursor (PILP) mineralization process, which yields a nanostructured composite closely mimicking the nanostructure of bone. This talk will focus on our studies comparing the effectiveness of different polymeric process-directing agents, as measured by the kinetics of mineralization, degree of mineral content, and depth of penetration of mineral into dense-packed collagen matrices.

**10:55 AM**

**Bionanomineralization through Genetically Engineered Peptides and Fusion Proteins:** *Candan Tamerler*<sup>1</sup>; <sup>1</sup>University of Washington & Istanbul Technical University

Biomimetic synthesis of nanoinorganics have been a major focus in hard tissue engineering as well as developing a new generation of hybrid materials through environmentally-benign processing. Bio-based molecular building blocks are, therefore, developed for practical water-based pathways to novel biologically compatible structures. Here we use recombinant DNA technologies and biochemical conjugation to produce single or multifunctional peptides and fusion proteins and enzymes that can controllably bind to a given solid material including variety of materials, and in particular to those relevant for medical applications. Examples of the use of solid-binding peptides are given with specific implementations in self-mineralization and in forming hybrid molecular scaffolds in tissue restoration and regeneration, surface biofunctionalization of implants with antibacterial bifunctional peptide coatings, and conjugated linkers towards directed enzyme immobilization. Research is supported the NSF-MRSEC at UW, NSF-BIOMAT, TUBITAK-NSF IRES Joint Projects, and TR-SPO.

**11:15 AM**

**Engineered Mineral-Directing Peptides for Hard Tissue Engineering:** *Mustafa Gungormus*<sup>1</sup>; Hanson Fong<sup>1</sup>; Joel Schneider<sup>2</sup>; Candan Tamerler<sup>1</sup>; Mehmet Sarikaya<sup>1</sup>; <sup>1</sup>University of Washington; <sup>2</sup>National Cancer Institute-Frederick

During normal development of hard tissues, mineral morphogenesis is heavily influenced by soluble extracellular matrix (ECM) proteins. Polymer scaffolds, while providing architectural support, lack the molecular control over mineralization. We demonstrate use of engineered peptides to functionalize scaffolds or defect sites to exert control on mineral formation at molecular level. Mineralization-directing peptides can be engineered to interact with the mineral surfaces or precursor ions to regulate the mineral formation mimicking the ECM proteins synthesized during tissue development. In vitro solution based or cell mediated mineralization assays have shown that a precise control can be achieved over the mineral morphology and the formation kinetics. Moreover, these peptides do not require any hostile chemistry for functionalization and show no cytotoxic effects. The results presented here indicate that these peptides may find substantial use in tissue engineering for successful restoration and regeneration of hard tissues. Research is supported by the NSF-MRSEC at UW.

**11:35 AM**

**Structural Characterization of the Mineral Phase in Bony Tissues: A Comparative Study:** *Po-Yu Chen*<sup>1</sup>; Maria Lopez<sup>2</sup>; Ekaterina Novitskaya<sup>1</sup>; Marc Meyers<sup>1</sup>; Joanna McKittrick<sup>1</sup>; <sup>1</sup>University of California, San Diego

Bone is a hierarchically structured composite of type-I collagen fibrils and mineral crystallites. We examined structural features of the mineral phase in some unique bony tissues, including antlers, turtle shells, armadillo carapaces and fish scales. A chemical method to completely remove the protein constituents without altering the original structure has been developed and verified. TEM observations of carbonated apatite crystallites derived from various bony tissues showed similar platelet-like geometry. The hierarchical structure of untreated and deproteinized samples was characterized by micro-computed tomography, optical microscopy, SEM, and AFM. The most significant finding was that the minerals retain structural integrity after completely removing protein constituents. High resolution SEM images showed minerals formed sheet-like structure, aligned in a coherent manner

along the orientation of collagen fibrils. Organized porous structure (vascular channels, lacunae, canaliculi) was observed. Comparisons between bony tissues were made. This research is supported by NSF Grant (Ceramics and Biomaterials Program) 1006931.

11:55 AM

**Bone Demineralization and Deproteinization Studies: A Biochemical-Kinetic Focus:** Ana Castro<sup>1</sup>; Ekaterina Novitskaya<sup>2</sup>; Po-Yu Chen<sup>2</sup>; M. del Pilar Sánchez-Saavedra<sup>1</sup>; Gustavo Hirata<sup>3</sup>; Joanna McKittrick<sup>2</sup>; <sup>1</sup>CICESE; <sup>2</sup>UC San Diego; <sup>3</sup>CNyN-UNAM

There is an increasing interest on the study of bone demineralization and deproteinization due to their different clinical applications and, the Material Science, also. In the present work, cortical and cancellous bovine femur bones were demineralized and deproteinized. Demineralization was performed at different temperatures and concentrations of hydrochloric acid. Deproteinization was carried out using 6% NaOCl at distinct temperatures. The goal of this work was to calculate the kinetic parameters of the demineralization and deproteinization reactions. Demineralization and deproteinization were found to follow first-order kinetics. The rate of demineralization increased with both HCl concentration and temperature. Three different stages were clearly identified during the demineralization reactions. The activation energy for demineralization increased with increasing HCl concentration. Concerning on deproteinization, the activation energy calculated was different between cortical and cancellous bovine femur bones. This work provides a better understanding of the details of bone demineralization and deproteinization reactions.

**Millisecond Thermoplastic Processing of Bulk Metallic Glasses:** William Johnson<sup>1</sup>; Georg Kaltenboeck<sup>1</sup>; Marios Demetriou<sup>1</sup>; Joe Schramm<sup>1</sup>; <sup>1</sup>California Institute of Technology

A novel method is introduced for millisecond time scale experiments and processing of bulk metallic glass forming liquids. Electrical energy is used to uniformly heat BMG cylinders, plates, and sheets to a predefined temperature in the undercooled (or equilibrium) liquid at rates of order  $10^6$  K/s. Excellent temperature uniformity is achieved throughout the sample. The sample can be deformed under mechanical loading or injected into mold cavities to form net shapes. Measurements are carried out in millisecond time scales under "near adiabatic" conditions. The platform can be used to measure liquid specific enthalpy  $h(T)$ , heat capacity  $c(T)$ , viscosity, crystallization kinetics, etc.. High speed video and infrared thermal imaging are used to collect data. The new "Rapid Discharge Heating and Forming" (RDHF) method overcomes limitations created by intervention of crystallization in glass forming liquids enabling measurements and processing of both marginal and superior glass forming alloys.

9:00 AM

**Bulk Metallic Glass: The Smaller the Better:** Golden Kumar<sup>1</sup>; Jan Schroers<sup>1</sup>; <sup>1</sup>Yale University

Despite their superb properties, bulk metallic glasses (BMGs) find limited utility due to their macroscopic brittle nature, high costs, and difficulty of

processing, particularly when complex shapes are desired. As a consequence of strong size-dependent mechanical properties of BMGs, abovementioned drawbacks can be mitigated when BMGs are used in miniature parts ( $< 1$  cm), an application which takes advantage of BMGs' enhanced plasticity at small length scales as well the insignificant material cost associated with such parts. As an alternative to traditional metal processing techniques, thermoplastic forming (TPF)-based microfabrication methods have been developed which can process some BMGs like plastics. We will discuss the properties and fabrication of BMGs for application in small-scale devices including miniature parts, nano-imprinting, and self-assembly substrates.

**The Production of Iron Based BMGs by Spray Forming:** Claudemiro Bolfarini<sup>1</sup>; Walter Botta<sup>1</sup>; Claudio Kiminami<sup>1</sup>; <sup>1</sup>Universidade Federal de São Carlos

This paper describes results obtained by spray forming of iron-based alloys, whose compositions derived from rapid solidification studies aiming to obtain amorphous structures. Atomization with high gas to metal flow ratio is necessary for amorphous phase formation, and most important for keeping it by avoiding excessive reheating and consequent crystallization during deposit build-up. The amorphous regions of the deposit were formed by the participation of a great numbers of amorphous particles that were kept in the supercooled liquid region for a sufficient time in order to allow bonding of one to each other and viscous flow under the influence of the gas pressure and impacting droplets. The [(Fe0.6Co0.4)0.75B0.2Si0.05]96 Nb4 al alloy presented the highest glass forming ability among the Fe-based alloys investigated, showing a high volume percent of amorphous phase formation up to 4mm thickness of the deposit, a similar value obtained for this alloy when processed by copper mould casting.

9:30 AM

**Development of Mass Production System for Zr-Based Bulk Glassy Alloys:** A. Inoue<sup>1</sup>; Y. Yokoyama<sup>1</sup>; <sup>1</sup>Institute for Materials Research

For the implementation of high-reproducibility and high-quality of bulk metallic glasses (BMGs), mass production system of Zr-based BMGs was newly developed. This mass production system is composed of three machines; weighing-, master alloying- and casting-machines. The automatic weighing is composed of three processes, materials feeding, cutting, and weighing, and these three processes are automatically controlled by LabVIEW in PC. The weight deviation of automatically measure system is about 1 % in this process, we are trying much higher accuracy of this value to be less than 0.5 %. Recently, full-automatic arc furnace was commercialized by DIAVAC Ltd. [<http://www.diavac.co.jp/>] using a patent developed by YKK co. Ltd. and Tohoku university. The usage of full-automatic arc furnace suppresses the human error and dependence human's skill. By using this machine, we can control the homogeneity of alloying as a relative evaluation. This developed mass production system will accelerate the standardization of BMGs.

**Ductility Enhancement and Size Enlargement of Bulk Glassy Alloys:** H. Tokunaga<sup>1</sup>; K. Fujita<sup>1</sup>; T. Yamasaki<sup>2</sup>; A. Yavari<sup>3</sup>; P. Liaw<sup>4</sup>; A. Inoue<sup>5</sup>; Y. Yokoyama<sup>5</sup>; <sup>1</sup>Department of Machine Engineering; <sup>2</sup>Department of Material Science and Engineering; <sup>3</sup>SIMAP-CNRS; <sup>4</sup>University of Tennessee; <sup>5</sup>Institute for Materials Research

We examined hypoeutectic Zr-Cu-Al bulk glassy alloys exhibit high-fracture toughness and almost no degradation in mechanical properties due to structural relaxation. Furthermore, in the quaternary Zr-Ni-Cu-Al alloys, the hypoeutectic Zr70Ni16Cu6Al8 bulk glassy alloy with extremely low Young's modulus (70 GPa) and high Poisson's ratio (0.39) enables to show the distinct tensile plastic elongation at room temperature. We also examined tensile plasticity of the hypoeutectic BMG at low temperature with various strain rate. Size enlargement of metallic glass has been performed by combination of compositional optimization and production process optimization. The former focused on the glass forming ability, and the later focused on the homogenizing and purification of master alloy to achieve vitrification. The quantity of master alloy should be limited for

homogenizing. Homogenized small master alloys promote easy handling of the melting and casting processes, whereas we have to fabricate the large number of master alloys.

**Bulk Metallic Glasses Form Like Plastics:** *Jan Schroers*<sup>1</sup>; <sup>1</sup>Yale University

The sluggish crystallization kinetic of bulk metallic glass results in two fundamentally different processing opportunities. BMG can be directly cast. But even for BMGs with low critical cooling rates geometries with high aspect ratio are particularly challenging since during casting cooling and filling of the mold must occur simultaneously. This limits the complexity of the geometries that can be cast even when processing parameters are carefully balanced. Alternatively, BMG can be thermo plastically formed in the supercooled liquid region. In this case the required fast cooling and forming are decoupled. The BMG is formed in a high viscous state where it behaves very similar to plastics when compared by processing temperature and forming pressure. A measure for the formability of BMGs will be introduced. Processing potentials and challenges will be discussed and various examples will be given including blow-molding, miniature fabrication, and nano-patterning.

#### 10:30 AM

**A Novel Preparation Method for Mg-based BMG Matrix Composite with the In-Situ Ti Dispersoids:** *Hideki Oka*<sup>1</sup>; *Takeshi Wada*<sup>1</sup>; *Kunio Yubuta*<sup>1</sup>; *Hidemi Kato*<sup>1</sup>; *Akihisa Inoue*<sup>1</sup>; <sup>1</sup>Tohoku University

The Mg-Cu-RE (rare earth) bulk metallic glass (BMG) is known for its high specific strength ( $\sim 2.2 \times 10^5$  Nm/kg), which is higher than the conventional AZ91 alloy ( $\sim 1.4 \times 10^5$  Nm/kg). However, the fracture toughness of the alloy is comparable to the ceramics, which is a serious disadvantage for the practical use. For improving the fracture toughness of the alloy, Mg-Cu-RE BMG matrix composites have been developed by dispersing the ex-situ particles such as Fe, TiB<sub>2</sub>, SiC, Ti and so on. Although the plastic elongation of the Mg-based BMG is highly enhanced by these particles, the composite effect is achieved only in the compressive mode. In this work, we intend to introduce a novel method of dispersing in-situ  $\alpha$ - &  $\beta$ -Ti particles in a Mg-Cu-Gd BMG based on an earlier work by Li et al. (Mater. Trans. 48(2007)3193) to improve the fracture toughness of the brittle Mg-based BMG.

**Novel Net-Shape Processing of Metallic Glass by Rapid Joule Heating:** *Marios Demetriou*<sup>1</sup>; *Georg Kaltenboeck*<sup>1</sup>; *Joseph Schramm*<sup>1</sup>; *William Johnson*<sup>1</sup>; <sup>1</sup>California Institute of Technology

In an effort to process metallic glass into net shape, thermoplastic methods that take advantage of the vitreous state of the undercooled liquid have been explored. These methods are limited by the relatively low stability of the liquid against crystallization, which prohibits processing within the optimum viscosity range of 10-1000 Pa-s utilized in conventional thermoplastic processes. Consequently, thermoplastic forming of metallic glass typically requires very high pressures, often approaching the flow stresses of tools. Recently, a joule heating method for processing metallic glass has been developed. The method takes advantage of the unique electrical properties of the metallic glass to heat rapidly and uniformly across the entire undercooled liquid region bypassing crystallization. Processing in the viscosity range of 10-1000 Pa-s is achievable by this method, which promotes low-cost fabrication of high-precision net-shape metallic glass parts. The rapid joule heating and forming method constitutes a powerful platform for processing metallic glass.

#### 11:00 AM Invited

**The Effect of Purification on the Glass-Forming Ability of Pd-Cu-Si Alloys:** *Ke-Fu Yao*<sup>1</sup>; *Sheng-Bao Qiu*<sup>1</sup>; *Hong-Yu Ding*<sup>1</sup>; *Yang Li*<sup>1</sup>; <sup>1</sup>Tsinghua University

In present work, the Pd-Cu-Si alloy melt has been purified by fluxing with B<sub>2</sub>O<sub>3</sub> at high temperature and effect of melt purification on the glass-forming ability has been studied. It has been found that with the purified Pd-Cu-Si ingots glassy bars with a diameter of 8 mm have been successively

prepared by water quenching method and the glassy bars with a diameter of 4 mm have been prepared by copper mould casting. But without purification even for 2mm glassy bar it could not be prepared. It has also been found that the glassy alloy prepared with purified ingots exhibits much higher thermal stability than that prepared with the ingots without purification. The present results indicate that melt purification can effectively enhance the glass-forming ability of Pd-Cu-Si alloys through removing the inhomogeneous nucleus by fluxing method.

**Processing and Tensile Tests of Amorphous Wires:** *Yong Zhang*<sup>1</sup>; <sup>1</sup>University of Science and Technology Beijing

The amorphous wires of Cu<sub>50</sub>Zr<sub>46</sub>Al<sub>4</sub> and Co<sub>36</sub>Fe<sub>36</sub>Nb<sub>4</sub>Si<sub>4.8</sub>B<sub>19.2</sub> alloys were prepared by the In-rotation water melting spinning and Taylor-Ulitovsky technique, respectively. The amorphous wires of Cu<sub>50</sub>Zr<sub>46</sub>Al<sub>4</sub> alloy can be in diameter of 50-120  $\mu$ m and length of 1 m, while the amorphous wires of Co<sub>36</sub>Fe<sub>36</sub>Nb<sub>4</sub>Si<sub>4.8</sub>B<sub>19.2</sub> alloy by Taylor-Ulitovsky method can be in diameter of 10-50  $\mu$ m and length of 5 m or more, and with glass coated. The tensile strength of the Cu<sub>50</sub>Zr<sub>46</sub>Al<sub>4</sub> amorphous alloy wires is about 1800 MPa, that of Co<sub>36</sub>Fe<sub>36</sub>Nb<sub>4</sub>Si<sub>4.8</sub>B<sub>19.2</sub> alloy is about 2400 MPa. The tensile strength of the glass coated amorphous wire of Co<sub>36</sub>Fe<sub>36</sub>Nb<sub>4</sub>Si<sub>4.8</sub>B<sub>19.2</sub> alloy linearly increases from 800 MPa to 2400 MPa with the ratio of the diameter of the inner amorphous wire to the outer diameter with the glass coating from 0.3 to 0.9. The wire forming parameters were compared with the glass forming ability of the alloys.

#### 11:40 AM Invited

**Formation and Properties of New Zr-Based Bulk Glassy Alloys with High Glass-Forming Ability:** *Wei Zhang*<sup>1</sup>; *Yanhui Li*<sup>2</sup>; *Chuang Dong*<sup>2</sup>; *Akihisa Inoue*<sup>1</sup>; <sup>1</sup>Institute for Materials Research, Tohoku University; <sup>2</sup>School of Materials Science and Engineering, Dalian University of Technology

Although Zr-Al-Ni alloy system is the first Zr-based glassy alloys reported in 1990 [1], the glass-forming ability (GFA) and mechanical properties have not been investigated yet systematically. Here we report on the thermal stability, GFA and mechanical properties of Zr-Al-Ni glassy alloys with high Zr concentrations. The glassy rods with critical diameter (dc) above 10 mm were obtained in a wide composition range. The maximum dc of  $\sim 15$  mm was formed for an off-eutectic Zr<sub>60</sub>Ni<sub>25</sub>Al<sub>15</sub> alloy, which has the largest supercooled liquid region and  $\Delta T_c$  value. Compression tests revealed that the bulk glassy alloys exhibit high yield strength of over 1.65 GPa and a distinct plastic strain [2]. The effects of additional alloying elements on the thermal stability, GFA, mechanical properties, and corrosion resistance of Zr-Al-Ni glassy alloys are also investigated. [1] A. Inoue et al., Mater. Trans. JIM. 31, 177 (1990). [2] Y.H. Li et al., Intermetallics. (2010), on line.

#### 12:00 PM Invited

**High Strength Amorphous and Nanocrystalline Ni-W Electrodeposits:** *Tohru Yamasaki*<sup>1</sup>; *Masako Sonobe*<sup>1</sup>; *Kazutaka Fujita*<sup>2</sup>; *Takeyuki Kikuchi*<sup>1</sup>; *Hye Jung Chang*<sup>3</sup>; *Do Hyang Kim*<sup>3</sup>; <sup>1</sup>University of Hyogo; <sup>2</sup>Ube National College of Technology; <sup>3</sup>Yonsei University

Structure and tensile plastic deformation behaviors of amorphous and nanocrystalline Ni-W electrodeposited alloys have been examined. By controlling the surface roughness of the Cu-substrate, a high strength nanocrystalline Ni-16.9 at % W alloy with mesoscale Ni-segregated network structure has been prepared by electrodeposition. When the W-content was increased to 22 at. %, the alloy has consisted of amorphous phase in general. Nominal tensile strength of the Ni-16.9 at % W alloy was attained to about 2,900 MPa with the total strain before fracture was about 3 % containing the large plastic strain of about 1.0 %. A large necking phenomenon of about 30% at the fracture surface was observed, resulting the high true tensile strength at fracture of about 4,100 MPa. These results have suggested that the Ni-segregated mesoscale structure is effective for improvement of the tensile plasticity of high strength nanocrystalline alloys.

12:20 PM

**Synthesis of Plastic Mg-Based Bulk Metallic Glass Matrix Composites by the Bridgman Solidification:** *Liang Zhang*<sup>1</sup>; <sup>1</sup>Nanjing University of Science and Technology

The microstructures of the in situ Mg-based bulk-metallic-glass-matrix composites synthesized by the copper-mold suction casting are inhomogeneous, and the optimized mechanical properties were usually realized through alloy composition design. In this paper, Mg-based bulk-metallic-glass-matrix composites containing uniform flake-shaped precipitates with a fixed composition of Mg<sub>70</sub>Cu<sub>8.33</sub>Y<sub>8.33</sub>Gd<sub>8.33</sub>Zn<sub>5</sub> are synthesized by the Bridgman solidification. The sizes and volume fractions of precipitates in the composites are controlled by adjusting the withdrawal velocities. Large plasticity can be obtained by only controlling the cooling condition. The Bridgman solidification is an effective way not only to fabricate the homogeneous BMG-matrix composites but also to tailor and optimize its mechanical properties.

### **Characterization of Minerals, Metals and Materials: Characterization Methods and Synthesis Techniques**

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS/ASM: Composite Materials Committee, TMS: Materials Characterization Committee  
*Program Organizer:* Sergio Monteiro, State University of the Northern Rio de Janeiro - UENF

Monday AM  
February 28, 2011

Room: 14B  
Location: San Diego Conv. Ctr

*Session Chairs:* Jian Li, CANMET-MTL; Sergio Monteiro, UENF

8:30 AM

**Materials with Controlled Microstructural Architecture (MCMA) Fabricated by Electron Beam Melting (EBM):** *Sara Gaytan*<sup>1</sup>; *Diana Ramirez*<sup>2</sup>; *Lawrence Murr*<sup>1</sup>; *Edwin Martinez*<sup>1</sup>; *Jose Martinez*<sup>1</sup>; *Daniel Hernandez*<sup>1</sup>; *Brenda Machado*<sup>1</sup>; *Frank Medina*<sup>1</sup>; *Ryan Wicker*<sup>1</sup>; <sup>1</sup>UTEP

While traditional or contemporary materials science and engineering utilizes various processing technologies including thermo-mechanical or mechanical processing to create and manipulate microstructures to control properties and establish performance features, there are currently no processing routes for the selective or systematic organization of microstructures to create architectures. In this paper we demonstrate the novel development of carbide (M<sub>23</sub>C<sub>6</sub>) precipitate architecture in the EBM fabrication of Co-base alloy components, and an oxide (Cu<sub>2</sub>O) precipitate-dislocation architecture in the EBM fabrication of Cu components. These architectures are characterized by special arrays of precipitate columns extending (generally) in the EBM build direction for the additive (powder layer) manufacturing process. Microstructures and associated architectures have been examined by optical metallography, and scanning and transmission electron microscopy.

8:45 AM

**Quantifying Damage Accumulation during Ductile Plastic Deformation Using Synchrotron Radiation:** *Reeju Pokharel*<sup>1</sup>; *Jonathan Lind*<sup>1</sup>; *Xi Tan*<sup>1</sup>; *Robert Suter*<sup>1</sup>; *Anthony Rollett*<sup>1</sup>; <sup>1</sup>CMU

High Energy X-ray Diffraction and absorption tomography were used to study void nucleation process in polycrystalline materials, during ductile fracture. The experimental techniques were developed at the Advanced Photon Source beam line 1-ID. Preliminary tests were performed on the tabletop microtomography system at Carnegie Mellon University. 1mm diameter Cu wire was selectively electropolished to form a neck of ~200um in the middle, to localize the strain. Synchrotron diffraction and tomography data were collected while performing in-situ uniaxial tensile test. These non-destructive techniques were able to more accurately confirm the position of the void nucleation sites in relation to the crystallographic orientation and microstructural features, such as, grain boundaries, triple points, and

quadruple points. This study will aid in quantifying anisotropic microstructural distribution of strain and understanding damage accumulation, which are the main sources of failure in polycrystalline materials.

9:00 AM

**Design and Implementation of Low Cost Measurement System for Determination of Thermal Conductivity Coefficient:** *Juan Calderón*<sup>1</sup>; *Nora Ramírez*<sup>1</sup>; *Leobardo López*<sup>1</sup>; <sup>1</sup>ITESM Campus Toluca

One of the most important parameters to characterize the thermal behavior of any material is the coefficient of thermal conductivity. The present work proposes a design of a low cost measurement system in order to determine this coefficient with the lower possible error. The system is based on ASTM C 518 – 04 and integrated by two plates. A control system checks in real time plates temperatures in order to determine the effective power applied to the system. The contact faces of the plates contain a group of temperature sensors connected to a data acquisition system that process and records the temperature in each measurement point. With the power applied to the system, the measurement of temperatures and a process of calibration it is possible to determine the coefficient of thermal conductivity.

9:15 AM

**Material Performance of TBCs at High Temperature in Moisture-Containing Environments Using a Load-Based Micro-Indentation Technique:** *Jared Tannenbaum*<sup>1</sup>; *Bruce Kang*<sup>1</sup>; *Mary Anne Alvin*<sup>2</sup>; <sup>1</sup>West Virginia University; <sup>2</sup>National Energy Technology Laboratory

A load-based micro-indentation technique has been developed for damage assessment and non-destructive spallation detection of TBCs at room temperature. This micro-indentation technology has been further extended to the development of a high temperature (HT) test methodology. Elastic modulus calibration tests performed on H13 Tool Steel to 500°C and Haynes 230 at 1000°C displayed excellent agreement with reported values. Moreover, indentation creep tests of Haynes 230 at 1200°C were found to be in agreement with known creep exponents as well. Finally, a HT thermal flux indentation apparatus was assembled for conducting TBC turbine component testing under high temperature moisture-containing environments (e.g. =50% steam with controlled gas content temperatures up to 1250°C). Description and design considerations of this test apparatus are discussed. Preliminary tests of RenéN5/MCrAlY/APS TBC coupons in =50% steam/air environments with in-situ HT micro-indentation testing are conducted. Furthermore, the coupon is removed and examined for damage assessment at periodical intervals.

9:30 AM

**Raman Spectroscopy of C-A Domain Switching in (001) BaTiO<sub>3</sub> Single Crystals under Uniaxial Loading:** *Carolina Diliegros Godines*<sup>1</sup>; *Juan Muñoz - Saldaña*<sup>1</sup>; *Molly Gentleman*<sup>2</sup>; *Amy Bolon*<sup>2</sup>; *Luis Gutierrez Ladron de Guevara*<sup>1</sup>; <sup>1</sup>Cinvestav-Queretaro; <sup>2</sup>Texas A&M University

Ferroelastic domain switching occurs progressively as a function of applied stress in ferroelectric-ferroelastic materials such as BaTiO<sub>3</sub>. The first steps of switching were characterized using 325 nm polarized confocal Raman spectroscopy on a (001) oriented BaTiO<sub>3</sub> single crystal with 90°-aa and cc domain arrangements under compressive loading. Direction of the polarization vectors for a-domains from the unloaded crystal were unambiguously identified by Raman mapping, through observation of orientation intensity gradients due to contribution from subsurface a and c domains. A similar gradient was observed by measuring the elastic modulus across 90°-ac domains by nanoindentation. A set of mappings was recorded from the loaded surface as a function of applied stress that shows the switching sequence. Under this mechanical configuration out-of-plane domains from the surface become unstable and switch to in-plane domains. Raman spectroscopy also allowed identification of the preferential switching sites and A+x, A-x, A+y or A-y domains.

MONDAY AM

9:45 AM

**Synthetic Generation of Annealing Twins in Three-Dimensional Microstructures:** *Lisa Chan*<sup>1</sup>; Michael Groeber<sup>2</sup>; Gregory Rohrer<sup>3</sup>; Anthony Rollett<sup>3</sup>; <sup>1</sup>EDAX-TSL; <sup>2</sup>Air Force Research Laboratory; <sup>3</sup>Carnegie Mellon University

In face-centered cubic metals, the density of high symmetry boundaries is often maximized in order to improve grain boundary dependent properties. Twinning events have been found to be very effective in increasing the density of these high symmetry boundaries that are denoted by low sigma values for Coincident Site Lattice relationships. In this study, annealing twins are generated in synthetic microstructures by using the  $\Sigma 3$  cluster distribution as the target. To illustrate the capabilities of the method, a 3D dataset for a nickel alloy was collected using serial sectioning in a dual-beam FIB with OIM™. Twin-related grains were synthetically removed from the structure and subsequently regenerated. The statistics used to quantify the differences between the twin-regenerated and experimentally observed microstructures are texture, five-parameter grain boundary character distribution, and the number and area fractions of  $\Sigma 3$  boundaries.

10:00 AM Break

10:15 AM Invited

**Experimental Characterization of Negative Thermal Expansion in Oxides:** *Fernando Rizzo*<sup>1</sup>; Monica Ari<sup>1</sup>; Bojan Marinkovic<sup>1</sup>; Paula Jardim<sup>1</sup>; Roberto de Avillez<sup>1</sup>; Fabio Furlan Ferreira<sup>2</sup>; <sup>1</sup>PUC Rio de Janeiro; <sup>2</sup>ABC Federal University

For several technological applications such as Fiber Bragg gratings sensors, illumination system, integrated circuits, electronic components, optical devices, shock thermal resistance, etc, controllable thermal expansion materials, pure or composites are required. It has been the driving force in the search for crystal phases with unusually low, zero, or even negative thermal expansion (NTE). Some open-framework classes of known ceramics, such as AO<sub>2</sub>, AMO<sub>5</sub>, AM<sub>2</sub>O<sub>7</sub>, A<sub>2</sub>O<sub>5</sub> and A<sub>2</sub>M<sub>3</sub>O<sub>12</sub> have emerged as potential sources of crystal phases with low or NTE. The A<sub>2</sub>M<sub>3</sub>O<sub>12</sub> family is especially attractive due to the chemical flexibility that results in a large range of variation of linear coefficients of thermal expansion ( $\alpha$ ) after phase transition from monoclinic to orthorhombic structure. Both structures consist of corner-sharing AO<sub>6</sub> octahedra and MO<sub>4</sub> tetrahedra. It is assumed that the low-energy transverse thermal vibration of the oxygen in the A–O–M linkage within lower-density orthorhombic structure produces NTE.

10:45 AM

**Digital Construction and Characterization of Reticulated Porous Microstructures from Sacrificial Templates:** *Jason Kulp*<sup>1</sup>; Stephanie Lin<sup>2</sup>; Jason Nadler<sup>2</sup>; <sup>1</sup>Georgia Institute of Technology; <sup>2</sup>Georgia Tech Research Institute

A numerical method has been developed to predict the microstructural characteristics of reticulated metal foam. The porosity of this foam is derived from sacrificial template particles of known particle size distribution, which are incorporated with other precursor components. In this approach, a porous structure is numerically generated starting with Powell's sphere packing algorithm. The resulting stochastic structure has characteristics similar to those of corresponding metal foam. Deterministic inter-sphere connections are calculated to more accurately model the pore morphology that evolves during thermochemical synthesis. Estimations of pore morphology and specific surface area of the simulated material are compared to lab-synthesized materials composed of equivalent constituent compositions. In addition, the effect of template particle size, inter-sphere connections, and the geometric constraints on pore morphology and permeability are investigated to refine microstructural evolution and design.

11:00 AM

**Thermodynamic Measurement of CaO-P<sub>2</sub>O<sub>5</sub>-SiO<sub>2</sub> System:** *Takashi Nagai*<sup>1</sup>; Hisao Kimura<sup>1</sup>; Masafumi Maeda<sup>1</sup>; <sup>1</sup>The University of Tokyo

Hot metal pretreatment for de-phosphorization is a common practice in the iron and steel industry, and has been developed as an effective refining process. Although a molten flux was used traditionally in this process, a

multi-phase flux, which contained liquids and solidus phases, is used today in order to avoid use of harmful element for environment such as fluorine. In addition, it is possible to reduce wasted flux by use of this flux because P<sub>2</sub>O<sub>5</sub> is increased to solidus phase in the flux. Since the solidus phase is based on CaO-P<sub>2</sub>O<sub>5</sub>-SiO<sub>2</sub> system, thermodynamic properties of this system are necessary to improve this process optimally. However, the available thermodynamic information on this system is limited. In this study, activity of P<sub>2</sub>O<sub>5</sub> in CaO-P<sub>2</sub>O<sub>5</sub>-SiO<sub>2</sub> system was measured by double Knudsen cell mass spectrometry. And the optimal condition of this process was considered.

11:15 AM

**Applying Modular DOE to Improve Material Characterization and Performance:** *Paul Funkenbusch*<sup>1</sup>; <sup>1</sup>University of Rochester

Design Of Experiments (DOE) methods are routinely applied in many engineering applications. However, they have not been as extensively used for material characterization and, when applied, they have often been in the form of standard product/process optimization methodologies (e.g. "Taguchi methods") that may not be well adapted to material engineering applications. The modular approach to DOE seeks to build experimental designs tailored to specific applications, by allowing the designer to make appropriate choices for each of four design element (array design, choice of the characteristic response, incorporation of variability, and data analysis). In this presentation, the use of a modular approach to build experimental designs suitable for characterizing material performance is illustrated using a variety of examples. These include development of an erosion testing protocol, identification of tool material property effects on precision grinding performance, and characterization of diamond bur performance degradation in dental burrs.

11:30 AM

**Selective Removal of Thiophene from Liquid Fuels over Nickel-Based Nanocrystalline Zinc Oxide:** *Mohammad Islam*<sup>1</sup>; Jewel Gomes<sup>1</sup>; Hylton McWhinney<sup>2</sup>; Doanh Tran<sup>1</sup>; Sameer Pallavkar<sup>1</sup>; Md Islam<sup>1</sup>; George Irwin<sup>1</sup>; David Cocke<sup>1</sup>; <sup>1</sup>Lamar University; <sup>2</sup>Prairie View A&M University

Low temperature deep desulfurization of fuels via selective adsorption of sulfur compound is receiving increasing attention worldwide in order to satisfy the upcoming environmental regulations and fuel specifications. The Ni/ZnO adsorbents were prepared by thermal decomposition and incipient impregnation method from their nitrate precursors. A model fuel (20 mL) consisting of pentane (C<sub>5</sub>H<sub>12</sub>), heptane (C<sub>7</sub>H<sub>16</sub>) and thiophene was prepared and adsorption experiments were performed by a batch method under ambient conditions. The physicochemical behaviors of the adsorbents were obtained using BET, XRD, XRF, TG-DSC, SEM/EDAX, and XPS. The sulfur concentration in the mixture was monitored by UV-vis spectrophotometry. The adsorption reaction confirmed that ZnO played a crucial role in taking up S element to convert it into ZnS. The deposition of nickel on ZnO is an innovative approach which takes advantage of the selectivity of Ni towards S species and the high adsorptive capacity of ZnO support.

11:45 AM

**Extending the Effective Range of Wilkinson's Method Via a Geometry-Based Pattern Center Correction Algorithm:** *Calvin Gardner*<sup>1</sup>; Brent Adams<sup>1</sup>; David Fullwood<sup>1</sup>; <sup>1</sup>Brigham Young University

Electron Backscatter Diffraction based Orientation Imaging Microscopy has generated worldwide interest in the localized recovery of the elastic displacement gradient tensor in diverse crystalline materials. Wilkinson's cross-correlation based method, with angular resolution of  $\pm 0.006^\circ$ , is sufficiently precise to determine the sought-after tensor. However, the method is limited by reliance on the comparison of two like oriented patterns that must be of similar pattern center, collected within  $\sim 75$  micrometers of one another. Moreover, if the absolute pattern center is not known, the method's accuracy decreases correspondingly. Both a single crystal germanium scan and a series of simulations are presented to demonstrate the problems of pattern center variation and imprecise absolute pattern center. An analytic algorithm based in system geometry is employed to correct for pattern center variations and the effective range of Wilkinson's method is extended to  $\sim 500$

micrometers. Additionally, an analysis of the necessary absolute pattern center precision is presented.

#### 12:00 PM

**Thermodynamical Studies on the Carbothermal Reduction and Nitride Preparing for Vanadium Nitride:** *SS Yu<sup>1</sup>; WX Li<sup>1</sup>; ZL Ji<sup>1</sup>; NX Fu<sup>2</sup>; ZT Sui<sup>2</sup>*; <sup>1</sup>Shenyang University of Chemical Technology; <sup>2</sup>Northeastern University

In this paper, the producing process of using V<sub>2</sub>O<sub>3</sub> as raw material to obtain vanadium nitride was analyzed through the predominance area diagrams. The analysis shows that VN-phase can be accessed in the conversion process of V<sub>2</sub>O<sub>3</sub> by controlling gas phase composition and temperature of the reaction system and the one-step method preparing for vanadium nitride is feasible. Thermalgravimetric analysis and X-ray diffraction were used to determine the reaction pathways of vanadium carbide, namely the following sequential reaction: V<sub>2</sub>O<sub>3</sub>  $\square$  V<sub>8</sub>C<sub>7</sub> in higher temperature stage, the rule of vanadium nitride synthesized was established, and defined conditions of temperature for the production of the carbides and nitrides were determined. The nitridation process is simultaneous with the carbothermal reduction. A one-step mechanism of the carbothermal reduction with simultaneous nitridation led to a lower terminal temperature in nitridation process for vanadium nitride produced, compared with that of carbothermal reduction process without nitridation.

**Development of a Novel High-Chloride Circuit for the Starfield Resources' Ferguson Lake Project:** *Mike Dry<sup>1</sup>; Niels Verbaan<sup>2</sup>; Ernesto Bourricaudy<sup>2</sup>; Michael Moran<sup>3</sup>*; <sup>1</sup>Arithmetek Inc.; <sup>2</sup>SGS Canada Lakefield; <sup>3</sup>Starfield Resources Inc.

Starfield Resources is developing a novel circuit for the recovery of nickel, copper, cobalt, iron oxide and possibly also precious metals from the Ferguson Lake deposit in Nunavut, Canada. This deposit contains massive sulphides in which pentlandite is too finely disseminated in pyrrhotite for the production of a smelter-grade nickel concentrate at anywhere near an acceptable nickel recovery, meaning that commercial exploitation of this orebody is not possible via established technology. The circuit under development contains leaching, oxidation of ferrous chloride, hydrolysis of ferric chloride to saleable hematite and gaseous hydrochloric acid that is recycled and conventional steps for separating and recovering the valuable metals from the solution after hydrolysis. This paper presents a process model of the circuit and the results of experimental work on the main enabling steps, viz. the leaching, the oxidation of ferrous chloride and the hydrolysis of ferric chloride to hematite and gaseous hydrochloric acid.

#### 9:20 AM

**Synthesis of TiO<sub>2</sub> by an Innovative Atmospheric Mixed Chloride Leach Process:** *V.I. Lakshmanan<sup>1</sup>; Ram Sridhar<sup>1</sup>; Raja Roy<sup>1</sup>*; <sup>1</sup>Process Research Ortech Inc.

TiO<sub>2</sub> is used in paints, plastics, rubber, paper, inks, textiles and other miscellaneous applications. The demand for the pigment grade TiO<sub>2</sub> is growing at 3.0% on average and this invites for the development of innovative and cost effective processes. The current processes are not designed to recycle the reagents and thereby discharge the effluents into the environment causing an environmental concern.

During this study, synthesis of TiO<sub>2</sub> from an ilmenite concentrate was investigated using an innovative atmospheric mixed chloride leach process. The solution purification was carried out using solvent extraction in two stages. In the first stage iron removal was carried out and in the second stage titanium was extracted. The strip solution obtained from the second stage solvent extraction contained the purified titanium and from this stream pigment grade TiO<sub>2</sub> was recovered. The barren solution was used for reagent recovery and the regenerated leach liquor was recycled.

#### 9:45 AM

**Solvent Extraction for the Separation into Nickel and Cobalt with Anionic Extractant:** *Tomohiko Yokogawa<sup>1</sup>; Satoshi Matsumoto<sup>1</sup>; Nobuhiro Matsumoto<sup>1</sup>*; <sup>1</sup>Sumitomo Metal Mining Co., Ltd.

At Niihama Nickel Refinery (NNR), the plant capacity of electrolytic nickel expanded from 36kt/A to 41kt/A as nickel/cobalt mixed sulfide (MS) feed increased. At the same time, cobalt input from MS also increased. For the separation into nickel and cobalt, NNR has installed a solvent extraction process by using tri-n-octylamine (TNOA) as anionic extractant to change into the effective purification. As a result, NNR has achieved cost reduction, more stable operation and products of better quality, comparing new process with conventional ones of oxidation and neutralization. This paper describes improvements of the operation conditions such as continuous phase control.

#### 10:25 AM

**Integrated Plant to Recover Zinc, Lead and Silver from Crude Zinc Oxides Applying ZINCEX and PLINT Technologies:** *Carlos Frias Gomez<sup>1</sup>; Gustavo Diaz<sup>1</sup>; Daniel Martin<sup>1</sup>; Francisco Sanchez<sup>1</sup>; Ana Mejias<sup>1</sup>*; <sup>1</sup>Tecnicas Reunidas

Crude zinc oxides are the major source of secondary zinc and are produced from fuming processes like Waelz kilns. The impurities of crude zinc oxides make difficult their processing in primary zinc refineries due to mainly high chloride tenor. Washing with sodium carbonate is a costly operation and chloride removal efficiency is not good enough, so further purification steps are required. The crude zinc oxides are easily treated using ZINCEXTM technology based on leaching, solvent extraction, and electrowinning. The ZINCEXTM process is commercially available and is designed to be a perfect barrier for impurities and halogens, allowing selective zinc extraction in mixed chloride and sulphate leaching solutions. Other valuable components like lead and silver can be efficiently recovered from the leaching residue using PLINT technology in chloride media. Silver is recovered as silver cement and lead is precipitated as pure lead oxide or carbonate able for smelting at low temperature.

#### 10:45 AM

**N,N'-Tetrasubstituted Malonamide Derivatives and Hydrochloric Acid Solutions: An Interfacial Study:** *Maria Soledade Santos<sup>1</sup>; Marc Font Cornella<sup>1</sup>; João Nuno Reis<sup>1</sup>; Sandra Santos Reis<sup>1</sup>; Ana Paiva<sup>1</sup>*; <sup>1</sup>FCUL

N,N'-tetrasubstituted malonamides have increasingly been used as extractants for various metal ions, such as Fe(III) and platinum-group metals, from HCl media, hence it is important to understand the involved interfacial phenomena. In this work, the influence of the malonamide structure, acidity of the aqueous phase and diluent on the equilibrium interfacial tension (IT) of N,N'-dimethyl-N,N'-diphenylmalonamide and N,N'-dimethyl-N,N'-dicyclohexylmalonamide in 1,2-dichloroethane, and N,N'-dimethyl-N,N'-dicyclohexylmalonamide in toluene, with aqueous HCl, were investigated.

ITs were determined using the Du Nouy ring method. Densities of the organic phases were also determined, and used to screen solute-diluent interactions. Formation of third phases was never observed; furthermore, ITs increase with the phase separation period, constant values being obtained for separation periods larger than 1000 seconds. Each malonamide interfacial efficiency at the oil/water interface is interpreted in terms of malonamide basicity, diluent polarity and malonamide - hydrochloric acid- diluent interfacial interactions.

#### 11:10 AM

**Recovery of Precious Metals from Base Metal Sulfide Ores by a Hydrometallurgical Process:** *V.I. Lakshmanan*<sup>1</sup>; Ram Sridhar<sup>1</sup>; Raja Roy<sup>1</sup>; <sup>1</sup>Process Research Ortech Inc.

Base metals and PGMs are currently recovered from sulfide concentrates using pyrometallurgical processes. These processes suffer from several limitations such as being capital intensive, scaling problems, SO<sub>2</sub> emissions and long delay in value recognition. Alternative hydrometallurgical technologies have so far not been successful and currently total pressure oxidation and partial pressure oxidation hydrometallurgical technologies are being evaluated. Process Research ORTECH has developed a unique hydrometallurgical process to recover base metals and precious metals using mixed chloride technology. In a first stage leach, base metals are recovered and elemental sulfur is liberated from hydrogen sulfide formed during this leaching stage. During second stage leach, precious metals are recovered using proven separation technologies. Some of the advantages of the process are the recovery of elemental sulfur from sulfide sulfur, recycle of the chloride lixiviant thereby eliminating effluent treatment steps and use of excess energy from the Claus reactor for the pyrohydrolysis step.

#### 11:35 AM

**Recovery of Precious Metals from Chloride Media Using Microalgae Waste from Biofuel Extraction:** *Katsutoshi Inoue*<sup>1</sup>; Kanjana Khunathai<sup>1</sup>; Keisuke Ohto<sup>1</sup>; Hidetaka Kawakita<sup>1</sup>; Kinya Atsumi<sup>2</sup>; Hisaya Kato<sup>2</sup>; <sup>1</sup>Saga University; <sup>2</sup>Denso Corporation

Crosslinked microalgae were prepared from the residue generated in the production of biofuel, by crosslinking-condensation in concentrated sulfuric acid. These microalgae were tested for adsorption of various metal ions in hydrochloric acid medium. The crosslinked microalgae exhibited high selectivity for Au(III) over other precious and base metal ions. From an isotherm experiment, the maximum adsorption capacity was evaluated to be 3.25 mol/kg of dry gel for Au(III) which was many times higher than that of the original microalgae residue. SEM and X-ray diffraction confirmed the formation of metallic gold particles, suggesting the occurrence of a redox reaction between surface functional groups on the gel surface and trivalent gold ion.

## Computational Thermodynamics and Kinetics: Defects: Thermodynamics and Kinetics of Grain Boundaries, Interfaces, Surfaces and Dislocations

#### 8:30 AM

**Grain Boundary Energy in Binary Alloys:** *Jonathan Stolle*<sup>1</sup>; Nikolas Provatas<sup>1</sup>; <sup>1</sup>McMaster University

The microstructure of a metal -- and hence grain boundaries -- determines its macroscopic properties. The structural component of grain boundary energy is analytically described by the Read-Shockley (RS) Law (1951). The RS law can be applied rigorously for the low angle grain boundaries, where it is related to elastic coefficients, and empirically for large angles. Recently, Elder and Grant (2004) and Mellenthin et al (2008) have used a phase field crystal method (PFC) to demonstrate that the Read Shockley law can be used to describe grain boundary energy in pure materials. This work extends those investigations by using a binary alloy PFC model in conjunction with the Gibbs absorption theorem to systematically investigate the role of alloying impurities on grain boundary energy, wetting, and pre-melting.

#### 8:45 AM

**A First Principles Investigation into Hydrogen-Grain Boundary Binding in bcc Fe:** *William Counts*<sup>1</sup>; Ron Gibala<sup>2</sup>; Chris Wolverton<sup>1</sup>; <sup>1</sup>Northwestern University; <sup>2</sup>University of Michigan

Hydrogen embrittlement of iron and steels is a classic but still unresolved problem in metallurgy. While hydrogen can freely move through the Fe lattice, its diffusion is hindered by lattice imperfections. Experimentally quantifying the binding energy of hydrogen to these defects has proven to be difficult. Fortunately, computational tools are ideally suited to study defect trapping because it is possible to isolate individual traps. Density function theory was used to quantify the binding energy of hydrogen to a number of Sigma boundaries in bcc Fe. We find that the H-Sigma boundary binding energies range from 0.1 to 0.5 eV. We observe that the H binding energy to Sigma boundaries with mirror symmetry across the grain boundary plane correlates with grain boundary energy, while the H binding energy for boundaries without the mirror symmetry is related to the grain boundary volume.

#### 9:00 AM

**Interaction of Grain Boundaries with Voids:** *Stephen Foiles*<sup>1</sup>; <sup>1</sup>Sandia National Laboratories

The Zener-Smith model for the pinning of microstructures by precipitates assumes that the interaction energy between the precipitate and boundary is given by the product of the grain boundary energy times the area of the intersection of the precipitate with the boundary. Here we perform atomic-scale simulations of the interaction energy between a grain boundary and a void in Ni in order to test this assumption. It is found that the interaction energy is close to the Zener-Smith approximation, but that a better estimate is obtained if one includes an additional energy term that dimensionally is equivalent to a line energy associated with the boundary-void junction. Sandia

is a multi-program laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under Contract DE-AC0494AL85000.

#### 9:15 AM

**On the Interaction of Point Defects with Semicoherent Heterophase Interfaces:** *Kedarnath Kolluri*<sup>1</sup>; Michael Demkowicz<sup>1</sup>; <sup>1</sup>Massachusetts Institute of Technology

We use atomistic modeling to investigate the relation between atomic structure of semicoherent heterophase interfaces and their interaction with point defects. Using Cu-Nb Kurdjumov-Sachs interfaces as a model system, we show that misfit dislocations present at such interfaces play a governing role in point defect absorption and migration. Interactions between point defects and the interface misfit networks can be described quantitatively within dislocation theory. Implications of these insights for predicting point defect interactions with interfaces in other orientations like Nishiyama-Wasserman and in other semicoherent heterophase systems like Cu-V are discussed. This material is based upon work supported as part of the Center for Materials at Irradiation and Mechanical Extremes, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number 2008LANL1026.

#### 9:30 AM

**First Principles Modeling of Dislocation/Twin Boundary and Oxygen Solute Interactions in Ti:** *Maryam Ghazisaeidi*<sup>1</sup>; Dallas Trinkle<sup>1</sup>; <sup>1</sup>university of Illinois at Urbana-Champaign

Interaction of gliding dislocations and twin boundaries influences the plastic deformation of titanium. In addition, oxygen greatly affects both strength and twinning in Ti. Predictive models of strength and twinning rely on understanding the underlying atomic-scale deformation mechanisms. We model a [1-210] screw dislocation interacting with a Ti (10-12) twin boundary using density functional theory that provides more accurate results for dislocation/twin boundary interactions compared to previous classical potential approaches and allows for considering the effects of oxygen. Flexible boundary conditions are used to calculate the accurate geometry. We compute the dislocation core structure and transmission stresses through the boundary and repeat these calculations with an oxygen solute. This is a computationally tractable approach that marks the first ab initio study of isolated line defects in interfaces. The results show the effect of oxygen on core structure and transmission mechanisms of a screw dislocation interacting with a twin boundary.

#### 9:45 AM

**Stacking Fault Energies in Fe-Mn-C: Ab Initio Determination of Thermodynamic and Chemical Trends:** *Alexey Dick*<sup>1</sup>; Tilmann Hickel<sup>1</sup>; Afshin Abbasi<sup>1</sup>; Joerg Neugebauer<sup>1</sup>; <sup>1</sup>Max-Planck-Institut fuer Eisenforschung GmbH

High-Mn steels are promising candidates for light-weight high-strength materials. Their excellent mechanical properties are caused by sophisticated deformation mechanisms: the transition induced and the twinning induced plasticity. The preference of a certain mechanism is directly related to the stacking fault energy (SFE) of the material. The latter can be determined using CALPHAD based Gibbs free energies in relations that typically contain empirical, experimentally not accessible parameters. Extending the concept of density functional theory to finite temperatures by taking the effect of lattice vibrations, chemical and magnetic disorder into account, we were able to determine the chemical trends for both, the empirical parameters and the stacking fault energy. A combination of this knowledge with CALPHAD bulk data allows to predict mechanism maps over the entire composition range of Fe-Mn-C alloys.

**Topological Characteristics and Events in 3D Grain Growth:** *Burton Patterson*<sup>1</sup>; Robert DeHoff<sup>1</sup>; Alan Sprague<sup>2</sup>; Zhiwei Sun<sup>2</sup>; Veena Tikare<sup>3</sup>; <sup>1</sup>University of Florida; <sup>2</sup>University of Alabama at Birmingham; <sup>3</sup>Sandia National Laboratory

Topological description of the 3D grain structure throughout grain growth provides a novel insight into the process. Characteristics investigated include stability of the grain volume and face class distributions and the tendencies for different grain classes to have preferred contact and interaction among themselves and with different topological events, such as contacting a disappearing grain or making or breaking contact, respectively, to form and lose faces. Characterization of grain shape enables following the path of topological decay of grains to final disappearance. The balance of the different topological rates of the different face classes leads to the eventual stability of the face and volume distributions. Determination of these parameters is available from 3D computer simulation and serial sectioning.

#### 10:30 AM

**An Inverse Problem in Nucleation and Growth:** *Mark Jhon*<sup>1</sup>; Siu Sin Quek<sup>1</sup>; David Wu<sup>1</sup>; <sup>1</sup>Institute of High Performance Computing

There has been recent interest in constructing realistic, polycrystalline microstructures based on a given grain size distribution. Such configurations may be analyzed using various simulation techniques to help develop property-structure relationships. Methods based on the reverse Monte Carlo algorithm have been shown to be very successful in reproducing size distributions. However, such methods have not yet been related to a physically meaningful growth process. In the present study, reverse Monte Carlo algorithms are developed that are consistent with diffusion-limited and interface-limited growth. These techniques are compared using characteristics of the grain distribution that are not explicitly fitted.

#### 10:45 AM

**Application of a Monte Carlo Grain Growth Simulation to Test the Growth Path Envelope Analysis Formalism:** *Robert DeHoff*<sup>1</sup>; Burton Patterson<sup>1</sup>; Alan Sprague<sup>2</sup>; Zhiwei Sun<sup>2</sup>; Veena Tikare<sup>3</sup>; <sup>1</sup>University of Florida; <sup>2</sup>University of Alabama at Birmingham; <sup>3</sup>Sandia National Laboratory

During grain growth the volume of a grain varies with time along some path,  $V = V(V_0, t)$ , called its growth path. The collection of growth paths for all the grains in the structure is defined to be the growth path envelope for the process. Analysis of a Monte Carlo simulation of grain growth developed at Sandia National Laboratories permits the full determination of the growth path envelope. This envelope is not directly experimentally accessible for grain growth in real physical grain structures. However, an analysis exists that permits its determination from the time dependence of the grain volume distribution, which is experimentally accessible. At the base of this analysis are two critical assumptions. The simulation provides both the growth path envelope and the time dependence of the grain volume distribution, and therefore an assessment of the applicability of these assumptions in modeling real grain growth.

#### 11:00 AM

**Phase Field Simulation of Grain Growth in a System with Dissolving Precipitates:** *Sina Shahandeh*<sup>1</sup>; Matthias Militzer<sup>1</sup>; <sup>1</sup>University of British Columbia

Controlling grain boundaries migration with addition of second phase particles has important technological applications. Conventional theories assume inert particles. However, in many processes particles are not stable at high temperature. Dissolution of precipitates changes particles size and volume fraction thus decreasing particle pinning force on the interface. On the other hand, particle dissolution injects solutes to the matrix therefore increasing solute drag effect. Phase field method has been used to simulate grain growth combined with an effective formulation for the interface drag using a friction force. The approach includes interface drag caused by both particles and solutes. Kinetics of grain growth and grain size distributions have been predicted in 3D simulations. Based on these studies conditions can

MONDAY AM

be quantified where the variable interface drag due to gradual dissolution of particles can trigger abnormal grain growth.

**11:15 AM**

**A Phase-Field Model for Recrystallization Grain Growth: Effects of Grain Boundary Energy Anisotropy and Second-Phase Particles:**

*Mohsen Asle Zaeem*<sup>1</sup>; *Haitham El Kadiri*<sup>1</sup>; *Paul Wang*<sup>1</sup>; *Mark Horstemeyer*<sup>1</sup>;  
<sup>1</sup>Mississippi State University

We use a phase-field model to investigate the effects of grain boundary (GB) energy anisotropy and the presence of second-phase inert particles on grain growth (GG) in polycrystalline materials. Different conditions are studied. System of grains with anisotropic GB energies is considered by including models of low and high misorientation angles between adjacent grains. Systems without particles reach a steady state grain growth rate and this rate decreases by including GB anisotropy. The presence of particles significantly alters the microstructures during grain growth. It was shown that for systems with particles the critical average grain size to stop grain growth depends not only on volume fraction and size of particles but also on GB anisotropy.

**11:30 AM**

**Phase-Field Simulation of Segregation to Stacking Fault (Suzuki Effect) in Co-Ni Based Superalloy:**

*Yuichiro Koizumi*<sup>1</sup>; *Sho Suzuki*<sup>1</sup>; *Takuma Otomo*<sup>1</sup>; *Shingo Kurosu*<sup>1</sup>; *Yunping Li*<sup>1</sup>; *Hiroaki Matsumoto*<sup>1</sup>; *Akihiko Chiba*<sup>1</sup>;  
<sup>1</sup>Tohoku University

Co-Ni based superalloy exhibits excellent high-temperature mechanical properties[1,2] and peculiar microstructural development such as: good creep resistance with dynamic strain aging, ultra-grain refinement by conventional rolling-and-annealing process and very wide extension of stacking faults (SFs). These behaviors have been attributed to the chemical interaction between SFs and solute atoms, i.e. Suzuki effect. However, Suzuki effect has not been verified either experimentally or theoretically. In this study, a phase-field simulation for evaluating Suzuki effect has been developed and applied to Co-33Ni-20Cr-10Mo (wt%) alloy which exhibits the peculiar behaviors remarkably. The simulation suggested that Co-segregation and Ni-depletion can be very significant, and the deviation in concentration can exceed 10wt% at 973 K, for instance. Thus, Suzuki effect has been verified computationally. This approach may be applicable to many alloys for optimizing material properties. [1] Takahashi, Sugawara, Chiba: US Patents 2005/0016645 A1, [2] Chiba et al. Philos Mag A 1999;79:1533.

**11:45 AM**

**Simulating Triple Junction Drag Using a 2D Phase Field Model:**

*Anthony Johnson*<sup>1</sup>; *Peter Voorhees*<sup>1</sup>; <sup>1</sup>Northwestern University

Two-dimensional grain growth kinetics have been shown to deviate from the classical Von Neumann-Mullins relation at low temperatures or for small grains due to limited triple junction mobility. A multiorder parameter phase field model was developed to account for triple junction mobility. In a tri-crystal system, decreasing the triple junction mobility causes the triple junction velocity to decrease and the angle to decrease well below its isotropic equilibrium value of  $120\sqrt{176}$ . For a range of triple junction mobilities, this simple geometry remains consistent with the analytical theory developed by Gottstein and Shvindlerman, et al. Triple junction energies have also been measured as a function of the parameters in the phase field model. For larger 2D polycrystalline systems, preliminary simulations using this model show that the triple junction mobility significantly alters (quantitatively and qualitatively) the grain growth kinetics: triple junction angles deviate significantly from  $120\sqrt{176}$  and the growth rate is slowed.

**12:00 PM**

**Thermal-Activated Buckling Swapping of Topological Defects in Graphene:**

*Chun-Wei Pao*<sup>1</sup>; *Te-Huan Liu*<sup>2</sup>; *Chien-Cheng Chang*<sup>2</sup>; <sup>1</sup>Research Center for Applied Sciences, Academia Sinica; <sup>2</sup>Institute of Applied Mechanics, National Taiwan University

Topological defects in graphene, such as dislocations and grain boundaries, often introduce out-of-plane bucklings. For example, symmetrical tilt grain boundaries in graphene are consisted of regular arrays of dislocations,

and some of them can introduce bucklings. In this paper, we present our recent long-time-scale accelerated molecular dynamics simulation results on the swapping dynamics of these out-of-plane bucklings at symmetrical tilt graphene grain boundaries. We demonstrate that these even-distributed out-of-plane bucklings along grain boundaries can have thermal-activated deflections swapping: they can swap from deflecting upward to downward with rates up to thousands of times per second at room temperature. Our discovery will shed new lights on the mechanisms of defects migration in graphene, and the potential possibilities of fabricating extremely durable nanoscale actuators.

**12:15 PM**

**Defects in Ferrite: An Ab Initio Based Description of Long-Range Elastic Effects:**

*Alexander Udyansky*<sup>1</sup>; *Johann von Pezold*<sup>1</sup>; *Alexey Dick*<sup>1</sup>; *Vladimir Bugaev*<sup>2</sup>; *Jörg Neugebauer*<sup>1</sup>; <sup>1</sup>Max-Planck-Institut für Eisenforschung GmbH; <sup>2</sup>Max-Planck-Institut für Metallforschung

We study interstitial Fe-based solid solutions containing C, N, O, B, C+N and H impurities by combining first principles simulations with the reciprocal space microscopic elasticity theory (MET), which allows us to account for long-ranged elastic interactions. The short-range chemical interactions, as well as the parameters entering the MET are obtained by density functional theory (DFT) in the generalized gradient approximation, using rather modest supercell sizes. This approach provides a direct insight into the formation mechanism of martensite and its stability limits: in particular, tetragonal states are predicted to be preferred even at low impurity concentrations due to a thermodynamically driven orientational ordering of impurities. The temperature of the martensitic cubic-tetragonal transition is found to be in agreement with available experimental data and sensitively depends on the external pressure. Furthermore, the impurity content strongly affects the vacancy concentration within the host matrix.

**What Controls the Choice of the Slip Systems in Different Compounds with B2 Structure:** *Vasek Vitek*<sup>1</sup>; *Yi-Shen Lin*<sup>1</sup>; *Miroslav Cak*<sup>1</sup>; *Vaclav Paidar*<sup>2</sup>; <sup>1</sup>University of Pennsylvania; <sup>2</sup>Academy of Sciences of the Czech Republic

Usual slip systems in B2 compounds are  $\langle 111 \rangle \{101\}$  and  $\langle 010 \rangle \{101\}$  but different slip systems dominate in different alloys. The dislocation property that often controls the choice of the slip system is dislocation dissociation and thus available stacking fault-like defects. A common wisdom has been that such fault is the  $\frac{1}{2}\langle 111 \rangle$  APB but, as shown in 1981 by Pope and co-workers, it may but need not exist. The existence of stacking faults was studied by calculating  $\{101\}$  \{111\}-surfaces in nine B2 compounds using a density functional theory based method. The displacement vectors of stacking fault-like defects differ from  $\frac{1}{2}\langle 111 \rangle$ . Using this information and anisotropic elasticity theory we analyzed dislocation dissociations and

concluded that in order to decide which slip system dominates it is necessary to consider elastic anisotropy, vectors of stacking faults and their energies. The corresponding analysis is in full agreement with observations.

**Recent Development of Porous Materials Based on Aluminide Intermetallics:** *C. T. Liu*<sup>1</sup>; Yuehui He<sup>2</sup>; Baiyun Huang<sup>2</sup>; <sup>1</sup>Hong Kong Polytechnic University; <sup>2</sup>Central South University

Porous metals are of great interest as a potential engineering material in various industrial fields. Aluminide intermetallics based on TiAl, NiAl and FeAl are particularly suitable for use as porous materials for gas and liquid permeation applications because of their good oxidation resistance at elevated temperatures, high corrosion resistance in acid and alkali solutions, good high and room temperature strength, and excellent thermal shock resistance. This paper summarizes the recent work on low-cost manufacturing of aluminide porous materials by self-propagation high-temperature synthesis, where the size, shape and their distribution can be well controlled by exothermal reactions and preheating conditions. The near-net-shape porous tubes have been verified to possess excellent corrosion & oxidation resistance, microstructure stability, and mechanical strength for filtering industrial applications. \*This research was supported by Natural Science Foundation and National High-Tech R&D Program of China, and internal funding from Honk Kong Polytechnic University

**Size-Affected Flow and Intermittency in Small Ni3Al Crystals:** *Dennis Dimiduk*<sup>1</sup>; Michael Uchic<sup>1</sup>; Ed Nadgorny<sup>2</sup>; Satish Rao<sup>3</sup>; Jaafar El-Adawy<sup>4</sup>; Paul Shade<sup>4</sup>; Chris Woodward<sup>1</sup>; <sup>1</sup>Air Force Research Laboratory; <sup>2</sup>Michigan Technological University; <sup>3</sup>UES, Inc.; <sup>4</sup>UTC, Inc.

Experimental studies reveal that nano- and micrometer-scale crystals show strengthening effects, irrespective of the material type. Their flow behavior is characterized by four clear attributes: (i) a rising flow stress with decreasing sample size; (ii) stochastic variation in flow stress that exhibits wider scatter at smaller sample sizes; (iii) intermittent flow as revealed by either repeated load drops or constant-stress flow avalanches; and (iv) an extended elastic-plastic transition. These attributes are known for FCC, BCC and HCP metals, LiF and other metallic alloys. However, studies show that Ni3Al exhibits selected unique characteristics at small scales. The present work examines the microcrystal phenomenology of Ni3Al and, evaluates behavior mechanisms relative to samples size or conditions for this material. The evaluation suggests that limitations exist for understanding Ni3Al behavior from current data and, that some of these limitations pertain for microcrystal deformation behavior more generally.

#### 10:05 AM

**Plasticity of L1<sub>2</sub> Intermetallics: A New Insight Using AFM Observations:** *Joël Bonneville*<sup>1</sup>; Christophe Coupeau<sup>1</sup>; <sup>1</sup>University of Poitiers

Atomic force microscopy (AFM) is an experimental technique that allows for the investigation of surface structures at the atomic scale, which is particularly sensitive to surface relief. When dislocations move on crystallographic planes, they produce steps at the intersection of these planes and the crystal surfaces. The steps appear as lines at the sample surface, whose tracking gives information on dislocation movements. Slip lines are therefore intimately associated with both the crystal structure and plastic deformation, and give useful information concerning the elementary dislocation processes. We intend to present a study of L1<sub>2</sub> intermetallic plasticity using AFM by investigating the number, height and length of slip lines that reflect dislocation source activity and dislocation mean free path, which are key parameters for the understanding of crystal plasticity. The contribution of D. Pope to the understanding of the plastic behaviour of L1<sub>2</sub> intermetallics will be highlighted.

**Properties of New Cobalt Alloys with High Volume Fractions of Ordered Precipitates:** *Tresa Pollock*<sup>1</sup>; Akane Suzuki<sup>2</sup>; <sup>1</sup>University of California Santa Barbara; <sup>2</sup>GE Global Research

New cobalt-base alloys containing ordered L12 precipitates have been investigated. Two phase  $\gamma-\gamma'$  microstructures are maintained with additions of Cr, Mo, Ni, Re, Ta and V to the ternary Co-Al-W system. Solidus and liquidus temperatures are 100 – 150°C higher than advanced nickel-base single crystal alloys strengthened with the L12 phase. An anomalous rise in flow stress with temperature is observed. The temperature dependence of deformation mechanisms has been studied. Single crystals have been solidified and partitioning during solidification is limited in the ternary system, suggesting a high resistance to convective instabilities. Directions for alloy design will be discussed.

#### 11:00 AM Invited

**Temperature Dependence of Yield Stress and Dislocation Dissociation in L12-Ordered Intermetallic Compounds:** *Haruyuki Inui*<sup>1</sup>; <sup>1</sup>Kyoto University

L12 compounds are usually classified into three groups depending on their yield stress versus temperature curves. All these temperature dependences of yield stress have been explained in terms of the planarity of dislocation cores. While the core of 1/2[110] dislocations separated by APB on {111} is planar, those of 1/2[110] dislocations separated by APB on {001} and 1/3[121] dislocations separated by SISF on {111} are believed to be non-planar, giving rise to the rapidly decreasing yield stress at low temperatures for some types of L12 compounds such as Pt3Al and Co3Ti. However, our recent study indicates that the rapidly decreasing yield stress at low temperatures can also be observed for many L12 compounds with dislocations being dissociated into two 1/2[110] partials separated by APB on {111}. The classification of L12 compounds in terms of the temperature dependence of yield stress is discussed in relation to the observed dislocation dissociation modes.

**Microstructure and Mechanical Properties of Dual Two-Phase Intermetallic Alloys Composed of Geometrically Close Packed Ni<sub>3</sub>Al and Ni<sub>3</sub>V Structures:** *Takayuki Takasugi*<sup>1</sup>; Yasuyuki Kaneno<sup>1</sup>; <sup>1</sup>Osaka Prefecture University

The so-called dual two-phase intermetallic alloy, which is composed of Ni<sub>3</sub>Al(L1<sub>2</sub>) and Ni solid solution (A1) phases at high temperature and is additionally refined by a eutectoid reaction at low temperature aging, according to which the Al phase is decomposed into the Ni<sub>3</sub>Al(L1<sub>2</sub>)+Ni<sub>3</sub>V(DO<sub>22</sub>) phases, was recently developed. The dual two-phase intermetallic alloys showed high tensile strength, accompanied with high tensile elongation and fracture toughness over a broad temperature range, and also superior oxidation/corrosion resistance. Also, wear resistance at high temperature was very excellent and therefore attractive as high temperature tool. The obtained results are thus promising for the development of the dual two-phase intermetallic alloy as a new-type of high-temperature structural material. In the presentation, microstructure, various properties and applications of dual two-phase intermetallic alloys will be presented.

## Dynamic Behavior of Materials V: Fundamentals of Dynamic Behavior

#### 8:40 AM Keynote

**Impact Testing and Dynamic Behavior of Materials:** *Lothar Meyer*<sup>1</sup>; Norman Herzig<sup>1</sup>; Frank Pursche<sup>1</sup>; Shawkly Abdel-Malek<sup>1</sup>; <sup>1</sup>Nordmetall GmbH

An overview about different testing facilities and the mechanical material behavior including monoaxial and multi axial testing under high rate loading is given. Special emphasis is laid on difficult loading conditions and loading states like high temperature and high strain loading ( $T > 1200^{\circ}\text{C}$ ,  $\dot{\gamma} > 1$ ) and multiaxial impact tests. Thereby, the impact behavior of selected materials is presented and compared under different loading conditions. A distinction is made between virgin and manufactured material behavior (e.g. welding) or pre-damaged materials. Especially, if the influence of the manufacturing history is investigated, under certain loading states the impact material properties show a dramatic difference compared to virgin material state. This paper shows some examples of different material behavior under the conditions described before.

#### 9:20 AM

**Atomistically-Informed Dislocation Dynamics Simulations of High Rate Deformation of Single fcc Crystals:** *Zhiqiang Wang*<sup>1</sup>; <sup>1</sup>University of North Texas

Predicting dynamic deformation of single fcc crystals with dislocation dynamics (DD) has been a new computational approach to connecting fundamental dislocation mechanisms and microstructure evolutions to macroscopic behavior of materials. In DD method, some physical parameters are essential in controlling the behavior of individual dislocations, and thereafter macroscopic properties. Dislocation mobility is one of the most important among them, which are hard to be measured with experimental techniques while critical to the fidelity of DD methods. This talk will present some results of determining dislocation mobility under complex loading conditions with atomistic simulations. Large scale DD simulations, integrating atomistic results, are applied to predict stress-strain curves of single crystal materials in high rate deformation. It is shown that accurate dislocation mobility information is of paramount importance to develop a reliable mesoscale DD method.

#### 9:40 AM

**Plastic Response of Low- and High-Energy Grain Boundaries in Copper under Shock Loading:** *Christian Brandl*<sup>1</sup>; Timothy Germann<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

Previous molecular dynamics (MD) simulations have revealed that the preferred nucleation sites for partial dislocations at grain boundaries are related to the local atomic interface structure. Moreover, shock experiments discovered different post-mortem defect structures for low-energy and high-energy grain boundaries. In the present study, MD simulations are conducted to understand the structural origin of the differences in dislocation activity under shock compression, and failure upon unloading. We present MD simulations of shock/spallation loading conditions in copper bicrystals corresponding to grain boundaries studied in recent shock experiments. The defect structures produced in the MD studies are compared with the

experimental post-mortem defect analysis, and the differences in the dynamic response are discussed in terms of the local grain boundary structures.

#### 10:00 AM

**Void Initiation, Growth and Collapse in BCC Tantalum: Molecular Dynamics Simulations:** *Yizhe Tang*<sup>1</sup>; Eduardo Bringa<sup>2</sup>; Bruce Remington<sup>3</sup>; Marc Meyers<sup>1</sup>; <sup>1</sup>University of California, San Diego; <sup>2</sup>Univ. Nac.Cuyo; <sup>3</sup>Lawrence Livermore National Laboratory

The growth and collapse of nanoscale voids in BCC tantalum is investigated under different stress states and strain rates. Three principal mechanisms of deformation were identified and quantitatively evaluated: (a) shear loop emission and subsequent expansion from the surface of the void; (b) cooperative shear loop emission from slip planes that parallel to the same  $\langle 111 \rangle$  slip direction and their combination, forming prismatic loops; (c) twinning starting at the void surface. The generation and evolution of these defects is found to be a function of stress state and strain rate. Void initiation in Nanocrystalline tantalum was also discussed

#### 10:20 AM Break

#### 10:30 AM Invited

**Atomistic Simulations of Shock-Induced Plasticity in Tantalum:** *Eduardo Bringa*<sup>1</sup>; J. Hawreliak<sup>2</sup>; N. Park<sup>3</sup>; A. Higginbotham<sup>4</sup>; <sup>1</sup>CONICET-Universidad Nacional de Cuyo; <sup>2</sup>Lawrence Livermore National Laboratory; <sup>3</sup>AWE; <sup>4</sup>University of Oxford

We have carried non-equilibrium atomistic simulations of shocks in tantalum, using 0.5-100 million atoms, with samples nearly 1 micron long and shock rise times of up to 200 ps. Our samples include perfect single crystals, single crystals with dislocation sources, and polycrystals. We find agreement with the experimental Hugoniot of polycrystalline Ta up to ~20% compression. We present an analysis of the resulting plastic behavior as a function of strain rate and shock pressure. There is no homogeneous nucleation of dislocations as in simulations of fcc metals. Dislocations originate only from pre-existing dislocations sources. Twinning dominates plastic deformation at high stress and strain rate, as suggested by high pressure recovery experiments from gas-guns. X-ray diffraction simulations are used to mimic future experiments that will take advantage of dynamic diffraction capabilities.

#### 11:00 AM

**The Viscosity of Liquid Tantalum\*:** *James Belak*<sup>1</sup>; <sup>1</sup>Lawrence Livermore National Laboratory

Tantalum is used as a prototype material for multi-scale modeling. Despite this attention, the interatomic force models have been validated with static experimental information only. Dynamic information, e.g. dislocation mobility, has proven a difficult experiment. Here we focus on a different kinetic experiment, the shear viscosity of the liquid. Because of tantalum's high melting point, limited viscosity data is available. In a tour de force experiment, Paradis et al. used electrostatic levitation to measure the relaxation of liquid droplets and extracted viscosity data. Use non-equilibrium molecular dynamics, our simulated the shear viscosity (validated on copper) agrees with the experiment at the melting point. However, the temperature dependence (activation energy) is significantly softer in the simulation, suggesting a possible reinterpretation of the experiment. Results will be presented for both the MGPT and Finnis-Sinclear models for tantalum. \*Work performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344.

#### 11:20 AM

**"Driving Forces" for Moving Inclusion and Inhomogeneity Boundaries with Transformation Strains:** *Xanthippi Markenscoff*<sup>1</sup>; Luqun Ni<sup>1</sup>; <sup>1</sup>University of California, San Diego

A half-space constrained Eshelby inclusion (in an infinite elastic matrix) with general uniform eigenstrain (or transformation strain) is analyzed when the plane boundary is moving from rest in general subsonic motion. The radiated fields are calculated based on the Willis expression for constrained time dependent inclusions, which involves the three-dimensional dynamic Green's function in an infinite traction-free body, and they constitute the

unique elastodynamic solution, with initial condition the Eshelby static fields obtained as the unique minimum energy solution by a limiting process from the spherical inclusion. The mechanical energy-release rate and associated "driving force" to create dynamically an incremental region of eigenstrain (due to any physical process) is calculated for general eigenstrain. By extending the Eshelby equivalent inclusion method to dynamics, the solution for a moving inhomogeneity (different elastic constants) is also obtained. In the absence of dissipation, Noether's theorem requires that the total (with external loading) "driving force", or total dynamic J integral (equal to the energy-release rate) vanishes, which yields the "kinetic relation", comprising a Peach-Koehler type force and a self-force. This, in turn, results in an evolution equation for a moving plane phase boundary.

#### 11:40 AM

**Dynamic-Tensile-Extrusion Response of Polymers:** *Eric Brown*<sup>1</sup>; George Gray<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

Dynamic-Tensile-Extrusion (Dyn-Ten-Ext) experiments have been utilized to probe the dynamic tensile responses of polytetrafluoroethylene (PTFE) and polychlorotrifluoroethylene (PCTFE). These fluoropolymers exhibit more irregular deformation and stochastic-based damage and failure mechanisms than the stable plastic elongation and shear instabilities observed in metals. Similar to the observed ductile-to-brittle transition for Taylor Impact loading, PCTFE failure occurs at a peak velocity greater than for PTFE. However, for the Dyn-Ten-Ext PCTFE exhibits even greater resistance to failure due to the tensile stress-state. While PTFE generates a large number of small fragments when extruded through the die, PCTFE draws out a smaller number of larger particles that dynamically evolve during the extrusion process through a combination of local necking mechanisms and bulk relaxation.

#### 12:00 PM

**The Dynamic Constitutive Response of Four Light Metals: Al 7039, Al 5083, Al 5059, and AZ31B:** *Sara Perez-Bergquist*<sup>1</sup>; George Gray III<sup>1</sup>; Ellen Cerreta<sup>1</sup>; Carl Trujillo<sup>1</sup>; Mike Lopez<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

While a great number of studies have examined the uni-axial stress behavior of a wide range of light metals and their alloys under quasi-static loading conditions, less is known about the dynamic response of these same metals as a function of stress state. For this reason, the dynamic constitutive response of four light metals has been examined as a function of stress state, temperature, texture, and dynamic strain rate. Specimens of Al 7039, Al 5083, Al 5059, and AZ31B, a magnesium alloy, have been characterized prior to deformation and then dynamically loaded in compression, tension, shear, and torsion. Post mortem characterization of these specimens, using optical microscopy, scanning electron microscopy, and electron back scattered diffraction has been utilized to correlate the observed mechanical response to the microstructural evolution during loading and leading to damage and failure of these materials.

#### 12:20 PM

**Structure and Shear Resistance of an Asymmetric Tilt Grain Boundary as Function of Temperature:** *Saryu Fensin*<sup>1</sup>; Mark Asta<sup>2</sup>; Richard Hoagland<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory; <sup>2</sup>University of California, Berkeley

Grain boundaries play an important role in governing the microstructure and deformation evolution in a material. Hence, it is important to understand the structure of grain boundaries that are subjected to high homologous temperatures. Boundaries that are susceptible to extreme structural disorder as the temperature is increased might drastically change the dynamic damage in a material under shock loading conditions. In this talk we will present the results of molecular dynamics simulations studying the temperature dependence of the structure of an asymmetric tilt grain boundary in copper. At high homologous temperatures a grain boundary can either form a disordered structure or can completely premelt. The change in grain boundary structure can be drastic enough to alter its response to an applied external force. The nature of the structural disorder in the grain boundary will be investigated by using the grain boundary width and its resistance to an applied shear strain.

## Fatigue and Corrosion Damage in Metallic Materials: Fundamentals, Modeling and Prevention: Fundamentals of Fatigue Damage and Modeling

**High Resolution EBSD Studies of Fatigued Metals:** *Angus Wilkinson*<sup>1</sup>; Philip Littlewood<sup>1</sup>; Benjamin Britton<sup>1</sup>; Phani Karamched<sup>1</sup>; <sup>1</sup>University of Oxford

We have used the relatively new cross-correlation-based analysis of EBSD patterns to map variations of elastic strain and lattice rotation tensors within selected grains of cyclically deformed metals. This method gives improved sensitivity of  $\sim 10^{-4}$  (rads) compared to  $\sim 10^{-2}$  rads for conventional Hough-transform-based analysis. The measured rotation (and elastic strain) gradients have been used within the Nye geometrically necessary dislocation (GND) framework to generate maps of the GND density distribution. Examples will be given for cyclically loaded OFHC Cu and Ti-6Al-4V polycrystal. The method allows the GND density distributions to be correlated with the orientation of a particular grain and those in its neighbourhood. We have also applied the technique to examine the plastic zones associated with fatigue crack tips. Examples will be given for cracks grown in single crystal Ni-based superalloy at elevated temperature and mid-Paris regime loading conditions.

#### 8:55 AM

**A Quantitative Crystallographic Model for Fatigue Crack Propagation through Grain Boundaries:** *Wei Wen*<sup>1</sup>; Tongguang Zhai<sup>1</sup>; <sup>1</sup>University of Kentucky

A crystallographic model for short fatigue crack propagation through grain boundaries was developed to quantify the resistance of grain boundaries to crack growth. The model was based on the early discovery that the twist and tilt components of crack plane deflection across a grain boundary were the key factors controlling the crack growth in high strength Al alloys. The model developed in this work was a function of twist angle at each grain boundary that interacted with a short crack, and allowed calculation of variation in growth rate at different grain boundaries and prediction of the crack front. Further work needs to be done to incorporate other factors, such as tilt angle and Schmidt factor, into the model to simulate the growth behavior of a short fatigue crack in 3-D.

#### 9:15 AM Invited

**Cyclic Deformation and Fatigue Cracking Mechanisms of F.C.C. Crystalline Materials:** *Zhefeng Zhang*<sup>1</sup>; Peng Li<sup>1</sup>; Peng Zhang<sup>1</sup>; Shen Qu<sup>1</sup>; Zhenjun Zhang<sup>1</sup>; <sup>1</sup>Institute of Metal Research, Chinese Academy of Sciences

The cyclic dislocation evolution and fatigue cracking behaviors in various f.c.c. metal and alloys, including various single crystals, Cu bicrystals and polycrystals, Cu-Al and Cu-Zn polycrystalline alloys, ultrafine-grained Cu-Al and Cu-Zn alloys, were systematically investigated and reviewed. It is confirmed that the effect of stacking fault energy (SFE) on cyclic deformation behaviors of f.c.c. single crystals is decisive and a new criterion is proposed to judge the formation of regular saturation dislocation patterns or not in various f.c.c. single crystals. In Cu, Cu-Al, Cu-Zn single crystals, fatigue cracking always nucleates along slip bands (SBs) and strain localization becomes weak gradually with decreasing SFE. The large-angle

grain boundaries (GBs) also become preferential sites for crack nucleation in Cu bicrystals and polycrystals. Fatigue cracking can also nucleate along SBs and twin boundaries (TBs) in pure Cu, Cu-Al and Cu-Zn alloys. The fatigue cracking mechanisms along SBs, GBs, TBs were compared and discussed.

**9:35 AM Invited**

**The Effect of Pore Position in Depth on Stress Field around the Pore on Sample Surface:** Zhiqiang Xu<sup>1</sup>; Wei Wen<sup>2</sup>; *Tongguang Zhai*<sup>2</sup>; <sup>1</sup>Yanshan University; <sup>2</sup>University of Kentucky

Stress field around a pore was analyzed as a function of the pore position in depth in the surface of a linear elastic solid using FEM. It was found that the pore depth dominated the stress field around the pore on surface and that the maximum stress was increased sharply when the pore intercepted with the surface at its top. Given the applied nominal stress, the magnitude of the maximum main stress only depended on the relative depth of the pore, while the pore size affected the stress distribution in surface. An elastic-plastic model was also used to account for the yielding effect in the region where stress was over the yield strength. The results still indicated a significant maximum stress concentration when the pore was just buried underneath the surface, but with a lowered value than that of the linear elastic model. These results were consistent with experimental observations.

**9:55 AM Invited**

**Fatigue Weak-Link Density and Strength Distribution in High Strength Al Wrought and Cast Alloys:** *Tongguang Zhai*<sup>1</sup>; Yuanbin Zhang<sup>2</sup>; <sup>1</sup>University of Kentucky; <sup>2</sup>Shandong Jianzhu University

An experimental methodology was developed to measure fatigue weak-link density and strength distribution by measuring surface crack population as a function of the maximum applied stress. The method was applied to wrought and cast Al alloys such as AA8090 Al-Li, AA2026, AA2524, AA2024 and A713 alloys where fatigue cracks were initiated at either coarse particles or pores on surface. It was found that the surface crack populations were a Weibull function of the applied maximum stress. By fitting this measured curves, fatigue weak-link density could be quantified in these alloys. The derivative of the measured Weibull function was the strength distribution of the fatigue weak-links. Fatigue weak-link density and strength distribution are materials fatigue properties and useful for alloy development and applications.

**10:15 AM Break**

**10:25 AM**

**Effect of Cooling Rate on the Fatigue Life of a Nickel-Base Superalloy Used for Disc Rotor Applications:** *Mark Hardy*<sup>1</sup>; Robert Mitchell<sup>1</sup>; Hang-Yue Li<sup>2</sup>; <sup>1</sup>Rolls-Royce plc; <sup>2</sup>University of Birmingham

It is understood that the strain hardening behaviour of precipitation strengthened nickel alloys is produced from the interactions of dislocations with gamma prime particles. Furthermore, the degree of resistance to inelastic deformation is determined by the volume fraction and size of these particles. Since the particles that are precipitated from quenching after solution heat treatment offer the most effective resistance to inelastic deformation, this study has evaluated the effect of cooling rate on the fatigue endurance of alloy RR1000. It was found from testing at 300°C that fatigue life at this temperature is sensitive to cooling rate under conditions that produce limited plasticity. Under conditions that give rise to either significant inelastic strain or lives beyond 105 cycles, in which the deformation is predominantly elastic, endurance was found to be relatively insensitive to cooling rates. A rationale for the observed behaviour is proposed.

**10:45 AM**

**An Energy-Based Microstructure Model to Account for Fatigue Scatter in Polycrystals:** *Michael Sangid*<sup>1</sup>; Huseyin Sehitoglu<sup>1</sup>; <sup>1</sup>University of Illinois, Urbana-Champaign

Excessive scatter is observed in the fatigue response of a nickel-based superalloy, U720, which is partly attributed to the variability in the microstructure. There is great interest in linking the microstructure to fatigue properties using a multi-scale approach that focuses on integrating the results of atomic simulations to the continuum level. Our approach is to model

the energy of a persistent slip band (PSB) structure and use its stability with respect to dislocation motion as our failure criterion for fatigue crack initiation. Through this methodology, the fatigue life is predicted based on the energy of the PSB, which inherently accounts for the microstructure of the material. From this framework, we construct simulated microstructures based on the measured distributions of grain size, orientation, neighbor information, and grain boundary character, which allows us to calculate fatigue scatter using a deterministic approach. Good agreement is shown between the model predictions and experimental data.

**11:05 AM**

**Tail Departure of Log-Normal Grain Size Distribution in 3D Synthetic Microstructures:** *Joseph Tucker*<sup>1</sup>; <sup>1</sup>Carnegie Mellon University

Techniques are discussed that have been used to produce statistical volume elements using geometric shape distributions to simulate single-phase polycrystals. Current methods assume log-normal distributions of grain size; this gives rise to an issue with nonphysical large grains that cannot be accommodated in finite simulation volumes. Other distributions which have better control of the upper tails, e.g. truncated distributions, resolves the problem and allows more realistic distributions to be generated. These points are illustrated with an example of generation of a synthetic 3D microstructure to represent a 7075-T651 aluminum alloy.

**11:25 AM**

**Fatigue Crack Initiation Processes in a Polycrystalline Ni-Base Superalloy:** *Jiashi Miao*<sup>1</sup>; Tresa M. Pollock<sup>2</sup>; J. Wayne Jones<sup>1</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>University of California, Santa Barbara

The very high cycle fatigue behavior of a polycrystalline nickel-based superalloy René 88 DT was investigated under fully reversed loading at a frequency of 20 KHz at room temperature using an ultrasonic fatigue system. Microstructural features associated with microcrack initiation and failure were identified by orientation imaging microscopy. Focused ion beam sectioning was used to examine selected microcrack initiation sites. Deformation substructures were characterized using transmission electron microscopy. The early stages of fatigue were dominated by localized slip adjacent to twin boundaries in grains at the high end of the grain size distribution. A fatigue crack initiation model is proposed that incorporates local microstructure features in the initiation process as well as the interaction between local microstructure and small crack growth. A novel approach to quantify crack initiation life using in situ nonlinear ultrasonic analysis is described.

**11:45 AM**

**3D Short Fatigue Crack Investigation Using Diffraction and Phase Contrast Tomography:** *Michael Herbig*<sup>1</sup>; *Wolfgang Ludwig*<sup>1</sup>; Henry Proudhon<sup>2</sup>; Peter Reischig<sup>3</sup>; Andrew King<sup>4</sup>; Jean-Yves Buffière<sup>5</sup>; <sup>1</sup>ESRF / INSA Lyon; <sup>2</sup>MINES ParisTech; <sup>3</sup>ESRF / KIT; <sup>4</sup>GKSS-Research Center; <sup>5</sup>INSA Lyon

In order to investigate the influence of the microstructure on the propagation of short fatigue cracks, a combination of two synchrotron imaging techniques has been used. Grain shape and orientation are measured non-destructively in 3D by means of X-ray diffraction contrast tomography. The crack propagation is monitored at regular intervals using high resolution phase contrast tomography, a technique capable of revealing cracks of sub-micrometer thickness. A technique enabling visualization of the fracture surface orientation and, for the first time, quantification of the local crack growth rate in the bulk of the material has been developed. Its application on two beta titanium alloys gives new insight into several aspects of crack - microstructure interactions during the growth of microstructurally short fatigue cracks.

## Friction Stir Welding and Processing VI: High Temperature Materials I

#### 8:50 AM Keynote

##### A Decade of Progress in Friction Stirring of High-Temperature Materials: Carl Sorensen<sup>1</sup>; <sup>1</sup>Brigham Young University

Friction stir welding and processing of high-temperature materials, such as ferrous alloys, has been reported in the literature for a little more than a decade. The past decade has seen significant improvements in tool materials, changes in tool features, new understanding of recommended parameters, and an increased number of high-temperature materials being welded. This presentation surveys the state of the art in welding of steel, stainless steel, nickel-base alloys, copper alloys, and titanium alloys. Tool materials, tool features, control parameters, tool performance, and material properties are covered. Based on the history of the past decade, prospects for the future are considered. New applications in tool steels and pipeline steels for the oil and gas industry are presented, along with demonstrations for naval applications. The most significant obstacles to commercial implementation are discussed. With continued development, friction stir processing of high temperature materials shows promise for a bright future.

#### 9:20 AM

##### Development of Co-Based Alloy FSW Tool for High-Softening-Temperature Materials: Yutaka Sato<sup>1</sup>; Masahiro Miyake<sup>1</sup>; Hiroyuki Kokawa<sup>1</sup>; Toshihiro Omori<sup>1</sup>; Kiyohito Ishida<sup>1</sup>; Shinya Imano<sup>2</sup>; Seung Hwan Park<sup>2</sup>; Satoshi Hirano<sup>2</sup>; <sup>1</sup>Tohoku University; <sup>2</sup>Hitachi, Ltd.

The authors have developed new friction stir welding (FSW) tool that enables to weld high-softening-temperature materials, such as steels and titanium alloys. The new tool is made of Co-based alloys which are strengthened by dispersing intermetallics, Co<sub>3</sub>(Al,W), with L12 structure at high temperatures. The Co-based alloy tool can be manufactured at a low cost through a simple production method consisting of casting, heat-treatment and then cutting. They exhibit yield strengths higher than 500 MPa at 1000 degC, so that they might have great potential as FSW tool for high-softening-temperature materials. In this study, feasibility of the Co-based alloy tool to various high-softening-temperature materials, such as carbon steels, Ti-6Al-4V and so on, was examined. Change in tool shape during FSW, and the weld appearances and microstructure produced with the Co-based alloy tool will be briefly shown.

#### 9:40 AM

##### Friction Stir Welding and Processing of Advanced Materials for Coal and Nuclear Power Applications: Glenn Grant<sup>1</sup>; Scott Weil<sup>1</sup>; Yuri Hovanski<sup>1</sup>; Jens Darsell<sup>1</sup>; <sup>1</sup>Pacific Northwest National Laboratory

A wide range of materials are anticipated in the next generation of power plant designs. To increase efficiency and reduce carbon emissions, boilers, heat exchangers, and turbines all will be asked to perform at higher temperature and pressure. New alloys including precipitation hardenable Ni alloys, Ferritic ODS, and high-chrome steels will be employed. A significant barrier to implementing many of these is that joining technologies are either immature or unknown. This is especially true for ODS alloys where

conventional fusion welding produces a weld nugget that does not have the creep performance of the parent material. Friction Stir Welding has an opportunity to provide a joining solution to these difficult to weld materials. This presentation will outline efforts to develop the FSW weld process on several materials including Ni-alloys, ferritic ODS, and 9Cr2Mo steels. Data will be presented on high-temperature strength, creep performance, and joint microstructure.

#### 10:00 AM

##### Friction Stir Welding of Alloy 22: Bharat Jasthi<sup>1</sup>; Willaim Arbegast<sup>1</sup>; Stanley Howard<sup>1</sup>; <sup>1</sup>South Dakota School of Mines and Technology

The main objective of this work is to characterize and compare Alloy 22 weld microstructures formed in friction stir (FS), gas tungsten arc (GTA), and electron beam (EB) welding. Topologically closed packed (TCP) phases were identified in all the as-welded condition. TCP phases that precipitated in the FS weld nugget were extremely small (~50 to 300 nm) compared to those in the EB and GTA welds. Compared to the parent material the FS weld nugget microhardness increased from (~206 HV) to (~327 HV). Only a slight increase in microhardness was observed for the EB and GTA welds. The area fraction of the TCP phases in FS weld nugget increased with aging temperature and time. The activation energy calculated for the TCP phase growth in friction stir welds was determined to be ~252.5 kJ/mol.

#### 10:20 AM

##### Effect of Processing Parameters and Post-Weld Microstructure on Friction Stir Welded HSLA-65 Charpy V-Notch Impact Toughness: Sam Sanderson<sup>1</sup>; Tracy Nelson<sup>1</sup>; <sup>1</sup>Brigham Young University

Correlations between post-weld mechanical properties, post-weld microstructure and processing parameters in FSW HSLA-65 were investigated. FSW was conducted at combinations of spindle speed and welding speed to cover a range of heat inputs, from about 1 kJ/mm to 4 kJ/mm. Longitudinal, all-weld tensile tests, and Charpy V-notch (CVN) impact tests of weld centerline and heat-affected zone (HAZ) were evaluated. CVN results of weld centerline showed increased transition temperature over base metal transition temperature, with a large spread in absorbed energies near the transition temperature. Results from CVN testing of weld HAZ showed the transition temperature to be at or below base metal transition temperature. Longitudinal, all-weld tensile tests exhibited ultimate tensile strengths above ASTM A945 requirements for HSLA-65, while yield strengths were slightly below ASTM specification. The results show strong correlations between post-weld microstructure, tensile properties and weld heat input, while CVN results show only weak correlations.

#### 10:40 AM

##### Friction Stir Processing of Cast Inconel 718: Bharat Jasthi<sup>1</sup>; Edward Chen<sup>2</sup>; William Arbegast<sup>1</sup>; Matthew Heringer<sup>1</sup>; Douglas Bice<sup>2</sup>; Stanley Howard<sup>1</sup>; <sup>1</sup>South Dakota School of Mines and Technology; <sup>2</sup>Transition45 Technologies, Inc

The objective of this work was to investigate the effects of friction stir processing (FSP) on the microstructure and mechanical properties of Inconel 718 castings. Polycrystalline cubic BN pin tools were used to process 0.35-in. thick cast Inconel 718 plates. Successful bead-on-plate welds were produced at a rotational speed of 225 RPM and travel speed of 0.5 IPM. FSP created a homogeneous microstructure and produced extremely fine grains (< 10 μm) in the weld nugget while eliminating casting defects. Post-FSP heat treatment cycles increased the strength of the FSP nugget over that of the parent material. Fracture toughness and microhardness of the welds were superior to that of parent material. This paper describes the microstructure and the mechanical properties of friction stir processed Inconel 718 castings.

**Fabrication of Nanostructured Tool Steel Layer by Combination of Laser Cladding and Friction Stir Processing:** *Yoshiaki Morisada*<sup>1</sup>; Hidetoshi Fujii<sup>2</sup>; Tadashi Mizuno<sup>3</sup>; Genryu Abe<sup>3</sup>; Toru Nagaoka<sup>1</sup>; Masao Fukusumi<sup>1</sup>; <sup>1</sup>Osaka Municipal Technical Research Institute; <sup>2</sup>Joining and Welding Research Institute, Osaka University; <sup>3</sup>AMC Corporation

A fabrication process of the nanostructured tool steel layer with various carbides by the combination of laser cladding and friction stir processing (FSP) was proposed. The segregated carbide particles on the grain boundary of the matrix formed by the laser cladding with a coaxial cladding head were crushed into the carbide nanoparticles during the FSP, and were uniformly dispersed in the matrix. The carbide nanoparticles assisted in forming the fine recrystallized grains of the matrix by the FSP due to the increment in the induced stress and a pinning effect for the static grain growth. The nanostructured tool steel layer showed a higher hardness than conventional tool steel.

## 11:30 AM Invited

**Friction Stir Welding of Oxide Dispersion Strengthened Alloy MA956:** *Michael West*<sup>1</sup>; *bharat jasthi*<sup>1</sup>; Peter Hosemann<sup>2</sup>; Viswanath Sodesetti<sup>1</sup>; <sup>1</sup>South Dakota School of Mines and Technology; <sup>2</sup>University of California at Berkeley

Ferritic oxide dispersion strengthened MA956 alloys (ODS) were joined using friction stir welding (FSW) as a means of joining these alloys without disturbing the dispersion characteristics. Two MA956 plates of thickness 12.7 mm and 6.4 mm were successfully plasticized by friction stir welding (FSW). Fully consolidated welds were made at 400 RPM (50 mm/min) with Q60 composite pin tools and 600 RPM (13 mm/min) with W-Re pin tool. Post weld heat treatment was performed at 1000°C and 1300°C to observe the effects of heat treatment on the weld properties. Microstructural characterization, grain size analysis, and mechanical property measurements were performed as a function of weld processing parameters. Microhardness in the weld region showed a modest reduction in the strength compared to the as-processed MA956. The oxide dispersion between the bulk and the weld was analyzed by small angle neutron scattering (SANS) and scanning electron microscope (SEM).

## 11:55 AM

**Friction Stir Processing of Ti-6Al-4V for Grain Size Reduction in Fusion Welds:** *Jason Livingston*<sup>1</sup>; Jeff Rodelas<sup>1</sup>; John Lippold<sup>1</sup>; <sup>1</sup>The Ohio State University

Friction Stir Processing (FSP) is a solid-state process that produces microstructure modification in a wide range of materials (Al, Ti, Cu, Ni, and steels). In Ti alloys, such as Ti-6Al-4V, fusion welding results in coarse-grained microstructure with reduced mechanical properties (toughness and ductility). In this study, FSP was used to both modify the as-welded and base metal microstructure. FSP was conducted on beta-processed Ti-6Al-4V plate using a tungsten-rhenium tool. The as-received base material exhibited a prior beta grain size in the range from 1.2 to 1.5mm, while FSP produced a fine, equiaxed alpha microstructure with grain diameters from 1 to 5 microns. Thermal data collected in situ confirmed processing temperatures were below the beta transus. Single pass GTAW welding on FSP-conditioned base metal resulted in reduced weld metal grain size, based on epitaxial nucleation and growth from the refined microstructure. Optical metallography and EBSD were used to characterize these microstructures.

## 12:15 PM

**Microstructure and Mechanical Properties of Friction Stir Processed Grade 40 Grey Cast Iron:** *Michael West*<sup>1</sup>; Bharat Jasthi<sup>1</sup>; Nicholas Smith<sup>1</sup>; Josiah Oduor<sup>2</sup>; Yong-Ching Chen<sup>3</sup>; <sup>1</sup>South Dakota School of Mines and Technology; <sup>2</sup>University of Tennessee, Knoxville; <sup>3</sup>Cummins Technical Center

Friction stir processing (FSP) of Grade 40 grey cast iron was performed using bead-on-plate friction stir welds with a PCBN pin tool. Approaches for FSP focused on the use of induction preheating and the use of a mild steel

cover plate. Successful welds were made using the cover plate approach in forge force mode. Microhardness tests show high hardness (~600 HV) in regions of mixed cast iron and steel above the weld nugget. Significant refinement in the graphite structure and increase in microhardness is observed in the nugget region compared to the base material. Results of tensile testing are also presented. Transverse tensile specimens show low strength because of alignment of graphite flakes in the thermo-mechanically affected regions adjacent to the weld nugget region.

## Frontiers in Solidification Science: Atomistic Simulations

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Chemistry and Physics of Materials Committee, TMS: Solidification Committee

*Program Organizers:* Jeffrey Hoyt, McMaster University; Daniel Lewis, Rensselaer Polytechnic Institute

Monday AM  
February 28, 2011

Room: 6E  
Location: San Diego Conv. Ctr

*Session Chair:* To Be Announced

## 8:30 AM Invited

**Characterization of the Structure, Thermodynamics and Transport at the Chemically Heterogeneous Cu/Pb Interface by Atomistic Simulation:** *Brian Laird*<sup>1</sup>; J. Pablo Palafox-Hernandez<sup>1</sup>; Mark Asta<sup>2</sup>; <sup>1</sup>University of Kansas; <sup>2</sup>University of California-Berkeley

Using MD simulation, we examine the equilibrium interface between crystalline Cu and liquid Pb, modeled. This interface is characterized by the calculation of density, energy, stress and diffusion profiles, and by Fourier analysis of the interfacial layers for two crystal orientations: (100) and (111). At 625 K, we observe significant surface alloying in the first layer of the (100) interface, consistent with earlier investigations. No surface alloying is seen in the (111) orientation; however, a "prefreezing" layer of crystalline Pb, approximately 2-3 lattice layers in thickness, is observed to form at the (111) Cu surface. These layers are hexagonal with a lattice spacing that is 33% larger than the underlying Cu (111) planes and rotated by an angle of ~6.176 relative to the Cu lattice. Further simulations show that the prefreezing layers significantly enhance heterogeneous nucleation in the (111) orientation relative to (100).

## 9:00 AM Invited

**Finite Size Effects in Molecular Dynamics Simulations of Nucleation and Growth:** *James Morris*<sup>1</sup>; Trevor Pate<sup>2</sup>; Lujian Peng<sup>2</sup>; <sup>1</sup>Oak Ridge National Laboratory; <sup>2</sup>University of Tennessee

Molecular dynamics provides a direct, unbiased approach for simulating the processes associated with phase transformations. However, the small size and time scales can limit the applicability of these methods. In this talk, recently observed finite-size effects in simulations of both crystal nucleation times and growth are reviewed: both nucleation dynamics and initial grain structures have been shown to have important size effects, sometimes requiring millions of atoms to converge. Both size effects are statistical in nature. We examine the connection between these two effects, and demonstrate that simple arguments can provide estimates of the relevant size scale and how this depends on undercooling conditions. Moreover, the nucleation times are well predicted by nucleation theory, without fitting parameters, in contrast to experimental work in both colloids and glasses. This research was sponsored by the Division of Materials Sciences and Engineering, U.S. Department of Energy, Office of Basic Energy Sciences.

### 9:30 AM Invited

**Heterogeneous Nucleation of Solid Al from the Melt: Molecular Dynamics Studies:** Junsheng Wang<sup>1</sup>; Peter D. Lee<sup>1</sup>; Andrew Horsfield<sup>1</sup>; Peter Brommer<sup>2</sup>; Udo Schwingenschloegl<sup>3</sup>; <sup>1</sup>Imperial College London; <sup>2</sup>Universität Stuttgart; <sup>3</sup>King Abdullah University of Science and Technology

Nucleation of solid Al from the melt by TiB<sub>2</sub> is well established, but the atomic scale mechanisms are not fully understood. It is believed to be a two step process: Al<sub>3</sub>Ti is formed which then nucleates solid Al. Using molecular dynamics (MD) simulations with embedded atom method potentials we simulated the nucleation and early stages of growth of Al on Al<sub>3</sub>Ti. A strong anisotropy in the growth depending on the crystal orientation was found and explained in terms of interfacial energies. Using Density Functional Theory MD the early stages of Al nucleation on TiB<sub>2</sub> were simulated. We find no signs of incipient growth of solid Al at the B-terminated surface, but see fcc-like ordering at the Ti-terminated surface. For the Al<sub>3</sub>Ti substrate, fcc-like structures are observed which extend rapidly into the melt.

### 10:00 AM Break

### 10:15 AM Invited

**Molecular Dynamics Simulations of Alloy Rapid Solidification:** Mark Asta<sup>1</sup>; Hariith Humadi<sup>2</sup>; Yang Yang<sup>3</sup>; Brian Laird<sup>4</sup>; Deyan Sun<sup>3</sup>; Jeff Hoyt<sup>2</sup>; <sup>1</sup>University of California, Berkeley; <sup>2</sup>McMaster University; <sup>3</sup>East China Normal University; <sup>4</sup>University of Kansas

Molecular dynamics (MD) simulations are employed to investigate the kinetic properties of alloy crystal-melt interfaces under rapid-solidification conditions. The MD simulations yield results for velocity dependent partition coefficients, and the relationship between interface velocity and thermodynamic driving force. Both sets of results are compared to available sharp-interface models for solute trapping and solute drag. The MD results for fcc-based alloy systems can be characterized as follows. For interface mobilities, the MD results are best described by models that account for some degree of solute drag. Results for solute trapping are best described by models that account for an abrupt transition to partitionless growth at a critical velocity. A key finding in the MD simulations is the presence of a significant degree of crystalline anisotropy and composition dependence of interface mobility. Preliminary results for bcc alloys will also be described.

### 10:45 AM Invited

**Heterogeneous Nucleation of Liquid at Grain Boundaries:** T. Frolov<sup>1</sup>; Y. Mishin<sup>1</sup>; <sup>1</sup>George Mason University

At temperatures approaching the bulk melting point, many grain boundaries exhibit premelting by developing liquid-like layers. Some boundaries can be overheated above the melting point until the material suddenly melts. Both premelting and melting processes can involve nucleation of liquid droplets existing in unstable equilibrium with the boundary. We report on atomistic simulations of grain boundary premelting, melting and formation of critical liquid nuclei at grain boundaries in copper. We show, in particular, that nuclei can be effectively stabilized using the NVE ensemble of molecular dynamics, allowing systematic studies of the nucleus size and shape depending on temperature. By varying the system size, different morphologies of the nuclei are observed, including the cylindrical (quasi-2D) and the lens (3D) shapes. We demonstrate how a cylindrical nucleus can break up into several lens-shape nuclei when the system size is increased. The results are compared with homogeneous liquid nucleation inside the crystal.

### 11:15 AM Invited

**Molecular Dynamics Study of Solid-Liquid Interface Migration in FCC Metals:** Mikhail Mendeleev<sup>1</sup>; <sup>1</sup>Ames Laboratory

The recent MD simulation results for the solid-liquid interface (SLI) migration in fcc metals will be discussed. First, it will be shown that the generation of latent heat at the moving SLI during MD simulations can lead to significant underestimations of the interface mobility. Second, the kinetic coefficient for all systems will be compared to theoretical predictions. It will be shown that near the melting temperature the magnitude of the kinetic coefficient correlates well with the value of the diffusion coefficient in the liquid. Finally, the results of the MD simulation of the SLI migration at very

low temperatures will be presented. It will be shown that the results of such simulations are extremely sensitive to the way how the liquid part of the simulation cell was created. Work at the Ames Laboratory was supported by the Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-07CH1135.

## Geek Speak on the Hill: Communicating Science to Policy Makers

*Sponsored by:* The Minerals, Metals and Materials Society, TMS: Public and Governmental Affairs Committee

*Program Organizers:* Jud Ready, Georgia Tech; Marlit Hayslett, Georgia Tech

Monday AM  
February 28, 2011

Room: 17B  
Location: San Diego Conv. Ctr

*Session Chair:* Marlit Hayslett, Georgia Tech

### 8:30 AM Introductory Comments by Kevin Hemker, Chair, Public & Governmental Affairs Committee

### 8:35 AM Invited

**Recap of Congressional Visit Days:** Iver Anderson<sup>1</sup>; <sup>1</sup>Iowa State University  
TMS, MRS, ASM, FMS, IEEE, and numerous other societies visit congressional leaders each year to provide them with scientific information (typically in the spring: Next for TMS is April 6-7, 2011). This talk will include an overview of that "CVD" program as well as details for upcoming events.

### 8:55 AM Invited

**Legislative Process 101:** Arnie Thomas<sup>1</sup>; <sup>1</sup>Senior Vice President, Client Relationships, CQ Rollcall Group

The many stakeholders, nuances and steps involved in legislative public policy will be covered. The role of committees, special interests, lobbyists and other aspects of the legislative process are included.

### 9:15 AM Break

### 9:30 AM Invited

**Case Studies in Reality Colliding with Science-Policy:** Jim Treglio<sup>1</sup>; <sup>1</sup>Consultant, Technology and Marketing, Molecular Metallurgy

The speaker will share real-world examples where scientific interchange with policy makers could have resulted in a different outcome.

### 9:50 AM Invited

**Communicating Science to Policy Makers:** Marlit Hayslett<sup>1</sup>; <sup>1</sup>Director, Office of Policy Analysis and Research

This talk will encompass how to translate technical jargon into a language understandable by federal, state and local public policy makers.

### 10:10 AM Invited

**Tools and Techniques for Being an Effective Communicator:** Gina Schatteman<sup>1</sup>; <sup>1</sup>University of Iowa

This session will review tactics and approaches for effective delivery of scientific information to public policy makers. Oral and written testimony, letters to representatives, constituent visits and other types of interactions will be discussed.

### 10:30 AM Break

### 10:45 AM Panel Discussion

**"The Congress shall promote the progress of science..." US Constitution; Article 1, Section 8**

Each speaker will participate in a strategic discussion of how members of the materials community can effectively interact with federal, state and local legislatures to influence public policy for the betterment of society.

### 11:45 AM Concluding Comments

## General Abstracts: Electronic, Magnetic and Photonic Materials Division: Session I

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Alloy Phases Committee, TMS: Biomaterials Committee, TMS: Chemistry and Physics of Materials Committee, TMS: Electronic Materials Committee, TMS: Electronic Packaging and Interconnection Materials Committee, TMS: Energy Conversion and Storage Committee, TMS: Magnetic Materials Committee, TMS: Nanomaterials Committee, TMS: Thin Films and Interfaces Committee

February 28, 2011

Room: 16B  
Location: San Diego Conv. Ctr

Session Chair: To Be Announced

8:30 AM

### Charged Point Defect Configurations, Domain Stabilization Effects, and Ferroelectric Aging: Tianle Cheng<sup>1</sup>; Yu Wang<sup>1</sup>; <sup>1</sup>Michigan Technological University

Configurations of charged point defects and resultant internal electric field are investigated based on point ion model to understand ferroelectric aging phenomenon. Analysis of the energetics of various defect configurations reveals that the interactions among point defect dipoles play a most important role, which leads to a formation of asymmetric L-shaped defect configuration, generating internal electric field sufficient to stabilize ferroelectric domains. Such short-range ordering of charged point defects is believed to be the origin of ferroelectric aging. To study domain stabilization effect in aged ferroelectrics, domain-dependent internal electric field associated with the short-range ordering of charged point defects is incorporated into phase field ferroelectric model. Computer simulation is performed to estimate the internal electric field strength. Clausius-Clapeyron-type thermodynamic analysis of field-induced ferroelectric phase transition is used to evaluate aging-associated internal electric field magnitude from available experimental data, which is in agreement with the theoretical analysis and computer simulation.

8:50 AM

### Correlated Nucleation and Self-Accommodating Kinetic Pathway of Ferroelectric Phase Transformation: Jie Zhou<sup>1</sup>; Tian-Le Cheng<sup>1</sup>; Yu Wang<sup>1</sup>; <sup>1</sup>Michigan Technological University

Mechanisms of nucleation and growth of domains during ferroelectric phase transformation are investigated by using theoretical and computational approaches. It is shown that ferroelectric phase transformation exhibits some interesting behaviors due to strong long-range dipole-dipole-like interactions involved in the system. Incorporation of electrostatic and elastostatic energies into the classical Landau-Ginzburg-Devonshire theory effectively modifies the coefficients of the polynomial free energy function and introduces extra energy barrier for ferroelectric phase transformation. It is found that independent nucleation of ferroelectric phase in the context of classical nucleation theory is impossible, because electrostatic interaction generates an insurmountable energy barrier to isolated nucleus. Phase field simulation reveals that, in order to circumvent such an energy barrier, nucleation exhibits strong spatial correlation and self-organization behaviors from the very beginning, and ferroelectric phase transformation proceeds via spatial and temporal evolution of self-accommodating domains that provide a low-energy kinetic pathway throughout the entire phase transformation process.

9:10 AM

### Bipolar Resistive Switching Behavior in Ti/MnO<sub>2</sub>/Pt Structure for Nonvolatile Memory Devices: Min Kyu Yang<sup>1</sup>; Sun Young Choi<sup>1</sup>; Jeon Kook Lee<sup>1</sup>; <sup>1</sup>Korea Institute of Science and Technology

We examined the electrical properties of Ti/MnO<sub>2</sub>/Pt devices with stable and reproducible bipolar resistive switching behavior. The dependency of the memory behavior on the cell area and operating temperature suggest that the conducting mechanism in the low resistance states is due to the locally conducting filaments formed. X-ray photoelectron spectroscopy showed that non-lattice oxygen ions form at the MnO<sub>2</sub> surface. The mechanism of resistance switching in the system examined involves the generation and recovery of oxygen vacancies with the non-lattice oxygen ions. The Ti/MnO<sub>2</sub>/Pt device has potential applications in nonvolatile resistive switching memory devices due to the reasonable switching endurance over the course of 10<sup>5</sup> cycles, long term retention at 85 °C and a uniform distribution of both resistance states and operation voltage. A high content of non-lattice oxygen ions exists on the MnO<sub>2</sub> film surface. The switching behavior can be explained by the generation and recovery of oxygen vacancies with non-lattice oxygen ions.

9:30 AM

### Preparation and Characterization of Oxide Thin Films for the Resistance Random Access Memory (RRAM) Application: W. Z. Chang<sup>1</sup>; J. Chu<sup>1</sup>; S. F. Wang<sup>2</sup>; <sup>1</sup>National Taiwan University of Science and Technology; <sup>2</sup>National Taipei University of Technology

RRAM is considered as a promising candidate for next-generation memory application because of high-density, fast write/read access, low energy operation, and high performance of endurance and retention. Many oxide systems such as NiO, TiO<sub>2</sub>, and SrZrO<sub>3</sub> have been proposed for this application. In this study, sputtered HoScO<sub>3</sub> (HSO) and TiO<sub>x</sub> thin films with working atmospheres of different Ar/O<sub>2</sub> flow ratios have been characterized for the RRAM resistance switching (RS) behavior. After deposition, HSO and TiO<sub>x</sub> thin films with a thickness of approximately 50 nm are post-annealed in O<sub>2</sub> and N<sub>2</sub> atmospheres at various temperatures. As-deposited HSO films exhibit RS behavior, except at an Ar/O<sub>2</sub> ratio of 10/10, while as-deposited TiO<sub>x</sub> films exhibit RS behavior only with high O<sub>2</sub> pressures. HSO samples annealed in N<sub>2</sub> atmosphere exhibit a better RS behavior than those annealed in O<sub>2</sub>. However, an opposite trend is observed in the case of TiO<sub>x</sub> films.

9:50 AM

### Investigation of Electronic Properties for Nano-Titania/Metal-Ion-Doped Titania Semiconductor Prepared by Sol-Gel Methods: Leo Chau-Kuang Liao<sup>1</sup>; <sup>1</sup>Yuan Ze University

Semiconductor homojunction devices were designed and fabricated by coating a metal-ion-doped TiO<sub>2</sub> film on top of a TiO<sub>2</sub> nanoparticle film. The sample films were prepared with synthesized sol-gel TiO<sub>2</sub>, verified to be nano-size particles with anatase structure. The semiconductor characteristics of the ion-doped and undoped films were analyzed by current-voltage (I-V). Results showed that the semiconductor properties of TiO<sub>2</sub> were greatly influenced by doping with different types and amounts of metal ions, i.e. Fe<sup>2+</sup>, Cr<sup>3+</sup>, Zn<sup>2+</sup>, and Ag<sup>+</sup>. The semiconductor characteristics of the TiO<sub>2</sub>/metal-ion-doped TiO<sub>2</sub> devices, such as onset voltage and rectifying curves, were affected by the fabrication of the ion-doped layer. The fabricating conditions of the ion-doped layer, i.e. thickness, and types and amounts of metal ions, can change the electronic properties of the device.

10:10 AM Break

10:30 AM

### Effects of Structural Heterogeneities on Magnetization Processes in FePt Crystals: Yan Yang<sup>1</sup>; Jianyang Li<sup>1</sup>; Yongmei Jin<sup>1</sup>; <sup>1</sup>Michigan Technological University

Magnetic domain evolutions in FePt crystals of different structural heterogeneities are studied by micromagnetic modeling. In particular, {110} transformation twins and {111} annealing twins in L<sub>1</sub><sub>0</sub> phase, and A1+L<sub>1</sub><sub>0</sub> two phase systems are considered. Computer simulations reveal detailed

magnetization processes through domain wall motion and magnetization rotation, and show strong interactions of magnetic domain walls with twin boundaries and inter-phase interfaces. It is found that magnetostatic interaction between magnetic domains across interfaces generates local magnetic charges, which produce heterogeneous internal magnetic field. The competition between the internal and external magnetic fields under the constraint of high magnetocrystalline anisotropy of  $L1_0$  phase determines magnetic domain structures and their evolution paths, which explains the different characteristics of magnetic properties of FePt crystals with different structural heterogeneities. The influences of size and morphology of heterogeneities on magnetic processes are discussed.

#### 10:50 AM

**Phase Formation, Microstructure and Magnetic Properties of Rapidly Solidified SmCo Alloys Modified with Hf and C:** *Shampa Aich*<sup>1</sup>; Jeffrey Shield<sup>2</sup>; <sup>1</sup>Indian Institute of Technology; <sup>2</sup>University of Nebraska-Lincoln

A series of  $(\text{Sm}_{0.12}\text{Co}_{0.88/95}\text{Hf}_{3-x}\text{C}_x)$  ( $x = 0, 1, 2, 3, 4$  and  $5$ ) alloys were arc-melted in a TIG arc melting furnace and then melt-spun on a copper wheel surface at a wheel speed of 30 m/s. X-ray diffraction indicated that the primary phase was  $\text{SmCo}_5$ , with the metastable  $\text{TbCu}_5$ -type structure. While rapid solidification of binary Sm-Co alloys results in coarse grains (grain size  $\sim 1 \mu\text{m}$ ) and a coercivity of 0.8 kOe, combined additions of Hf and C resulted in effective grain refinement (grain size  $\sim 100$ -200 nm). The reduction in grain size resulted in dramatic increase in magnetic properties dependent on the Hf/C ratios. The coercivity ( $H_c$ ) increased systematically from approximately 6 kOe to 17 kOe and the magnetization ( $M_s$ ) decreased from 92 emu/g to 55.3 emu/g with a maximum reduced remanence ( $M_r/M_s$ ) value of 0.78 as the Hf/C ratio varied from 1/4, 2/3, 3/2, 4/1 to 5/0.

#### 11:10 AM

**Structure and Magnetic Properties Characterization of Electro-Deposited Co37Fe63 Containing Oxygen for Magnetic Recording Applications:** *Shereen Elhalawaty*<sup>1</sup>; Ray Carpenter<sup>1</sup>; Jinnie George<sup>2</sup>; Stanko Brankovic<sup>2</sup>; <sup>1</sup>Arizona State University; <sup>2</sup>University of Houston

Soft and high magnetic moment Co37Fe63 alloys have been electro-deposited with variable additives on Cu/Ti/Si substrate. The correlation between structure and magnetic properties has been investigated. TEM showed that the crystal structure of the deposits was BCC with a  $\langle 111 \rangle$  texture, and 10 to 20 nm grain size. Oxygen in the deposited film has been identified by High Annular Dark Field STEM combined with EDS and EELS. The oxygen content in the deposits has also been analyzed using RBS. SIMS showed that both oxygen and hydrogen are present in the deposited CoFe films. The magnetic properties of the deposits have been measured by magnetometer quantifying the impact of oxygen and hydrogen on the saturation magnetic flux density BS. Analytical results showed that the oxygen was mainly distributed along the grain boundaries in the CoFe film. Where oxygen was present in the film, the Fe content was enhanced relative to Co.

#### 11:30 AM

**High Permeability Co-Hf-Ta Thin Films:** *Shu-Wen Huang*<sup>1</sup>; Yuan-Tai Lai<sup>1</sup>; Jenq-Gong Duh<sup>1</sup>; <sup>1</sup>National Tsing Hua University

High permeability Co-Hf-Ta thin films were fabricated by adjusting the Hf content from 1 at.% to 8 at.%. It was revealed that appropriate Hf addition can effectively reduce the Co grain size and improve magnetic properties. Magnetic properties were shown to strongly depend on the microstructure of Co-Hf-Ta films. X-ray diffraction and transmission electron microscope diffraction patterns revealed that appropriate Hf addition would promote the formation of nanocrystalline structure. Such microstructure could be beneficial to obtain soft magnetic properties and a superior permeability ( $\mu'$ ). In this study, by optimizing the Hf content, the film with Hf concentration of 2.81 at.% exhibits excellent soft magnetic properties: high saturation magnetization (4pMS  $\sim 13.6$  kG), and low coercivity (HC  $\sim 0.6$  Oe). The effective permeability of the film reaches 800 and remains nearly unchanged up to 1 GHz.

#### 11:50 AM

**Tungsten Doping Effect on Thermoelectric Properties of Heusler Fe<sub>2</sub>VAl Alloy:** *Haruka Morishita*<sup>1</sup>; Masashi Mikami<sup>1</sup>; Kimihiro Ozaki<sup>1</sup>; Keizo Kobayashi<sup>1</sup>; <sup>1</sup>National Institute of Advanced Industrial Science and Technology

A Heusler alloy,  $\text{Fe}_2\text{VAl}$ , is a promising candidate for thermoelectric power generation near room temperature because of its high thermoelectric power factor  $PF (=S^2/\rho 63)$ , where  $S$  is the Seebeck coefficient,  $\rho 63$  is the electrical conductivity). However, the thermoelectric figure of merit  $Z (=S^2\sigma/\kappa)$  where  $\kappa$  is the thermal conductivity) of this alloy is poor by reason of its high thermal conductivity ( $\kappa = 28$  W/mK). We had reported that microstructural refinement using powder metallurgy technique enhances phonon scattering at grain boundaries, resulting in the reduction of  $\kappa = 16$  W/mK. In this study, we investigated the effect of substitution of W, which has the larger atomic mass, for V to achieve thermal conductivity reduction within grains by the mass-difference scattering. The  $\kappa$  of 6 W/mK was then obtained at 300 K for  $\text{Fe}_2\text{V}_{0.9}\text{W}_{0.1}\text{Al}$ . W doping effect on electric properties will also be presented.

#### 12:10 PM

**The Introduction of Nano-Scale Inclusions in to Bulk MgB<sub>2</sub> via Infiltration and Growth Process:** *Hari babu Nadendla*<sup>1</sup>; Anthony Dennis<sup>2</sup>; Yunhua Shi<sup>2</sup>; David Cardwell<sup>2</sup>; <sup>1</sup>Brunel University; <sup>2</sup>University of Cambridge

It is well established that magnetic flux pinning in MgB<sub>2</sub> bulk samples can be enhanced significantly by the introduction of nano-sized, non-superconducting second phase particles into the MgB<sub>2</sub> phase matrix, and this has been achieved primarily by co-sintering a mixture of MgB<sub>2</sub> and nano-scale second phases. The density of material fabricated by this technique, however, is low and bulk samples are typically porous, with a relatively low critical current density ( $J_c$ ). In this paper, we report an extension of the infiltration and growth process to the fabrication of high density (90-95% of theoretical), bulk MgB<sub>2</sub> that contains nano-scale inclusions (SiC, Y<sub>2</sub>O<sub>3</sub>, and ZrO<sub>2</sub>). This process also allows to fabricate complex shaped bulk MgB<sub>2</sub> superconductor. The influence of the presence of these inclusions on  $J_c$  as a function of external field in the temperature range of 5 K - 38 K is investigated in detail for various nano composites.

**A Model for the Collapse of the World Trade Center:** *Christian Simensen*<sup>1</sup>; <sup>1</sup>SINTEF

Two airplanes of Boeing 767 flew into the Twin Towers in the morning of September 11th 2001. The crashes caused petrol to come on fire, and the airplanes to be fragmented. They were subsequently heated to a high temperature. Aluminium alloys in the airplanes were melted at 660°C while the surrounding building was only heated to a much lower temperature due to suitable insulation. When the temperature reached 750-800°C, the approximately 30 ton melt managed to stream down to the lower floors. There it came in contact with water from the sprinkler devices and other sources. The encounter resulted in a series of fierce explosions by generation of hydrogen gas and local heating to high temperatures well above 1000°C. A section of the buildings was torn apart, and the upper part fell on the bottom part so the whole building collapsed.

9:00 AM

**Analysis on the Market Developing Conditions of Prebaked Carbon Anodes for the Aluminium Industries:** Guanghui Lang<sup>1</sup>; Chunyu Fu<sup>1</sup>; Ronald Logan<sup>1</sup>; Yan Li<sup>1</sup>; <sup>1</sup>Sunstone

In recent years, with the sustained and rapid development of the aluminium electrolytic industries worldwide, an unprecedented growth of Chinese prebaked carbon anode production has been achieved. The high-quality and abundant sources of raw materials for anode production, unique production technologies, experienced operators, governmental support of research, and efficient logistics have made the further development of large-scale and integrated anode production facilities possible. China is positioned to become the production base of prebaked carbon anodes for the electrolytic business all over the world in the future.

9:20 AM

**Qatalum – Organizational Challenges in Starting up a Modern Smelter:** Roald Holten<sup>1</sup>; Lene Solli<sup>1</sup>; Jan Arve Haugan<sup>2</sup>; <sup>1</sup>Norsk Hydro; <sup>2</sup>Qatalum

The Qatalum smelter in Qatar started its operation in December 2009, with target production of 585 kt by the end of 2010. Two experienced industrial partners teamed up to create this modern aluminium smelter: Hydro with its strong position in reduction technology and Qatalum Petroleum as a key provider of industrial infrastructure in Qatar. Bringing this new large plant up to speed demands an efficient organization with competent and well-trained employees as well as well-functioning organizational structures and processes. The diversity in having thousand employees of 32 nationalities and from 35 company cultures represents a challenge, as does serving demanding customers with customized, high-quality casthouse products. The Qatalum Production System, a local adaptation of Hydro's own production system, has been devised as the main mechanism to align the organization and ensure quality in all processes. This presentation summarizes experiences and main learning points from the first year of operation.

9:40 AM

**Building Qatalum – A Large, Modern Smelter:** Tom Rotjer<sup>1</sup>; Erik Smith<sup>1</sup>; Anton Husøy<sup>1</sup>; <sup>1</sup>Norsk Hydro

On December 19 2009 production started at the Qatalum aluminium smelter, a joint venture between Hydro and Qatar Petroleum. With this the main milestone of the USD 5.7 billion project was successfully achieved, and a modern smelter based on the HAL300 reduction technology was ready for ramp-up of production within cost, on time and according to specifications. A construction village was built to accommodate the huge number of workers, providing welfare standards that Hydro are proud of. Likewise, environmental considerations, safety precautions and working conditions were all along on top of the priority list of the project team. The project was managed by Hydro Projects and was divided into 21 main contracts based on an EPC procurement strategy. This presentation provides detailed insights into how the project team handled the technical and organizational complexities during its work to construct one of the largest aluminium smelter ever built in one step.

10:00 AM

**Removal of Fluoride from Waste Water of Aluminium Smelter by Aluminium Ion Loaded Ion Exchange Resin Method:** Balakrushna Padhi<sup>1</sup>; Arun Kumar Sharma<sup>1</sup>; <sup>1</sup>National Aluminum Company Limited

Strong Acid Cation resin has sulphonic acid functional group (H<sup>+</sup> form) possesses appreciable defluoridation capacity and it has been enhanced by chemical modification into Al<sup>3+</sup> form by loading of Aluminium ions in H<sup>+</sup> form of resin. The defluoridation Al<sup>3+</sup> forms was found to be 480 mg F-/kg, at 15 mg/L initial fluoride concentration. The nature and morphology of sorbents are characterized using XRD, FTIR and SEM analysis. The fluoride sorption was explained using the Freundlich, Langmuir and Redlich-Peterson isotherms and kinetic models. The calculated thermodynamic parameters such as  $\Delta G^\circ$ ,  $\Delta H^\circ$ ,  $\Delta S^\circ$  and sticking probability ( $S^*$ ) explains the nature of sorption. A Defluoridation Plant is in service at aluminium smelter of National Aluminium Company to treatment the waste water for removing Fluoride and reutilise the water to minimise the water loss.

10:20 AM Break

10:40 AM

**Theoretical Study of Light Weight Materials on Replacement of Traditional Materials:** Pradeep Raja<sup>1</sup>; <sup>1</sup>Government College of Technology

Materials innovation and application are increasingly vital to sustain advanced manufacturing and modern methods of construction. The demand for lighter designs is growing for a broad spectrum of products. In this juncture, the paper aims at the study in development of cost-effective, high-strength, lightweight materials that reduces the weight of a product without compromising cost, performance or safety that is necessary to compete in today's global market. As a result of more stringent requirements for improved fuel economy and emissions, there is a growing trend to substitute Al and Carbon-fiber for conventional steel and cast irons in vehicles. However, because of their different tribology, strength, and ductility, light-metal castings require improved foundry procedures and more sophisticated design rules before product engineers will use them in larger quantities. A major challenge for lightweight materials is the ability to produce a functional component at an acceptable price.

11:00 AM

**Corrosion Behavior of Cermet Anodes in Na<sub>3</sub>AlF<sub>6</sub>-K<sub>3</sub>AlF<sub>6</sub>-based Baths for Low-Temperature Aluminium Electrolysis Cells:** Guihua Wang<sup>1</sup>; Xiaofei Sun<sup>1</sup>; Wenshan Wang<sup>1</sup>; Deren Wang<sup>1</sup>; Yedong He<sup>1</sup>; <sup>1</sup>University of Science and Technology Beijing

5Cu/ (10NiO-90NiFe<sub>2</sub>O<sub>4</sub>) cermet anodes were tested in different Na<sub>3</sub>AlF<sub>6</sub>-K<sub>3</sub>AlF<sub>6</sub>-based electrolytes at three temperature regimes: 740-780, 820-840, 940-960 °C. Post-electrolysis microscopic examination was carried out with SEM-EDS and XRD. The Fe, Ni and Cu contents in the bath and aluminum were measured with ICP-AES, according to which the corrosion rate was calculated. The results indicate that low temperature electrolysis can reduce the corrosion rate effectively. However, as temperature decreases too near the liquidus line, solid cryolite can form on the cathode, and high current density can be caused locally, which is detrimental to the anodes. The cermet anodes show best anti-corrosion properties when electrolysis temperature is controlled at 830-840 °C, and the corrosion resistance can be further enhanced by increasing superheat degree.

11:20 AM

**Quantifying Casting Processing Variability Due to Ingot Source: Primary vs. Secondary:** Darius Singh<sup>1</sup>; Ian Paine<sup>2</sup>; <sup>1</sup>AUT University; <sup>2</sup>Glucina Alloys Ltd

A fundamental issue of processing variability still exists in industry in terms of casting products using ingots that have been produced from either primary, secondary, or directly internally recycled. Downstream problems of oxide and other non-metallic inclusion borne defects are usually attributed to a myriad of visible and directly controllable processing parameters, however the alloy source, its manufacturing technique, quality rating and testing is often overlooked or taken for granted as a "workable" baseline to operate from. This work investigates the quality of CC601/A356 ingots produced from a primary smelter vs. a secondary producer. Best practices in manufacturing each ingot are described from each plant and measurements of melt cleanliness are made using the following foundry techniques: Prefil Footprinter, Spiral mold, Tensile, K mold, plus a modified K+ mold technique. The sensitivities of each testing method are discussed and differences between the ingot quality are revealed.

11:40 AM

**Grain Refiner Characteristics of a Novel Chemical Grain Refiner for Al Alloys:** Hari babu Nadendla<sup>1</sup>; M Nowak<sup>1</sup>; <sup>1</sup>Brunel University

We have recently developed an effective chemical grain refiner for Al alloys. Addition of this grain refiner to commercial pure Al and Al-Si alloy is observed to decrease the undercooling of the melt. As a result, fine grain structure is obtained for Al alloys cast at various cooling rates. Microstructural investigations of newly developed master alloy reveals presence of fine sized second phases. Their chemical composition has been investigated using high

resolution electron microscopy. It is found that there is a good lattice match between the second phase and Al, suggesting that these particles enhance heterogeneous nucleation sites in the Al melt. The paper also discusses optimization of chemical composition of newly grain refiner, microstructures of various casting alloys and their mechanical properties.

12:00 PM

**Modern Trends and Methods for Debottlenecking Primary Aluminum Smelters:** *Joe Petrolito*<sup>1</sup>; <sup>1</sup>Hatch

At the advent of the global financial crisis, aluminum smelters around the world are faced with similar challenges: generate more revenue with minimum capital investments. Accordingly, smelters are paying close attention to their existing operations in order to increase production via amperage creep to improve the bottom line. However, this cannot be accomplished solely by operations, finance or engineering working in isolation. Determining the best practical approach which delivers the highest returns with the least technical risk requires the continuous collaboration of all three parties. This paper will examine the interface between these parties: what are the recent trends in terms of debottlenecking projects and what methods are being used to ensure that both capex and opex are properly analyzed to ensure the operational, financial and technical success of the project.

12:20 PM

**Preparation of Al-Mg Alloys from MgO in KCl-MgF<sub>2</sub>-LiF Electrolyte by Molten Salt Electrolysis Method:** Fengli Yang<sup>1</sup>; Sh Yang<sup>1</sup>; Xianwei Hu<sup>2</sup>; Zhaowei Wang<sup>2</sup>; Zhongning Shi<sup>2</sup>; Bingliang Gao<sup>2</sup>; <sup>1</sup>Jiangxi University of Science and Technology; <sup>2</sup>School of Materials and Metallurgy117#, Northeastern University

Aluminum-magnesium alloys were prepared from magnesium oxide by molten salt electrolysis method. 30w% KCl-40w% MgF<sub>2</sub>-30w% LiF was taken as electrolysis. Effect of temperature on electrolysis was great. Back electromotor force (BEMF) was reduced 0.2-0.4V with electrolytic temperature from 800° to 840°. The process of electrolysis was controlled together by electrochemical polarization and concentration polarization. Content of magnesium in alloys was 6-8w%, and to be controlled by electrolytic time. Prepared aluminum-magnesium alloys were even. The results showed it was feasible to prepare aluminum-magnesium alloys from magnesium oxide in KCl-MgF<sub>2</sub>-LiF electrolyte by molten salt electrolysis method.

**Hume-Rothery Symposium Thermodynamics and Diffusion Coupling in Alloys - Application Driven Science: Thermodynamics and Diffusion**

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Alloy Phases Committee

*Program Organizers:* Zi-Kui Liu, The Pennsylvania State University; Larry Kaufman, CALPHAD, Inc.; Annika Borgenstam, Royal Institute of Technology; Carelyn Campbell, NIST

Monday AM  
February 28, 2011

Room: 31A  
Location: San Diego Conv. Ctr

*Session Chairs:* Gary Purdy, McMaster University; Staffan Hertzman, Outokumpu Stainless Research Foundation

8:30 AM Introductory Comments

8:40 AM Keynote

**WILLIAM HUME-ROTHERY AWARD LECTURE: Thermodynamics and Diffusion Coupling in Alloys - Application Driven Science:** *John Agren*<sup>1</sup>; <sup>1</sup>Royal Institute of Technology

As emphasized by Stokes (1997) the common assumption of a linear progression from basic research (science), via applied research, to technological innovations (engineering), should be questioned. In fact society would gain much by supporting long-term research that stems from practical problems and has usefulness as a key word. Such research may be quite

fundamental and often it cannot be distinguished from "basic" research if it were not for its different motivation. The development of the Calphad method and the more recent development of accompanying kinetic approaches for diffusion, serve as excellent examples and are the themes of this symposium. The drivers are, e.g., development of new materials, processes, and life-time predictions. Many challenges of utmost practical importance require long-term fundamental research. This presentation will address some of them, e.g. effect of various ordering phenomena on activation barriers, the strength and practical importance of correlation effects, etc.

9:20 AM Invited

**Application of Thermodynamic Equilibria and Kinetic Calculations to Phase Transformations in High Performance Stainless Steels:** *Staffan Hertzman*<sup>1</sup>; <sup>1</sup>Outokumpu Stainless Research Foundation

In the development and processing of modern stainless steels the phase evolution during thermal cycles plays a crucial role since the microstructure strongly influences the material performance. In order to facilitate the understanding and control of the transformations, computational thermodynamics is a prerequisite. Alloy development, weldability, processability and service performance require however different approaches and examples are given to illustrate the importance of relevant thermodynamic and kinetic modelling tools.

9:50 AM Invited

**The Implications of Thermodynamic Models on Diffusion Simulations:** *Ursula Kattner*<sup>1</sup>; Carelyn Campbell<sup>1</sup>; <sup>1</sup>National Institute of Standards and Technology

The importance of appropriate models for phase descriptions in thermodynamic modeling of systems employing the Calphad method is well known. Models should take into account crystal structure and preferred site occupancies on deviation from stoichiometry in multicomponent systems and reflect whether an order/disorder transformation is present. Models must also use a minimum number of independent parameters to describe the thermochemistry of phases. These requirements necessitate that compromises be made in the description of many phases, resulting in so-called simplified model descriptions. Improper simplification of a phase may not necessarily manifest itself during the thermodynamic calculations, but may become present during diffusion simulations. For instance, describing order/disorder phases with an order/disorder model or different sublattice models may not result in noticeable differences in the calculated phase diagram but may produce unreliable results if thermodynamic and diffusion mobility descriptions do not agree. Examples from calculations of superalloys and photovoltaics will be presented.

10:20 AM Break

10:40 AM Invited

**Modeling of Diffusion-Controlled Phase Transformations in Steel:** *Joakim Odqvist*<sup>1</sup>; <sup>1</sup>Royal Institute of Technology (KTH)

The local equilibrium hypothesis is usually adopted when modeling diffusion-controlled phase transformations. However, for finite interface velocities there will be a deviation from local equilibrium at the moving phase interface. Different approaches to model this deviation for the austenite-ferrite transformation are reviewed and compared with recent experimental findings. Furthermore, Larsson's model for modeling diffusion in the lattice-fixed frame of reference is modified to account for a cooperative mechanism for the interface migration.

11:10 AM Invited

**A Computationally Based Approach to Homogenizing Advanced Alloys:** *Paul Jablonski*<sup>1</sup>; Christopher Cowen<sup>1</sup>; <sup>1</sup>US Department of Energy

We have developed a computationally based approach to optimizing the homogenization heat treatment of complex alloys. The Scheil module within the Thermo-Calc software is used to predict the as-cast segregation present within alloys, and DICTRA (Diffusion Controlled TRAnsformations) is used to model the homogenization kinetics as a function of time, temperature and microstructural scale. We will discuss this approach as it is applied to both Ni based superalloys as well as the more complex (computationally)

case of alloys that solidify with more than one matrix phase as a result of segregation. Such is the case typically observed in martensitic steels. With these alloys it is doubly important to homogenize them correctly, especially at the laboratory scale, since they are austenitic at high temperature and thus constituent elements will diffuse slowly. The computationally designed heat treatment and the subsequent verification real castings are presented.

### 11:40 AM Invited

**Kinetic Transitions in the Growth of Ferrite during the Decarburization of Alloyed Austenite:** Gary Purdy<sup>1</sup>; Hatem Zurob<sup>1</sup>; Damon Panahi<sup>1</sup>; Christopher Hutchinson<sup>2</sup>; Yves Brechet<sup>3</sup>; <sup>1</sup>McMaster University; <sup>2</sup>Monash University; <sup>3</sup>Institut National Polytechnique de Grenoble

The growth of ferrite from alloyed austenite under conditions of controlled decarburization has proven a rich area for study, permitting the inference of the contact conditions for carbon at a migrating planar interface. In this contribution, we summarize recent findings with emphasis on transitions between full local equilibrium in the absence of alloying element partitioning (LE-NP) and the constrained local equilibrium state, paraequilibrium (PE). We have utilized Agren's evaluations of the diffusion coefficients of carbon in ferrite and austenite, first to validate the binary (Fe-C) results, then for the evaluation of the interfacial carbon concentrations for several cases of ternary iron alloys (Fe-C-X, where X is a substitutional solute). The implications of these observations are discussed in terms of new models for the migrating interfaces.

### Hydrogen Storage in Materials: Theory and Experiment: Session I

*Sponsored by:* The Minerals, Metals and Materials Society, ASM Materials Science Critical Technology Sector, TMS: Energy Conversion and Storage Committee

*Program Organizer:* Louis Hector Jr, GM R&D Center

Monday AM

Room: 13

February 28, 2011

Location: San Diego Conv. Ctr

*Session Chair:* Eric Majzoub, University of Missouri - St. Louis

### 8:30 AM

**A Consistent Thermodynamic Description of Hydrogen Diffusion and Defect Interaction in a Material Containing Dislocations, Voids and Micro-cracks:** Kiran Solanki<sup>1</sup>; Douglas Bammann<sup>1</sup>; <sup>1</sup>Mississippi State University

A finite deformation, rate and temperature dependent model of inelasticity is developed within the thermodynamic framework of Gurtin to describe the hydrogen effect on material deformation and material deformation on hydrogen transport. Internal state variables associated with statistically stored dislocations, the concentration of hydrogen and associated gradients and a consistent damage-elastic strain metric are introduced into the Helmholtz free energy, in addition to the standard variable of temperature. The theory is developed for large strains, whereby the total deformation gradient is multiplicatively decomposed into contributions from elasticity, damage, plasticity and hydrogen effects. Thermodynamic restrictions from the dissipation inequality result in the restriction that the stress and microforces are defined as derivatives of the free energy with respect to elastic-damage metric, and H concentration and its gradient, respectively. Furthermore, a general form for the chemical potential is constructed, based upon thermodynamic restrictions. Simplified models are examined and compared with experimental examples.

### 8:50 AM Invited

**Formation of Hydrogen Cottrell Atmosphere in Palladium: Theory and Measurement from Inelastic Neutron Scattering:** Dallas Trinkle<sup>1</sup>; Hyunsu Ju<sup>1</sup>; Brent Heuser<sup>1</sup>; <sup>1</sup>University of Illinois, Urbana-Champaign

Palladium has a high hydrogen solubility and diffusivity. H can be stored both in octahedral sites and in dislocation cores, which act as nanoscale

H traps--forming Cottrell atmospheres that are metal-hydride-like at low temperatures. The formation of a Cottrell atmosphere can be measured in situ with inelastic neutron scattering. Ab initio density-functional theory computes the potential energy for a hydrogen in the core of a partial dislocation and with volumetric strains. We model changes in the hydrogen potential from neighboring Pd vibrations to predict the vibrational density of states for hydrogen from 0K to room temperature. The predicted inelastic neutron scattering intensity compare with new measurements, which show a shoulder at 0K from the core and hydride formation, widening of the peak at 200K from spreading of the Cottrell atmosphere, and a shift in the peak at 300K as the atmosphere dissolves

### 9:30 AM

**Effects of Gaseous Impurities in Hydrogen on the Long Term Cycling Stability and Storage Capacity of Li3N:** Joshua Lamb<sup>1</sup>; Dhanesh Chandra<sup>1</sup>; Wen-Ming Chien<sup>1</sup>; Delphine Phanon<sup>2</sup>; Nicolas Penin<sup>2</sup>; Radovan Cerny<sup>2</sup>; Klaus Yvon<sup>2</sup>; <sup>1</sup>University of Nevada, Reno; <sup>2</sup>University of Geneva

We have studied the effect of gaseous impurities in hydrogen on Li-N-H. The gaseous contamination effects were studied using 100 ppm levels of impurity gases such as O<sub>2</sub>, H<sub>2</sub>O, CH<sub>4</sub>, CO and NH<sub>3</sub> mixed with UHP hydrogen. In addition, commercial-grade industrial hydrogen was also used. In the case of industrial hydrogen we found a ~50% loss (~2.6wt% out of ~5.6wt%H<sub>2</sub>) after 1100 pressure cycles. X-ray diffraction studies revealed formation of Li<sub>2</sub>O. The addition of H<sub>2</sub>O, CH<sub>4</sub>, NH<sub>3</sub>, and CO showed varying degrees capacity loss. We observed significant improvement in the reversible capacity up to ~10wt.%H after 516 cycles with 80/20 H<sub>2</sub>/N<sub>2</sub> mixtures, an improvement of ~7.1wt.H as compared to using hydrogen without nitrogen additives. We attribute this enhancement to the reaction of nitrogen with liquid lithium during cycling as the Gibbs energies of formation of Li<sub>3</sub>N ( $\Delta G_o = -100.16$  kJ/mol) are more negative than that of LiH phase ( $\Delta G_o = -50.74$  kJ/mol).

### 9:50 AM

**Analysis of Deformation Twins and the Partially Dehydrogenated Microstructure in Nanocrystalline Magnesium Hydride (MgH<sub>2</sub>):** David Mitlin<sup>1</sup>; Mohsen Danaie<sup>1</sup>; Shu Xia Tao<sup>2</sup>; Peter Kalisvaart<sup>1</sup>; <sup>1</sup>University of Alberta and NINT NRC; <sup>2</sup>Eindhoven University of Technology

We employed cryo-stage transmission electron microscopy (TEM), supported by density functional theory (DFT), to explore the microstructure of magnesium hydride (MgH<sub>2</sub>) powders. Mechanical milling results in deformation twinning of the hydride. The crystallography of the twins is established. DFT analysis shows that the twin unit cell is just as thermodynamically stable as the un-deformed a-MgH<sub>2</sub> matrix. We hypothesize that the twins contribute significantly to the observed milling-induced kinetic enhancement, by acting as high diffusivity paths for hydrogen. Energy-Filtered TEM (EFTEM) analysis on partially desorbed MgH<sub>2</sub> demonstrates that nucleation and growth of metallic magnesium occurs non-uniformly. Larger powder particles are a composite of isolated magnesium grains heterogeneously nucleated on the remaining hydride. Smaller particles are either fully transformed to magnesium or remain entirely a hydride. There is little evidence for any "core-shell" structure. We also show that in-situ hydrogen desorption in the TEM is not representative of the elevated-temperature ex-situ sequence.

### 10:10 AM Break

### 10:30 AM

**Mechanical Properties and Hydrogen Sorption in Mg/Nb Multilayer Films:** Byoungsoo Ham<sup>1</sup>; Xinghang Zhang<sup>1</sup>; <sup>1</sup>Texas A&M University

Mg/Nb multilayers with layer thickness varying from a few to 200 nm were prepared by the magnetron sputtering technique. The as-deposited films have Mg (0002) and Nb (110) textures. The hardness of films is greater at smaller individual layer thickness, and approaches a maximum when h is a few nm. The strengthening mechanisms in the multilayer are discussed. Hydrogen sorption studies were performed in some of the sputtered Mg/Nb multilayers. Sputtered multilayer films were loaded in hydrogen for 24 hr

at elevated temperature. The hydrogen desorption characteristic of textured Mg/Nb multilayer films will be reported.

**10:50 AM**

**Mg-Based Nanocomposites for Room Temperature Hydrogen Storage:** *Mieczyslaw Jurczyk*<sup>1</sup>; Marek Nowak<sup>1</sup>; Leslaw Smardz<sup>2</sup>; Andrzej Szajek<sup>2</sup>; <sup>1</sup>Poznan University of Technology; <sup>2</sup>Polish Academy of Sciences

In the last decade a great interest has been observed in the field of nanoscale materials. In this work, we study experimentally the electrochemical and electronic properties of Mg<sub>2</sub>M/A (M = Ni, Cu; A = C, Pd) and Mg<sub>2</sub>Ni/LaNi<sub>5</sub>/A nanocomposite hydrides. The nanocomposites were prepared by mechanical alloying followed by annealing. Results showed that the XPS valence bands measured for MA nanocrystalline alloys and composites showed a significant broadening compared to those obtained for microcrystalline materials. Furthermore, the surface segregation process of La (Mg) atoms in LaNi<sub>5</sub>/A (Mg<sub>2</sub>M/A) nanocomposites is stronger compared to that observed for the MA nanocrystalline LaNi<sub>5</sub> (Mg<sub>2</sub>M) alloys. Additionally, the nanocomposite structure reduced hydriding temperature and enhanced hydrogen storage capacity of Mg-based materials. The nanocomposite Mg<sub>2</sub>Ni (50 wt%)-LaNi<sub>5</sub> (50 wt%) material releases 1.6 wt% hydrogen at 250C. The strong modifications of the electronic structure and surface segregation effect in the nanocomposites could significantly influence their hydrogenation properties.

**11:10 AM**

**Desorption Kinetics of the Alkali Hexahydride Alanates (M<sub>2</sub>M'AlH<sub>6</sub>) at Constant Pressure Thermodynamic Driving Forces:** *Hongwei Yang*<sup>1</sup>; Andrew Goudy<sup>1</sup>; <sup>1</sup>Delaware State University

A study was done to compare the desorption kinetics of the first decomposition step in a series of the hexahydride alanates (Na<sub>3</sub>AlH<sub>6</sub>, Na<sub>2</sub>LiAlH<sub>6</sub> and K<sub>2</sub>NaAlH<sub>6</sub>). This comparison was made using a novel procedure in which the ratio of the equilibrium plateau pressure (Pm) to the opposing pressure (Pop), or the N-value, was the same. This represents the first time that such a comparison has been made in a complex hydride displaying two decomposition steps. Since the Gibbs free energy change is proportional to Ln(Pm/Pop), it was concluded that these experiments were carried out under constant thermodynamic driving forces. The results demonstrate that appropriate cation substitutions can be adopted to stabilize or destabilize the complex hydride. Modeling studies reveal the mechanisms controlling the kinetics for each alanate.

**11:30 AM**

**Ammonia Borane at High Pressures:** *Jiuhua Chen*<sup>1</sup>; Helene Couvy<sup>1</sup>; Vadym Drozd<sup>1</sup>; Haozhe Liu<sup>2</sup>; Yongzhou Sun<sup>1</sup>; Shah Najiba<sup>1</sup>; <sup>1</sup>Florida International University; <sup>2</sup>Harbin Institute of Technology

In situ synchrotron x-ray diffraction and Raman spectroscopy experiments of ammonia borane were performed at high pressures up to 23 GPa and elevated temperatures (300K – 505K). At ambient temperature, one first-order phase transition (I4mm to Cmc21) was observed at 1.3 GPa and one second-order phase transition were observed at about 5 GPa. The experiments reveal a bulk modulus of  $K = 9.3 \pm 0.4$  GPa ( $K' = 4.8$ ) for the I4mm phase,  $K = 11.9 \pm 0.5$  GPa ( $K' = 4.6$ ) for the Cmc21 phase below 5 GPa, and  $K = 37 \pm 4$  GPa ( $K' = 4.6$ ) for pressure above 5 GPa. There is a 6% volume drop at the first order phase transition. Transition pressures from I4mm to Cmc21 phases were determined at elevated temperatures. The phase boundary has a negative claperon slope of -1.67MPa/K. Rehydrogenation of decomposed ammonia borane was observed above 6 GPa.

**11:50 AM**

**Hydrogen Interactions with Li<sub>3</sub>N and Formation of Intermediate Complex Hydride Phases:** *Joshua Lamb*<sup>1</sup>; Anjali Talekar<sup>1</sup>; Wen-Ming Chien<sup>1</sup>; Dhanesh Chandra<sup>1</sup>; Delphine Phanon<sup>2</sup>; Nicolas Penin<sup>2</sup>; Radovan Cerny<sup>2</sup>; Klaus Yvon<sup>2</sup>; <sup>1</sup>University of Nevada, Reno; <sup>2</sup>University of Geneva

Complex of Lithium nitride are important for hydrogen storage. In this study we found evidence of solid solution phases Li<sub>2-x</sub>NH<sub>1+x</sub>, particularly at  $x=1/2$  (Li<sub>1.5</sub>NH<sub>1.5</sub>) during the progression of hydrogenation of Li<sub>2</sub>NH. In-situ x-ray diffraction data shows the progression of Li<sub>2</sub>NH to Li<sub>1.5</sub>NH<sub>1.5</sub> to LiNH<sub>2</sub> transitioning through single and two phase regions as the concentration of

hydrogen increases. In-situ x-ray diffraction, thermodynamic data, such as heat capacities of Li<sub>3</sub>N and Li-N-H complex hydrides, differential scanning calorimetric and thermogravimetric data will be presented.

**12:10 PM**

**Aluminoboranes and Boron Compounds for Hydrogen Storage:** *Ji-Cheng Zhao*<sup>1</sup>; Xuenian Chen<sup>1</sup>; Zhenguo Huang<sup>1</sup>; Teshome Yisgedu<sup>1</sup>; Hima Lingman<sup>1</sup>; Beau Billet<sup>1</sup>; Sheldon Shore<sup>1</sup>; <sup>1</sup>The Ohio State University

Boron-containing compounds have been studied extensively around the world in recent years for hydrogen storage due to their high gravimetric hydrogen density. We are investigating many boron hydrides including aluminoboranes and boron-cage compounds in addition to borohydrides. The materials we are synthesizing and studying include AlB<sub>4</sub>H<sub>11</sub>, (NH<sub>4</sub>)<sub>2</sub>B<sub>10</sub>H<sub>10</sub>, and (NH<sub>4</sub>)<sub>2</sub>B<sub>12</sub>H<sub>12</sub>. Results we obtained on their syntheses, structures and desorption processes will be presented.

## **ICME: Overcoming Barriers and Streamlining the Transition of Advanced Technologies to Engineering Practice -- The 12th MPMD Global Innovations Symposium: Plenary Session and the Integration of ICME**

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division  
*Program Organizers:* Paul Mason, Thermo-Calc Software Inc; Mei Li, Ford Motor Company; James Warren, National Institute of Standards and Technology; Jeff Simmons, AFRL

Monday AM  
February 28, 2011

Room: 7A  
Location: San Diego Conv. Ctr

*Session Chair:* Paul Mason, Thermo-Calc Software

**8:30 AM Plenary**

**Integrated Computational Materials Engineering: Current Status and Future Challenges and Opportunities:** *John Allison*<sup>1</sup>; <sup>1</sup>Department of Materials Science and Engineering, The University of Michigan

ICME is now a recognized field of study within some sectors of the materials community and industry. ICME has lead to substantial increases in the efficiency with which new components are developed and promises to improve the efficiency and robustness of the development of new materials. When it is fully embraced as a discipline within the materials profession, ICME has the potential to revolutionize the way the materials community provides input to the engineering and scientific communities. This talk will attempt to define the current status of the field by drawing from a National Academies report on ICME and reflecting on what has transpired since that report. It will also draw from the presenter's prior experience at Ford Motor Company in development and implementation of a successful ICME tools. The author will attempt to identify future challenges and opportunities for realization of the full potential offered by ICME.

**9:05 AM Plenary**

**Recent Progress of Multi-Scale Modeling of Solidification Process of Shape Casting:** *Baicheng Liu*<sup>1</sup>; Tao Jing<sup>1</sup>; Qinyan Xu<sup>1</sup>; Zhiqiang Han<sup>1</sup>; <sup>1</sup>Tsinghua University

The development of manufacturing industries requires an advanced and comprehensive system which integrates and optimizes the product design and manufacturing process and makes the product development efficient, economic and environment friendly. Integrated computational materials engineering (ICME) could be considered as a promising approach to fulfill this requirement. This paper presents recent progress of ICME, especially multi-scale modeling of solidification process of shape casting in China, including mathematical models and engineering application as well. Some case studies, including microstructure simulation of unidirectionally solidified turbine blade castings for aviation industry, microstructure simulation of aluminum and magnesium alloy castings based on cellular

MONDAY AM

automaton and phase field methods for automobile industry and simulation of casting and heat-treatment processes of turbine blade casting of water-turbine are discussed.

#### 9:40 AM Plenary

**Microstructure-Based Descriptions of the Deformation of Metals:** *Peter Gumbsch*<sup>1</sup>; Daniel Weygand<sup>2</sup>; Stefan Sandfeld<sup>2</sup>; Dirk Helm<sup>1</sup>; Alexander Butz<sup>1</sup>; <sup>1</sup>Fraunhofer IWM; <sup>2</sup>izbs, KIT

Metal forming simulations today are based on classical constitutive descriptions of yield behavior and hardening. Microstructural materials characteristics like texture, grain size or dislocation microstructure are rarely considered and never systematically evolved. This is due to a lack of available methodology. There is therefore a need for mechanistic and physically-consistent descriptions of plastic deformation on all levels of structural complexity. I will address three levels. First, single crystalline microcomponents are assessed using discrete dislocation dynamics simulations, which are inherently able to represent size effects. Second, progress in the development of a dislocation density based continuum theory of plasticity is demonstrated. Third, advanced homogenization techniques are used to bridge from single crystal plasticity to the deformation behavior of polycrystals. In a "virtual lab" one thereby computes texture evolution and associated changes in the yield locus. Such computed data can then be used to adjust the parameters of classical plasticity models.

#### 10:30 AM Invited

**The Development of the ICME Supply-Chain: Route to ICME Implementation and Sustainment:** *David Furrer*<sup>1</sup>; <sup>1</sup>Rolls-Royce

Integrated computational materials engineering (ICME) has been an evolving field for many years. Models which simulate materials-related phenomena have been developed and are being validated for industrial application. The integrating computational methods into material, process and component design has been a challenge, however, in part due to the development of a supply-chain that supports this emerging technology area. ICME touches many disciplines, which results in a requirement for many levels of computational-based technology organizations to be involved to provide tools that can be rapidly developed, validated, deployed and maintained for industrial applications. This talk will assess the need and current state of ICME supply-chain development and future requirements for the continued pace of introduction of ICME into industrial design practices.

#### 10:55 AM Invited

**On the Competitive and Pre-Competitive Aspects of ICME in New Technology Insertion - A Material Supplier Perspective:** *Robert Bucci*<sup>1</sup>; Mark James<sup>1</sup>; Markus Heinimann<sup>1</sup>; Michael Kulak<sup>1</sup>; <sup>1</sup>Alcoa Technical Center

Analytical consensus between supplier and OEM is key to new product acceptance - particularly so when design/certification path changes are needed to capture full advantage of promising approaches. The underpinnings of ICME facilitate new technology insertion with benefits to all. This in turn enables competitive advantage via product differentiation and knowledge transfer. This presentation describes how Alcoa is deploying ICME and related best practices to accelerate new product development. Past examples of material solutions that did and did not transition are reviewed with key lessons learned. The presentation main focus is on Alcoa's current application of ICME to: a) Bulk residual stress management in large single-piece airframe components machined from Alcoa Signature Stress Relief™ aluminum die-forgings; b) Mature advanced hybrid structural concepts utilizing optimized combinations of aluminum alloys and fiber metal laminates. Finally, pre-competitive and competitive aspects of ICME are discussed in context of the preceding.

#### 11:20 AM Invited

**Air Force Adoption of ICME for Materials and Manufacturing R&D:** *Katherine Stevens*<sup>1</sup>; Chuck Ward<sup>2</sup>; <sup>1</sup>Air Force Research Laboratory; <sup>2</sup>US Air Force

Numerous challenges and opportunities face the Air Force with regard to materials and manufacturing R&D. An aging Air Force aircraft fleet, a smaller defense industrial base, fewer major weapon systems produced, and a need for a more rapid and agile development cycle are all current challenges. Advances in physical understanding of materials and computational capability, when combined with a holistic systems engineering approach toward design of and with materials, provide a compelling case for adopting ICME as the necessary path to take for conducting materials and manufacturing R&D. The emerging ICME paradigm for materials engineering holds promise for reducing development time, cost, and risk. The transition to that paradigm presents needs for improved data structures, model verification and validation standards, and growth in quantitative descriptions of material behavior and manufacturing methods. Efforts by the Materials and Manufacturing Directorate to adopt ICME throughout its research and development program will be described.

#### 11:45 AM

**Cyberinfrastructure Support for Integrated Computational Material Engineering:** *Tomasz Haupt*<sup>1</sup>; <sup>1</sup>Mississippi State University

The goal of this effort is to develop a cyberinfrastructure to exploit the recent transformative research in material science involving multiscale physics-based predictive modeling, multiscale experiments and design. The cyberinfrastructure comprises a collection of materials databases as well as model, model calibration, and simulation tools at multiple size scales. It streamlines the process of gathering experimental results and deriving material properties and linking processes and properties at different length scales enabling one to design and develop the next generation materials and structural components exploiting the integrative nature of ICME. Moreover, through an Open Source process, it serves as a platform for collaborative research and transitioning research tools and codes to more robust tools ready for industrial use. The cyberinfrastructure is implemented using the Web 2.0 technologies including Wiki, AJAX-based rich user interfaces, Service Oriented Architectures (SOA), Web Services and Grid computing.

#### 12:05 PM Invited

**Building Knowledge Systems for the Design and Processing of Materials with Improved Performance Characteristics:** *Surya Kalidindi*<sup>1</sup>; Stephen Niezgoda<sup>1</sup>; Tony Fast<sup>1</sup>; Giacomo Landi<sup>1</sup>; <sup>1</sup>Drexel University

There exists a critical need to couple simulations over several length scales to predict macroscale performance characteristics, which tantamounts to executing complex numerical models within other sophisticated numerical models in a hierarchical manner. High performance data-mining tools are critically needed for harvesting efficiently the essential knowledge contained in the very large experimental and modeling datasets being produced by experts in the materials related fields. We have developed a novel framework called Materials Knowledge Systems that aims to establish highly accurate local interaction laws at each length scale by data-mining results from numerical models. Once established these local influence laws can be exercised with minimal computational effort as part of a scale-bridging framework for multi-scale materials modeling and design problems.

**Robustness of Ultrasonic Nonlinearity Measurements:** *Aurora Zinck*<sup>1</sup>; Krishnan Balasubramanian<sup>2</sup>; Sridhar Krishnaswamy<sup>1</sup>; <sup>1</sup>Northwestern University; <sup>2</sup>IIT Madras

Ultrasonic nonlinearity has been shown to be highly sensitive to microstructural changes compared to conventional ultrasonic techniques for structural health monitoring. Changes in the ultrasonic nonlinearity parameter,  $\backslash 946$ , have been qualitatively linked to changes in dislocation structures of mechanically loaded metals. In this work the limitations of current experimental techniques for measuring the ultrasonic nonlinearity by second harmonic generation are studied. Polycrystalline copper samples are monotonically loaded and the varied nonlinearities are measured by longitudinal waves traversing through the samples. The effect of experimental variables is explored through the use of multiple laboratory setups and procedures are outlined for optimized experimentation. Finally, the non-destructive measurements are compared to corresponding destructive measurements for an evaluation of the change in  $\backslash 946$  with respect to plastic deformation. These results suggest a comparison of ultrasonic nonlinearity testing methods that could be applicable for future use of ultrasonic nonlinearity as a structural health monitoring tool.

### 8:55 AM

**Impact Monitoring for Composite and Ceramic:** *Jyoti Agrawal*<sup>1</sup>; Subu Nayak<sup>1</sup>; <sup>1</sup>ScienceTomorrow

A structural health monitoring technology for composite and ceramic structures based on differential sensors is developed. While vibration-based frequency response function (FRF) used for structural health monitoring, the threshold of damage detection is too high and in case of an externally imposed vibration (such as that of an engine in an aircraft). The differential sensor in ScienceTomorrow's technology eliminates the effect of temperature and external vibration. Differential strain gauges amplify signal and reduce noise, for example, by subtracting a compressive strain signal from a tensile signal. A neural network algorithm calibrates the signal against temperature, external signal and noise. Tunable amplitude modulation uses the externally imposed vibration as the carrier vibration and detects any transient change in vibration such as an impact loading. The SHM system records impact loading (the composite and ceramics are most susceptible to) and correlates any damages as indicated by shift in natural frequency.

### 9:20 AM

**Nanocomposite Sensing Skins for Damage Identification and Localization:** *Kenneth Loh*<sup>1</sup>; *Bryan Loyola*<sup>1</sup>; <sup>1</sup>University of California, Davis

Structural systems are susceptible to damage resulting from yielding, cracking, impact, and corrosion during operation or service. In this study, structural damage identification and localization is performed via layer-by-layer assembled carbon nanotube-polyelectrolyte "sensing skins." Previous studies have verified that these conformable films exhibit highly sensitive electromechanical and electrochemical responses to applied strain

and corrosion processes, respectively. Instead of using these thin films as point sensors, they are coupled with an electrical impedance tomographic (EIT) spatial conductivity mapping technique. EIT relies on boundary electrical measurements to reconstruct the spatial conductivity map of the nanocomposite. Since electrical conductivity is calibrated to applied external stimuli, the conductivity maps directly correspond to spatial damage maps; one can then use the maps to precisely identify damage location and severity. A series of experiments are conducted to characterize the damage identification and localization performance of the sensing skins, namely non-uniform strains, impact, and corrosion.

### 9:45 AM

**Recent Progress on Processing of Amorphous Coatings:** *Sandip Harimkar*<sup>1</sup>; <sup>1</sup>Oklahoma State University

Amorphous materials or bulk metallic glasses represent a new class of advanced materials exhibiting attractive combinations of properties such as high strength/hardness and excellent wear/corrosion resistance. Even though the rapid solidification (casting) methods for processing amorphous alloys are well established, the need for simultaneous mold filling and rapid cooling rate limits the range of geometries that can be formed. These processing difficulties in combination with low tensile ductility and toughness are likely to limit the applications of amorphous materials as bulk structural materials. However, the amorphous materials can be good candidates for wear/corrosion resistant coatings on the crystalline substrates. In this presentation, an overview of the newest processing approaches, including thermal spraying, cold spraying, electrodeposition, and laser surface treatments (surface amorphization and cladding) for the fabrication of amorphous coatings will be highlighted. Also, the results of our recent research on spark plasma sintering of iron-based amorphous coatings will be presented.

### 10:10 AM

**Thermography Detection of Both Crystalline and Amorphous Materials during Cyclic Loading:** *P. Liaw*<sup>1</sup>; *Gongyao Wang*<sup>1</sup>; *B. Yang*<sup>2</sup>; *L. Jiang*<sup>3</sup>; *Y. Yokoyama*<sup>4</sup>; *A. Inoue*<sup>4</sup>; <sup>1</sup>University of Tennessee; <sup>2</sup>Shell Company; <sup>3</sup>General Electric Global Research Center; <sup>4</sup>Institute for Materials Research

It is of critical importance to find new ways to in-situ monitor the structural material fatigue damage so that in-time repairs will be possible, and failures or losses can be controlled. Usually temperature patterns serve as fingerprints during loading. In our lab, a state-of-art infrared (IR) thermography camera is employed to monitor the temperature evolutions of both crystalline and amorphous materials during fatigue experiments. With the understanding of the temperature evolutions during fatigue, thermography could provide the direct information and evidence of the stress-strain distribution, crack initiation and propagation, shear-band formation and growth, and plastic-zone evolution, which will open up wide applications in studying the structural integrity of engineering components in service. In-situ visualizations as well as qualitative and quantitative analyses of fatigue-damage processes have been performed using thermography results. Theoretical models combining thermodynamics and heat-conduction theory are developed to understand the fatigue behavior of both crystalline and amorphous alloys.

### 10:35 AM

**Differential Signal vs. Differential Sensor in Structural Health Monitoring:** *Subu Nayak*<sup>1</sup>; <sup>1</sup>ScienceTomorrow

Structural health monitoring circuit design are typically based on differential signaling. While noise and distortion are reduced in differential signal, the resolution is limited by the sensitivity of the sensor. Also, temporal and spatial information is not captured or processed. In this work, a novel differential sensor approach is being proposed. In lieu of or in addition to differential signal circuit, differential pair of sensors is being used to improve structural health monitoring. For example, in a mechanical system sensors strategically located to capture tensile as well as compressive stress are most effective in determining stress and health of structures. In corrosion, sensors monitoring local anodes and cathodes work as differential sensor. In dynamic systems, additional information in form of time stamping can provide temporal resolution for more accurate monitoring such as an impact

loading. This new approach is also fault tolerant when used in a distributed sensor network.

### Magnesium Technology 2011: Opening Session

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Magnesium Committee

*Program Organizers:* Wim Sillekens, TNO Science and Industry; Sean Agnew, University of Virginia; Suveen Mathaudhu, US Army Research Laboratory; Neale Neelameggham, US Magnesium LLC

Monday AM                      Room: 6F  
February 28, 2011              Location: San Diego Conv. Ctr

*Session Chairs:* Wim Sillekens, TNO Science and Industry; Suveen Mathaudhu, US Army Research Office

### 8:30 AM Opening of the Symposium and Presentation of the Best Paper Awards 2010

#### 8:50 AM Keynote

**Magnesium in North America: A Changing Landscape:** *Susan Slade*<sup>1</sup>; <sup>1</sup>US Magnesium LLC

The changing landscape of North American manufacturing in the context of global competition is impacting the market of all raw materials, including magnesium. Current automotive fuel economy legislation and pending legislation on the emissions of greenhouse gases are impacting magnesium's largest consuming industries, such as aluminum, automotive components, steel and transition metals. These industries are all considering innovative ways to efficiently incorporate the needed raw materials into their processes. The North American magnesium market differs from other regions based on maturity, supply streams, changing manufacturing capabilities and trade cases, combined with the transformation of North American manufacturing. The impact of these factors on the supply/demand dynamics of the North American magnesium market in both the short and long-term will be reviewed. The influence of new applications, products, and legislative changes are considered in the equation.

#### 9:20 AM Keynote

**Global Magnesium Research: State-of-the-Art and What's Next?:** *Karl Kainer*<sup>1</sup>; <sup>1</sup>GKSS Research Centre Geesthacht

In recent years magnesium and its alloys have been successfully introduced into weight-saving applications in the transportation industries in order to reduce fuel consumption and greenhouse gas emissions as well as to increase the performance of modern cars. Besides advantages, e.g. superior specific strength and excellent processability, applications of magnesium alloys are limited due to their inferior properties at elevated temperatures, e.g. low creep resistance and reduced corrosion behavior, especially when in galvanic contact with other metallic materials. Current developments are revealing possibilities to improve these properties by using modern alloys and processing routes. While the majority of industrial applications utilize cast products, the use of wrought magnesium alloys is still at an early stage. Within the framework of ongoing research and development, the corrosion behavior of both cast and wrought magnesium materials in standalone uses or in galvanic couples with other metallic materials is gaining increasing attention. New coating systems tailored to selected applications will have to be developed in order to increase the usage of magnesium alloys in the transportation industries in the future. This work also needs to be coordinated with new processes for joining magnesium alloys with similar and dissimilar metals and alloys, to achieve a broad spectrum of materials that fulfill the requirements given by the applications. This presentation will first address these issues and challenges, then discuss new developments and finally show some examples of new applications. In the conclusions, gaps and challenges will be analyzed and recommendations for sustainable research and development will be given.

#### 9:50 AM Keynote

**Environmental Challenges for the Magnesium Industry:** *Robert E. Brown*<sup>1</sup>; <sup>1</sup>Magnesium Assistance Group Inc.

The subject of environmental concerns with magnesium production and magnesium processing first started showing up in technical analysis of problems about the time of Life Cycle Analysis articles. Magnesium is produced and processed in relatively small quantities throughout the world. Annual magnesium production has been around 500-700,000 metric tons per year. This compares to aluminum which is produced in annual amounts up to 35 million metric tons. There have been some excellent review papers done, but a great amount of work related to electrolytic magnesium production which was the predominant method of production. That situation has changed totally in the past 10 years and now 85% of the world's magnesium is produced by thermal processes and most of that is in China. Comparison papers have been written comparing the environmental impacts of the two main magnesium production processes. As the measurement technology improves and as the total information references are better understood the environmental challenges can be more clearly identified. This paper reviews the situation and suggests some forward looking steps that might need to be taken.

#### 10:20 AM Break

#### 10:40 AM Keynote

**Predicting Mg Strength from First-Principles: Solid-Solution Strengthening, Softening, and Cross-Slip:** *Dallas Trinkle*<sup>1</sup>; *Joseph Yasi*<sup>1</sup>; *Louis Hector*<sup>2</sup>; <sup>1</sup>University of Illinois, Urbana-Champaign; <sup>2</sup>General Motors R&D Center

Predictive modeling of strength from first-principles electronic structure methods offers great promise to inform Mg alloy design. Simulating the mechanical behavior for new alloys requires an understanding of mechanisms for deformation at atomic-length scales, with accurate chemistry, extended to larger length- and time-scales. To design ductile Mg alloys, we identify solutes that strengthen basal slip and increase cross-slip. We use first-principles modeling of dislocations to predict dislocation motion under stress through a field of solutes at a finite temperature. First-principles flexible boundary conditions compute accurate core structures of basal and prismatic dislocations, and dislocation/solute interactions. We develop new models to predict the solute-strengthening for basal dislocations; cross-slip from basal- to prismatic-slip for a-type screw dislocations; and cross-slip stress with solutes. The first-principles data provides insight into the response of dislocations to solutes and the quantitative data to build new predictive models.

#### 11:10 AM Keynote

**Biodegradable Magnesium Implants - How do They Corrode In-Vivo?:** *Frank Witte*<sup>1</sup>; *Norbert Hort*<sup>2</sup>; *Frank Feyerabend*<sup>2</sup>; <sup>1</sup>Hannover Medical School; <sup>2</sup>GKSS Research Centre

Biodegradable magnesium implants are currently breaking the paradigm of designing and producing only corrosion resistant metallic biomaterials. The academic and industrial interest in this novel class of biomaterials is increasing dramatically in the recent years. First biodegradable metal implants have been realized as vascular stents and bone screws. However, the knowledge of the underlying degradation mechanism of these metal implants remains mainly undiscovered. This lecture will summarize the current published knowledge and recent advances in elucidating the in-vivo corrosion processes of these novel biodegradable magnesium implants.

#### 11:40 AM Keynote

**The Next Generation of Magnesium Based Material to Sustain the Intergovernmental Panel on Climate Change Policy:** *Fabrizio D'Errico*<sup>1</sup>; *Gerardo Garces*<sup>2</sup>; *Stefano Fare*<sup>1</sup>; <sup>1</sup>Politecnico di Milano; <sup>2</sup>Consejo Superior de Investigaciones Científicas (CSIC)

Current Mg alloys have several drawbacks that limit wide and profitable utilization in the industrial sector. From an environmental point of view, lighter metals like magnesium are currently considered unclean products as they are energy-intensive. But they have been proven to be "clean" in

the transport sector, as they can reduce fuel consumption. Here the potential of magnesium based materials is addressed through double-tasking: a) establish innovative lean-manufacturing processes, avoid the classic melting step to substantially reduce carbon footprint of the magnesium products; b) encourage the using of no-melt processes, realizing high-resistant ultra-fine microstructures. In September the European Union started the "Green Metallurgy 2020" project through the LIFE+ 2009 Programme. The program, which is coordinated by the Politecnico di Milano (ITA), was started in September 2010. And by using the no-melting route CENIM (SPA) has achieved up to 400 MPa UTS and an elongation capability of about 13% for some ultrafine bi-phase Mg-Zn-Y.

#### 12:10 PM Keynote

**JIM INTERNATIONAL SCHOLAR AWARD WINNER: Fracture Mechanism and Toughness in Fine- and Coarse-Grained Magnesium Alloys:** *Hidetoshi Somekawa*<sup>1</sup>; *Alok Singh*<sup>1</sup>; *Toshiji Mukai*<sup>1</sup>; <sup>1</sup>National Institute for Materials Science

The fracture mechanisms in the extruded magnesium alloys with two different grain sizes, 2 and 50  $\mu\text{m}$ , were investigated by SEM, TEM and EBSD microstructural observations. The coarse-grained alloy showed that the {10-12} type deformation twins formed at the beginning of test, and the crack was propagated into the boundaries between twins and matrix. On the other hand, the fine-grained alloy showed that the sub-grain boundaries formed instead of the deformation twins. No formation of twins at the early deformation stage causes a crack-tip blunting, and thus, the fracture toughness is a high value.

### Massively Parallel Simulations of Materials Response: Session I

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS Structural Materials Division, TMS/ASM: Computational Materials Science and Engineering Committee, TMS: High Temperature Alloys Committee  
*Program Organizers:* Diana Farkas, Virginia Tech; Susan Sinnott, University of Florida

#### 8:30 AM Introductory Comments

#### 8:40 AM Keynote

**Mesoscale Molecular Dynamics with LAMMPS:** *Steve Plimpton*<sup>1</sup>; <sup>1</sup>Sandia National Labs

I'll briefly describe our LAMMPS molecular dynamics (MD) code and highlight some of its design features that have made it easy for users to modify and extend. One area of recent development in the code has been for modeling solvated nanoparticle or colloidal systems. In an MD code this requires coarse-graining to achieve meaningful simulation times for the study of rheological and other manufacturing properties. This involves treating the nanoparticles as single point particles, moving from explicit to coarse-grained to implicit solvent, and capturing hydrodynamic effects. I'll describe efficient techniques we've developed for several models. The first is nanoparticles in a Lennard-Jones solvent, which involves multiple length scales. The second is the stochastic rotation dynamics (SRD) formalism, where solvent particles interact with nanoparticles via collisions but not with each other. Together these algorithms can enable speed-ups of several orders of magnitude, making solvated nanoparticle systems more accessible to modeling.

#### 9:20 AM Invited

**Implementation of Multi-level Parallelism in LAMMPS for Improved Scaling on PetaFLOP Supercomputers:** *Axel Kohlmeyer*<sup>1</sup>; <sup>1</sup>Temple University

Understanding the properties of vesicles with diameters between a few tens and hundreds of nanometers has many applications from transport mechanism in cells to the formulation of consumer products. Mechanism that guide fusion of vesicles or stabilize them are to specific for continuum level theory and too costly for all-atom molecular dynamics simulations. Coarse grain potentials for MD can help to overcome this dilemma. Still, petaflop range supercomputers are required and scaling and throughput of LAMMPS need to be improved to make those kind of studies possible. This has motivated the implementation of a hybrid OpenMP/MPI parallelization strategy into many modules of LAMMPS that span nearly the full range of applications. We will discuss the results of benchmark calculations using a variety of test systems and supercomputers and demonstrate how to scale inputs with long-range electrostatic and tens of millions of particles to over 100,000 processor cores.

#### 9:45 AM Invited

**Atoms-to-Continuum (AtC): A User Package for LAMMPS:** *Jonathan Zimmerman*<sup>1</sup>; *Reese Jones*<sup>1</sup>; *Jeremy Templeton*<sup>1</sup>; *Gregory Wagner*<sup>1</sup>; <sup>1</sup>Sandia National Laboratories

To enhance the capabilities of LAMMPS and expand its usefulness in the modeling and simulation of nanostructures, we have developed the user package and associated "fix", atc (atoms-to-continuum). This multi-purpose toolset can perform coupled finite element-molecular dynamics simulations, as well as calculate on-the-fly estimates of continuum mechanical fields (e.g. stress, temperature, displacement gradient) based on atomistic simulation results. In this talk, we discuss objectives, capabilities, and use-details for this user package. We also present several examples of how it's been used to perform multi-scale analysis of phenomena in physics, materials science and applied mechanics. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

#### 10:10 AM Break

#### 10:25 AM Invited

**Large-scale Excited Electron Molecular Mechanics/Dynamics:** *Andres Jaramillo-Botero*<sup>1</sup>; *Julius Su*<sup>1</sup>; *William Goddard*<sup>1</sup>; <sup>1</sup>Caltech

To simulate large electronically excited systems, we have developed [at the Materials and Process Simulation Center at Caltech] a molecular dynamics (MD) method that considers electrons explicitly - called the Electron Force Field (eFF). In eFF, the electrons interact with the nuclei and each other via pairwise effective potentials, and their motions are propagated independently, making it possible to go beyond adiabatic dynamics. Unlike other fermionic MD methods, our approach achieves a balanced description of both ground-state condensed systems and highly excited systems containing ionized electrons. eFF is thus uniquely suited to simulate materials in extreme conditions, where many electronically excited states of matter can occur and coexist, and overcomes salient limitations of quantum mechanics methods, restricted to tens of atoms and sub-picosecond time scales. I will summarize recent progress in developing the method, as well as results using the extended capabilities of our parallel implementation under LAMMPS, code-named pEFF.

#### 10:50 AM Invited

**Interface Free Energy of CuNb Multilayers Using Massively Parallel Metropolis Monte Carlo Simulations:** *Alfredo Caro*<sup>1</sup>; *Enrique Martinez*<sup>1</sup>; <sup>1</sup>LANL

Recent experimental discoveries and computational modeling of CuNb multilayers under irradiation suggest a particularly high resistance of these nanostructures to extreme environments. In this work we investigate the connection between interface stability under extremes and interface free energy. We use a recently developed algorithm (B. Sadigh et al. to be

published) called variance constrained semi-grand canonical Metropolis Monte Carlo, implemented into Lammmps, to predict microstructure and free energy of several CuNb nanostructures.

**11:15 AM Invited**

**Simulation of Nanofoams under Irradiation:** *Eduardo Bringa*<sup>1</sup>; J. Rodriguez-Nieva<sup>2</sup>; J. Monk<sup>3</sup>; D. Farkas<sup>3</sup>; A. Caro<sup>4</sup>; R. Johnson<sup>5</sup>; <sup>1</sup>CONICET-Universidad Nacional de Cuyo; <sup>2</sup>Instituto Balseiro; <sup>3</sup>Virginia Polytechnic Institute and State University; <sup>4</sup>Los Alamos National Laboratory; <sup>5</sup>University of Virginia

High-porosity materials can be found in a number of situations, from reactor materials to grains in space. Using LAMMPS for molecular dynamics (MD) simulations, we analyze the case of high porosity nano-scale foams, where experimental techniques are difficult to use and interpret. We consider two irradiation scenarios: (a) irradiation with ions with energies in the range 1-25 keV, of interest for fusion and fission energy applications; (b) swift heavy ion irradiation, with energies up to 5 GeV, relevant for track formation and interstellar grain evolution. Irradiation effects have larger spatial extent than for compact, full-density solids, and include the production of point-defects and twins which change the foam mechanical properties. In addition, we analyze the swift-heavy ion induced sputtering of these nanofoams.

**11:40 AM**

**A Two Temperature Model of Radiation Damage in  $\alpha$ -Quartz:** *Carolyn Phillips*<sup>1</sup>; Rudolph Magyar<sup>2</sup>; Paul Crozier<sup>2</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>Sandia National Laboratories

Two temperature models are used to model the interaction between the electronic subsystem and the atomic subsystem during thermal transients such as radiation damage, laser heating, and cascade simulations. By coarse-graining the electronic subsystem, its impact on thermal transients can be modeled in longer and larger classical molecular dynamics simulations. Building on the LAMMPS code, we introduce a new version of an inhomogeneous finite reservoir two-temperature model applied to an insulator,  $\alpha$ -quartz, to model heat deposition in a SiO<sub>2</sub> lattice. Our model of the SiO<sub>2</sub> electronic subsystem is based on quantum simulations of the electronic response in a SiO<sub>2</sub> repeat cell. The parameterization of the electronic subsystem has a significant impact on the degree of permanent amorphization of the lattice. We argue that the inclusion of a simple electronic subsystem substantially improves the realism of such radiation damage simulations.

**12:00 PM**

**Parallel Molecular Dynamics for Radiation Damage Modeling in Structural Materials:** *Christophe Domain*<sup>1</sup>; Charlotte Becquart<sup>2</sup>; Ghiath Monnet<sup>1</sup>; Dmitry Terentyev<sup>3</sup>; <sup>1</sup>EDF R&D; <sup>2</sup>UMET, UMR 8207; <sup>3</sup>SCK-CEN

To understand the microstructure evolution under irradiation, the defect formation mechanisms and interaction with the microstructure have to be investigated. Neutron or ion irradiation leads to displacement cascades, phenomena occurring at nanometer scale for few tens of picoseconds. The cascades are simulated using millions of atoms simulation boxes. The study of the dislocation interaction with irradiation defects requires also very large simulation boxes and long simulations to achieve the level of dislocation velocity comparable with the experimental one. Large parallel MD simulations are thus also required. Parallel MD simulations done using the DYMOKA code in Fe will be discussed for the modeling of pressure vessel steels. The importance of ab initio calculations will be underlined to assess the validity of the interatomic potentials used [Phil. Mag. 89 (2009) 3215]. The use of these results in multiscale modeling will be presented emphasizing their integration in upper scale models.

## Materials and Society: Linking Science and Technology for Global Energy Solutions: Plenary Session

*Sponsored by:* The Minerals, Metals and Materials Society, TMS: Materials and Society Committee

*Program Organizer:* Christina Meskers, Umicore

Monday AM  
February 28, 2011

Room: 11A  
Location: San Diego Conv. Ctr

**8:30 AM Plenary**

**A Plan for a Sustainable Future Using Wind, Water, and Sun:** *Mark Z. Jacobson*<sup>1</sup>; <sup>1</sup>Stanford University

In this talk, I will lay out a plan for the world to supply 100% of its energy for all purposes from wind, water, and sunlight (WWS) within the next 20-40 years and how materials will play a role in this plan. The study starts by reviewing and ranking major proposed energy-related solutions to global warming, air pollution mortality, and energy security while considering other impacts of the proposed solutions, such as on water supply, land use, resource availability, reliability, wildlife, and catastrophic risk. It then evaluates a scenario for powering the world on the energy options determined to be the best while considering materials, transmission infrastructure, costs, and politics. The study concludes that powering the world with wind, water, and solar technologies, which are found to be the best when all factors are considered, is technically feasible but politically challenging.

**8:55 AM Plenary**

**Metallurgical Considerations in the Photovoltaic Module:** *Funsho Ojebuoboh*<sup>1</sup>; <sup>1</sup>First Solar, Inc.

The incipience of thin film photovoltaic as a commercial power generator has occurred even as the device continues to be developed. At the same time, the commercial deployment of photovoltaic module manufacturing and the deployment of photovoltaic power plants have together emerged as a business sector on its own. In particular, since its incipience, CdTe PV has been on the cutting edge of a drive to achieve grid parity. Materials are invariably critical to all aspects of power generation and photovoltaic power generation is no exception. In fact, photovoltaic power generation is an increasingly active research and development thrust in Materials Engineering. One aspect of the thrust is investigating the sources, synthesis and characterization of input materials (raw materials) and the management of output materials, including spent process materials. In this presentation, we consider materials important to the production of the photovoltaic module; invariably, our focus is on thin film modules and particularly CdTe PV. In accord with the theme of the session, "Linking science and technology for global energy solutions," the presentation includes a discussion of a world powered by clean, affordable solar electricity and the materials challenges.

**9:20 AM Plenary**

**Electrical Energy Storage for Renewable Integration and Grid Applications: Status, Challenges and Opportunities:** *Zhenguo "Gary" Yang*<sup>1</sup>; <sup>1</sup>Pacific Northwest National Laboratory

Growing concerns over the environmental consequences of burning fossil fuels and their resource constrains, along with the increasing world energy consumption, have spurred great interests in renewable energy from sources such as wind and solar. However, the power from these intermittent sources is constantly varied, making quite challenging for its use and dispatch through the aging electrical grid. One effective way to smooth out the intermittency is to employ electrical energy storage. There are potential technologies for the applications, including batteries, super-capacitors, fly-wheels, compress air, pump hydro, etc. But these technologies either cannot meet the performance and cost matrices for broad market penetration or are simply limited by site selection or environmental constrains. As such there have been growing

interests and R&D activities in advancing the storage technologies. This paper offers an overview on varied technologies, in particular batteries, and discusses the status, challenges and research needs.

#### 9:45 AM Plenary

**The Rare Earth Contributions to Global Energy Solutions:** *Karl Gschneidner*<sup>1</sup>; <sup>1</sup>Iowa State University

The rare earths have many unique physical and chemical properties which make them important, if not critical, components in a variety of energy technologies. In the transportation sector: La is used in batteries; Ce in gasoline cracking catalysts and in three-way catalytic converters; Nd in the electric motors; Y as an oxygen sensor to control lean/rich fuel mixtures and as an oxidation resistant coating in aircraft turbine engines; and Y, Gd, Lu as the hosts and Eu, Tb, Dy and Er as the activators in phosphors for display units. In the energy generating and transmission sectors: Nd in NdFeB permanent magnets for wind generators; and Y in YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> superconductors in both wind generators and electrical transmission lines. While in the energy efficiency sector: phosphors (as noted above) in lighting – compact fluorescent lamps (CFL) and LED devices; La, Nd and Gd in magnetic refrigeration.

**Materials R&D to Enable a Nuclear Energy Renaissance:** *Steven Zinkle*<sup>1</sup>; <sup>1</sup>Nuclear Science and Engineering Directorate Oak Ridge National Laboratory

As part of a balanced portfolio of sustainable energy options, nuclear energy offers significant promise as a proven, cost-effective, and reliable baseline power option. In order to explore the potential to enhance the nuclear power contribution beyond its current level of 20% of US electricity production, three key initiatives are under investigation. The first initiative is examining the potential to safely and reliably extend the operational lifetime of existing nuclear power plants by quantifying the key materials degradation mechanisms and identifying materials replacement or damage mitigation solutions. The second initiative is exploring a broad range of new fission reactor concepts, encompassing Small (<300 MW) Modular Reactor designs that may be attractive for replacement of aging fossil energy plants as well as so-called “Generation IV” reactor concepts that offer further improvements in fuel sustainability, economics and safety. Finally, materials challenges for realizing practical fusion energy systems will be briefly reviewed.

#### 10:50 AM Plenary

**Energy Efficiency Studies:** *Ken Somers*<sup>1</sup>; <sup>1</sup>McKinsey

Abstract not available.

**Materials Challenges for Solid Oxide Fuel Cells: Application of Metallic Materials and Analysis of Oxide Ionic Diffusion at the Component Interfaces:** *Teruhisa Horita*<sup>1</sup>; <sup>1</sup>AIST

Solid Oxide Fuel Cells (SOFCs) can convert the chemical energy to the electricity directly with high efficiency. Because of their high operation temperatures around 873-1273 K, the component materials should be high temperature resistance materials such as alloy and ceramics. In this presentation, technological issues and challenges will be shown for improving the SOFC performance. Our recent activities related to the SOFC materials will be presented: 1) high temperature oxidation of alloy and compositional modification of alloy, 2) oxygen ionization and oxide ionic diffusion of cell components, and 3) degradation and durability of SOFC component materials with small amount of impurities. A short technological review will be made on the SOFC demonstration project in Japan as well as PEFC commercialized system.

#### 11:40 AM Plenary

**The Pivotal Role of Materials Science and Engineering for an Energy Efficient and Low Carbon Economy:** *Diran Apelian*<sup>1</sup>; <sup>1</sup>Worcester Polytechnic Institute

The most critical issue we face as a global society for a sustainable 21st century on the planet earth is energy. During the last 10 years, world population increased by 1 billion - from 6 billion to 7 billion in one decade. Annual projections for population growth hover a bit over 1.4% whereas energy consumption is growing at a faster rate ~1.7%; certainly not a sustainable scenario. Innovation in materials and material processing technologies is critical to achieving the longer term objectives of an energy-efficient and low-carbon world. While significant efforts have been made to identify breakthrough materials and their benefits, less attention has been given to the integration with materials manufacturing, including synthesis science, needed to propel promising materials candidates across the “valley of death” into cost-effective application at scale. This presentation will provide an overview of a study commissioned by the U.S. Department of Energy focused on identifying those areas where materials science and engineering can have the most significant impacts on energy efficiency and carbon reduction.

**Nickel Alloys Used in Nuclear Power Systems:** *Julie Tucker*<sup>1</sup>; *George Young*<sup>1</sup>; *Micah Hackett*<sup>1</sup>; <sup>1</sup>Knolls Atomic Power Laboratory

Nickel based alloys are used extensively in nuclear power systems due to their excellent combination of corrosion resistance, strength, and toughness. However, primary water stress corrosion cracking (PWSCC) of Alloy 600-type materials has been a significant issue in the commercial nuclear industry. Attempts to mitigate PWSCC via weld repair using high chromium filler metals is hindered by their susceptibility to both subsolidus (e.g. ductility dip cracking) and supersolidus (e.g. solidification cracking) defects. New construction utilizing PWSCC resistant alloys (e.g. A690) face similar challenges; high chromium nickel based alloys are susceptible to welding-induced cracking. This talk presents an overview of weldability and environmentally assisted cracking in nuclear power systems; presents work to quantify and predict primary water stress corrosion crack growth rates; and summarizes alloy 690 weld metal development research. This research has resulted in a new nickel alloy filler metal with a desirable combination of PWSCC resistance and weldability.

#### 9:15 AM

**Effect of Residual Stresses on SCC Crack Growth Specimens Fabricated from Weld Metal:** *Matthew Kerr*<sup>1</sup>; *Mike Hill*<sup>2</sup>; *Alexandrea Bogdan*<sup>3</sup>; *Darrell Dunn*<sup>1</sup>; <sup>1</sup>US Nuclear Regulatory Commission; <sup>2</sup>Hill Engineering, LLC; <sup>3</sup>Argonne National Laboratory

Pressurized water reactor piping system dissimilar metal welds are susceptible to primary water stress corrosion cracking (PWSCC) as an active degradation mechanism. PWSCC is highly influenced by the state of stress within susceptible material with tensile residual stresses in welds an

established driving force for PWSCC. Proper predictions or measurements of these residual stresses are essential to accurate crack growth assessment. The US Nuclear Regulatory Commission Office of Research is currently undertaking several programs aimed PWSCC mitigation and weld residual stress characterization. This talk focuses on the effect of residual stresses on welded SCC crack growth specimens fabricated from weld metal typical of nuclear reactor piping systems.

9:35 AM

**Enhancement of Intergranular Corrosion Resistance of TIG Welded and Laser-surface Melted SUS 304 for Nuclear Power Plants:** *Joung Soo Kim*<sup>1</sup>; Chin-Man Chung<sup>1</sup>; Sung-Hoon Baik<sup>1</sup>; Sang-Bae Lee<sup>2</sup>; <sup>1</sup>Korea Atomic Energy Research Institute; <sup>2</sup>Korea Institute of Science and Technology

In order to improve intergranular corrosion including intergranular stress corrosion cracking resistance of Type 304 stainless steel weld, its surface was melted using an pulse Nd:YAG laser beam. The thickness of surface melted by the laser beam was obtained to be around 390  $\mu\text{m}$  at a scan speed of 600 mm/min. and a laser power density of 20 J/mm<sup>2</sup>. The microstructures of the TIG welded region and the region laser-surface melted on the TIG weld were observed and analyzed using OM, SEM, and TEM attaching EDS. Then intergranular corrosion resistance of the two different specimens were characterized using a double loop electrochemical potentiodynamic reactivation(DL-EPR) polarization method at the same test condition. Intergranular corrosion resistance of the laser-surface melted SUS 304 weld was observed to be much higher than that of only TIG welded SUS 304. In this presentation, the mechanism of intergranular corrosion improvement by laser-surface melting will be discussed.

9:55 AM

**Mechanical Properties and Microstructural Evolution of ODS Alloys Joined by Solid State Welding:** *Evan Young*<sup>1</sup>; James Carillo<sup>1</sup>; Brian Jaques<sup>1</sup>; Jatu Burns<sup>1</sup>; Larry Zirker<sup>2</sup>; Indrajit Charit<sup>3</sup>; Darryl Butt<sup>1</sup>; Megan Frary<sup>1</sup>; <sup>1</sup>Boise State University; <sup>2</sup>Idaho National Laboratory; <sup>3</sup>University of Idaho

Oxide dispersion strengthened (ODS) alloys are used in nuclear reactors for their excellent high temperature strength, corrosion resistance and radiation damage resistance. Although the properties of ODS alloys make them ideal for nuclear reactor applications, conventional joining techniques degrade material properties. This study evaluates the mechanical properties and microstructural evolution that result from joining a ferritic alloy (HT-9) to an ODS alloy (Fe-based MA956 or Ni-based MA754) using either friction stir welding or pressure resistance welding. The mechanical properties of the welds are determined using both hardness mapping across the weld interface and crack growth experiments. Microstructural evolution is evaluated using electron backscatter diffraction and energy dispersive spectroscopy. Results show discrete regions with differing grain size and orientation across the weld affected zone. The goal of the work is to develop better welding procedures for ODS alloys such that these materials could be used more widely in nuclear applications.

10:25 AM

**Laser Welding for Nuclear Power Systems:** *Julie Tucker*<sup>1</sup>; Terrance Nolan<sup>1</sup>; George Young<sup>1</sup>; <sup>1</sup>Knolls Atomic Power Laboratory

Advances in laser welding technology are increasing the applicability of this joining technique to nuclear system welds. Advantages of laser welding include fiber optic delivery, high power density, small heat affected zones, minimal distortion and limited susceptibility to solidification or liquation cracking. These advantages are of special interest to next generation nuclear power systems where dissimilar metal welds are likely. Laser welds can be prone to defects, especially porosity and oxide inclusions. This work uses the corrosion resistant, nuclear structural material Alloy 690 to illustrate the effects of shielding, travel speed, focal point, and joint type on the penetration, defect type, and defect density in autogenous welds. The test welds were characterized by light optical microscopy, scanning electron microscopy, and x-ray computed tomography to quantify welding defects. Results show that

defect density decreases with increasing defocus. Additionally shielding gas can have a large effect on defect type and weld penetration.

10:45 AM

**Pressure Resistance Welding for Advanced Reactor Applications:** *Nathan Jerred*<sup>1</sup>; Larry Zirker<sup>2</sup>; Indrajit Charit<sup>1</sup>; Jim Cole<sup>2</sup>; Brian Jaques<sup>3</sup>; Troy Bradshaw<sup>4</sup>; James Carrillo<sup>3</sup>; Evan Young<sup>3</sup>; Megan Frary<sup>3</sup>; Darryl Butt<sup>3</sup>; Mitch Meyer<sup>2</sup>; K. Murty<sup>4</sup>; <sup>1</sup>University of Idaho; <sup>2</sup>Idaho National Laboratory; <sup>3</sup>Boise State University; <sup>4</sup>North Carolina State University

Pressure resistance welding (PRW) has been used to produce solid-state joints of high temperature materials, such as oxide dispersion strengthened (ODS) alloys, ferritic/martensitic steels and tungsten. The key emphasis of this study is to optimize the PRW parameters and characterize the welds of these alloys joined in similar and dissimilar fashions, and establish appropriate processing-microstructure-property relationships to facilitate their use in various nuclear applications. Initial studies have suggested that high quality welds can be made between MA957 cladding tubes and HT9 end-plugs. Initial bend and burst tests have shown encouraging results. Current efforts also include joining similar ODS alloys (MA956 and MA754) and tungsten coupons. A multi-physics program (COMSOL) has been employed to model the PRW process and predict initial input parameters prior to welding. Weld characterization experiments include micro-hardness, three-point bend, burst and tensile tests for mechanical integrity, and optical microscopy and scanning electron microscopy for microstructural characteristics.

11:05 AM

**Surface Modification of 316L Stainless Steel by a Low Temperature Severe Plastic Deformation Linear Raking Process:** *Giovanni Facco*<sup>1</sup>; Shashank Shekhar<sup>1</sup>; Andreas Kulovits<sup>1</sup>; Ravi Shankar<sup>1</sup>; Jorg Wiecek<sup>1</sup>; <sup>1</sup>University of Pittsburgh

The plane-strain machining process, linear raking, is a novel technique to modify microstructures of complex multi component alloy systems, which can be easily up-scaled. Linear raking offers access to severe plastic straining at high rate, modifies heat treatment alloy responses, often improving properties. Here we apply linear raking to 316L stainless steel to produce nano-structured and grain-boundary-engineered sub-surface layers, which could provide for enhanced mechanical and corrosion performance and improve irradiation tolerance. We use electron backscatter diffraction in the scanning electron microscope and automated acquisition and indexing of transmission electron microscope diffraction patterns to monitor the microstructure changes imposed by linear raking and annealing based processing. We correlate them with mechanical properties and stress corrosion susceptibility studies. We acknowledge using facilities of the Materials Micro-Characterization Laboratory, Department of Mechanical Engineering and Materials Science, University of Pittsburgh, and support by a grant from the Nuclear Regulatory Commission, NRC-38-09-935.

11:25 AM

**Serrations in Austenitic Fe-Cr-Ni Alloys:** *Young Suk Kim*<sup>1</sup>; Sung Soo Kim<sup>1</sup>; Dae Whan Kim<sup>1</sup>; <sup>1</sup>Korea Atomic Energy Research Institute

Tensile tests were conducted on 316L stainless steel with nitrogen over a temperature range of RT to 750oC at different strain rates of 1x10<sup>-2</sup>/s to 2x10<sup>-4</sup>/s. The 316L stainless steel showed serrated flow, a linear increase of strain hardening from 400 to 600oC and a negative strain rate sensitivity of strain hardening due to dynamic strain aging (DSA). Using neutron diffraction, the lattice contraction due to short range ordering (SRO) was seen to occur in the 40% cold-worked 316 stainless steel on aging at 400oC corresponding to a minimum of the tensile elongations. We first suggest that SRO is the cause of shear localization and serrated flow in austenitic Fe-Cr-Ni alloys. Using TEM, planar dislocations were confirmed in the 316L stainless steel after tensile deformation at 400oC where SRO was operating. This study definitively demonstrates that SRO is the cause of serrations and DSA in austenitic Fe-Cr-Ni alloys.

11:45 AM

**Precipitation and Spinodal Decomposition in a Lean Grade of Duplex Stainless Steel:** *Julie Tucker*<sup>1</sup>; *George Young*<sup>1</sup>; *Daniel Eno*<sup>1</sup>; <sup>1</sup>Knolls Atomic Power Laboratory

Duplex stainless steels are desirable for use in power generation systems due to their attractive combination of strength, corrosion resistance, and cost. However, thermal embrittlement at high temperature (~750°C), due to the precipitation of undesirable phases, can complicate fabrication. Similar embrittlement at low temperatures (~475°C), via spinodal decomposition, limits upper service temperatures for many applications. The recent development of lean grade alloys may improve the manufacturing margin and potentially increase the upper service temperature of these alloys. The present work assesses the thermal stability of lean grade of duplex stainless steel, AL2003 through a series of isothermal agings between 280°C and 815°C for times between 1 and 10,000 hours. Aged samples were characterized by changes in microhardness and Charpy-impact toughness. Microstructural characterization of the aged samples via transmission electron microscopy was also performed. This analysis has determined the rates and the temperatures at which these phase transformations occur.

12:05 PM

**High Temperature Fracture Toughness of Thermally Aged Inconel 617:** *Mikhail A. Sokolov*<sup>1</sup>; *Randy Nanstad*<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

Nickel-base alloy Inconel 617 is being considered as a structural material for application in the secondary heat exchanger of the New Generation Nuclear Plant, a very high temperature gas-cooled reactor. Inconel 617 has previously been shown to exhibit degraded toughness following thermal aging at elevated temperatures. Thermal aging of Inconel 617 plate and welds is being performed with tensile, Charpy impact, and fracture toughness tests conducted at temperatures to 950°C. Results of testing for thermal aging to 2,000 h have been obtained and are presented; varying effects of thermal aging temperature and time on fracture toughness are observed.

## Materials Processing Fundamentals: Solidification, Deformation, and Heat Treatment

8:30 AM

**The Influence of Solidification Rates on Hot Workability and Mechanical Properties of AM60 Magnesium Alloy:** *Goran Kugler*<sup>1</sup>; *Milan Tercej*<sup>1</sup>; <sup>1</sup>University of Ljubljana, NTF-OMM

The use of the up-to date light alloys and their development are in the sharp ascent especially in transportation industry. In the last years the use of the magnesium alloys for the various purposes was strongly increased. The aim of present research was to study the influence of solidification rate on hot workability and on obtained mechanical properties of AM60 magnesium alloy. The study was also focused on possibility to omit prior homogenisation process which would result in cost reduction. The solidification of gravity cast alloy has been investigated with various methods of the thermal analysis: "in situ" simple thermal analysis and simultaneous thermal analysis. In order to reveal optimal hot working conditions the deformation behavior was studied in the temperature range 200-450 °C and strain rates between 0.001-10 s<sup>-1</sup>. Mechanical properties have been studied with tensile and impact toughness testing.

8:45 AM

**Interplay of Flow and Solidification in a Horizontal Centrifugal Casting:** *Autumn Fjeld*<sup>1</sup>; <sup>1</sup>University of Leoben

A large-scale industrial centrifugal casting is simulated to investigate the interplay of flow and solidification during filling. In the casting under study the behavior of the flow is not fully understood; the relative motion of molten metal in the axial and circumferential directions is examined as well as the existence of a layered structure as the liquid contacts the mold and begins to solidify. Pick-up speed of the incoming metal is determined and influences of casting temperature, heat extraction, pouring rate, and rotation are considered. A single alloy and dual-alloy casting are simulated. In the case of a dual-alloy casting the mixing of the two alloys as the second alloy is poured onto the existing first alloy layer is characterized.

9:00 AM

**On the Homogenization of Cobalt Modified 17-4 PH Stainless Steel:** *Arpana Murthy*<sup>1</sup>; *Simon Lekakh*<sup>1</sup>; *Von Richards*<sup>1</sup>; *David Van Aken*<sup>1</sup>; <sup>1</sup>Missouri S&T

Three heats of 17-4PH stainless steel: with zero, three percent, and seven percent cobalt addition were melted in a 45kg (100lb) induction furnace under argon; and cast into no-bake molds and investment shell molds. Specimens were sealed into quartz tubes under vacuum, and homogenized at 1200°C from 2h to 72h. Computational thermodynamics and optical microscopy were used to predict and characterize the microstructures. A compromise between decrease in segregation and increase in lath martensite packet size was chosen for homogenization time. The specimens were austenitized, quenched, and characterized for retained austenite using X-Ray diffraction. Age hardening kinetics were studied at 454°C(850°F), 468°C(875°F) 482°C(900°F), and the activation energies for precipitation of copper were calculated. Tensile properties and Charpy V-notch toughness were measured in the peak aged condition. Fracture surfaces were observed using Scanning Electron Microscope. The addition of cobalt was found beneficial for the improvement of strength and Charpy V-notch toughness.

9:15 AM

**Investigation of the Effects of Solidification Rate and Melt Hydrogen Concentration on Porosity Formation in Aluminum Alloy 2024:** *Prince Anyalebechi*<sup>1</sup>; <sup>1</sup>Grand Valley State University

The effects of solidification rate, melt hydrogen concentration, and grain refining on porosity formation in aluminum alloy 2024 have been investigated with unidirectionally cooled laboratory-size ingots. The ingots were prepared from melts containing hydrogen concentration of 0.067, 0.19 cm<sup>3</sup>/100 g, and 0.27 cm<sup>3</sup>/100 g and solidified at 0.2-10 K/s. As expected, the amount of porosity and average pore size increased with increase in melt hydrogen concentration and decrease in solidification rate. However, the effect of solidification rate was greater at the relatively very low melt hydrogen concentration (0.067 cm<sup>3</sup>/100 g). Interestingly, addition of grain refiner decreased the amount of porosity and the average pore size. These results are consistent with reported effects of solidification rate, melt hydrogen content, and grain refining on porosity formation in other aluminum alloys.

9:30 AM

**Characterization of the Microstructure of Commercial-Size Ingots of Aluminum Alloy 3004:** *Prince Anyalebechi*<sup>1</sup>; <sup>1</sup>Grand Valley State University

The as-cast microstructure of two commercial-size electromagnetic cast ingots of aluminum alloy 3004 was quantitatively characterized. This involved the quantitative determination of across-width and through-thickness variations in dendrite cell size, grain size, macrosegregation of alloying elements, interparticle spacing, and the types, volume fractions, and sizes of the constituent or second phase particles. A significant microstructural heterogeneity across the width and through the thickness of both ingots was observed. For example, macrosegregation, and the sizes of the constituent phase particles, dendrite cells, and grains increased concomitantly from edge to mid-width and from surface to center of the ingots. There was a -20% depletion of Mg and a +54-87% enrichment of Ti in the center of the ingots. With the exception of grain size, there was no significant microstructural difference between the two ingots examined. The causes and practical

MONDAY AM

implications of the observed microstructural heterogeneity in the ingots are discussed.

**9:45 AM**

**Expansion and Collapse of Liquid Aluminum Foams:** *Zhuokun Cao*<sup>1</sup>; Chuan Li<sup>1</sup>; Hongjie Luo<sup>1</sup>; Guangchun Yao<sup>1</sup>; <sup>1</sup>Northeastern University, China

The expansion rate and collapse time of liquid aluminum foams are essential for the determination of operating time and quality of the resulting foam. In the present paper, liquid aluminum foams was fabricated by adding in TiH<sub>2</sub> as blowing agent, and the variation of expansion rate with foaming time was non-contact detected by a laser distance measurer. The influence of different stabilizing agent and alloying elements was studied. The results show the fact that the fraction of stabilizing agent only perform little effects on the maximum expansion rate of liquid aluminum foams, while the influence of alloy elements are remarkable. The maximum expansion rate would increase much when Mg is added, and the liquid foam also collapse at a shorter time. Comparison was made between experimental results and mathematic cancelations, which reveal the fact that it is the change of TiH<sub>2</sub> decomposition responsible for the change.

**Review of Classical Design Methods as Applied to Aluminium Billet Heating with Induction Coils:** *Mark Kennedy*<sup>1</sup>; Shahid Akhtar<sup>1</sup>; Jon Bakken<sup>1</sup>; Ragnhild Aune<sup>1</sup>; <sup>1</sup>Norwegian University of Science and Technology

In the present study classical induction design tools are applied to the problem of heating non-magnetic metal billets, using 50 Hz AC. As an example of great practical industrial interest, the induction heating of aluminum billets is addressed specifically. The predicted work piece power is compared with the measured work piece power for a long and a short coil, using well established methods, such as those of Burch and Davis, introduced in 1926/28, Dwight and Bagai in 1935, Baker in 1944/57, Vaughan and Williamson in 1945, and by Tudbury in 1960. A calculation methodology based on a combination of the available tools is also introduced and discussed. The method has proven to give an error of <10% of the actual work piece power. An equation for Tudbury's work piece shortness correction factor is disclosed for the first time.

**10:30 AM**

**Interactions of Non-metallic Inclusions with Steel and Slag: Thermodynamic Modeling, Experiments and Metallographic Analyses:** *Susanne Michelic*<sup>1</sup>; Mario Hartl<sup>1</sup>; Christian Bernhard<sup>1</sup>; <sup>1</sup>University of Leoben

One aspect of an efficient process and product optimization of the liquid steelmaking process is the understanding of reactions and interactions between the components steel, slag and non-metallic inclusions. The present paper focuses on a fundamental study of this topic by combining the powerful methods of thermodynamic modeling with systematic experiments on a laboratory scale and subsequent SEM/EDS analyses. The modeling aspect is addressed by the commercial software FactSage 6.1; laboratory experiments are performed for a low-alloyed, Ca-treated carbon steel combined with varying slag compositions. The consequent SEM/EDS analyses provide a detailed insight into the inclusion landscape which offers a strong tool for characterizing the modification of inclusions. In the present study the combination of these methods is mainly applied to oxides, due to their crucial influence on the final product quality, thus giving important indications for further optimizing the secondary metallurgy processes.

**10:45 AM**

**Liquid Metal Flows under Non-Homogeneous Magnetic Field: Lorentz Force Flowmeters in Metallurgy:** *Jurijs Kolesnikov*<sup>1</sup>; Christian Karcher<sup>1</sup>; André Thess<sup>1</sup>; <sup>1</sup>Ilmenau University of Technology

During the motion of molten metal under external non-homogeneous magnetic field the induced electric currents produce Lorentz body forces in the opposite direction to the flow, causing deformation of velocity profile, vortical structures, and adding a pressure drop across the magnetic field. The same Lorentz force acts on the magnet system. We analyse these phenomena in metallurgy, namely, at molten metal pumping, stirring, continuous casting,

and in contactless Lorentz force flowmeter (LFF). Experiments with liquid metal alloy, including direct measurements of Lorentz forces, velocities, electrical potentials, and flow structure visualization were conducted. Based on this study the industrial prototypes of LFF systems were designed, built, and tested in non-ferrous metallurgy and secondary aluminium production. A molten metal flow at high temperature (700°C–1200°C) can be effectively measured. The LFF technique method allows measuring precisely the volumetric and mass flow rates linearly linked with Lorentz force, and the mass accumulated within production process.

**11:00 AM**

**Study of Bake Hardening Effect on Laser Welded Hot Rolled Bainitic Steel:** *Mehdi Asadi*<sup>1</sup>; Heinz Palkowski<sup>1</sup>; Nicole Schlosser<sup>1</sup>; <sup>1</sup>TU Clausthal

The influence of bake hardening (BH) effect on laser welded hot rolled bainitic steel (BS) with respect to the process condition was investigated. Two process conditions were developed for this study. At the first one the samples were pre-strained and then laser welded. At the second one the samples were firstly laser welded and then pre-strained. Pre-straining the samples with defined degrees of deformation and a subsequent aging treatment leads to enhanced hardness and strengthening for the both conditions. The microstructure of the laser track zone (LTZ) and heat affected zone (HAZ) was studied. A high volume fraction of martensite could be observed in the LTZ as well as HAZ. The BS steel exhibited a clear BH effect in both, the as-received and the laser welded conditions. The BH effect is more pronounced in the pre-strained laser welded condition.

**11:15 AM**

**Research on the Combination of Microwave and Heat Pump Drying of Silica Sand:** *Hao Niu*<sup>1</sup>; Yu Li<sup>1</sup>; Ying Lei<sup>1</sup>; Libo Zhang<sup>1</sup>; *Jinhui Peng*<sup>1</sup>; Huilong Luo<sup>1</sup>; Shenghui Guo<sup>1</sup>; <sup>1</sup>Key Laboratory of Unconventional metallurgy, Ministry of Education

In this work, the combination of microwave drying (MWD) and heat pump drying (HPD) drying experiments were designed by response surface methodology (RSM) based on central composite design (CCD) using design expert software (Version 7.15), and the process parameters were optimized. The conditions given by software are: the MWD time is 4.6 or 4.4 min; the HPD time is 9.0 or 8.6 min; and the sample mass is 620 or 600 g. Under those conditions the moisture content is 1.0 10-2kg water/kg wet basis, and the effectiveness ratio is 0.70 kg water/kwh. The results of confirmatory experiments conducted under the optimized conditions show the combined drying have superiority of decrease of energy consumption and increase of handling capacity over the single MWD or HPD.

**11:30 AM**

**Surface Modification by Burnishing and Shot Peening Processes:** *Syed Hasan*<sup>1</sup>; M.A. Sadiq<sup>1</sup>; G. Rangajanardhan<sup>2</sup>; V Murti<sup>3</sup>; <sup>1</sup>Deccan College of Engg & Tech; <sup>2</sup>J N T U Vijayanagaram; <sup>3</sup>S V I T S

Burnishing and shot peening are surface modification processes involving cold working of the cutaneous layer of the part surface. Their commonality extends to the generation of compressive residual stresses and improvement of fatigue strength. Burnishing employs a spherical ball to press and shot peening employs spherical shots to impinge on the target surface. Their relative characteristics form the subject of this study. Burnishing reduces surface roughness and produces highly improved surface texture. Whereas peening produces a coarse surface texture with increased surface roughness thus clearly demarcating their suitable applications for surface modification. Burnished surfaces showed furrows from penetration and feed of the ball along the surface. Shot peening produces a matty surface with overlapping dents from impinging shots. The residual stresses and microhardness were more in shot peening compared to burnishing. Stainless steel with higher yield strength had higher induced stresses as well as microhardness compared to aluminium.

## Microstructural Processes in Irradiated Materials: Defects and Defect Processes

### 8:30 AM Introductory Comments

#### 8:40 AM Invited

#### Modeling Point Defect Cluster Behavior and Their Impact on RPV Embrittlement: Roger Stoller<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

Almost all radiation damage accumulation is the result of incomplete recombination of the vacancies and interstitials produced by the primary damage events. Thus, understanding the behavior of these point defects is essential to any predictive radiation damage model. The role of point defect clusters is particularly important in the case of cascade-producing neutron irradiation. A previously developed kinetic embrittlement model has been revised to account for recent advances in cluster dynamics modeling and insights obtained from molecular dynamics simulations. The impact of these revisions will be presented and assessed in terms of available experimental data, including data from commercial reactor surveillance programs. The new model will provide an improved basis for evaluating the effects of neutron flux (displacement rate) which is critical for determining how high flux data is being used to obtain high fluence data for reactor life extension.

#### 9:20 AM

#### Evolution Kinetics and Sink Strength of Interstitial Loops in Irradiated Materials: A Phase-field Model: Shenyang Hu<sup>1</sup>; Chuck Henager Jr.<sup>1</sup>; Yulan Li<sup>1</sup>; Fei Gao<sup>1</sup>; Xin Sun<sup>1</sup>; Mohammad Khaleel<sup>1</sup>; <sup>1</sup>Pacific Northwest National Laboratory

Interstitial loops are one of evolving defects in irradiated alloys. Their evolution, including spatial and size distributions, affects both vacancy and interstitial accumulation in the matrix, hence, the void formation and volume swelling. In this talk, we present a phase-field model to simulate the growth kinetics of interstitial loops under irradiation. The model takes into account the generation and reaction of vacancies and interstitials, and elastic interaction between interstitial loops and point defects. The local defect flux around the interstitial loop, the effect of defect generation rate, defect mobility and elastic interaction on growth kinetics and the sink strength, and the stability of interstitial loops are investigated. We will compare and discuss the results obtained from simulations and calculated by an empirical formula that is derived with a number of assumptions.

#### 9:40 AM

#### Void Ordering and Swelling Saturation as a "Chicken and Egg Problem": Stanislav Golubov<sup>1</sup>; Alexander Barashev<sup>2</sup>; Roger Stoller<sup>1</sup>; <sup>1</sup>ORNL; <sup>2</sup>The University of Liverpool

Formation of void lattices in metallic crystals exposed to irradiation with energetic particles is a most intriguing phenomenon, which has drawn the attention of both experimentalists and theoreticians for about 40 years. Two striking features of the void lattices are: (1) coincidence of their type and orientation with the crystal lattice and (2) the saturation of swelling. It is commonly believed that (1) is due to one-dimensional migration of self-interstitial clusters produced in displacement cascades, while (2) is due to the resistance of voids to growth when arranged in a lattice. However, there is a

contradiction between these two explanations since the swelling rate would increase due to free channel formation. In this paper the situation is critically analyzed, so as to determine whether either phenomenon can be implicated as the cause of the other, or whether an underlying mechanism is responsible for both the void lattice and swelling saturation.

#### 10:00 AM

#### Non-Saturable Sinks at Grain Boundaries in Nanostructured Molecular Dynamics Simulations: Yongfeng Zhang<sup>1</sup>; Hanchen Huang<sup>2</sup>; Paul Millett<sup>1</sup>; Michael Tonks<sup>1</sup>; Dieter Wolf<sup>1</sup>; Simon Phillpot<sup>3</sup>; <sup>1</sup>Idaho National Lab; <sup>2</sup>University of Connecticut; <sup>3</sup>University of Florida

The defect accumulation in nanocrystalline Mo under electron irradiation is studied using molecular dynamics (MD) simulations. The nanostructured Mo is simulated using a bi-crystal model with  $<100>$   $\square$   $29$  twist boundaries as representation of high angle/energy grain boundaries. By assigning a kinetic energy of 40 eV to randomly selected Primary Knock-on Atoms (PKA), electron irradiation is simulated under 2000K until the defect concentration reaches steady state (in  $< 100$  ns). The development of defect concentration obtained from MD simulations agrees well with the prediction of rate theory with parameters derived from MD simulations. With regard to the constant sink strength used in rate theory, this result suggests that high angle/energy grain boundaries are non-saturable sinks for point defects under electron irradiation. In supporting, structural analysis of both short range order by pair correlation function and long range order by planar structure factor shows no change in the grain boundary structure.

#### 10:20 AM Break

#### 10:40 AM

#### Modelling of Displacement Cascades in Thin Foils of Iron: Andy Calder<sup>1</sup>; Yuri Osetsky<sup>2</sup>; David Bacon<sup>1</sup>; Alexander Barashev<sup>1</sup>; <sup>1</sup>University of Liverpool; <sup>2</sup>ORNL

Recent MD simulations of cascades in bulk iron have revealed a sub-picosecond shock-front mechanism for the creation of large interstitial clusters and that the nature of this damage is determined before the thermal spike phase of the cascade. A decelerating supersonic front from the primary recoil event produces an expanding volume of destroyed lattice. Large self-interstitial clusters form on the transonic boundary of this zone if a peripheral hypersonic recoil had created a secondary zone just ahead of this boundary. Where the two zones meet, one injects atoms into the low-density core of the other and they become interstitial clusters. Modelling has now been extended to study free-surface effects in thin samples of iron, allowing direct comparison with experimental results on ion-irradiated films from earlier TEM studies and current picosecond-to-microsecond time-resolved x-ray scattering measurements of displacement cascade dynamics.

#### 11:00 AM

#### Stoichiometry Dependence of the Evolution of Irradiation-Induced Defect Clusters in $Ce_xLa_{1-x}O_2$ : Wei-Ying Chen<sup>1</sup>; Di Yun<sup>2</sup>; Aaron Oaks<sup>1</sup>; Bei Ye<sup>1</sup>; Mark Kirk<sup>2</sup>; James Stubbins<sup>1</sup>; Yinbin Miao<sup>1</sup>; <sup>1</sup>U of Illinois at Champaign-Urbana; <sup>2</sup>Argonne National Lab

To study the stoichiometry dependence of irradiation effects in fluorite-type mixed oxide nuclear fuel ( $UPuO_2$ ), the technique of ion implantation in La doped ceria ( $Ce_xLa_{1-x}O_2$ ) is used. Xe ions were implanted into cerium dioxide single crystals with 0%, 5% and 25% La concentration at 600°C. In-situ transmission electron microscope (TEM) was utilized to observe the damage process and defects created by the ion beam irradiation. A substantial difference in dislocation loop density for 5% and 25% cases was observed at the same dose. For example, loop density is  $2 \times 10^{11} \text{ cm}^{-2}$  on  $CeO_2$  doped with 5% La and  $2 \times 10^{10} \text{ cm}^{-2}$  with 25% La when the dose reaches  $1 \times 10^{14} \text{ ions/cm}^2$ . Kinetic Monte Carlo calculations were also performed to study the oxygen diffusivity in  $Ce_xLa_{1-x}O_2$  at different stoichiometric conditions. Calculation results show the oxygen diffusivity dependence on La concentration, which compliments the experiment results.

11:20 AM

**Relevance of fcc-bcc Interface Structure to Defect Properties at Interfaces in Irradiation Environment:** *Xiang-Yang Liu*<sup>1</sup>; Richard Hoagland<sup>1</sup>; Michael Demkowicz<sup>2</sup>; Xiang-Ming Bai<sup>1</sup>; Blas Uberuaga<sup>1</sup>; Michael Nastasi<sup>1</sup>; Amit Misra<sup>1</sup>; John Hirth<sup>1</sup>; <sup>1</sup>Los Alamos National Lab; <sup>2</sup>Massachusetts Institute of Technology

Nanolayered Cu-Nb composites exhibit high strength and enhanced radiation damage tolerance. To understand the relevance of interface structure to interface properties in fcc-bcc systems, tunable potentials offer a fairly simple way to selectively vary parameters independently. In this work, the parameterization of the EAM interatomic potential in fcc-bcc system is modified to understand the interface properties. We first change the dilute heats of mixing between Cu and Nb and investigate the effect on interface structure and defect formation energies near interface. To understand the interface behavior in different lattice misfit environment, the relative lattice constants between Cu and the bcc crystal are varied. Interface dislocation analysis based on Frank-Bilby formulation is to be presented, together with atomistic simulation result. Defect-interface interactions are studied with molecular dynamics (MD) and accelerated MD method, to predict the radiation damage tolerance of these interface systems.

11:40 AM

**Towards a Unified Framework for Interatomic Potential Development: Application to the Fe-He System:** *Mark Tschopp*<sup>1</sup>; Kiran Solanki<sup>1</sup>; Mike Baskes<sup>2</sup>; Mark Horstemeyer<sup>1</sup>; Fei Gao<sup>3</sup>; Xin Sun<sup>3</sup>; Moe Khaleel<sup>3</sup>; <sup>1</sup>Mississippi State University; <sup>2</sup>LANL; <sup>3</sup>PNNL

Atomistic simulations require interatomic potentials that are able to reproduce electronic structures information while predicting properties outside of the values they were fit to. However, the design cycle for new interatomic potential development is often a lengthy process. The objective of this research is to outline a methodology for efficiently probing potential parameter space to locate optimal interatomic potentials. Here, we use a combination of random sampling techniques, response surface methodology, and optimization methods to develop an Fe-He modified embedded atom method (MEAM) interatomic potential. This methodology will be used to develop multiple Fe-He potentials, which will then be used to calculate the variability in atomistic properties based on the interatomic potential. Moreover, this methodology will be applied to other interatomic potentials to show the robustness of the methodology. Atomistic simulations rely upon good interatomic potentials and shortening this design cycle can encourage tailoring interatomic potentials for specific applications.

12:00 PM

**A New Directional Model for the Electronic Frictional Forces in Molecular Dynamics Simulations of Radiation Damage in Metals:** *Christopher Race*<sup>1</sup>; Daniel Mason<sup>2</sup>; Adrian Sutton<sup>2</sup>; <sup>1</sup>Max-Planck-Institute for Iron Research; <sup>2</sup>Department of Physics, Imperial College London

The damage caused by collision cascades in irradiated materials forms the initial conditions for longer term microstructural evolution. The exchange of energy between electrons and ions during cascades can significantly affect this damage. Models for incorporating this exchange within classical molecular dynamics (MD) simulations exist, but all approximate the ion-electron energy transfer via a damping force, opposed to ionic motion. Although such forces predict the total energy transfer over the duration of cascades, they do not capture the complex dependence of the electronic friction force on the speed, direction and atomic environment of individual ions. Here we present a new model for the electronic friction force, derived from quantum-classical Ehrenfest dynamics, which captures this complexity and is suitable for inclusion in existing MD codes at near zero computational cost. We show that our model reproduces the atomic level detail of the electronic friction force in time-dependent tight-binding simulations of cascades.

## Neutron and X-Ray Studies of Advanced Materials IV: Interfaces, Surfaces, Nanostructures

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Chemistry and Physics of Materials Committee

*Program Organizers:* Rozaliya Barabash, Oak Ridge National Laboratory; Xun-Li Wang, Oak Ridge National Laboratory; Jaimie Tiley, Air Force Research Laboratory; Peter Liaw, The University of Tennessee; Erica Lilleodden, GKSS Research Center; Brent Fultz, California Institute of Technology; Y-D Wang, Northeastern University

Monday AM  
February 28, 2011

Room: 10  
Location: San Diego Conv. Ctr

*Session Chairs:* Dean Haefner, Argonne National Laboratory; Rozaliya Barabash, Oak Ridge National Laboratory

8:30 AM Keynote

**Study of Advanced Materials and Devices Using High-Resolution Hard X-Ray Microscopy:** *Jörg Maser*<sup>1</sup>; Martin Holt<sup>1</sup>; Robert Winarski<sup>1</sup>; Volker Rose<sup>1</sup>; Peter Fuesz<sup>1</sup>; Brian Stephenson<sup>1</sup>; <sup>1</sup>Argonne National Laboratory

The Center for Nanoscale Materials' Hard X-ray Nanoprobe (HXN) provides characterization of composition and structure of nanoscale materials and devices with high spatial resolution. A major contrast mode is nanodiffraction, which allows mapping of local phase and strain with a spatial resolution of 40 nm. This provides a powerful tool for investigation of advanced thin film materials and devices, where strain can play an important role in materials properties such as phase transition temperature and electrical conductivity. Our high spatial resolution allows us to study materials systems at technologically relevant length scales. We will present studies of structural changes in resistive RAM structures, strained nanoscale silicon-on-insulator channels, and ferroelectric domains in nanocapacitors, as well as discuss a coherence-based techniques for the high resolution study of crystalline thin films.

8:55 AM

**Depth-Dependent Strain Gradients and Interface Strength of Submicron Single Crystalline Mo in Brittle or Ductile Environment from 3D Micro-Laue Diffraction:** *Rozaliya Barabash*<sup>1</sup>; Hongbin Bei<sup>1</sup>; Yanfei Gao<sup>1</sup>; Oleg Barabash<sup>1</sup>; Gene Ice<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

Advanced composites with metal or ceramic constituents offer high strength and have a number of advantages with respect to individual phases. As the size of reinforcing fibers/whiskers/lamellae decreases, the importance of defects, boundaries and interfaces increase. Using 3D X-ray microdiffraction we nondestructively probe the depth-dependent strain gradients and interface strength in model systems of submicron single crystalline Mo in NiAl or Ni matrix (JMR 25, 2, 2010). Coupled with micromechanical analysis, our study shows that the relaxation of the residual thermal strains in the NiAl/Mo or Ni/Mo composites results in the formation of the near-surface "slip zone" with large strain gradients in both the reinforcing Mo fibers and the matrix. Based on these results we suggest a new approach to determine the fiber/matrix interface strength for nano- and micro-composites. Research was supported by the Materials Sciences and Engineering Division, Office of Basic Energy Science, U.S. Department of Energy.

9:10 AM Invited

**Strain Screening by Oxygen Vacancies in SrTiO<sub>3</sub>:** *Joel Brock*<sup>1</sup>; <sup>1</sup>Cornell University

Recently, Freedman et al. [Phys. Rev. B80, 064108, 2009] calculated the elastic dipole tensor for several types of point defects in SrTiO<sub>3</sub> and showed that it is nearly traceless for oxygen vacancies. Thus, oxygen vacancies are able to screen elastic strain fields. Here, we report detailed diffuse x-ray scattering measurements of bulk SrTiO<sub>3</sub> crystals prepared with controlled oxygen vacancy distributions. We verify the traceless nature of the elastic

dipole tensor of an oxygen vacancy and demonstrate both correlations between oxygen vacancies and elastic strain screening by oxygen vacancies.

#### 9:30 AM Invited

**Structure and Thermal Evolution of a Metallic Glass That Grows from the Melt through a First-Order Transition:** *Gabrielle Long*<sup>1</sup>; *Karena Chapman*<sup>1</sup>; *Peter Chupas*<sup>1</sup>; *Leonid Bendersky*<sup>2</sup>; *Lyle Levine*<sup>2</sup>; *Judith Stalick*<sup>2</sup>; *Frederic Mompiou*<sup>3</sup>; *John Cahn*<sup>4</sup>; <sup>1</sup>Argonne National Laboratory; <sup>2</sup>NIST; <sup>3</sup>CNRS; <sup>4</sup>University of Washington

In recent decades, metallic glass structures have been documented with increasing precision, but our understanding is still at best incomplete. One direct proof of this is the proliferation of partially successful models attempting to classify the underlying generalized structure. To approach a fundamental understanding of metallic glasses, it can be illuminating to investigate extreme examples. We investigated an unusual metallic glass that grows from the melt by a first order phase transition in the manner of a crystal, but scatters as a metallic glass. Well-defined nano-domains that closely resemble atomic arrangements within alpha-AlFeSi were identified. Under an isothermal anneal, the glass rejects aluminum and relaxes into a more stable and persistent configuration. As the anneal continues, there is a peritectic reaction in which the rejected aluminum-plus-glass undergoes a first order phase transition to a crystalline phase unrelated to the nano-ordered domains in the original glass, as if no nano-ordering existed.

**Nanosecond Piezoresponse Measurements on Thin Epitaxial Ferroelectric Films at the Hard X-Ray Nanoprobe Beamline:** *Matthew Highland*<sup>1</sup>; *Martin Holt*<sup>1</sup>; *Robert Winarksi*<sup>1</sup>; *John Pearson*<sup>1</sup>; *G. Brian Stephenson*<sup>1</sup>; *Jorg Maser*<sup>1</sup>; *Stephen Streiffer*<sup>1</sup>; *Ralu Divan*<sup>1</sup>; *Carol Thompson*<sup>2</sup>; <sup>1</sup>Argonne National Laboratory; <sup>2</sup>Northern Illinois University

Our goal is to study polarization dynamics in nanoscale ferroelectric heterostructures as the size of the structure approaches the domain size, and in ultrathin films where interfacial effects dominate. In this talk, we describe the development of stroboscopic scattering techniques using the Hard X-ray Nanoprobe at the Advanced Photon Source by implementing a chopper to isolate individual 100 ps x-ray pulses and synchronize them to electrical stimulation of the sample. We also describe our progress in developing protocols to pattern and integrate working devices from ultrathin epitaxial PbTiO<sub>3</sub> films on SrRuO<sub>3</sub>/SrTiO<sub>3</sub> substrates. These devices retain the ferroelectric properties and crystalline quality of the virgin film, and allow electrical access within the constraints imposed by nanoprobe focusing optics. Results are presented showing nanosecond piezoelectric response of thin ferroelectric films using these devices. Work supported by US-DOE under Contract No. DE-AC02-06CH11357.

#### 10:10 AM Invited

**Kinetic Studies of Microstructure Evolution in Nanostructured Materials:** *Matteo Leoni*<sup>1</sup>; *Paolo Scardi*<sup>1</sup>; *Mirco D'Incau*<sup>1</sup>; <sup>1</sup>University of Trento

The knowledge of the evolution in temperature of a nanocrystalline material is the key to its optimization for industrial applications. Synchrotron radiation X-ray diffraction and modern line profile analysis (e.g. the Whole Powder Pattern Modeling) are ideal tools to follow in situ kinetics on the nanoscale. The microstructure evolution data obtained from the analysis of diffraction patterns collected in ramp at several heating rates, show how X-ray diffraction can be the ideal complementary tool to thermal analysis. Basics and examples will be discussed.

#### 10:30 AM Keynote

**Advances in Neutron and X-ray Micro/Nano Diffraction:** *Gene Ice*<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

Both X-ray and neutron microdiffraction methods are rapidly evolving due to the availability of powerful new sources and advanced focusing optics and detectors. Achromatic optics and methods are particularly interesting for studies of materials with unknown crystallographic orientation, and are essential to efficiently use spallation neutron sources. We describe recent spatially-resolved studies with X-ray and neutron probes that illustrate the

future of these methods. We also describe how these techniques can be optimized to exploit a coming generation of new ultra-high-brilliance third generation X-ray sources and the new spallation neutron sources. Work sponsored by the U.S. Department of Energy (DOE), Office of Basic Energy Sciences, Division of Materials Sciences and Engineering. Experiments performed on Beamline 34-ID at the Advanced Photon Source Argonne II, and the SNAP beamline at the SNS. Both 34-ID and SNAP are supported by the DOE Office of Basic Energy Science, Division of User Facilities.

#### 11:05 AM Invited

**Adhesion, Cohesion and Plasticity of Thin Metal Films:** *Ralph Spolenak*<sup>1</sup>; <sup>1</sup>ETH Zurich

Thin metal films as conductor materials for wearable microelectronics are usually deposited on polymeric substrates. Thus in addition to their electrical resistivity, the adhesion to the substrate, their plastic deformation modes and their resistance against fracture are of relevance for the application. In the current paper comprehensive studies of fracture patterns by direct observation (optical and scanning electron microscopy) as well as synchrotron based X-ray diffraction are presented. The materials range from brittle Ta and Ti films, where the effects of phase and patterning on fracture are discussed, to the precursors of plastic failure in the Au-Cu, Al-Mg and Al-Li systems. X-ray peak shifts as well as peak broadening is related to microstructural changes in the thin film materials and pathways for optimal ductility are elucidated.

#### 11:25 AM Invited

**X-Ray Diffraction Studies of Structural Transitions in Some Pnictide Superconductors:** *Zahirul Islam*<sup>1</sup>; *Jiun-Haw Chu*<sup>2</sup>; *Ian Fisher*<sup>2</sup>; <sup>1</sup>Argonne National Laboratory; <sup>2</sup>Stanford University

In FeAs-based superconductors a structural transition coincides with or precede the antiferromagnetic transition for compositions in the underdoped regime. This transition lowers the rotational symmetry (e.g. from 4-fold to 2-fold in the case of tetragonal to orthorhombic transition) of the lattice. In these materials a strong anisotropy in electronic resistivity is observed, which increases as the superconducting phase is approached with compositional variation. Although a resistivity anisotropy is expected to arise from electronic order of some kind, its origin is made difficult to determine by the onset of a structural transition. In order to clarify the role of the lattice symmetry in this anisotropy a set of single-crystal diffraction studies of structural transitions was carried out. Results of these studies reveal that the degree of structural anisotropy is inadequate to account for resistivity anisotropy indicating an electronic origin.

#### 11:45 AM Invited

**X-Ray Diffraction in Short-Period Superlattices:** *Emil Zolotoyabko*<sup>1</sup>; <sup>1</sup>Technion

Short-period superlattices, based on semiconductor or oxide layers, have wide range of applications ranging from infrared imaging to giant magneto-resistance. Some applications require deposition of sub-layers with thicknesses one monolayer and below. Under such conditions, the interface quality becomes crucial for device functioning. Most common imperfections are related to atomic intermixing during growth, which on this scale is difficult to characterize by electron microscopy methods. In this paper, we show how atomic intermixing levels can be extracted from high-resolution X-ray diffraction (HRXRD) data. For this purpose, we develop fast algorithm, which is based on analyzing the positions of diffraction peaks originated from the substrate and superlattice layers. High-resolution transmission electron microscopy (HRTEM) and scanning tunneling microscopy (STM) are applied as complementary characterization methods in order to estimate the number of atomic planes constituting different sub-layers. HRTEM and STM data are then used as an input for HRXRD analysis.

**12:05 PM Invited**

**Wafer Curvature and Stress Measured in-situ for Sputtered WSi<sub>2</sub>/Si Multilayer Thin Films on Silicon Wafers:** K. MacArthur<sup>1</sup>; B. Shi<sup>1</sup>; R. Conley<sup>1</sup>; *Albert Macrander*<sup>1</sup>; A. Genis<sup>2</sup>; L. Zhou<sup>3</sup>; Y-P. Wang<sup>3</sup>; H. Zhou<sup>3</sup>; M. Li<sup>3</sup>; R. Headrick<sup>3</sup>; <sup>1</sup>Argonne National Laboratory; <sup>2</sup>Northern Illinois University; <sup>3</sup>University of Vermont

Wafer curvature was measured in-situ in a magnetron sputtering chamber at Argonne National Laboratory as a function of the pressure of the Ar plasma. Pressures between 2.3 mTorr and 18 mTorr were studied to investigate the trade-off between interface roughness [Y-P Wang et al., J. Appl. Phys. 101, 023503 (2007)] and stress in choosing the optimal pressure for growing thick multilayer stacks. The results support conclusions of in-situ x-ray diffuse scattering experiments at beamline X21 at NSLS at Brookhaven National Lab. The x-ray diffuse scattering measurements lead to the conclusion that there is a transition from deposition of atoms at low pressure to deposition of nanoparticles at high pressure [L. Zhou et al., Phys. Rev. B 82, 075408 (2010)]. Work supported by U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under contracts DE-AC02-06CH11357 and DE-AC02-98CH10886, and under Department of Energy Grant DE-FG02-07ER46380.

**12:25 PM Invited**

**Understanding Structural Effects upon Macroscopic Phenomena in Strained Ordered Oxide Films:** *Philip Ryan*<sup>1</sup>; Jong Woo Kim<sup>1</sup>; Steve May<sup>2</sup>; Evguenia Karapetrova<sup>1</sup>; <sup>1</sup>Argonne National Laboratory; <sup>2</sup>Drexel University

The plethora of rapidly emerging high quality epitaxial, strained complex ordered oxide films have demonstrated several macroscopic phenomena including magnetism, metal-insulator transitions and multiferroicity whereby strain induces or changes the respective phenomenon. Understanding the coupling between the structure, including spin and charge, and the macro-characteristic is examined using synchrotron based resonant x-ray diffraction. In this talk I will present examples of recent measurements on strained nickelate(M-I transition), manganate (Enhanced TN) and titanate (Multiferroicity) films. The results will demonstrate the invaluable information that standardized albeit advanced x-ray scattering techniques provide for emerging novel ordered oxide film systems.

**12:45 PM Invited**

**Correlation Phenomena in Wurtzite-type GaN-based and ZnO Epilayers:** *Alois Krost*<sup>1</sup>; Juergen Blaesing<sup>1</sup>; <sup>1</sup>Otto-von-Guericke University Magdeburg

In this contribution we report on extremely sharp x-ray peaks which very often appear in transverse omega scans of, e.g. InAlN, AlGaIn, or ZnO thin films. Such correlation peaks are still visible in (0002) omega scans of 500 nm GaN which might mislead an observer to conclude incorrectly that there exists an extremely high structural quality. As one source of correlation peaks a high density of spatially correlated edge-type dislocations with in-plane Burgers vector and associated stacking faults could be identified. Another source might be surface steps on the sapphire substrate.

**Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Next Generation Packaging**

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Electronic Packaging and Interconnection Materials Committee  
*Program Organizers:* Indranath Dutta, Washington State University; Darrel Frear, Freescale Semiconductor; Sung Kang, IBM; Eric Cotts, SUNY Binghamton; Laura Turbini, Research in Motion; Rajen Sidhu, Intel Corporation; John Osenbach, LSI Corporation; Albert Wu, National Central Univ, Taiwan; Tae-Kyu Lee, Cisco Systems

**8:30 AM Introductory Comments**

**8:35 AM Keynote**

**Creation and Manipulation of Aligned Nanowires for Packaging and Circuit Integration:** *Sungho Jin*<sup>1</sup>; <sup>1</sup>University of California San Diego

Control of the nanowire structure is essential for their successful electronics applications including advanced solder connections and other packaging. Some electronic consumer products require protection against water-related damages through packaged structures, for which a superhydrophobic surface can be useful. Ceramic or metallic superhydrophobic coatings are more desirable than polymer coatings for long term, wear-resistant performances. In this talk, novel fabrication approaches to create vertically aligned nanowire configurations will be discussed, some of which exhibit superhydrophobic, non-wetting surface properties. Well controlled and processed vertically aligned semiconductor nanowire arrays can also be useful for solar cells and vertical nanotransistor arrays. Planarization of such periodically-arranged nanowire structures will be discussed in relation to circuit interconnection and routing of hundreds of millions of vertical nanodevices as well as for construction of three-dimensional multilayer device configurations.

**9:15 AM Keynote**

**All Copper Flip-Chip Interconnect:** *Paul Kohl*<sup>1</sup>; Hyo-Chol Koo<sup>1</sup>; Ping Nicole An<sup>1</sup>; Rajarshi Saha<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology

A novel flip-chip technology using electroless copper deposition has been used to produce all-copper, chip-to-substrate interconnect. This process replaces solder in flip-chip connections by electrolessly joining copper pillars or pads between the chip and substrate. Solder has many weaknesses such as the formation of brittle intermetallics and poor electromigration resistance. The electroless copper joints formed in this project are annealed after plating to improve the copper bond strength. The process parameters and bond strength were investigated as a function of pillar diameter, and offset distance between the chip and its substrate. The composition of the plating bath determines the bond strength of the copper joints. Plating bath additives, such as surfactants, accelerators, and suppressors influence the quality of electroless joint. A finite element model was developed to understand the stress distribution within the copper pillar and joined components.

### 9:55 AM Invited

#### **Plasticity and Reliability: From Unexpected Plasticity-Induced Damages in Advanced Cu Interconnects to Novel Reliability Phenomena in 3-D Interconnect Schemes Using Through-Silicon Vias (TSV) Technology:**

*Arief Budiman*<sup>1</sup>; Rao Morusupalli<sup>2</sup>; Tae-Kyu Lee<sup>2</sup>; Yu-Lin Shen<sup>3</sup>; Sung-Hwan Hwang<sup>4</sup>; Byoung-Joon Kim<sup>4</sup>; Ho-Young Son<sup>5</sup>; Min-Suk Suh<sup>5</sup>; Qwan-Ho Chung<sup>5</sup>; Kwang-Yoo Byun<sup>6</sup>; Martin Kunz<sup>6</sup>; Nobumichi Tamura<sup>6</sup>; Young-Chang Joo<sup>4</sup>; <sup>1</sup>Los Alamos National Laboratory; <sup>2</sup>Cisco Systems, Inc.; <sup>3</sup>University of New Mexico; <sup>4</sup>Seoul National University; <sup>5</sup>Hynix Semiconductor Inc.; <sup>6</sup>Lawrence Berkeley National Laboratory

Plastic deformation plays an important role in the control of mechanical properties and reliability of advanced microelectronics devices. Studying how materials evolve during the service of the devices will be crucial in understanding the degradation mechanisms leading to the eventual failures of the devices. In an effort to shed light on these topics, experiments using in situ synchrotron-based white-beam (Laue) x-ray microdiffraction technique to measure plasticity and mechanical stresses in the devices during their real and/or accelerated service conditions were conducted. In this talk, I will highlight two cases – advanced Cu interconnects and a 3-D interconnect scheme using TSV technology, in which this technique has been utilized to reveal degradation mechanisms that could lead to eventual failures. Our findings in these two cases further underline the importance of both measuring and controlling plasticity and stresses in the technology development as well as reliability improvement of advanced interconnect schemes.

### 10:20 AM Invited

#### **Residual Stress of Si near Through-Silicon-Via Structure for 3-Dimensional Packaging:**

*Young-Chang Joo*<sup>1</sup>; Arief Budiman<sup>2</sup>; Sung-Hwan Hwang<sup>1</sup>; Byoung-Joon Kim<sup>1</sup>; Ho-Young Son<sup>3</sup>; Min-Suk Suh<sup>3</sup>; Kwang-Yoo Byun<sup>3</sup>; Nobumichi Tamura<sup>4</sup>; Martin Kunz<sup>4</sup>; <sup>1</sup>Seoul National University; <sup>2</sup>Los Alamos National Laboratory; <sup>3</sup>Hynix Semiconductor Inc.; <sup>4</sup>Lawrence Berkeley National Laboratory

Through-silicon via technology is widely used for 3-dimensional integration. However, stress arise in Si near TSV due to the difference in the coefficient of thermal expansion of Si and Cu. Devices cannot be located in the strained Si region (keep-away zone) due to mobility change. The plastic deformation of Cu during thermal load is the cause of the residual stress of Si, so comparing the stresses of Si and Cu is important in understanding the origin and size of keep-away zone. We used the synchrotron white beam X-ray to measure stresses of Cu and Si in TSV. Finite element method simulation was also conducted to analyze the keep-away zone. Keep-away zone was about 30  $\mu\text{m}$  away from edge of TSV. By the comparison of the evolution of Cu and Si stresses and Cu grain structure during annealing, the cause of Si residual stress is discussed.

### 10:55 AM Invited

#### **The Effect of Filler-Network Heterogeneity on the Thermal Resistance of Polymeric Thermal Bondlines:**

*David Rae*<sup>1</sup>; Peter Borgesen<sup>2</sup>; Eric Cotts<sup>2</sup>;

<sup>1</sup>Universal Instruments; <sup>2</sup>Binghamton University

The influence of processing on filled-polymeric bondline thermal performance was examined, with a focus on factors that promote local filler entrapment and compaction. The materials studied were viscously applied, adhesive thermal interface materials with dispersed filler particles. All stages of bondline assembly were controlled in an attempt to create high density regions of compacted filler particles. These included material deposition (initial material location and thickness), bondline formation (normal forces, assembly speeds, assembly temperatures), and post-formation bondline stabilization (force during cure). Following cure, bondline thermal resistances and microstructures were characterized. For one high-performing, commercial thermal interface material, a four-fold decrease in thermal resistance was achieved. The general response of filled-polymeric thermal interface materials to such processing is under investigation.

### 11:20 AM Invited

#### **Recent Development of Lead-Free Nano-Solders for Nanowire and Nanoelectronics Assembly:**

*Zhiyong Gu*<sup>1</sup>; <sup>1</sup>University of Massachusetts Lowell

Many new nanomaterials and nanostructures have been fabricated in the past twenty years. With the dramatic development of nanotechnology in the past decade, promise has been shown in many potential applications of nanomaterials, including nanoelectronics, nanosensors, nanophotonics, and nanomedicine. However, in order to realize the manufacturing of nanoelectronic devices and systems, efficient and effective integration strategies have to be developed. In this talk, I will present our recent effort in the synthesis of lead-free nano-solders and the development of “nano-soldering” techniques. We have used the electrodeposition method in nanoporous templates to synthesize multisegmented nanowires with nano-solders, with diameter of 15-200 nm and length up to 20  $\mu\text{m}$ . Self-assembly method, such as magnetic assembly or dielectrophoretic (DEP) assembly, has been utilized to integrate nanowires into large-scale 2D or 3D network structures with conductive solder joints. These nanowires and nano-soldering techniques have great potential in the assembly and integration of functional nanoelectronics devices.

### 11:45 AM

#### **Deformation and Interfacial Effects during Thermal Cycling of Cu Filled Through-Silicon Vias (TSV):**

*Praveen Kumar*<sup>1</sup>; Indranath Dutta<sup>1</sup>; Muhannad Bakir<sup>2</sup>; <sup>1</sup>Washington State University; <sup>2</sup>Georgia Institute of Technology

Large shear stresses develop at interfaces between dissimilar materials during thermal excursions when there is a significant difference in the coefficient of thermal expansion between them. In TSVs, these interfacial shear stresses prevail over a larger fraction of via-length as the chip thickness becomes smaller. Under thermal cycling conditions, the interface may slide via diffusional process, thereby accommodating relative dimensional changes between via-fill(Cu) and Si. This phenomenon can become a significant reliability issue in 3-D interconnect architectures involving TSVs. Here we present experimental evidence of interfacial sliding between Cu and Si in Cu filled TSV. TSV samples were thermally cycled under different conditions (temperature ranges and heating/cooling rates). Under rapid cycling conditions, evidence of interfacial fracture was found, whereas significant diffusional sliding was found to occur at the Cu-Si interface during slow cycling. A simple 1-D analytical model and associated numerical simulations will be presented to rationalize the experimental observations.

### 12:05 PM

#### **Adhesive Selection and Bonding Parameter Optimization for Hybrid Bonding in 3D Integration:**

*Kuan-Neng Chen*<sup>1</sup>; Chuan-An Cheng<sup>1</sup>; Wen-Chun Huang<sup>1</sup>; Cheng-Ta Ko<sup>1</sup>; <sup>1</sup>National Chiao Tung University

Bonding technology is one of the key technologies for 3D integration in future packaging and semiconductor applications. Bonding temperature optimization of several polymer materials for metal/adhesive hybrid bonding was investigated. In general, the strong bond quality can be achieved with the increase of bonding temperature. However, when the bonding temperature reaches to certain point, bond failure of adhesive wafers were observed. In this research, several analysis techniques were used to evaluate the evolution of adhesive properties during the bonding process. Mechanisms are proposed to explain the failure of each adhesive. This study further conducts the criteria of adhesive selection for hybrid bonding in different 3D-IC applications.

## Physical and Mechanical Metallurgy of Shape Memory Alloys for Actuator Applications: Characterization of Shape Memory Alloys: Deformation Behavior

*Sponsored by:* The Minerals, Metals and Materials Society  
*Program Organizers:* S. Raj, NASA Glenn Research Center; Raj Vaidyanathan, University of Central Florida; Ibrahim Karaman, Texas A&M University; Ronald Noebe, NASA Glenn Research Center; Frederick Calkins, The Boeing Company; Shuichi Miyazaki, Institute of Materials Science, University of Tsukuba

### 8:30 AM Welcome and Introductory Remarks

#### 8:35 AM Plenary

**Recent Development of High Temperature Shape Memory Alloys for Actuator Applications:** *Shuichi Miyazaki*<sup>1</sup>; *Hee Young Kim*<sup>1</sup>; <sup>1</sup>University of Tsukuba

Ti-Ni alloys have been extensively developed to expand their application fields by adding new characteristics, shapes and dimensions, e.g., small transformation temperature or stress hysteresis, high transformation temperatures, porous structures, tubes, fine wires and thin films. Among them, some high temperature shape memory alloys have been developed: e.g., Ti-Ni-X (X=Au, Pd, Pt, Hf, Zr). The transformation temperatures of these alloys reach up to 1273K. However, it is not easy to make fine wires or thin plates with these alloys because of their lack of ductility. Recently, deformable high temperature shape memory alloys such as Ti-Ni-Zr(Hf)-Nb, Ti-Ta-Al have been developed, and they can reveal SME at temperatures between 373K and 473K, where commercial Ti-Ni alloys can not reveal SME. They can be cold-rolled with reductions higher than 60% and 90%, respectively, without revealing final fracture. In this lecture, the development of the Ti-Ni-Zr(Hf)-Nb and Ti-Ta-Al alloys is to be presented.

#### 9:05 AM Invited

**Energetics of Plastic Deformation and Transformation in NiTi:** *Huseyin Sehitoglu*<sup>1</sup>; *Tawhid Ezaz*<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign

The shape memory alloys are an important class of materials that undergo reversible transformations. We provide an overview of the plastic deformation and its consequences in NiTi class shape memory alloys. Initially, we are concerned with determining the energy barriers associated with twinning and slip in the B2 phase. The NiTi alloys are considerably more ductile compared to their B2 counterparts, which points to the occurrence of twinning in the B2 phase. We study the energetics of twinning via atomistic simulations and continuum theory. Then, we study twinning in the martensitic phase. The results should shed light into several issues. What are the approximate magnitudes of the energy barriers for different shears for twinning and slip? What new information can be obtained from simulations to design new shape memory alloys with higher levels of recoverable strains?

#### 9:25 AM Invited

**Deformation of the U-14at% Nb Shape Memory Alloy: Experiments and Modeling:** *Robert Field*<sup>1</sup>; *Carlos Tomé*<sup>1</sup>; *Rodney McCabe*<sup>1</sup>; *Amy Clarke*<sup>1</sup>; *Donald Brown*<sup>1</sup>; *Catherine Tupper*<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

U-14at%Nb is a shape memory effect (SME) alloy that undergoes deformation by the motion of complex twins and twin related lath boundaries up to the limit of SME deformation (~7%). In the SME regime a simple Bain strain model qualitatively predicts variant selection, texture development in polycrystalline samples, and stress-strain behavior as a function of parent phase orientation in single crystal micropillars. In the post-SME regime, unrecoverable deformation occurs by a combination of slip and twinning, with the first few percent of strain in tension apparently governed by a

twin species specifically associated with the monoclinic distortion in the martensite phase. A review of the Bain strain model for SME deformation will be presented in conjunction with experimental data. In addition, results from modeling of post-SME behavior using the Visco-Plastic Self-Consistent (VPSC) model will be compared to experimental texture measurements.

#### 9:45 AM Invited

**Observations on the Deformation Characteristics of NiTi:** *Santo Padula*<sup>1</sup>; <sup>1</sup>NASA Glenn Research Center

Transformation-induced plasticity (TRIP) and slip are among the more common explanations provided for the dimensional instability observed in shape memory actuators, but alternate mechanisms have been shown to be responsible for the evolution in macroscopic strain. Many conditions including altering the upper-cycle temperature (UCT), performing multiple thermal cycles under load or mechanically cycling the material have all been shown to create dimensional instability. Through in situ neutron diffraction experimentation, it has been shown that martensite texture evolution and retained martensite are the dominant mechanisms responsible for the observed evolutionary response. It has also been shown that the isothermal, cyclic deformation response of NiTi (in combined tension and compression) is different than that observed for traditional elastic-plastic materials. The aforementioned experimental observations will be discussed in relation to the limited role of plasticity in shape memory behavior.

#### 10:05 AM Break

#### 10:15 AM Invited

**Modeling and Experimental Study of Simultaneous Creep, Plasticity and Transformation of High Temperature Shape Memory Alloys during Cyclic Actuation:** *Yves Chemisky*<sup>1</sup>; *Parikshith Kumar*<sup>2</sup>; *George Chatzigeorgiou*<sup>1</sup>; *Ibrahim Karaman*<sup>3</sup>; *Dimitris C. Lagoudas*<sup>1</sup>; *Glen Bigelow*<sup>4</sup>; *Ron Noebe*<sup>4</sup>; <sup>1</sup>Texas A & M University, Aerospace Engineering; <sup>2</sup>Texas A & M University; <sup>3</sup>Texas A & M University, Mechanical Engineering; <sup>4</sup>NASA Glenn Research Center

High Temperature Shape Memory Alloys (HTSMAs) represent a class of Shape Memory Alloys (SMAs) with transformation temperatures greater than 100°C. As a consequence of their high transformation temperatures, the HTSMAs can be exposed to a temperature regime where creep behavior can occur simultaneously during the transformation. This effect has a critical impact on the actuation response, due to the generation of irrecoverable strains. The creep behavior of ternary NiTiPd and the interaction between transformation and creep occurring simultaneously has been recently studied and a thermodynamic model was developed to capture this interaction. However the experimental and modeling effort were limited to one actuation cycle. An extensive experimental effort on a NiTi30Pd was conducted in order to determine the cyclic actuation response of such HTSMAs. In addition to plastic strains during martensitic transformation, retained martensite due to thermomechanical cycling and irrecoverable strains due to primary and secondary creep

#### 10:35 AM

**Low Temperature Creep Behavior of Extruded Near-Stoichiometric NiTi Alloy:** *S. Raj*<sup>1</sup>; *Ronald Noebe*<sup>1</sup>; <sup>1</sup>NASA Glenn Research Center

It is expected that NiTi shape memory alloys (SMA) actuators would provide simple and light weight replacements for controlling chevron-shaped nozzles in aircraft engines to reduce jet engine noise. An understanding of the low temperature creep properties of NiTi is important in determining the design life of these SMA actuators. Long term constant load tensile creep tests lasting several months to about a year were conducted on hot-extruded NiTi specimens at room temperature, 373 and 473 K under initial applied stresses varying between 250 and 350 MPa. These temperatures correspond to the martensitic, two-phase and the austenitic phase fields, respectively. The range of stresses corresponded to the region of the stress-strain curves for the alloy, where detwinning of the martensitic structure occurs. The low temperature creep behavior of NiTi are discussed. The results of stress and temperature change experiments conducted between room temperature and 473 K are reported.

10:50 AM

**In Situ Observations of Deformation and Fracture in Single Crystal NiTi:** *Adam Creuziger*<sup>1</sup>; *Laura Bartol*<sup>2</sup>; *Ken Gall*<sup>3</sup>; *Wendy Crone*<sup>2</sup>; <sup>1</sup>National Institute of Standards and Technology; <sup>2</sup>University of Wisconsin-Madison; <sup>3</sup>Georgia Institute of Technology

The pseudoelastic transformation and fracture behavior of two crystallographic orientations of a single crystal NiTi shape memory alloy (SMA) were investigated. Uniaxial tension and notched tension samples are considered with the tensile axes along the [100] and [111] directions. The phase transformation was observed using optical techniques in situ. For the uniaxial tension samples, martensite plates and Luders-band structures are observed. For the notched samples, transformation structures in the [100] sample appeared predominantly on the sides of the notch and crack tip with stable crack propagation. In the [111] notched samples transformation occurred directly ahead of the notch and unstable crack propagation is observed. An available work criterion is used to predict the location of the transformation, with good agreement to the experimental observations. The different fracture behavior of the two notched sample orientations is explained utilizing the available work calculations.

11:05 AM

**NiTiHf High-Temperature Shape-Memory Alloys for near Term Applications:** *Glen Bigelow*<sup>1</sup>; *Sayed Saghaian*<sup>2</sup>; *Haluk Karaca*<sup>2</sup>; *Santo Padula*<sup>1</sup>; *Anita Garg*<sup>3</sup>; *Darrell Gaydosh*<sup>4</sup>; *Ronald Noebe*<sup>1</sup>; *Yuriy Chumlyakov*<sup>5</sup>; <sup>1</sup>NASA Glenn Research Center; <sup>2</sup>University of Kentucky; <sup>3</sup>University of Toledo; <sup>4</sup>Ohio Aerospace Institute; <sup>5</sup>Siberian Physical Technical Institute

Although high-temperature shape-memory alloys (HTSMA) with useful transformation temperatures above 150°C are highly desirable, there is a near-term need for alloys with transformation temperatures even slightly above what conventional binary NiTi alloys can provide. Such materials would find immediate on-wing and in-cabin applications in the aeronautics sector, and would be equally utilized in the automotive and other commercial sectors. Polycrystalline and single crystal ([001], [-340], and [678] orientations) Ni<sub>50.3</sub>Ti<sub>29.7</sub>Hf<sub>20</sub> with an MF ~130°C was investigated using isothermal compression tests in the martensite and austenite states and load-biased thermal cycling to determine its viability in the aforementioned applications. Unlike conventional SMA actuator materials, the NiTiHf alloy investigated here exhibited high work output, good dimensional stability, and varying amounts of superelasticity, without the need for complicated thermomechanical processing. Results of the polycrystalline and single crystal tests will be compared and reasons discussed for the inherent dimensional stability of the polycrystalline material.

11:20 AM

**Thermo-Mechanical Behavior of Cu-Al-Ni SMA for High Temperature Actuators:** *Jose San Juan*<sup>1</sup>; *Iñaki Lopez-Ferreño*<sup>1</sup>; *Tomasz Breczewski*<sup>1</sup>; *Isabel Ruiz-Larrea*<sup>1</sup>; *Angel López-Echarri*<sup>1</sup>; *María N6*<sup>1</sup>; <sup>1</sup>Universidad del Pais Vasco

Among the different families of shape memory alloys, Cu-Al-Ni alloys are firm candidates to be used in the temperature range between 100°C to 200°C as SMA actuators. In the present work we have studied the thermo-mechanical properties of several alloys exhibiting the martensitic transformation in such temperature range 100°C-200°C. Both, superelastic and shape memory effects have been characterized, as well as the evolution of the transformation behavior with thermal treatments and transformation cycling. The thermal transformation behavior under stress has been also studied in order to obtain a precise determination of the Clausius-Clapeyron stress line, and the shape recovery under stress. Finally we discuss the microstructural design of Cu-Al-Ni SMA and the different measured properties, in terms of their capability to be used in real high temperature actuators.

11:35 AM

**Microstructure Analysis and Thermomechanical Behaviour during Superelastic Cycling in Cu-Al-Ni Single Crystals:** *Maria N6*<sup>1</sup>; *A. Ibarra*<sup>1</sup>; *A. López-Echarri*<sup>1</sup>; *I. Ruiz-Larrea*<sup>1</sup>; *D. Caillard*<sup>2</sup>; *J. San Juan*<sup>2</sup>; <sup>1</sup>Universidad del Pais Vasco; <sup>2</sup>CEMES-CNRS

The aim of this work is to establish the relationship between the macroscopic behaviour during tensile superelastic cycling in Cu-Al-Ni shape memory alloy single crystals and the evolution of the microstructure. The analysis has been carried out as a function of the temperature, the maximum reached deformation and the number of cycles. Tensile superelastic cycles were performed in two samples with different compositions, which themally transform to different kinds of martensite. A calorimetric study and a TEM (post mortem and in situ) analysis were carried out on these superelastic cycled samples in order to determine the evolution of thermal transformation. Finally the results obtained by tensile superelastic cycling are discussed and compared with the previously obtained results on the same single crystal alloys by compression superelastic tests.

11:50 AM

**Superelastic Phenomena and Martensite Destabilization in Ni-Mn-Ga Alloys:** *Volodymyr Chernenko*<sup>1</sup>; *E. Villa*<sup>2</sup>; *S. Besseghini*<sup>3</sup>; *J.M. Barandiaran*<sup>4</sup>; *V. A. L'vov*<sup>5</sup>; <sup>1</sup>Universidad del Pais Vasco UPV/EHU - and - Ikerbasque, Basque Foundation for Science; <sup>2</sup>CNR-IENI, C.Promessi Sposi; <sup>3</sup>CNR-IENI, C. Promessi Sposi; <sup>4</sup>Universidad del Pais Vasco; <sup>5</sup>Institute of Magnetism

Thermomechanical properties of two Ni-Mn-Ga single crystalline alloys with MT temperatures of 310 K (A1) and 620 K (A2) are studied. DMA Q800 analyzer made it possible to register, from the same sample, temperature dependencies of elastic modulus in the dynamic tensile mode, stress versus strain curves at constant temperatures, and strain versus temperature curves at zero stress in static tensile mode. A multistep superelasticity of about 10% and one-step superelasticity of about 7% have been found in alloys A1 and A2, respectively. The stress - temperature phase diagrams of MTs are constructed. The stress-strain curves for alloy A2 demonstrate the gradual elevation of plateau as a result of mechanical cycling through MT. Theoretical estimations showed that this effect may be due to a decrease of MT temperature caused by the mechanical cycling. In correspondence to the commonly used terminology this effect should be referred to as martensite destabilization.

## Polycrystal Modelling with Experimental Integration: A Symposium Honoring Carlos Tome: Emerging Polycrystal Models with Experimental Integration I

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Materials Processing and Manufacturing Division, ASM-MSCTS: Texture and Anisotropy Committee, TMS/ASM: Mechanical Behavior of Materials Committee, TMS/ASM: Computational Materials Science and Engineering Committee  
*Program Organizers:* Ricardo Lebensohn, Los Alamos National Laboratory; Sean Agnew, University of Virginia; Mark Daymond, Queens's University

Monday AM  
February 28, 2011

Room: 6C  
Location: San Diego Conv. Ctr

8:30 AM Introductory Comments

8:40 AM Keynote

**Modeling of Polycrystal Plasticity: A Personal Overview of Past, Present and Future:** *Carlos Tome*<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

In this talk I review, from my personal experience, the advances made in the last 25 years in the areas of crystal and polycrystal plasticity. I will

MONDAY AM

emphasize how advances in experimental methods and in computational capabilities have motivated and accompanied the development of increasingly sophisticated models and increasingly physically-based constitutive descriptions. The temporal line of research spans from simple Taylor models of aggregates in the past, to sophisticated polycrystal models that account for microstructural evolution (dislocations, twins, grain size, grain boundaries) in the present, and ambitious, but at the moment incipient, scale-linking approaches in the future. The theoretical developments have been aided by phenomenal advances on material characterization techniques, such as automated EBSD, FIB sectioning, X-ray and neutron diffraction, in-situ TEM.

**First Evaluation of ALAMEL - Predictions of Texture-Induced Plastic Anisotropy:** *Paul Van Houtte*<sup>1</sup>; *Jurij Sidor*<sup>2</sup>; *Xie Qingge*<sup>1</sup>; *Laurent Delannay*<sup>3</sup>; *Bert Van Bael*<sup>1</sup>; *Leo Kestens*<sup>2</sup>; <sup>1</sup>Katholieke Universiteit Leuven; <sup>2</sup>Ghent University; <sup>3</sup>Université Catholique de Louvain

Texture-induced plastic anisotropy is usually assessed by means of mechanical testing, for example by measuring  $r$ -values. It can also be predicted by a multi-scale model for the plastic deformation of polycrystalline materials. Before using such virtual test data to identify an anisotropic constitutive law to be implemented in FE simulations of metal forming processes, it is recommended to make a serious assessment of the multi-scale model used. Best known model for this application is the Taylor model, experimental validation having been published. However, several other, more advanced models exist which could also be used. One of these is the ALAMEL model, known to be successful in the prediction of deformation textures. So far, no systematic experimental validations of plastic anisotropy modeling using ALAMEL have been published. In this paper, a first series of such results will be given, as well as comparisons with the results of some other models.

#### 9:50 AM

**Microstructural Influences on the Local and Global Deformation of TiAl Polycrystal Investigated by Experiments and Numerical Multi-Scale Approach Incorporating Crystal Plasticity FE Model:** *Mohammad Rizviul Kabir*<sup>1</sup>; *Liudmila Chernova*<sup>1</sup>; *Marion Bartsch*<sup>1</sup>; <sup>1</sup>German Aerospace Center (DLR)

The influences of the microstructural heterogeneity on the local and global mechanical behavior of a TiAl polycrystal have been investigated with experiments and numerical modeling. Two types of microstructure, duplex and near-lamellar, which are classified according to the presence of globular grains (consists of  $\gamma$ 947-phases) and lamellar colonies (consists of  $\gamma$ 945<sub>2</sub>+ $\gamma$ 947-phases), have been studied. The representative microstructures were calculated from SEM and TEM analysis and were incorporated in a two-scale FE model. The micromechanics of deformation of the phases are described in a crystal plasticity FE model. With this polycrystal modeling approach microstructure dependent alloy properties were reliably predicted, with focus on the influence of the microstructural heterogeneity on the elastic properties at grain scale, anisotropic dependency of the material yield and contribution of dislocation-slip of the phases to the plastic deformation at local and global scale.

**Elastic Viscoplastic Heterogeneous Materials: From the Inclusion Problem to Homogenization Schemes:** *Alain Molinari*<sup>1</sup>; *Sébastien Mercier*<sup>1</sup>; <sup>1</sup>Université Paul Verlaine-Metz

Micro-macro transition schemes contain two important steps. First, the localization process must link the fields inside the inclusion to those applied at the remote boundary. Secondly, an averaging process is used to derive the macroscopic behaviour. Molinari et al. (1987) have developed the tangent model where the non-linear viscoplastic behavior of the material is approximated by a first order Taylor expansion at the overall strain rate. This model is dedicated to rigid viscoplastic material. To account for elasticity, a simple interaction law has been proposed based on the tangent approximation

of the non-linear Eshelby problem. This interaction law has been validated using Finite Element calculations and is used to develop Mori-Tanaka and self consistent schemes, Mercier and Molinari, (2009). Applications are shown for cyclic loading of composite materials.

#### 10:45 AM Invited

**On New Intermediate Modeling for the Large Viscoplastic and Elastic-Viscoplastic Deformation Behavior of Polycrystals: The Intermediate Phi-Model:** *Said Ahzi*<sup>1</sup>; *Siham M'Guil*<sup>1</sup>; <sup>1</sup>University of Strasbourg

In a first part of the presentation, we discuss the problem of homogenization of polycrystalline metals. Then, we present the new homogenization technique leading the formulation of the viscoplastic intermediate phi-model for crystal plasticity. With the phi-model, as in the self-consistent approach, a non-linear interactions law is derived but without the call for the Eshelby tensor. Thus, the phi-model takes into account the grain interactions with the homogeneous equivalent medium but without explicit shape effects. In a second part of the presentation, we present the extension of the phi-model to large elastic-viscoplastic deformation. Finally, we compare the results predicted from our new modeling, in terms of stress-strain response, textures, slip activity, ..., to those of the viscoplastic self-consistent model as well as to the experimental results.

#### 11:10 AM Invited

**Insights into Microstructure Evolution Using Crystal Plasticity Modelling:** *Matthew Barnett*<sup>1</sup>; <sup>1</sup>Deakin University

Crystal plasticity ignores certain mechanisms of microstructure evolution. However, it can shed important light on the operation of these very mechanisms. The present talk examines four attempts to use crystal plasticity models in this manner. Taylor type modelling is employed to examine the generation of high angle boundaries in shear. Self consistent type modelling is employed to reveal the abnormal formation of secondary twins, the possible role of grain boundary sliding and the formation of dynamically recrystallized grains. Although these uses of the models push the limits of what they were designed to achieve, important insight can be gained into how new structures are generated during plastic deformation.

#### 11:35 AM Invited

**Effects of Crystallographic Orientation vs. Grain Interaction on Slip Systems:** *Grethe Winther*<sup>1</sup>; <sup>1</sup>Risø DTU

When studying the deformation behaviour of individual grains both the overall rotation of the crystallographic grain orientation and the subdivision of grains are of interest. Often grains of similar orientations are compared to study the effect of grain orientation vs. grain interaction. Such investigations reveal both similarities and differences. The present contribution gives an overview of a series of investigations, including transmission electron microscopy as well as three-dimensional x-ray diffraction on polycrystalline aluminium deformed to strains of 5-50%. The data are analysed focusing on the set of activated slip systems, more precisely whether the observed differences can be attributed to fluctuations in the relative activities of the same set of systems or whether activation of truly different systems is the origin of the variations between and within grains.

#### 12:00 PM

**VPSC Modelling in the Development of a Commercial Product:** *Dincer Bozkaya*<sup>1</sup>; *Peter Jepson*<sup>1</sup>; <sup>1</sup>H.C. Starck Inc.

Texture Control is very important for planar sputtering targets, since the sputtering rate of a grain depends on its orientation. When tantalum is rolled to plate using conventional methods, the texture developed at mid-thickness is different from that developed near the surface because of differences in shear strain. At H.C. Starck, we used an FEM code and VPSC together to create models and thereby speed up the development of a product with no through-thickness texture gradient. The development of the new rolling process will be described, with emphasis on how VPSC was used and its usefulness.

12:20 PM

**Modelling of Texture and Microstructure Evolution during Dynamic Recrystallization:** *Denis Solas*<sup>1</sup>; Julien Thebault<sup>2</sup>; Julien de Jaeger<sup>2</sup>; Colette Rey<sup>2</sup>; Thierry Baudin<sup>1</sup>; <sup>1</sup>Univ Paris Sud; <sup>2</sup>Ecole Centrale Paris

The changes in texture and microstructure during thermomechanical process are related to crystal plasticity and annealing phenomena. Numerical studies has been carried out in which a crystalline plasticity modelling implemented in the finite element code Abaqus® coupled to a recrystallization Cellular automaton code. A sequential approach is used to simulate hot forging of a nickel based superalloy. Modelling is performed on aggregates built up from EBSD maps. Each grain is decomposed into smaller domains. In particular, the deformation model predicts intragranular deformation in terms of misorientations between elements and local variations in stored energy. A cellular Automaton algorithm is used for simulating nucleation and grain boundary migration. The parameters used for the sequential modelling were identified using an inverse method from experimental results. This numerical and experimental approach is used to understand the experimental observations and it improves our knowledge of the recrystallization process.

12:40 PM

**A Physically-Based Fatigue Model for Prediction of Crack Initiation from Persistent Slip Bands in Polycrystals:** *Huseyin Sehitoglu*<sup>1</sup>; Michael Sangid<sup>1</sup>; <sup>1</sup>University of Illinois

A model is constructed for prediction of fatigue crack initiation based on the material's microstructure. Our approach is to model the energy of a persistent slip band (PSB) structure and use its stability with respect to dislocation motion as our failure criterion for fatigue crack initiation. The components that contribute to the energy of the PSB are identified, namely, the stress field resulting from the applied external forces, dislocation pile-ups, and work-hardening of the material is calculated at the continuum scale. Further, energies for dislocations creating slip in the matrix/precipitates, interacting with the GBs, and nucleating/agglomerating within the PSB are computed via atomistics. The predicted fatigue life is driven by the microstructure such as grain orientations, widely distributed grain sizes, precipitates, PSB-GB interactions, as well as the effect of neighboring grains. Good agreement is shown between the model predictions and experimental data.

**Recent Developments in the Processing, Characterization, Properties and Performance of Metal Matrix Composites: General and Nano-Composites**

*Sponsored by:* The Minerals, Metals and Materials Society  
*Program Organizers:* Martin Pech-Canul, Centro de Investigacion y de Estudios Avanzados del Instituto Politecnico Nacional; Zariff Chaudhury, Arkansas State University; Golam Newaz, Wayne State University

Monday AM

8:30 AM

**Al/Al-Cu-Fe Metal Matrix Composites:** *Guillaume Laplanche*<sup>1</sup>; Joël Bonneville<sup>1</sup>; Anne Joulain<sup>1</sup>; Véronique Brunet-Gauthier<sup>1</sup>; Sylvain Dubois<sup>1</sup>; <sup>1</sup>University of Poitiers

The mechanical properties of icosahedral quasicrystalline (i-QC) Al-Cu-Fe alloys make them very attractive as reinforcement particles for metallic matrix composites (MMC). Al-base composites reinforced by i-QC Al-Cu-Fe particles have been synthesised since nearly two decades, but their mechanical properties are still poorly known. In this work, Al/Al-Cu-Fe MMCs were produced at two temperatures, i.e. T=673K and T=873K, by hot isostatic pressing. Crystallographic and chemical composition investigations were performed on the as-synthesised MMCs for identifying the resulting phases.

At T=673K, the reinforcement particles are still of the original i-QC phase, whereas at T=873K a phase transformation occurs for the reinforcement particles, which have the ω-Al-Cu-Fe tetragonal crystalline structure. The flow stress of both composites is strongly temperature dependent, suggesting that thermally activated processes control plastic flow. Transmission electron microscopy observations suggest that micro- and nano-particles play different roles in the strengthening of the two composites.

8:50 AM

**Copper Matrix Composites Reinforced with a High Fraction of Alumina Particles:** *Carmen Krueger*<sup>1</sup>; Andreas Mortensen<sup>1</sup>; <sup>1</sup>EPFL STI IMX LMM

The aim of this project is to explore the production of copper-based composites containing a high volume fraction of ceramic particles. Alumina is chosen as ceramic reinforcement phase due to its high Young's modulus, low density, chemical compatibility with copper and high availability, in combination with matrices of aluminum bronze. Two processing routes are explored, namely (i) pressure infiltration, and (ii) in-situ reaction, the latter being based on the thermic reduction of copper-oxides by aluminum. Success in the former method is shown to hinge on control of the structure and evolution of the metal/ceramic interface, while the latter is tributary to the rates of competing interdiffusion phenomena, as often found with in-situ composite production methods.

9:10 AM

**Low Density Magnesium Matrix Syntactic Foams:** *John DeFouw*<sup>1</sup>; Pradeep Rohatgi<sup>1</sup>; <sup>1</sup>University of Wisconsin Milwaukee

Low density magnesium matrix syntactic foams were synthesized through pressure infiltration of a packed bed of hollow carbon spheres with liquid magnesium of both pure and alloy (AZ91) compositions. Through varying the applied gas pressure for infiltration, the resulting composites varied in density as low pressures resulted in incomplete infiltration of regions between spheres and higher pressures resulted in infiltration into sphere interiors through cracks or small pores producing higher densities, ranging from 0.7 to 1.1 g cm<sup>-3</sup> (40-60% relative density). The foams were studied under mechanical compression with modulus, strength, and energy absorption described in relation to foam density and heat treatment as well as microstructural observations of metal matrix fraction, hollow sphere porosity, incomplete infiltration porosity, and carbide formation.

9:30 AM

**Metal Matrix Composites: History, Status, and Future:** *Ajith Cyriac*<sup>1</sup>; Jay Hanan<sup>1</sup>; <sup>1</sup>Oklahoma State University

A study of the history, status, and opportunities of Metal Matrix Composites is presented by evaluating the progression of available literature. The trends that existed and issues that still prevail are discussed and a prediction of the future for MMCs is presented. In many developed countries and in several developing countries there exists continued interest in MMCs. Researchers tried numerous combinations of matrices and reinforcements since work on MMCs began in the 1950s. This led to developments for aerospace, but resultant commercial applications were limited. The introduction of ceramic whiskers as reinforcement and the development of in-situ eutectics in the 1960s aided high temperature applications in aircraft engines. In the late 1970s the automobile industries started to take MMCs seriously. In the last 20 years, MMCs evolved from laboratories to a class of materials with numerous applications and commercial markets. A summary histogram depicting the progression is presented.

9:50 AM

**Processing, Characterization and Thermal Properties of Diamond-Containing Metal Matrix Composites:** *Vikas Sinha*<sup>1</sup>; Sabyasachi Ganguli<sup>1</sup>; Robert Wheeler<sup>1</sup>; Jonathan Spowart<sup>1</sup>; <sup>1</sup>Air Force Research Laboratory

An ideal substrate/ packaging material for high power density electronic component should have a very high thermal conductivity and a coefficient of thermal expansion (CTE) comparable to the electronic component. Diamond-containing Ag-matrix and Cu-matrix composites potentially can be excellent solutions for thermal management. In the current research, diamond-containing Ag-matrix and Cu-matrix composites were fabricated

MONDAY AM

via spark-plasma-sintering or liquid-metal-infiltration techniques. Cu was pre-alloyed with Cr or B, whereas Ag was pre-alloyed with Si. The effects of different micro-alloying elements on thermal properties were compared. Thermal conductivity of composites was modeled to estimate thermal conductance for metal/diamond interfaces for different material and processing conditions. The CTE of composites were compared with model predictions. Prior studies indicate that the interface chemistry has a strong influence on thermal properties. The chemistry changes near the metal/diamond interfaces were examined via High-Resolution Transmission Electron Microscopy (HRTEM), using energy dispersive spectroscopy and energy-filtering techniques.

#### 10:30 AM

**Use of Cenosphere for Making Functionally Graded Aluminum Cenosphere Syntactic Foam through Liquid Metallurgy Route:** *Dehi Mondal*<sup>1</sup>; Satyabrata Das<sup>1</sup>; <sup>1</sup>Advanced Materials and Processes Research Institute

Attempts have been made to make functionally graded aluminum cenosphere syntactic foam wherein volume fraction of cenosphere varies along the thickness of the casting. Cenosphere has been used to make such microporous materials. The sample from different depths were examined for cenosphere volume fraction, density, hardness and compressive stress-strain curves and these properties are varying along the depth. The thickness of the layer corresponding to particular average cenosphere content and the average volume fraction of cenosphere in each layer was found to be strong function of processing parameters like melt temperature, cooling rate, number of heating and cooling cycles. As the frequency of heating and cooling cycles increases, the volume fraction of cenosphere at top most surface increases. Through this process, thus a bulk dense material with functionally graded microporous syntactic foam on one side could be made where a strong bonding between the foam and bulk material will exist.

#### 10:50 AM

**Micro-Tomography Based Characterization and Geometrical Parameter Evaluation of Advanced Woven Ceramic-Matrix Composites:** *Hrishikesh Bale*<sup>1</sup>; David Marshall<sup>2</sup>; Brian Cox<sup>2</sup>; Robert Ritchie<sup>1</sup>; <sup>1</sup>University of California Berkeley; <sup>2</sup>Teledyne Scientific LLC

Structural components operating under extreme environments (>1200°C) demand the use of a new class of advanced materials. Environments typically experienced in rocket engines, hypersonic flow paths and thermal protection systems are beyond the realm of current structural materials. However, woven ceramic-matrix composites (CMC's) incorporating textile manufacturing techniques utilizing 3-D architectures makes the development of such structures feasible. Lifetime prediction within CMC's is non-trivial though; microscopic flaws within fibres and matrix can be governing factors controlling the ultimate performance of these materials in service. Synchrotron micro-tomography was utilized to evaluate CMC's in 3-D with ~1-µm resolution. The use of micro-tomography in evaluating the otherwise difficult-to-measure structural parameters such as 3-D tow spacing, orientation, cross section and matrix porosity in SiC/SiC CMC's is demonstrated which facilitates the understanding of damage and failure. This would further lead in developing comprehensive and accurate constitutive laws for computational models.

#### 11:10 AM

**Synthesis and Characterization of Hot Extruded Al-15wt%Mg2Si In-Situ Composite:** *Ashkan Zolriasatein*<sup>1</sup>; *Masoud Emamy*<sup>2</sup>; *Amin Bahrami*<sup>3</sup>; *Hamid Reza Jafari Nodooshan*<sup>4</sup>; *Ali Shokuhfar*<sup>4</sup>; <sup>1</sup>K. N. Toosi University of Technology; <sup>2</sup>Tehran University; <sup>3</sup>Imam Khomeini International University; <sup>4</sup>Islamic Azad University

This study investigates the hot extrusion of Al-15wt%Mg2Si in-situ composite at various extrusion ratios (6:1, 12:1, and 18:1) to determine the relationship between the process parameters, microstructure and the properties of the extruded composite. Microstructure of the composite after this type of extrusion was studied by optical microscopy. Mechanical

properties of the composite after various extrusions were tested by hardness and tensile tests. These results indicate that extrusion leads to reduction of porosity and particle fracture. With the increase of the extrusion ratio at a relatively low temperature, the microstructure of the extruded samples becomes finer and more uniform, and higher mechanical properties can be brought for the as-extruded samples in comparison with as-cast samples.

#### 11:30 AM

**Thermal Conductivity and Interfacial Nanostructure in Diamond Based Composites:** *F. Khalid*<sup>1</sup>; <sup>1</sup>GIK Institute of Engineering Sciences and Technology

Processing parameters is critical in achieving the interfacial nanostructure of Al/diamond and Cu/diamond composite materials. These composites are produced by sintering and pressurised liquid metal infiltration have the potential for thermal management Applications. Attempts have been made to develop new composites to improve thermal conductivity. In this work it is demonstrated that thermal conductivity of diamond based composites can be achieved up to 700 Wm/K. It is illustrated that the liquid metal infiltration is better production route for Al-diamond and Cu/diamond composites. The examination of the interfacial nanostructure of the composite samples by using advanced analytical techniques is carried out. Emphasis is also placed on the understanding of preferential interfacial bonding between matrix and diamond (100) and (111) surfaces. The formation of Al<sub>4</sub>C<sub>3</sub> particles at the interface between Al and diamond particles was found that indicated a greater level of stability and bond strength between the diamond particles and matrix.

#### 8:30 AM

**Study of Twins in Nanoscale Pd Films with High Strain Hardening Capacity:** *Dominique Schryvers*<sup>1</sup>; *Hosni Idrissi*<sup>1</sup>; *Binjie Wang*<sup>1</sup>; *Marie-Stéphane Colla*<sup>2</sup>; *Jean-Pierre Raskin*<sup>2</sup>; *Thomas Pardoen*<sup>2</sup>; <sup>1</sup>University of Antwerp; <sup>2</sup>Université Catholique de Louvain

Nanocrystalline metallic films often suffer from a lack of ductility due to poor strain hardening capacity. Nanograin Pd thin films (80 - 310 nm film thickness) with very large strain hardening when deformed by on-chip nanomechanical tensile testing have been produced by low pressure chemical vapour deposition and photolithography. TEM and HRTEM reveal the presence of a few coherent growth twins in more than 20% of the grains, offering additional barriers to dislocation motion, as well as sources for dislocation storage and multiplication. The twin boundaries become incoherent after a few percent of plastic deformation. The related dislocation/twin boundary reactions explain part of the high strain hardening capacity, the remaining resulting from microstructure heterogeneities with softer and harder grains, leading to a long elastoplastic transition. These two aspects constitute the main ingredients of a multigrain homogenization model which provides a rationale for the evolution of the strain hardening capacity.

### 8:50 AM

**Effects of Differently Oriented Twin Boundaries on Mechanical Properties in Nanotwinned Ag Films:** Daniel Bufford<sup>1</sup>; Xinghang Zhang<sup>1</sup>; Haiyan Wang<sup>1</sup>; <sup>1</sup>Texas A&M University

Epitaxial nanotwinned Ag (111) and Ag (110) films were deposited by magnetron sputtering. Although both films were deposited with similar deposition parameters, the twin boundary spacing is 9 nm in Ag (111) and 42 nm in Ag (110). Twin boundaries in the Ag (111) films are oriented normal to the growth direction and at an angle in the Ag (110) films. The fine twins greatly enhance the indentation hardness of both films, and there is a factor of two differences in hardness between the (111) and (110) Ag films. The mechanisms for twin formation and the influences of twin boundary orientation on mechanical deformation will be discussed.

### 9:10 AM Invited

**Inverse Grain-Size Effect on Twinning in Nanocrystalline FCC Metals:** Yuntian Zhu<sup>1</sup>; Xiaolei Wu<sup>2</sup>; <sup>1</sup>North Carolina State University; <sup>2</sup>Chinese Academy of Sciences

A long-standing controversy exists between molecular dynamics (MD) simulations and experiments on the twinning propensity of nanocrystalline (nc) face-centered-cubic metals. For example, three-dimensional MD simulations rarely observed twins in nc Ni, whereas experiments readily observed them. Here this discrepancy is resolved by experimental observation of an inverse grain-size effect on twinning. Specifically, decreasing the grain size first promotes twinning in nc Ni and then hinders twinning due to the inverse grain-size effect. Interestingly, no inverse grain-size effect exists on stacking fault formation. These observations are explained by generalized planar fault energies and grain-size effect on partial emissions.

### 9:40 AM

**A Twist of the Eshelby Twist: Unraveling the Mystery of Twinning:** Ting Zhu<sup>1</sup>; Ju Li<sup>2</sup>; Sankar Narayanan<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology; <sup>2</sup>University of Pennsylvania

The principal difficulty in understanding the deformation mechanisms of small-volume crystals has been to explain how the plastic deformation carriers such as dislocations and twins are generated and multiplied. The sources of such carriers and associated triggering processes have not been well established. In 1953 Eshelby showed that the central region of a rod can act as a trap to stabilize the screw dislocation that, in turn, induces the torsional deformation of the rod. While studying this so-called Eshelby twist effect, we incidentally discovered a twinning mechanism in fcc Cu. We found that the axial screw can initiate the regenerative twinning through a 3D process of dislocation intersection followed by spiral gliding of a sweeping dislocation around the pole. Our work is the first atomistic realization of 3D twinning, and it opens up the possibilities of studying the experimentally relevant twinning mechanisms for a wide range of materials and applications.

### 10:30 AM

**Detwinning Mechanisms for Growth Twins in Epitaxial Nanotwinned Cu:** Nan Li<sup>1</sup>; Jian Wang<sup>1</sup>; Xinghang Zhang<sup>2</sup>; Jianyu Huang<sup>3</sup>; Amit Misra<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory; <sup>2</sup>Texas A&M University; <sup>3</sup>Sandia National Laboratory

Using in situ nanoindentation in a transmission electron microscope (TEM), we have studied the migration mechanisms of S3 {112} incoherent twin boundary (ITB) in epitaxial nanotwinned Cu films. ITB's migrate via the collective glide of multiple twinning dislocations that form an ITB and the propagation steps or disconnections are with heights of three or multiples of three {111} interplanar distances. The migration may lead to de-twinning process of nanotwins in face-centered cubic metals. The transmission of a glide dislocation across an ITB is shown to form a sessile dislocation in the ITB and locally pin the boundary at the site of the slip transmission.

### 10:50 AM Invited

**Deformation Effects in Cu with Highly Aligned Nanotwins:** Julia Weertman<sup>1</sup>; Carla Shute<sup>1</sup>; <sup>1</sup>Northwestern University

Nanotwinned metals have been found, by the work of K. Lu, S. Suresh, and others, to be very strong, with stable microstructures and possessed of moderate ductility. The present research examines the effect of various forms of deformation on the internal structure, damage and crack nucleation in Cu with highly aligned columns of nanotwins. It is found that surface fatigue cracks form at the intersection of regions where there is incompatibility in the deformation process, e.g. between a nanotwinned and de-nanotwinned region. High densities of dislocations form in such places. The median spacing of nanotwin boundaries in the samples is unchanged by fatigue, except in the close vicinity of cracks, where there is a substantial increase. TB spacing under extreme compression decreases in the amount expected from the negative strain. HPT experiments indicate the limit of stability of the nanotwins under shear strain.

### 11:20 AM

**Fatigue Properties of Nano Structured Copper:** Aparna Singh<sup>1</sup>; Lei Lu<sup>2</sup>; Ming Dao<sup>1</sup>; <sup>1</sup>MIT; <sup>2</sup>Chinese Academy of Sciences

Nano twinned materials exhibit a combination of both high strength and ductility unlike nano grained materials. However, their properties under cyclic loading have not been explored as yet. In this presentation, we outline our results of fatigue studies done on nano twinned materials, and the observations are compared with those for nano grained materials in order to get conclusions on the role of micro structural size scale in influencing the damage tolerance characteristics of metals. General strategies for improving strength, ductility, damage resistance and tolerance will be presented.

### 11:40 AM

**Tensile Plastic Deformation of Gradient Nano-Grained Copper:** W. L. Li<sup>1</sup>; N. R. Tao<sup>1</sup>; K. Lu<sup>1</sup>; <sup>1</sup>Chinese Academy of Sciences

Nanocrystalline or nano-grained metals are strong, but brittle. Experimental identification of plastic deformation mechanisms of nano-grained structures is challenging, indeed, because tensile plastic strain cannot be sustained in nano-grained samples which has basically no work-hardening. In this work, we prepared a unique sample for experimental study on the plastic deformation of nano-grained metals: a gradient nano-micro-grained (GN) surface layer on a bulk Cu specimen. The GN layer is produced by means of surface mechanical grinding treatment (SMGT) at cryogenic temperature. The GN samples exhibit a considerable plastic strain above 30% in tension, indicating that the nano-grained structure can be plastically deformed with a substantial tensile strain. Systematic structure characterization revealed that plastic deformation of the nano-grained structure is localized and accompanied with stress-induced grain growth. Discussions will be made on accommodation capability of plastic deformation in the GN structure in comparison with that of the polycrystalline coarse-grained structure.

## Surfaces and Heterostructures at Nano- or Micro-Scale and Their Characterization, Properties, and Applications: Growth, Characterization, and Devices I

#### Transforming Semiconductor Nanowires into Heterostructures and Superlattices by Size-Dependent Cation Exchange Reactions: *Ritesh Agarwal*<sup>1</sup>; <sup>1</sup>University of Pennsylvania

The unique properties of nanostructured materials enable their transformation into complex, kinetically-controlled morphologies which cannot be obtained otherwise. Solution-phase cation-exchange reactions can transform sub-10 nm nanocrystals/nanorods into varying compositions and superlattices; however, due to their small size, cation-exchange reaction rates are extremely fast which limits control over the transformed products. Nanowires are routinely synthesized via gas-phase reactions with 5-200 nm diameters and to realize their full potential, it is desirable to develop techniques which can transform nanowires into tunable morphologies. We report transformation of single-crystalline cadmium-sulfide nanowires into composition-controlled  $Zn_xCd_{(1-x)}S$  nanowires, core-shell heterostructures, metal-semiconductor superlattices, ZnS nanotubes, and metallic Zn nanowires by utilizing size-dependent cation-exchange reactions. Simulations that account for elastic interactions and diffusional kinetics reveal the conditions for forming these structures and the peculiarities of 1D systems. This versatile ability to transform nanowires offers new opportunities to study size-dependent phenomena and tune their chemical/physical properties to design reconfigurable circuits.

#### Does Function Follow Form? Coiled Carbon Nanotube and Nanowire Structures- Thermodynamic Model, Experiment, and Applications: *Prabhakar Bandaru*<sup>1</sup>; Apparao Rao<sup>2</sup>; <sup>1</sup>University of California San Diego; <sup>2</sup>Clemson University

New paradigms in materials and devices lead to new technologies, which are necessary for continued scientific progress. We have determined, in foundational studies, that nonlinear nanostructures, such as carbon nanotube based helices and coils, may be synthesized through the use of specific catalysts in chemical vapor deposition and could open up new vistas in electrical, mechanical, and optical engineering, e.g. as electrical inductors, nanoscale mechanical springs, and metamaterials. First, a thermodynamic model based on exclusion volume principles common in chemical and biological systems that could potentially explain coiling in nanostructures, will be introduced. The crucial role of the interactions between specific catalyst particles, e.g. indium and tin, and the growing nanostructure for coil growth, which has been verified through experiment, will be elucidated. The talk will be concluded with a brief exposition on the unique applications of these structures, say in localized energy absorption and electromagnetic radiation coupling.

#### 9:35 AM Invited

#### Atom-by-Atom Characterization of Low-Dimensional Materials: *Stephen Pennycook*<sup>1</sup>; Matthew Chisholm<sup>1</sup>; Gerd Duscher<sup>2</sup>; Timothy Pennycook<sup>3</sup>; James McBride<sup>3</sup>; Sandra Rosenthal<sup>3</sup>; <sup>1</sup>Oak Ridge National Laboratory; <sup>2</sup>University of Tennessee; <sup>3</sup>Vanderbilt University

The aberration-corrected scanning transmission electron microscope offers a new level of sensitivity for revealing the origin of nanomaterials functionality through its ability to image and identify individual substitutional dopants and adatoms. Examples will be shown of O and C dopants in monolayer BN and of defects and adatoms in monolayer graphene. In the case of semiconducting nanocrystals, their size, shape and crystal termination can be identified with no lower size limit. Such images reveal the mechanisms behind the growth and luminescent properties of core/shell quantum dots and ultrasmall white light-emitting nanocrystals.

#### 10:05 AM Invited

#### Micro and Nanostructured Porous Heterostructures by Electrodeposition: *Martin Bakker*<sup>1</sup>; Nikolas Cordes<sup>1</sup>; Franchesca Saylor Maddox<sup>1</sup>; Jan-Henrik Smatt<sup>2</sup>; Mika Linden<sup>2</sup>; <sup>1</sup>The University of Alabama; <sup>2</sup>Ako Akademi University

Electrodeposition into insulating templates is an extremely powerful method of making metal/insulator heterostructures. With careful selection of the electrochemistry, electrodeposition can also be used to deposit the insulating templates. We will present recent work on 1) electrodeposition of mesoporous silica thin films, and electrodeposition of micrometer structured mesoporous silica on planar and three dimensional substrates, 2) electrodeposition of metal into electrodeposited mesoporous silica templates 3) the use of humidity to control the electrodeposition of metals into the mesoporous of hierarchically meso-microstructured porous silica monoliths.

#### Synthesis and Characterization of Silicon Oxide Nanowires Using Nickel Nanoparticles: *Seonhee Jang*<sup>1</sup>; Youngil Lee<sup>1</sup>; Suhwan Cho<sup>1</sup>; Jungwook Seo<sup>1</sup>; Donghoon Kim<sup>1</sup>; <sup>1</sup>Samsung Electro-Mechanics

We attempt to produce silicon oxide nanowires (SiOxNWs) in a simple way without complicated deposition processes, gaseous Si containing precursors, or starting material of SiO<sub>2</sub>. Nickel (Ni) nanoparticles (NPs) were applied on Si wafer and thermally treated in a furnace. The temperature in the furnace was kept in the ranges between 900 and 1100 °C and a forming gas, i.e. mixture of nitrogen (N<sub>2</sub>) and hydrogen (H<sub>2</sub>) flowed through the furnace. The growth of SiOxNWs was obtained via carbothermal reduction of NiO. The SiOxNWs had widths ranging from 100 to 200 nm with length extending up to ~ 10 μm and their structure was amorphous. Ni NPs were acted as catalysts. Photoluminescence (PL) showed that blue emission spectrum was centered at the wavelength of 450 nm (2.76 eV). The details of growth mechanism of SiOxNWs and the effect of Ni NPs on the formation of SiOxNWs will be presented.

#### 11:15 AM

#### Novel Architectures of Hierarchical Heterostructures: Non-Catalytic Growth of ZnO Nanowires and Their Multifunctional Heterostructures with Gold Nanoparticles: *Wenwu Shi*<sup>1</sup>; Austin Starnes<sup>1</sup>; Nitin Chopra<sup>1</sup>; <sup>1</sup>The University of Alabama

Multi-functional heterostructures comprised of semiconducting nanowires and metal nanoparticles are of significance for optoelectronics and energy applications. Herein, for the first time, we report a simple and non-catalytic CVD process that produced branched ZnO nanowires (BZN). As a next step, gold nanoparticles were nucleated on the surface of BZN in a surfactant-free approach resulting in novel nanowire-nanoparticle heterostructures. Fundamental understanding of the heterostructures and their crystal structures, phases, interfaces, chemical functionality, composition, and thermal stability was developed using SEM, HR-TEM, XRD, DTA-TGA, FT-IR. The kinetics of heterostructure formation and their unique optical properties were studied in real-time. The growth mechanisms of BZN and their unique branched configuration have also been discussed here.

11:30 AM

**Induced Chemical Changes in Ni/NiO Core Shell-Carbon Nanotube Heterostructures in a High Temperature Post-Fabrication Treatment:** *Hylton McWhinney*<sup>1</sup>; *Wenwu Shi*<sup>2</sup>; *Nitin Chopra*<sup>2</sup>; <sup>1</sup>Texas A & M University; <sup>2</sup>The University of Alabama

High temperature surface migration of Ni/NiO core-shell nanoparticles (~5-10 nm) on the surface of carbon nanotubes (CNC Heterostructures, Shi, Krews, and Chopra, *Materials Technology*, 2010) was thoroughly studied. Heat treatments were carried out in a nitrogen-enriched furnace and the CNC heterostructures were carefully dispersed on a substrate. The samples were treated between 125 – 750 °C for 1 h. It was observed in SEM, TEM, and EDS analysis that nanoparticles significantly migrate on the CNT surfaces and their morphology was changed. In addition, massive agglomeration of nanoparticles was observed at higher annealing temperatures. XPS analysis of the heterostructures, as a function of their heat treatments, suggested that nanoparticle precursor solution, CNT surface, and annealing temperature played an important role in the morphological evolution of nanoparticles on CNTs. Shifts in the XPS elemental peaks revealed new critical information about the bonding characteristics of such heterostructures.

11:45 AM

**Nanoparticle Cluster Size Control using Chemically Modified Self-Assembly on Copolymer Surfaces:** *Sarah Adams*<sup>1</sup>; *Regina Ragan*<sup>1</sup>; <sup>1</sup>University of California Irvine

Organized clustering of metallic nanoparticles was examined for the development of field-enhanced chemical and biological detection devices, with the capacity to achieve single-molecule level detection resulting from surface enhanced Raman scattering, associated with closely-spaced noble metal nanostructures. Using chemical self-assembly techniques, we attached monodisperse, colloidal gold nanoparticles on self-organized polymer templates, patterning arrays of nanoparticle clusters with sub-10 nanometer interparticle spacing, to engineer enhanced optical fields. Poly(methyl methacrylate) domains in phase-separated polystyrene-*b*-poly(methyl methacrylate) diblock copolymer thin films were chemically modified with surface amination for controlled arrangements. Chemically synthesized sub-20 nanometer diameter gold nanoparticles were attached to the amine-functionalized surfaces using EDC crosslinking chemistry with thioctic acid ligand-bound to the nanoparticle surface, preferentially immobilizing the Au nanoparticles on PMMA domains of the copolymer template. By controlling particle size relative to PMMA domain size, nanoparticle clustering was controlled.

12:00 PM

**Thermodynamics and Processing of Nanomaterials:** *Ramana Reddy*<sup>1</sup>; <sup>1</sup>The University of Alabama

This presentation includes nanoscale materials thermodynamics and processing. Thermodynamic properties of nano-particles are different as compared to that of bulk material due to the surface energy changes. Melting temperature of nano-particles varies with the size (radius) of particles. This variation in melting temperature was calculated for different nanoscale materials. In-situ processing of nanomaterials has immense potential over the conventional nanoscale materials due to several advantages such as inherent chemical stability, lack of impurities, and fine dispersion. The results of thermal plasma production of nanoscale metal, ceramic and composite powders and the various process parameters that influence the final product were discussed.

12:15 PM

**Magnetron Sputtering of Thin Film MIM Capacitors with Al and Pt Electrodes:** *Jack Murray*<sup>1</sup>; *Wayne Huebner*<sup>1</sup>; *Matthew O'Keefe*<sup>1</sup>; <sup>1</sup>Missouri University of Science and Technology

The deposition of thin film metal-insulator-metal (MIM) capacitors for high frequency applications by magnetron sputtering was investigated. Pt-Al<sub>2</sub>O<sub>3</sub>-Pt and Al-Al<sub>2</sub>O<sub>3</sub>-Al with symmetric electrode areas were the material combinations tested in this study. All devices were deposited through a shadow mask under the same sputtering conditions resulting in a metal electrode thickness of ~160 nm and dielectric thickness of ~450 nm.

DC current-voltage measurements ( $E = 5 \text{ MV/cm}$ ) coupled with impedance analysis ( $\approx 15 \text{ MHz}$ ) was used to characterize the resulting devices. MIM structures with Pt electrodes exhibited a significantly lower resistivity and higher permittivity than devices with Al electrodes. These results indicate the formation of a space charge layer near the metal/insulator interface that depends on the electrode material.

8:35 AM

**Mechanical Recycling of Electronic Wastes for Materials Recovery:** *Viktor Laurmaa*<sup>1</sup>; *Jaan Kers*<sup>1</sup>; *Kaspar Tall*<sup>1</sup>; *Valdek Mikli*<sup>1</sup>; *Dmitri Goljandin*<sup>1</sup>; *Kristiina Vilsaar*<sup>1</sup>; *Priidu Peetsalu*<sup>1</sup>; *Mart Saarna*<sup>1</sup>; *Riho Tarbe*<sup>1</sup>; <sup>1</sup>Tallinn University of Technology

In this paper, the mechanical milling of the Printed Circuit Boards (PCB) was carried out. First goal of the work was to examine the management of the WEEE, in particular the re-use of PCB. Firstly, recycling methods of PCBs were summarized. During the study, mechanical separation methods (magnetic-, density- and air separation), electrical, and chemical methods were examined. Secondly, the optimal particle size for air-classification was determined. Several tests were carried out to find the most effective separation method for separation of different material groups from PCB scrap. The new air classification stand was developed for testing the separation of lightweight particles such as tin foil stripes and plastics. The test results showed sufficiently good separation of heavier Al and Cu. For milled materials characterization, the SA, IA, laser diffraction analysis and SEM were used. The chemical composition of the PCB powders was studied by means of energy dispersive X-ray microanalysis (EDS).

9:05 AM

**Processing of Discarded Liquid Crystal Display for Recovering Indium:** *Gjergj Dodbiba*<sup>1</sup>; *Kunihiko Takahashi*<sup>1</sup>; *Toyohisa Fujita*<sup>1</sup>; *N. Sato*<sup>2</sup>; *Seiji Matsuo*<sup>1</sup>; *Katsunori Okaya*<sup>1</sup>; <sup>1</sup>The University of Tokyo; <sup>2</sup>Tohoku University

Different materials are used for manufacturing various parts of a cellular phone. Considering that a great number of mobile phones are being discarded every year, it is important to recover these materials and then recycle them in order to save resources. The primary objective of this work is, therefore, to find and suggest ways on how to recover various materials from discarded cellular phones for recycling. Much effort, for example, has been put into recovering and recycling tin oxide (ITO), a mixture of indium(III) oxide, (In<sub>2</sub>O<sub>3</sub>) and tin(IV) oxide from the discarded LCDs. Here we report a simple and cost-effective process, which includes a HCl treatment process for altering the structure of the indium(III) compound into a chloride-induced indium compound, in order to facilitate the vaporization of indium at a relatively low temperature. The chloride-induced indium compound is then vaporized, condensed and recovered.

MONDAY AM

9:35 AM

**Green Pyrolysis of Used Printed Wiring Board Powders:** *Lucas Damoah*<sup>1</sup>; Xiangjun Zuo<sup>1</sup>; Lifeng Zhang<sup>1</sup>; Thomas Schuman<sup>1</sup>; <sup>1</sup>Missouri University of Science and Technology

Rapid technological innovation has propelled the use of electronic equipment leading to the generation of more and more waste electrical and electronic equipments (WEEE). Printed wire board (PWB) is a component made of one or more layers of insulating material with electrical conductors. Current technology for recycling PWBs uses pyrometallurgical or hydrometallurgical methods, which generate atmospheric pollution releasing dioxins and furans or high effluent volumes. To investigate an environmentally friendly process to recycle PWBs, 50g each of PWB samples with and without 10g of CaCO<sub>3</sub> additives were pyrolyzed in a tube furnace. Liquid, gas and solid products were realized with a PWB conversion fraction of 52.65 %. Analysis of the exhaust gases from the experiments using GCMS and MS showed that without CaCO<sub>3</sub> additives poisonous gases such as C<sub>6</sub>H<sub>6</sub> and HBr are produced which are adequately controlled when CaCO<sub>3</sub> is added. The exhaust gas was treated using concentrated NaOH solution.

10:05 AM

**Leaching of Lead from Solder Material Used in Electrical and Electronic Equipment:** *Manis Kumar Jha*<sup>1</sup>; Pankaj Choubey<sup>1</sup>; Archana Kumari<sup>1</sup>; Rakesh Kumar<sup>1</sup>; Vinay Kumar<sup>1</sup>; Jae-chun Lee<sup>2</sup>; <sup>1</sup>National Metallurgical Laboratory (CSIR); <sup>2</sup>Korea Institute of Geosciences & Mineral Resources

Present work is a part of developing novel recycling technique for waste printed circuit boards (PCBs), i.e. the liberation of metals from PCBs by organic swelling followed by the treatment of resin to remove/ recover hazardous soldering materials. In order to recover the hazardous metallic constituent lead from the liberated resin, initially the leaching studies were made using fresh solder containing 63.9% Pb and remaining tin. Experimental results obtained in different conditions viz. time, temperature and acidity showed ~97.20% of lead dissolution with 6M HNO<sub>3</sub> at solid to liquid (S:L) ratio 1:10 (g/mL) and temperature 90°C in 75 minutes. The result of the studies validated with crushed PCBs shows that almost total lead and tin was leached out with 6M HNO<sub>3</sub> and 6M HCl respectively at S:L ratio 1:10 (g/mL) and temperature 90°C within 50 minutes. The results will be useful for the treatment and safe disposal of PCBs resin.

10:35 AM Break

10:45 AM

**Copper Recovery from Printed Circuit Board of E-Waste:** *Toyohisa Fujita*<sup>1</sup>; Hiroyuki Ono<sup>1</sup>; Gjergj Dodbiba<sup>1</sup>; Seiji Matsuo<sup>1</sup>; Katsunori Okaya<sup>1</sup>; <sup>1</sup>The University of Tokyo

Here, we discuss the copper recovery from circuit boards. In an attempt to raise the copper grade of printed circuit boards (PCB), carbonization treatment was investigated. The crushed PCB without surface-mounted parts was carbonized under nitrogen atmosphere. After screening, the char was classified by size into oversized pieces, undersized pieces and powder. The copper foil and glass fiber pieces were liberated and collected in undersized fraction. The copper foil was liberated easily from glass fiber by a "stamping" treatment. Liberation rate of copper foil was high at high carbonized temperature. The experimental results indicated that 90% of oversized char was liberated and the copper foil recovery from PCB carbonized at 1073 K was 110 kg/t. The copper recovery from char powder by flotation was also investigated. Of the copper grade 15% and of the copper recovery 80% were obtained.

11:15 AM

**Recovery of Silver from Spent Plasma TV Monitors:** *Katsutoshi Inoue*<sup>1</sup>; Biplob Biswas<sup>2</sup>; Hidetaka Kawakita<sup>1</sup>; Keisuke Ohto<sup>1</sup>; Atsushi Hoshino<sup>2</sup>; <sup>1</sup>Saga University; <sup>2</sup>Nishinohon Kaden Recycle Corporation

The method of extraction of silver from scrap of plasma TV monitors using noncyanide reagents – sodium thiosulfate and acidothiourea – was investigated, which was followed by silver recovery from acidothiourea leach solutions. It was found that acidothiourea solution gave almost

complete extraction of silver while thiosulfate provided only 40% extraction. The rate of silver extraction using acidothiourea solution was found to be extremely fast. An increased dissolution rate was also found at elevated temperature. The recovery of silver through coagulation-precipitation from acidothiourea leach solutions was carried out with a natural biodegradable material, persimmon tannin extract. It was proved to be a promising material for complete silver recovery. Besides, precipitative recovery of silver by means of cementation with zinc powder was conducted. It was found that simple cementation with zinc powder exhibits a very good precipitative property for which it could be used in hydrometallurgical processing.

11:45 AM

**A Process for Efficient Material Recovery from Scrap Electronics:** *Jeffrey S. Spangenberg*<sup>1</sup>; Joseph Pomykala<sup>1</sup>; John Hryn<sup>1</sup>; Bassam Jody<sup>1</sup>; Edward Daniels<sup>1</sup>; <sup>1</sup>Argonne National Laboratory

End-of-life electronic devices continue to grow rapidly. With only about 20% of these devices entering the existing recycling infrastructure valuable resources are ending up in our landfills limiting the supply of raw material feed for the electronics industry. We evaluated the recovery rate of various materials in electronic scrap using our versatile material recovery pilot plant. The process uses a 2-stage approach; the first stage is a bulk separation which classifies materials into specific types while the second stage refines these materials further. The scrap processed for this study included electronics of various types including computers, copiers, and musical keyboards but not video monitors. The study focused on the segregation of circuit board material from commingled shred. A novel method was evaluated to concentrate this material so that platinum group metals could be recovered. Ferrous and non-ferrous metals, along with polymers were separated for recovery and subsequent re-use as well.

## Thermally Activated Processes in Plastic Deformation: Nucleation and Diffusive Processes

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS/ASM; Computational Materials Science and Engineering Committee  
*Program Organizer:* Christopher Woodward, Air Force Research Laboratory

Monday AM

February 28, 2011

Room: 1B

Location: San Diego Conv. Ctr

*Session Chairs:* Jeffery Rickman, Lehigh University; Carelyn Campbell, NIST

8:30 AM Invited

**Challenges in the Modeling of Nucleation and Growth Processes:** *Jeffrey Rickman*<sup>1</sup>; <sup>1</sup>Lehigh University

In this talk I will review several methodologies for modeling nucleation and growth processes in different contexts. In particular, I will first outline the calculation of nucleation rates using both atomic-level and coarse-grained descriptions of transforming systems and highlight the computational challenges that must be overcome to perform these calculations. In addition, I will explore the use of stochastic geometry to characterize the kinetics of a first-order phase transition and suggest several microstructural descriptors that can be employed to distinguish among different nucleation scenarios. Finally, as an application of the methods described here, I will examine the problem of deducing nucleation conditions from a coalesced microstructure and the tailoring of microstructures in transforming, misfitting thin films.

9:00 AM Invited

**Analysis and Modeling of Nucleation Controlled Reactions:** *John Perepezko*<sup>1</sup>; Seth Imhoff<sup>1</sup>; <sup>1</sup>University of Wisconsin Madison

Nucleation reactions control the initial stage of microstructure development. The product phase number density, size distribution and morphology are nucleation reaction signatures that are directly related to the nucleation

pathway. An effective experimental study of nucleation reactions requires the documentation of the nucleation reaction signatures and the associated stochastic behavior. Kinetic models based upon the classical nucleation theory can provide valuable mechanistic insight on the rate controlling steps. An inherent characteristic of nucleation reactions is the initial metastable state of the parent phase that is often treated as a uniformly undercooled or supersaturated condition, but recent developments in local atomic structure analysis indicate that nanoscale heterogeneities can be important at high driving free energies. Several aspects of the experimental modeling and analysis approaches are illustrated from recent progress in the examination of nanoscale microstructures and nucleation statistics measurements.

#### 9:30 AM Invited

**Diffusive Molecular Dynamics:** *Ju Li*<sup>1</sup>; Sanket Sarkar<sup>2</sup>; William Cox<sup>2</sup>; Thomas Lenosky<sup>2</sup>; Erik Bitzek<sup>1</sup>; Yunzhi Wang<sup>2</sup>; <sup>1</sup>University of Pennsylvania; <sup>2</sup>The Ohio State University

The interplay between diffusional and displacive atomic movements is a key to understanding deformation mechanisms and microstructure evolution in solids. The ability to handle the diffusional time scale and the structural complexity in these problems poses a general challenge to atomistic modeling. We present here an approximate approach, called Diffusive Molecular Dynamics (DMD), which can capture diffusional time scale while maintaining atomic resolution, by coarse-graining over atomic vibrations. DMD combines long-range elastic and short-range atomic coordinate interactions simultaneously with gradient chemical thermodynamics. The model is applied to nanoindentation, void growth under tension and sintering. Intimate coupling between diffusional mechanisms such as diffusional creep and displacive mechanisms such as dislocation nucleation, are observed in these processes.

#### 10:00 AM Invited

**Predicting Diffusion Coefficients of Multi-Component Solids from First Principles:** *Anton Van der Ven*<sup>1</sup>; <sup>1</sup>University of Michigan

Diffusion in technologically important materials often involves non-dilute atomic transport that depends on the nature of intrinsic defects, the energetically most favorable hop mechanisms and the degree of short- and long-range order among the constituents of the solid. In this talk, I will describe how these factors can be rigorously accounted for in a first-principles prediction of diffusion coefficients in non-dilute alloys. The approach relies on the evaluation of Kubo-Green expressions, which provide the link between macroscopic diffusion coefficients and atomic trajectories sampled in kinetic Monte Carlo simulations. A first-principles description of the thermodynamics of short- and long-range order in multi-component solids is achieved with the cluster expansion formalism. I will describe recent work on the prediction of diffusion coefficients in intermetallic compounds and Li ion battery electrode materials.

#### 10:30 AM Break

#### 10:45 AM Invited

**Predicting Volume-Based Diffusion in Multicomponent Multiphase Alloys:** *Carelyn Campbell*<sup>1</sup>; <sup>1</sup>National Institute of Standards and Technology

Modeling of many thermally activated processes requires accurate prediction of the volume-based (bulk) diffusion in a multicomponent multiphase alloy. CALPHAD-based multicomponent diffusion mobility databases, in combination with multicomponent thermodynamic databases, provide a powerful tool for predicting multicomponent diffusion behavior. The development of these multicomponent diffusion databases requires assessment of diffusion mobilities based on the optimization of individual diffusion coefficient measurements, measured multicomponent diffusion couple profiles, and available first principle data. These assessment methods are applied to both disordered and ordered phases in a variety of alloy systems, including Ni-based superalloys, steels, and Cu-In-Se based photovoltaic absorber materials. The quality of the assessment is determined by comparing the assessment predictions to available experimental data not included in the assessment process and various published diffusion correlations. The inclusion of additional diffusion mechanisms, such as

grain boundary and stress-induced mechanisms, to the bulk diffusion will be discussed.

#### 11:15 AM Invited

**Advanced Methods for Modeling Thermally Activated Processes:** *Arthur Voter*<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

A significant issue in accurately modeling diffusion in materials is that the dominant mechanisms are not always the simple unit processes we might think they are. Thus, even if barriers and prefactors are calculated accurately using a high-quality potential or electronic structure method, the predicted evolution may be wrong because key reaction paths are missing from the kinetic model. I will present an introduction to methods such as adaptive kinetic Monte Carlo and accelerated molecular dynamics, developed beginning in the late 1990's, for simulating the long-time dynamics of diffusive systems with no prior assumptions about the reaction mechanisms. I will discuss the strengths and weaknesses of the different methods and give some examples of recent results. I will also discuss prospects for the future and the main issues standing in the way of making these methods into general tools that can reach relevant time scales for real engineering materials.

#### 11:45 AM Invited

**Equilibrium and Time-Dependent Solute Segregation at Grain Boundaries: Systematic Monte Carlo Studies:** *Irina Belova*<sup>1</sup>; *Graeme Murch*<sup>1</sup>; Thomas Fiedler<sup>1</sup>; <sup>1</sup>The University of Newcastle

Solute segregation to grain boundaries has long been quantified by segregation factors. Segregation factors are generally obtained in a grain boundary diffusion experiment in the Harrison Type-B and C kinetics regimes. The location of the limits and even the existence of the Harrison kinetics regimes are poorly known in the presence of segregation and this has important consequences on the experimental values of segregation factors. Another important aspect is that the segregation is assumed to be at equilibrium at all times. This requirement may not always be fulfilled in a transient diffusion experiment. In this talk, we provide an overview of solute segregation, the Harrison kinetics regimes and the recent progress that has been made using the Lattice Monte Carlo method for delineating these regimes in the presence of segregation for various grain boundary diffusion models. The time dependence of the segregation factor and associated effects will also be discussed.

#### 12:15 PM

**Atomistic Modeling of Interactions of Dislocation Pile-Up with Grain Boundaries:** *Jian Wang*<sup>1</sup>; Steven Valone<sup>1</sup>; Richard Hoagland<sup>1</sup>; Timothy Germann<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

Interfaces are a common planar defect in materials and can act as Sources, Sinks and Barriers for point defects and line defects. Interfaces possess many metastable states for a given set of macroscopic degrees-of-freedom. These various states may differ in energy, but by relatively small amounts, and may be separated by small energy barriers. Consequently, they may easily change state and configuration in response to changes in stress, temperature, and composition. These easy configurational changes enable such multi-state interfaces to actively participate in and influence a broad array of reactions and processes. Using atomic scale models (topological model and atomistic simulation), interface structures and properties and the interaction of interface with dislocations are studied. The results show that interfaces play a crucial role in determining material strength due to the dislocations-interfaces interactions and in nucleating lattice dislocations in associated with the reconstruction of interface structures.

## Ultrasonic Welding for Lightweight Components: Session I

*Sponsored by:* The Minerals, Metals and Materials Society, American Welding Society, TMS Light Metals Division, TMS Structural Materials Division, TMS: Young Leaders Committee, ASM-MSCTS: Materials and Processing Committee, METSOC-CIM: Metal Processing and Fabrication Committee

*Program Organizer:* Frank Balle, University of Kaiserslautern

Monday AM Room: 33A  
February 28, 2011 Location: San Diego Conv. Ctr

*Session Chair:* Frank Balle, Institute of Materials Science and Engineering, University of Kaiserslautern (Germany)

### 8:30 AM Introductory Comments, Frank Balle, Organizer

#### 8:35 AM

**Mechanisms of Joint Formation in Ultrasonic Spot Welding Aluminium Automotive Sheet:** *Phil Prangnell*<sup>1</sup>; Dimitrios Bakavos<sup>1</sup>; Yingchun Chen<sup>1</sup>; <sup>1</sup>The University of Manchester

High power ultrasonic spot welding (HP-USW) is an extremely efficient new method for welding Al alloys using ~ 2% of the energy of RSW. The overall objective of this work was to improve our current poor understanding of the mechanisms of weld formation when HP-USW is applied to aluminium automotive sheet. To this end, we report on the results of a detailed investigation, where we have studied the material flow, combined with x-ray tomography, FEG-SEM and EBSD, to characterise the weld defects, stages of weld formation, and microstructure evolution, as a function of welding energy, for a standard automotive material AA6111-T4 in 0.92 mm thick sheet. Results include a discussion of the origin of the complex flow features, noted by other researchers, which were found to occur on three length scales, the observation of a HAZ, and the grain structure developed in a typical weld.

#### 8:55 AM

**Ultrasonic Welding of Cables and Wires:** *Stefan Heinz*<sup>1</sup>; Dietmar Eifler<sup>1</sup>; Guntram Wagner<sup>1</sup>; <sup>1</sup>University of Kaiserslautern

In the automotive industry the ultrasonic metal welding technology is an established method to join aluminium or copper wires. At the WKK systematic investigations with ultrasonic welded Al-wires and flat flexible cables (FFCs) made of copper were carried out. In the case of Al-wires, joints with a cross sectional area of up to 120 mm<sup>2</sup> and a maximum tensile shear load of about 3500 N were realized. In addition, methods to reduce the unintentional adherence between the sonotrode coupling face and the Al-wires were developed. For FFCs, ultrasonic spot welding systems as well as ultrasonic torsion welding systems were used to weld wire to wire and wire to connector joints. With these joints maximum tensile shear loads comparable to the base material were achieved. Furthermore, a system was developed, which enables the welding of FFCs through the insulation of the cables.

#### 9:15 AM Invited

**Ultrasonic Metal Welding of Hybrid Joints:** *Guntram Wagner*<sup>1</sup>; Frank Balle<sup>1</sup>; Dietmar Eifler<sup>1</sup>; <sup>1</sup>University of Kaiserslautern

A central research field of the WKK is the realization of innovative hybrid joints by ultrasonic metal welding. The presentation gives an overview about suitable ultrasonic welding systems and essential machine and material parameters which influence the quality of the welds. Besides the ultrasonic welding of dissimilar metals such as Al to Cu or Al to steels, also welds between nonstandard materials like aluminum foam sandwiches or Al-wires can be realized. Moreover, the joining of glass and ceramic with metals is a point of interest at the WKK. By using the ultrasonic metal welding process, it is possible to realize glass/metal welds with tensile shear strengths of 50 MPa. Even, for ceramic/metal-joints actually shear strengths values up to 120 MPa were measured. Finally, selected results about the effects of

thermally induced residual stresses on the hybrid joints and questions of the bonding mechanisms will be discussed.

#### 9:45 AM

**Optimization of Aluminium to Magnesium Ultrasonic Spot Welding:** *Lexi Pantelli*<sup>1</sup>; Yingchun Chen<sup>1</sup>; David Strong<sup>1</sup>; Xiaoyun Zhang<sup>2</sup>; Phil Prangnell<sup>1</sup>; <sup>1</sup>The University of Manchester; <sup>2</sup>Beijing Institute of Aeronautical Materials

Dissimilar joining of aluminium and magnesium alloys is problematic due to the formation of brittle intermetallic phases at the interface. Successful joining will afford significant weight savings in the automotive industry as dissimilar materials combinations could be used to create lighter, more fuel efficient multi-material structures. Ultrasonic welding may offer a joining solution, but the process of joining aluminium to magnesium is not well understood. Here, we have investigated the effect of energy input and welding time on joint formation between aluminium 6111 and magnesium AZ31, and report on the optimum welding conditions, interfacial heat generation and the formation of a significant intermetallic layer. Further, the effect of pre-coating the magnesium with aluminium is discussed and the resulting reduction in intermetallic formation is shown.

#### 10:05 AM Break

#### 10:15 AM

**Fatigue Failure Behavior and Life Estimation of Ultrasonic Spot Welds in Lap-Shear Specimens of Magnesium and Steel Sheets:** *Teresa Franklin*<sup>1</sup>; Jwo Pan<sup>1</sup>; Michael Santella<sup>2</sup>; Tsung-Yu Pan<sup>2</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>Oak Ridge National Laboratory

Fatigue behavior of ultrasonic spot welds in lap-shear specimens of magnesium AZ31B-H24 and hot-dipped-galvanized mild steel sheets is investigated based on experimental observations and a fatigue life estimation method. Optical micrographs of the welds before and after fatigue tests are examined to understand the failure mechanism of the welds. The optical micrographs indicate that the magnitude of the load range has significant influence on the location of kinked fatigue crack initiation. The location of the kinked fatigue crack initiation affects the failure mode of the welds. The failure mode changes from a partial nugget pullout mode through the magnesium sheet at high load ranges to an eyebrow crack growth mode through the magnesium sheet at lower load ranges. A structural stress model based on the closed-form structural solution is adopted to predict the fatigue lives of spot welds. The predicted fatigue lives are compared with the experimental results.

#### 10:35 AM

**Effect of Zinc Coatings on Joint Properties and Interface Reactions in Aluminum to Steel Ultrasonic Spot Welding:** *Farid Haddadi*<sup>1</sup>; Phil Prangnell<sup>1</sup>; <sup>1</sup>The University of Manchester

Dissimilar joining of aluminium to steel sheet is an important potential application of USW for multi-material automotive structures. Here, the weldability of un-coated and zinc coated steel with aluminium is discussed, using a 2.5 kW USW welder. Results show that zinc steel results in a higher weld performance than uncoated steel. The effect of parameters such as energy and clamping force have been investigated. For Al6111-T4 to DC04 joints it has been found that the tensile strength reaches a maximum after ~1.5 second welding time before decreasing, which is about 90% of the strength of an Al-Al joint. In comparison welds between Al6111-T4 and zinc coated steel took longer to achieve the same weld energy and maximum strength, because of melting of the Zinc coat, but matched the Al-Al joint properties. The reasons for these different behaviours are discussed in terms of the interfacial reactions, that take place.

#### 10:55 AM

**Ultrasonic Spot Welding of AZ31B to Galvanized Mild Steel:** *Michael Santella*<sup>1</sup>; Teresa Franklin<sup>2</sup>; Tsung-Yu Pan<sup>1</sup>; Elliot Brown<sup>3</sup>; Jwo Pan<sup>2</sup>; <sup>1</sup>Oak Ridge National Laboratory; <sup>2</sup>University of Michigan; <sup>3</sup>EB Scientific Enterprises

Ultrasonic spot welds were made between sheets of 0.8-mm-thick hot-dip-galvanized mild steel and 1.6-mm-thick AZ31B-H24. Lap-shear strengths of 3.0-4.2 kN were achieved with weld times of 0.3-1.2 s. Failure to achieve

strong bonding of joints where the Zn coating was removed from the steel surface indicate that Zn is essential to the bonding mechanism. Microstructure characterization and microchemical analysis indicated temperatures at the AZ31-steel interfaces reached at least 344°C in less than 0.3 s. The elevated temperature conditions promoted annealing of the AZ31-H24 metal and chemical reactions between it and the Zn coating.

**11:15 AM**

**Ultrasonic Welding of Hybrid Aluminum/CFRP-Joints: Microstructure, Monotonic Properties and Fatigue Behavior:** Stefan Huxhold<sup>1</sup>; Frank Balle<sup>1</sup>; Guntram Wagner<sup>1</sup>; Dietmar Eiffler<sup>1</sup>; <sup>1</sup>University of Kaiserslautern

Ultrasonic metal welding is well suited to realize aluminum alloy/carbon fiber reinforced polymer (CFRP) – joints. Important advantages of the ultrasonic welding process are: welding times less than three seconds and welding temperatures below 450°C. The joints are realized by softening and displacing of the polymer out of the welding zone as a result of the ultrasonic shear oscillation. In contrast to conventional joining processes this is the pre-condition that a direct contact between the aluminum and the carbon fibers takes place. In investigations with rolled blank sheets shear strengths of about 30 MPa were realized for AA5754/CF-PA66 – joints. By special surface pre-treatments of the metal, like shot peening or etching, the joint strength was increased up to 60% and the aging behavior of the joints was enhanced. Furthermore, bonding mechanisms and the fatigue behavior of the ultrasonic welded hybrid joints were examined in detail.

**2:00 PM Introductory Comments**

**2:05 PM Invited**

**Titanium Oxides Thin Film Anodes for All-Solid-State Lithium Ion Batteries:** Ming-Che Yang<sup>1</sup>; Danijel Gostovic<sup>2</sup>; Shirley Meng<sup>2</sup>; <sup>1</sup>University of Florida; <sup>2</sup>U.C. San Diego

The requirements of low power and small size energy source in CMOSRAM and Micromechanics (MEMS) have brought up the use of all-solid state thin film batteries. Metallic lithium is not a suitable anode material for all-solid-state thin film batteries because of the large irreversible capacity and high reactivity with air. Spinel lithium titanate Li<sub>4</sub>Ti<sub>5</sub>O<sub>12</sub> and anatase TiO<sub>2</sub> have attracted great attention as potential anode materials because of the following attributes: stable in the air atmosphere, good Li-storage capacity, safety against overcharging and stable voltage plateau. Pulsed laser deposition was used for the electrode deposition. Film depositions were carried out at different temperature, different oxygen partial pressure and different substrate. In order to understand the relationship between crystal structure and electrochemical properties of thin films, the thin films were studied by X-ray diffraction, scanning electron microscopy (SEM), and TEM. Electrochemical performances were investigated by galvanostatic techniques in lithium cells.

**2:35 PM**

**Synthesis of Titania Nanotubes for Lithium Ion Batteries:** Hyukjae Lee<sup>1</sup>; Sang-Jun Park<sup>1</sup>; <sup>1</sup>Andong National University

Titania nanotubes are synthesized via hydrothermal and anodization techniques for an alternative anode material of lithium ion battery and their properties are measured via X-ray diffraction, electron microscopy, potentiostat, etc. Different synthetic conditions and post synthesis treatments cause various crystallographic phases and structural morphologies in the synthesized titania nanotubes. The lithium electrochemical behavior of the synthesized titania nanotubes is studied by the use of coin cells, and the results show that final crystallographic phase and morphology are the most important factors for lithium intercalation behavior in both synthetic methods. However, there are distinct differences in lithium intercalation behavior between titania nanotubes synthesized from hydrothermal and anodization methods as well. The lithium intercalation performance of titania nanotubes are further enhanced by the introduction of the carbon sources during synthesis which, in turn, results in carbon coating or doping at titania nanotubes.

**2:50 PM**

**Nanogenerators from Piezoelectric-Coated Carbon Nanotubes:** David Stollberg<sup>1</sup>; <sup>1</sup>Georgia Tech Research Institute

This research creates an energy harvesting device that harnesses ambient and extraneous motion of a vehicle or wind, etc. and converts it to electrical energy: a “nanogenerator” using carbon nanotubes (CNTs) and piezoelectrics. The CNTs serve as an efficient, lightweight, robust electrical conduit and structural support for nanothickness piezoelectrics, zinc oxide (ZnO). Arrays of ZnO-coated CNTs are built on rigid silicon substrates or flexible carbon fiber substrates. Disturbances, vibrations and other inertial motions cause the ZnO-coated CNTs to bend and stress, producing a current. A simple ZnO-coated CNT structure can generate an electric current density of ~0.3 μA/cm<sup>2</sup> to 4 mA/cm<sup>2</sup> with a power density of 0.1pW/cm<sup>2</sup> to 0.01μW/cm<sup>2</sup> under a small applied load. With optimization of the pattern and dimensions, there is promise for significantly increasing the current density to over 40 mA/cm<sup>2</sup> and the power density to over 10μW/cm<sup>2</sup>, enough to power small sensors and/or MEMS/NEMS devices.

**3:05 PM**

**Structural and Electrochemical Characterization of Individual Nanowires for Li-ion Batteries:** John Sullivan<sup>1</sup>; Arunkumar Subramanian<sup>1</sup>; Jianyu Huang<sup>1</sup>; Michael Shaw<sup>1</sup>; Nicholas Hudak<sup>1</sup>; Yongjie Zhan<sup>2</sup>; Jun Lou<sup>2</sup>; <sup>1</sup>Sandia National Labs; <sup>2</sup>Rice University

Nanowire (NW) anode and cathode materials offer the possibility of increased capacity and/or rate performance in Li-ion batteries through better accommodation of the large stresses incurred during lithiation/delithiation and through reduction in the path length for Li-ion or electron transport. One challenge with NW materials development is their electrochemical characterization, particularly diagnostics at the individual NW level. To meet this need, we have developed chip-based platforms that allow the isolation and electrochemical, structural, and electrical characterization of individual NWs. We have demonstrated this approach by isolating single MnO<sub>2</sub> NW cathodes and measuring their structural changes by transmission electron microscopy following increasing levels of electrochemical lithiation. We observe a rapid disordering of the MnO<sub>2</sub> lattice and a monotonic decrease in electrical conductance with increasing Li content. Sandia is operated by Sandia Corp., a wholly owned subsidiary of Lockheed Martin Co., for the U.S. DOE's NNSA under contract DE-AC04-94AL85000.

**3:20 PM**

**Phase Field Simulations of Morphological Evolution during Lithium Intercalation/Extraction in Li-ion Batteries:** Saswata Bhattacharya<sup>1</sup>; Linyun Liang<sup>1</sup>; Long-Qing Chen<sup>1</sup>; <sup>1</sup>Pennsylvania State University

We present a three-dimensional phase field model to study the morphological evolution during the intercalation/extraction of Li-ions into a host electrode in Li-ion batteries. The effects of anisotropic diffusional mobility of Li-ions in the electrode host lattice, flux of Li-ions across the electrode/electrolyte interface, and coherency strains arising from the lattice parameter mismatch

MONDAY PM

between the lithiated and unlithiated phases are studied using  $\text{LiFePO}_4$  as an example. We use spectral smoothed boundary method to solve the governing equations. Our simulations show the formation of plate-like crystallites of the lithiated phase when anisotropic bulk transport of Li-ions is assumed to be the rate limiting mechanism. We compare the microstructural features obtained from our simulations with available experimental observations.

**Dye Sensitized Solar Cells with 3-Dimensional Anodes, and Prospects for Incorporating Unusual Photophysical Processes:** *Michael Tauber*<sup>1</sup>; <sup>1</sup>University of California, San Diego

Dye sensitized solar cells (DSSCs) are an emerging class of photovoltaics that are potentially much less expensive than traditional silicon solar cells. Presently the record-holding 11% efficient DSSC is only half as efficient as the best commercial silicon solar cells. Furthermore, the challenge of large-area scaling of DSSCs has slowed their commercialization and utilization. We have designed and constructed new DSSCs that incorporate titanium dioxide nanotubes anodically grown in a 3-D array from titanium metal substrate. The cells have >5% efficiency, and are free of transparent conductive oxide. The highly conductive all-metal substrates will make cells of this kind easy to scale to large areas, and at low cost. The 3-D cells are an optimal platform for testing new dyes and dye mixtures in DSSCs. Prospects for exploiting unusual photophysical processes in DSSCs, including triplet excited states and singlet fission, will be described.

### 4:20 PM

**Formation of Silver Nanocube Array via Silica-Polymer Nanocomposites:** *Chi-Kai Chiu*<sup>1</sup>; *Yong-Jae Choi*<sup>1</sup>; *Tzy-Jiun Luo*<sup>1</sup>; <sup>1</sup>North Carolina State University

Silver nanocubes are spontaneously formed at room temperature on the surface of sol-gel silica nanocomposite film that consists of polyethyleneglycol (PEG) and silver ions. The formation of silver nanocubes can be achieved without the presence of poly(vinylpyrrolidone), which was found to enhance the sharpness of nanocube edges. The geometry (e.g., spherical or cubic shape) nanocubes are critically dependent on the thickness of nanocomposite film while the dimension of nanocubes are the function of film thickness. The spontaneous reduction of silver occurs inside the nanoporous structures of silica where PEG serves as both mobile phase and reducing agent. This phenomenon is driven by the shrinkage of the sol-gel silica layer during aging process and is controllable through surface functional groups. The ability to create silver nanocubes on a solid substrate at room temperature suggests that it is possible to control both position and size of silver nanocubes using imprint technique.

### 4:35 PM

**Self-Assembled Epitaxial Quantum Dot Multilayers: A Stochastic Continuum Modeling Approach:** *Lawrence Friedman*<sup>1</sup>; <sup>1</sup>National Institute of Standards and Technology

Some strained semiconductor heterostructures such as  $\text{Ge}_x\text{Si}_{1-x}/\text{Si}$  and  $\text{In}_y\text{Ga}_{1-y}\text{As}/\text{GaAs}$  spontaneously form into zero-dimensional nanoelectronic structures known as self-assembled quantum dots (SAQDs). These structures are simple in composition, yet they exhibit rich behavior such as strain-induced zero- and finite-temperature phase transitions, nanoscale stochastic behavior and the ability to form multilayer superlattices that are ordered by strain-coupling. Thus, modeling their formation addresses many interesting aspects of nanoscale science and nanomechanics, while at the same time aiding in the design and manufacture of functional materials. To investigate the ordering (quality improving) and disordering (quality degrading) influences, a previously developed continuum stochastic model is refined and adapted to SAQD multilayers. The continuum stochastic approach enables large volume and long-time scale modeling that is necessary to collect statistics that characterize the order and quality of self-assembled quantum dots.

### 4:50 PM

**Three Dimensional Carbon Nanotube Photovoltaics:** *Jack Flicker*<sup>1</sup>; *Jud Ready*<sup>2</sup>; <sup>1</sup>Georgia Institute of Technology; <sup>2</sup>Georgia Tech Research Institute

The use of a nanostructured, three dimensional morphology in photovoltaics devices has occurred only relatively recently. We introduce a three dimensional photovoltaic device with carbon nanotube pillars coated with photoactive materials to create a solar cell. The extra dimensionality of this cell added by the nanotubes has been theorized to increase the relative energy generated over planar cells by up to four times. The energy increase is due to an increase in the interactions between photons and the photoactive material as the sun is at an off normal angle to the cell substrate. Prototypes of these cells have been made and, although suffering from a low overall efficiency, do show an increased energy production in the same manner that theory predicts when the light source is at an off normal angle. Increases in device efficiency by evolution of processes and structures will also be discussed.

### 5:05 PM

**New Silicon Alloy Nano-Particulate Materials for Lithium Ion Battery Anodes:** *Emma White*<sup>1</sup>; *Lisa Rueschhoff*<sup>1</sup>; *Iver Anderson*<sup>2</sup>; *Steve Martin*<sup>3</sup>; <sup>1</sup>Iowa State University & Ames Laboratory; <sup>2</sup>Ames Laboratory & Iowa State University; <sup>3</sup>Iowa State University

Lithium ion batteries currently offer the highest energy density, ~400 mAh/g, combined with high voltage, but the theoretical energy density of metallic lithium, ~4,000 mAh/g, has been difficult to achieve so far in a secondary cell. Poor cycle life has limited the use of higher charge capacity materials, such as silicon. A novel composite material made of alloyed silicon nano-particles has been produced which may circumvent the previous issues in using pure silicon as an anode material. The spark discharge method of particle production, the characterization of the resulting particles, and their initial performance in a lithium battery cell will be described. Funding provided by Ames Lab Seed Fund through Ames lab Contract DE-AC02-07CH11358.

### 2:00 PM

**A Study of Coal-Based Direct Reduction of Composite Binder Magnetite Preheated Pellets:** *Deqing Zhu*<sup>1</sup>; *Tiejun Chun*<sup>1</sup>; *Vinicius Mendes*<sup>1</sup>; *Jian Pan*<sup>1</sup>; *Jian Li*<sup>2</sup>; <sup>1</sup>Central South University; <sup>2</sup>Research Institute of Baosteel

A study of the coal-based direct reduction behaviors of composite binder magnetite pellets was carried out in a simulating coal-based grate-rotary kiln process. It is shown that preheated pellets possess much better reducibility than fired oxide pellets: 40 min are required for preheated pellets to reach over 90% metallization degree compared to 100 min for fired oxide pellets. The compressive strength of preheated pellets decreases dramatically at the earlier stage of reduction, climbs quickly after reducing for 30min and achieves a high value at the end of reduction. However, the compressive strength of metallized pellets from reducing of fired pellets is much lower,

more cracks and fractures being formed. In the preheated pellets, crystallite of metal iron is coarse. In the oxide pellet, a large number of interconnected crystals of metal iron are formed inside pellets, and pellet structure is very compact.

**2:20 PM**

**A Model of Decarburization of Iron/Carbon Droplets:** *Mark Schwarz*<sup>1</sup>; <sup>1</sup>CSIRO

A computer model which follows decarburization of Fe/C/S droplets and predicts the onset of "carbon boil" has been developed based on the mechanism of El-Kaddah and Robertson. According to this mechanism, boil occurs when the supersaturation pressure of CO within the droplet reaches a critical value. Predicted times to boil have been compared with measurements made at CSIRO under various operating conditions. The model results generally agree well with measured times to boil, thereby validating the boil mechanism. The critical supersaturation pressure for boil determined by comparing predicted and measured boil times is similar to that determined by El Kaddah and Robertson (48-240 atm) and depends on the kinetics of the surface decarburization reaction. The computer model predicts that the time to boil decreases as the gas-droplet velocity increases, as the drop temperatures decreases and as the droplet diameter decreases.

**2:40 PM**

**Non-Isothermal Kinetics of Reduction Reaction of Oxidized Pellet under Microwave Irradiation:** *Wu Kai*<sup>1</sup>; *Huang Zhu-Cheng*<sup>1</sup>; *Peng Hu*<sup>2</sup>; <sup>1</sup>CSU; <sup>2</sup>Syno-Therm Co. Ltd

The microwave heating characteristics of the mixture of acid pellet and coal was researched, and the non-isothermal reductive dynamics was discussed in the paper. The results show that, the slow-heating stage of the temperature rising process can be segmented into two heating temperature curve that have good linear relationship. It can be seen temperature programming. In the first stage, i.e., between 827K and 1073K, the reaction mechanism obeys three-dimensional diffusion model. In the second stage, i.e., between 1093K and 1323K, the reaction mechanism obeys chemical reaction model. The apparent activation energies are found respectively to be 63.96kJ/mol for the first stage and 61.27kJ/mol for the second stage. That is lower than the apparent activation energy under conventional heating. The research of the microstructure shows microwave can improve the kinetics of the reduction. Microwave has anxo-action to the reaction obviously.

**3:00 PM**

**Microwave Dielectric Properties of Pyrolyzed Carbon:** *Zhiwei Peng*<sup>1</sup>; *Jiann-Yang Hwang*<sup>1</sup>; *Wayne Bell*<sup>1</sup>; *Matthew Andriese*<sup>1</sup>; *Shuqian Xie*<sup>2</sup>; <sup>1</sup>Michigan Technological University; <sup>2</sup>Northeastern University

Pyrolyzed carbons are generally known as good microwave absorbers and their dielectric properties still remain to be fully explored. In the present study the dielectric properties and dielectric polarization-relaxation phenomenon of a typical activated carbon was investigated. The experimental results indicate the complex permittivity is highly dependent on temperature and frequency. The decrease of permittivity with increasing temperature from room temperature to ~100 °C is probably ascribed to the release of the water vapor adsorbed on the surface of activated carbon, and the variations of permittivity with temperatures between 100 °C and 450 °C in the frequency range of 300 MHz to 3000 MHz are mainly attributed to the decreased relaxation time of dielectric polarization.

**3:20 PM**

**Fugitive Emissions Related to Oxidation of Liquid Silicon During Ladle Refining:** *Mari Ness*<sup>1</sup>; *Gabriella Tranell*<sup>1</sup>; *Nils Eivind Kamfjord*<sup>1</sup>; <sup>1</sup>Norwegian University of Science and Technology

In oxidative ladle refining (OLR) of silicon, the metal surface is oxidized resulting in the formation of a condensed silica fume (SiO<sub>2</sub>). In the current work, industrial measurement campaigns were performed aiming to measure the fume generation during OLR. A thorough discussion of the possible mechanisms has been included in order to get a better understanding of the system. The measurement campaigns were done at the Elkem Salten plant in Norway. In addition to fume generation from OLR, the metal temperatures

and ladle purge gas amount were recorded. Other mechanisms of SiO<sub>2</sub> formation were considered, however found insignificant. The results of this work suggest that the dominant source of SiO<sub>2</sub> fume generation during OLR is the oxidation of the metal surface, with oxygen transport to the metal surface being the limiting factor.

**3:40 PM**

**Reduction Kinetics of Iron Oxide in CaO-SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub>-Fe<sub>x</sub>O-C Mixtures:** *Yuanyuan Zhang*<sup>1</sup>; *Patrick Masset*<sup>1</sup>; <sup>1</sup>TU Bergakademie Freiberg

In iron and steelmaking technologies, the determination of the interfacial reaction kinetics between CO/CO<sub>2</sub> based mixtures and iron ores represents a challenging and valuable input for the modelling of such high temperature conversion processes. In this work, experiments on the reduction of iron oxides were carried out using high pressure thermogravimetric analysis (HP-TGA) under CO/CO<sub>2</sub> mixtures at temperatures and pressures up to 1000°C and 5 bars, respectively. Through analyzing the TGA curves recorded at different heating rates, the reduction rate of the iron oxides by CO/CO<sub>2</sub> mixtures and the activation energies of the reduction reactions have been determined. For well defined transformation rate, the iron oxide particles were observed by SEM/EDX analysis to understand the reaction mechanism occurring at the oxide/gas interface. In addition, Mössbauer spectroscopy was used to estimate Fe<sup>3+</sup>/Fe<sup>2+</sup> ratio.

**4:00 PM Break**

**4:10 PM**

**Optimization of the Process Variables for Making Direct Reduced Iron by Microwave Heating using Response Surface Methodology:** *Linqing Dai*<sup>1</sup>; *Jinhui Peng*<sup>1</sup>; *Hongbo Zhu*<sup>1</sup>; <sup>1</sup>Kunming University of Science and Technology

To optimize the process variables for making direct reduced iron (DRI) by microwave heating, the reduction temperature, reduction time and the ratio of coal to material were studied with the central composite design (CCD) and their interactions on the Metallization rate were also investigated. The predictive polynomial quadratic equations model was analyzed by ANOVA. Optimal conditions of making DRI can be concluded as follows: 28 min at 1139°, the ratio of coal to material is 20.95%. Under these conditions, the metallization rate is up to 97.06%.

**4:30 PM**

**Study on Nucleation and Growth Mechanism of Iron Crystal Grain in Coal-Based Shaft Furnace Direct Reduction Iron Pellets by Microwave Heating:** *Zhucheng Huang*<sup>1</sup>; *Zhenyuan Liao*<sup>1</sup>; *Bing Hu*<sup>1</sup>; *Lingyun Yi*<sup>1</sup>; *Yuanbo Zhang*<sup>1</sup>; <sup>1</sup>Central South University

Nucleation and growth mechanism of iron crystal grain in coal-based shaft furnace direct reduction process by microwave heating were investigated by optical microscope, scanning electron microscope and EDX. The results indicate that microwave has selectivity on various minerals which absorb microwaves. The high temperature in certain area of pellets and thermal stress on the interface of minerals are formed, results in the wustite grain smashed along the joints, and iron crystal grains turned out a spherical shape obviously. The iron crystal nucleus is formed firstly at the edge of wustite, on the interface between grains and in the holes in pellets, and grows gradually while reduction carries on from surface layer to inner core. Microwave heating promotes the rate of transportation and accumulation of the iron crystal grain, increases growth rate of iron crystal grain and contributes to formation of dense iron-jointed crystal texture eventually.

**4:50 PM**

**In-Situ Mass, Temperature, and Resistance Measurements during Microwave Metallization of Iron Ore and Zink Dust for On-Line Optimization:** *Wayne Bell*<sup>1</sup>; <sup>1</sup>Michigan Technological University

Microwave reduction furnaces have a great potential to eliminate traditional electric arc and blast furnaces that are inefficient and environmentally unfriendly. A rotary microwave/electric arc reduction furnace was developed at Michigan Technological University to be marketed commercially in the United States with the hope of rapidly becoming the first green alternative to existing reduction-metallization technologies. Materials are fed onto a 6'

refractory disc in a waveguide attached to 3 100kW microwave applicators. Upon formation of a conductive metallic network from microwaving, an electric arc is used to melt the network into a nugget for extraction. To effectively and continuously run a microwave/EAF furnace, several working parameters must be controlled by the user before operation: Microwave and EAF power, processing speed, mixing ratios of input materials. Using a simple household microwave, several materials properties (resistance, mass, and temperature) can be easily measured and correlated to expose the unknown on-line working parameters.

#### 5:10 PM

**Research on the Reduction Mechanism of Vanadium Oxides in Lumpy Zone in Blast Furnace:** *YongHong Wang*<sup>1</sup>; Bing Xie<sup>1</sup>; QingYun Huang<sup>1</sup>; JiaRong Yang<sup>1</sup>; <sup>1</sup>ChongQing university

Vanadium-bearing titanomagnetite is used as one of raw materials in blast furnace in Panzhihua Iron and Steel Group Corp. Thermodynamic calculation on reduction of vanadium oxides from ore in lumpy zone of blast furnace showed that with the occurrence of iron the pressure of PCO<sub>2</sub>/PCO of the vanadium oxides reduction could evidently increased because vanadium could unlimitedly dissolve in liquid iron. Also, the process of iron and vanadium reduction from magnetite ore is simulated in reduction furnace. Chemical analysis method is used to analysis the composition of reduction samples. It is concluded that the reduced degree of iron oxide can be higher than 80% after three hours. And when the reduced degree of iron oxide is between 85% and 90%, vanadium oxides begin to be reduced and the content could reach 0.083% when the reduced degree is 97.4%.

#### 5:30 PM

**Investigation on a Microwave High-Temperature Air Heat Exchanger:** Jianhua Liu<sup>1</sup>; Yingwei Li<sup>1</sup>; Lijun Liu<sup>1</sup>; Jinhui Peng<sup>1</sup>; Libo Zhang<sup>1</sup>; *Shenghui Guo*<sup>1</sup>; Huilong Luo<sup>1</sup>; Hongpo Wang<sup>1</sup>; Guo Chen<sup>1</sup>; <sup>1</sup>Kunming University of Science and Technology

As essential equipment in the metallurgical industry, current air heat exchanger can not meet the requirements of high temperature heat transfer. In present paper, an energy efficient air heat exchanger, based on accumulation of the heat generated by microwave absorbing materials is presented according to heat transfer theory and principle of the microwave field. A tubular shape structure of heat exchanger was designed and built up through temperature-rising curve, heat transfer performance of different materials heat exchanger. And it was indicated from experiments that tubular shape heat exchanger fabricated by using material B could be used for high temperature heat transfer system, and equilibrium temperature could reach up to 457—485°C.

## Advances in Science-Based Processing of Superalloys for Cost and Sustainment: Application of Modeling and Simulation to Component Design and Life Prediction

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS Structural Materials Division, TMS/ASM: Computational Materials Science and Engineering Committee, TMS: High Temperature Alloys Committee, TMS: Advanced Characterization, Testing, and Simulation Committee

*Program Organizers:* Donna Ballard, US Air Force; David Furrer, Pratt & Whitney; Paul Jablonski, US Department of Energy; Christopher Woodward, Air Force Research Laboratory; Jeff Simmons, AFRL; Mark Blodgett, Wright-Patterson AFB

Monday PM

#### 2:00 PM Invited

**Extreme Values in Materials Microstructure:** *Anthony Rollett*<sup>1</sup>; Seth Wilson<sup>1</sup>; Jeff Simmons<sup>2</sup>; Katayun Barmak<sup>1</sup>; Michael Groeber<sup>2</sup>; David Rowenhorst<sup>3</sup>; <sup>1</sup>Carnegie Mellon University; <sup>2</sup>Air Force Research Lab.; <sup>3</sup>Naval Research Lab.

Materials scientists and engineers commonly report a single value for a property or microstructural feature. Some properties, however, probe the weakest link in a system. Thus there are references to the use of extreme value statistics to link particle sizes to fatigue life, for example, going back to the 1940s. Grain size is an example where the community has been content to argue over the applicability of, say, the log-normal distribution versus other candidate distributions. Yet, the impact of grain size may be through the presence of large grains in the system, rather than the average. Thus determining the extreme values for grain size is also important for understanding microstructure-property relationships. Several experimental data sets and some derived from computer simulation of microstructure evolution are analyzed to characterize the upper tails of the grain size distribution.

#### 2:30 PM Invited

**Uncertainty in Process-Structure-Property Relations: Robust Materials Design:** *David McDowell*<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology

Designing materials for targeted performance requirements demands a combined strategy of bottom-up and top-down modeling, simulation, experiments, and systems engineering. In materials design applications, uncertainty can be both stochastic and epistemic. Stochastic (i.e., aleatory) uncertainty stems from stochastic variability and inherent randomness of material processing and morphology, as manifested in heterogeneous, randomly distributed microstructure attributes and defects. Epistemic (i.e., model) uncertainty stems from limits to the knowledge captured in models (model idealization and approximation of reality) and databases. This manifests itself in the limited fidelity and accuracy of predictions, inevitable lack of information, and modeling errors due to interpolations, approximations, convergence, assumptions, and other factors related to methods of obtaining approximate solutions. Characterizing and managing both types of uncertainty are essential in pursuing materials design applications. Components of a practical approach for robust design of materials to achieve specified functionality are presented, addressing uncertainty.

### 3:00 PM Invited

#### **Rolls-Royce Perspective on Advances in Science-Based Processing of Superalloy Materials and Components:** *Mary Lee Gambone*<sup>1</sup>; <sup>1</sup>Rolls-Royce

Recent advances in superalloy material and component capabilities have been attributed to the refinement of processing methods and controls. These refinements have been supported and driven by further understanding of the metallurgical phenomena that subsequently result in enhanced mechanical performance. Physics-based understanding of microstructure evolution and deformation processes has led to unique combinations of processes and processing control methods. Efforts to develop and apply fundamental understanding of physical and mechanical metallurgy of superalloy materials is not new, however recent discoveries in mechanical behavior and material characterization methods have provided renewed emphasis and insight into the importance of processing. This talk will provide an industrial perspective on how recent advances in focused technical areas are leading to further superalloy capabilities through advances in science-based processing.

### 3:30 PM Break

### 3:45 PM Invited

#### **Modeling and Simulation in Fossil Energy Systems – Current Prospectus:** *Jeffrey Hawk*<sup>1</sup>; Liang Jiang<sup>2</sup>; <sup>1</sup>U.S. Department of Energy; <sup>2</sup>GE Global Research

Within the realm of energy research, there are many opportunities for modeling and simulation, from large scale power plant systems to the interaction between atoms in an alloy. Specifically in the materials science focus area at NETL, materials modeling and simulation has been used to expedite the development of new materials as well as improve upon, and/or optimize, existing alloys for new fossil energy applications. At GE modeling and simulation research is directed at accelerating the introduction of a component into an existing energy platform through Materials Design Acceleration (MDA). Superalloys remain near the forefront of these activities due to their widespread use in current generations of gas turbines and their potential incorporation into A-USC power plants. Modeling activities at NETL and GE specific to superalloy development and product incorporation will be discussed with emphasis on the computational materials modeling approaches in each instance.

### 4:15 PM

#### **Modeling Deformation Mechanisms and Grain Structure Evolution during Forging of Powder-Metallurgy Nickel-Base Turbine Disk Alloy:** *Wen Tu*<sup>1</sup>; Tresa Pollock<sup>2</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>University of California - Santa Barbara

The properties of superalloy disk materials are sensitive to the microstructure at the end of a series of thermomechanical processing. In this study, high temperature compression testing combined with high resolution Electron Backscatter Diffraction (EBSD) analysis has been used to analyze microstructural-scale straining processes that occur during high temperature forging of a nickel-base superalloy, René 88DT. Orientation imaging has been employed to study grain-level straining and strain storage. Using experimental evidence, constitutive models of deformation mechanisms and microstructure evolution during high temperature compression are proposed. The models predict: 1.) boundaries of superplastic deformation as a function of temperature, strain rate, and grain size, 2.) rate of superplasticity-enhanced grain growth as a function of strain, strain rate, and temperature and 3.) the saturation recrystallized grain size as a function of strain rate and temperature. The sum of the models predicts grain structure evolution during high temperature forging of Ni-base superalloys.

### 4:35 PM

#### **The Progression of Oxidation Damage for an Advanced Powder Metallurgy Disk Superalloy:** *Chantal Sudbrack*<sup>1</sup>; James Smialek<sup>1</sup>; Tim Gabb<sup>1</sup>; David Hull<sup>1</sup>; Timothy Gorman<sup>2</sup>; Doug Wei<sup>3</sup>; Jeff Marshman<sup>3</sup>; <sup>1</sup>NASA Glenn Research Center; <sup>2</sup>University of Dayton; <sup>3</sup>Carl Zeiss SMT Inc.

With the drive towards higher operating temperatures in newly developed gas turbine engines, oxidation resistance and protection of advanced nickel-

based turbine disk components are becoming increasingly important. Oxidizing environments are known to impair disk fatigue life at temperatures above 500°C, yet development of protective disk coatings is still in its infancy. Microstructural response of an ME3 disk superalloy is evaluated for moderate (704°C) and aggressive (760-816°C) isothermal exposures up to 2,020 hours. Slow growing Cr-rich scales form superficially and deviate from classic parabolic growth, possibly due to Cr<sub>2</sub>O<sub>3</sub> grain boundary (GB) diffusion or shifts in Cr<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-CrTaO<sub>4</sub>-Al<sub>2</sub>O<sub>3</sub> complex scale phase make-up. Cross section analysis reveals sub-surface damage (significant for aggressive exposures) that consists of Al<sub>2</sub>O<sub>3</sub> “fingers”, interfacial voids, a recrystallized precipitate-free layer and GB carbide dissolution. The effects of a Nichrome coating on this response are also assessed. Detailed spatial and chemical quantification of these microstructures are presented.

### 4:55 PM

#### **Diffusion Simulation and Oxidation Life Prediction of Turbine Metallic Coatings:** *Fan Zhang*<sup>1</sup>; Shuanglin Chen<sup>1</sup>; Weisheng Cao<sup>1</sup>; Y. Austin Chang<sup>2</sup>; Kang Lee<sup>3</sup>; Donna Ballard<sup>4</sup>; Jeff Simmons<sup>4</sup>; <sup>1</sup>CompuTherm, LLC; <sup>2</sup>University of Wisconsin-Madison; <sup>3</sup>Rolls-Royce Corporation; <sup>4</sup>Air Force Research Laboratory

Oxidation protection coatings have become an integral part of advanced gas turbine engine hot section components. These coatings rely on the formation of a slow-growing and adherent Al<sub>2</sub>O<sub>3</sub> scale. Due to the scale formation/spallation at the coating/gas interface and Al diffusion into the superalloy at the coating/substrate interface during service, aluminum is depleted from coating materials. The oxidation life of a coating ends when aluminum is depleted below the critical concentration. In this study, we have developed a modeling tool which integrates thermodynamic calculation, 1-D diffusion model, and an empirical oxidation model (COSIP) to understand the oxidation life of coatings. With this modeling tool, the aluminum depletion due to diffusion and Al<sub>2</sub>O<sub>3</sub> scale formation/spallation can be simulated. The oxidation life of a coating, therefore, can be predicted as a function of coating and alloy type and service condition, which is critical for intelligent coating selection, component design, and component maintenance.

### 5:15 PM

#### **Nitridation of HAYNES® NS-163® Alloy: Thermodynamics and Kinetics:** *Michael Fahrman*<sup>1</sup>; Krishna Srivastava<sup>1</sup>; <sup>1</sup>Haynes International Inc.

Nitride dispersion-strengthened HAYNES® NS-163® alloy is a new unique cobalt-base sheet alloy that offers significantly enhanced creep strength over HAYNES® 617, 230®, and even 188 alloys at temperatures exceeding 1650°F (900°C). This new alloy approaches the performance of oxide dispersion-strengthened alloys while being fabricable and less costly to process since it employs conventional mill technologies. Nitride dispersion strengthening is accomplished via a post-fabrication heat treatment. A thorough understanding and control of the nitridation process will be key to the alloy's commercial viability. In this context, microstructures of partially and fully nitrided sheet samples have been examined. The nitride reaction front advanced following a parabolic growth law. The nature and sequence of formation of the various nitride compounds formed is rationalized by comparing their respective Gibbs free energies of formation. Dispersoid nucleation densities and morphologies are discussed in terms of the locally varying speed of the reaction front.

## Alumina and Bauxite: Bauxite Resources and Utilisation

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee

*Program Organizers:* James Metson, University of Auckland; Carlos Suarez, Hatch Associates Consultants Inc

Monday PM                                      Room: 17A  
February 28, 2011                                Location: San Diego Conv. Ctr

*Session Chair:* To Be Announced

### 2:00 PM Introductory Comments

#### 2:05 PM

**New Development Model for Bauxite Deposits:** *Peter-Hans ter Weer*<sup>1</sup>; <sup>1</sup>TWS Services and Advice

Developing a greenfield bauxite deposit generally includes constructing an alumina refinery. Economics have resulted in ever-increasing production capacities for recently-built and future planned greenfield refineries. Rationale: economy of scale. As a result the complexity of a greenfield project has significantly increased and its capital cost has grown to several billion USD. Important consequences: 1. Project owners aim at risk reduction through project financing and formation of joint ventures, further complicating project implementation; 2. Globally only a limited number of (large) companies have the resources to develop greenfield bauxite & alumina projects; 3. Only a limited number of engineering firms have the required skills and experience to successfully implement these mega projects; 4. Only large bauxite deposits get developed. This paper proposes an alternative development model for bauxite deposits resulting in a more efficient use of resources and a lower threshold to develop bauxite & alumina projects.

#### 2:30 PM

**Study on the Characterization of Marginal Bauxite from Pará/Brazil:** *Fernanda Silva*<sup>1</sup>; João Sampaio<sup>2</sup>; Marta Medeiros<sup>1</sup>; Francisco Garrido<sup>1</sup>; <sup>1</sup>IQ/UFRJ - CETEM; <sup>2</sup>Centro de Tecnologia Mineral

Bauxite from Pará is divided into five different layers. However, only one is processed. The crystallized-amorphous (BCBA) phase is considered a marginal bauxite because it presents a high quantity of SiO<sub>2</sub> reactive and its use depends on special technologies. BCBA was characterized and results were compared to the bauxite used, nowadays, in the alumina plant. Characterization was performed by XRD, XRF, chemical analysis, TGA and SEM. XRD determined the mineral content: such bauxite is gibbsitic and has been associated with kaolinite and hematite. XRF determined the sample's chemical composition. The chemical content of Al<sub>2</sub>O<sub>3</sub> available and SiO<sub>2</sub> reactiva was determined by potentiometric titration and FAAS. The results found for the Bayer process sample were 41.7% and 7.1%, respectively. TGA observed the bauxite decomposition and SEM supplied chemical and thermal analysis. Thus, based on stoichiometric relations of the bauxite components decomposition, it was possible to confirm the following phases: gibbsite and kaolinite.

#### 2:55 PM

**Resource Utilization of High-Sulfur Bauxite of Low-Median Grade in Chongqing China:** *Jianguo Yin*<sup>1</sup>; Wentang Xia<sup>1</sup>; Mingrong Han<sup>1</sup>; <sup>1</sup>Chongqing University of Science and Technology

Resource utilization of high-sulfur bauxite is one of technical problems for alumina refineries in China. There are a lot high-sulfur bauxite of low-median grade in Chongqing China, which are not been utilized until now. Sulfur in bauxite will cause many negative effects on the alumina production. There exist some disadvantages for current desulfurization technologies. It is difficult to attain breakthrough progress from the view of desulfurization technologies. So it is necessary to have fundamental theoretical studies on the occurrence of sulfur in high-sulfur bauxite, occurrence, reaction behavior and changing rule for sulfur in the production process and its effect. Combined

theoretical research with experiments, it is possible to develop a feasible desulfurization process. It will be technical support and theory guidance for utilization of high-sulfur bauxite in Chongqing, and also advantageous for prolonging bauxite resource guarantee for Chinese alumina industry.

#### 3:20 PM Break

#### 3:30 PM

**Development of Bauxite and Alumina Resources in the Kingdom of Saudi Arabia:** *AbdulGhafoor Al-Dubaisi*<sup>1</sup>; <sup>1</sup>Saudi Arabian Mining Co. (Maden)

Driven by desire to diversify its economy in an oil rich country and by the need to create jobs for the increasing number of Saudi youth, the Kingdom of Saudi Arabia established the Saudi Arabian Mining Company (MA'ADEN) to develop its mineral resources. Local bauxite will be developed into an integrated mine-to-metal aluminum industry. Numerous challenges have to be overcome. Major Infrastructure has to be built; construction and operating costs have to be contained to ensure the economic viability of the project. The lack of expertise in the kingdom to run such an operation created the need to involve an international joint venture partner. The human development is no less challenging and early plans have to be in place to recruit and train a large number of Saudis to be the core of the operating organization.

#### 3:55 PM

**Digestion Studies on Central Indian Bauxite:** *Puliyur Krishnaswamy Narasimha Raghavan*<sup>1</sup>; Nand Kumar Kshatriya<sup>1</sup>; <sup>1</sup>Bharat Aluminium Co. Ltd., (A Unit of Vedanta Resources Plc.), BALCO Nagar, Korba

Indian bauxite deposits are grouped into five namely, Eastern Ghats, Central Indian, West Coast, Gujrat and Jammu & Kashmir. Each of the Bauxite has its own typical digestion and settling conditions due to variation in mineralogy. Bauxite digestion depends much on the temperature-pressure conditions, the recycled liquor concentration bauxite mineralogy and charge quantity. The productivity of the entire Bayer process depends to a large extent on the digestion process. In an attempt to optimize the digestion conditions for the central Indian Bauxites, in order to achieve low caustic soda loss coupled with minimum bauxite consumption a series of experiments were conducted to find out the best parameter for conducting digestion at laboratory scale. The effect of deslucation and digestion temperature, bauxite charge, lime quantity and digestion liquor MR is discussed in this paper. Attempt shall be made to compare the conditions with Bauxite from other locations.

#### 4:20 PM

**Effects of Roasting Pretreatment in Intense Magnetic Field on Digestion Performance of Diasporic Bauxite:** *Zhang Ting-an*<sup>1</sup>; Dou Zhihe<sup>1</sup>; Lv Guozhi<sup>1</sup>; Liu Yan<sup>1</sup>; Du Juan<sup>1</sup>; Wang Xiaoxiao<sup>1</sup>; Li Yan<sup>1</sup>; <sup>1</sup>Northeastern University

This paper investigated the changes of phase and apparent morphology under the combined effects of intense magnetic field and temperature field and the effect law of different roasting conditions on the digestion performance of roasted diasporic. The results indicated that the roasting pretreatment under high magnetic field can change the microstructure and improve the digestion properties of bauxite. The reasonable roasting conditions of intense magnetic field follow as that the roasting temperature is 550°, roasting time is 60min and the magnetic field intensity is 6T. The digesting rate of alumina of roasted ore is 84.17% and the digesting liquid ratio is 1.39 while the digesting temperature is 190° with the digestion time of 60mins. The digesting rate of alumina of roasted ore increases higher 52.85% than this of the raw ore. The digesting temperature of roasted ore decreases lower 30° than this of the raw ore.

### 2:00 PM

#### Modeling Performance of Protection Materials Aluminum 7020-T651 and Steel: John Chinella<sup>1</sup>; <sup>1</sup>U.S. Army Research Laboratory

This presentation compares protection and characteristics of aluminum 7020-T651 and a modern rolled homogeneous armor steel (RHA) and compares performance to historical protection levels of RHA. Comparisons are shown with RHA plots of protection level mean response, confidence intervals, and cumulative probability distributions over the range of performance. The protection levels and the failure modes of 7020-T651 aluminum suggest that weight savings will be achieved through: (1) excellent protection, multiple hit or projectile damage tolerance, and minimal need for spall liners; and (2) equal structural stiffness at half the weight of steel. Results of ballistic test characterization in this study, literature of Al-Zn-Mg alloys, Thermo-Calc phase diagrams, and JMatPro temperature step calculations reveals alloy 7020 has unique metallurgical characteristics and capabilities to meet improvements in structural, monolithic or advanced armor designs, and the needs of processing, fabricability or field repair, durability, weight and cost efficiency, and extreme climate.

### 2:20 PM

#### The Influence of Temperature on the Tensile Anisotropy of a Forged 7XXX Aluminum Alloy: Agouti Siham<sup>1</sup>; Bozzolo Nathalie<sup>1</sup>; Bouchard Pierre-Olivier<sup>1</sup>; Le Brun Pierre<sup>2</sup>; Piellard Mickael<sup>3</sup>; <sup>1</sup>Centre of materials forming; <sup>2</sup>Voreppe Research Center; <sup>3</sup>Aubert et Duval Isoire

Aluminum ingots are usually submitted to hot forging processes to increase their ductility before the final stamping process. The subject of this work is to investigate the effect of temperature on the mechanical anisotropy of a forged 7XXX Aluminium alloy. At the as forged state, this material contains iron-intermetallics observed as large heaps of particles. At room temperature, the longitudinal direction is more ductile than the forging direction as the iron-intermetallics are oriented along the longitudinal direction. On the contrary, tensile tests at high temperatures (300-430°C) showed that the forging direction is more ductile than the longitudinal direction. Microstructure investigations along the strain gradient produced on tensile test specimens allowed to understand deformation and damage mechanisms occurring at high temperature and the resulting mechanical anisotropy.

### 2:40 PM

#### Modeling the Strain Path Change Effect in 5754-O Aluminum Alloy Sheet: Lin Hu<sup>1</sup>; Anthony Rollett<sup>1</sup>; Mark Iadicola<sup>2</sup>; Tim Foecke<sup>2</sup>; Steve Banovic<sup>2</sup>; <sup>1</sup>Carnegie Mellon University; <sup>2</sup>National Institute of Standards and Technology

Strain-path change tests were performed on 5754-O aluminum alloy sheet sample by using equibiaxial stretch followed by uniaxial tension. A self-consistent viscoplastic polycrystal model was used to simulate the material response under non-linear strain paths and fit the experimental data. Recovery that occurred during the first and second loading steps was also assessed. Anisotropic strain hardening behaviors were incorporated in the model, which accounted for the transient behaviors upon the strain path change.

### 3:00 PM

#### Micromechanical Simulations for Fatigue Damage Incubation at Debonded Particles Using Cohesive Zone Model: Tong Li<sup>1</sup>; Yibin Xue<sup>1</sup>; <sup>1</sup>Utah State University

Fatigue damage initiates at debonded micrometer-sized intermetallic particles for some high strength Al alloys in the high cycle fatigue regime. Cohesive zone model is implemented to investigate the interfacial debonding and propagation under cyclic loads. Representative Volume Elements (RVE) are set to position the intermetallic particle at different spatial locations regarding the boundary of the RVEs to account for the random distribution of the particle in the alloys. Maximum plastic shear strain range (MPSS) and Fatemi-Socie (FS) parameter for multiaxial fatigue are introduced as nonlocal damage parameters to evaluate the severity of the damage level of RVEs and loading sets. This set of the simulations will be compared with simulation results on fatigue damage incubated at the fractured particles. This effort completes the fatigue damage incubation evaluation for wrought Al alloys.

### 3:20 PM

#### Comprehensive Thermo-Mechanical Validation of Extrusion Simulation Cycle for Al 1100 Using HyperXtrude: Abdulafoo Parker<sup>1</sup>; Clemence Bouvard<sup>1</sup>; Stephen Horstemeyer<sup>1</sup>; Esteban Marin<sup>1</sup>; Paul Wang<sup>1</sup>; Mark Horstemeyer<sup>1</sup>; <sup>1</sup>Center for Advanced Vehicular Systems, Mississippi State University

A laboratory-scale extrusion capability facilitates parametric study of metal extrusion processes. Commercial simulation code, HyperXtrude, was used to simulate laboratory experiments performed using a flat-die. In the experiments, ram velocity and billet temperature were the process parameters that were controlled. Simulation model was validated by comparing the results with experimentally obtained load and temperature histories on tooling. The results of simulation and experiments were found to be in good agreement. 'Optimized' values for friction and convection film-coefficient were used to reach the best fit. The breakthrough load is predicted with good accuracy; however, the accuracy in load correlation is not sustained throughout the process duration as the predicted load trend deviates from experimental data towards the end of the ram stroke. The aim of this work is to benchmark a commercial extrusion simulation code for a range of profiles.

### 3:40 PM Break

### 3:55 PM

#### Deformation and Rupture Modeling of an Aluminum Metal Matrix Composite: James DeMarco<sup>1</sup>; Justin Karl<sup>1</sup>; Ali Gordon<sup>1</sup>; <sup>1</sup>UCF MMAE Dept.

While aluminum metal-matrix composites (MMCs) have come into broader use for high-tech applications where their combined light weights and large elastic moduli are sufficiently advantageous, widespread application is limited by high processing costs. In the case of hot-rolled aluminum MMC sheets, material lost to edge cracking is a major contributor to decreased production yield and high cost. Determining the optimal thermo-mechanical processing parameters which minimize losses due to edge cracking can be achieved through numerical modeling of the temperature-dependent mechanical response of the material. An elastic-viscoplastic constitutive model incorporating strain rate and temperature dependence is presented for A359-SiC -30%. Perzyna viscoplasticity and Cockroft-Latham ductility are assumed. Modeling parameters for the as-cast material are optimized to fit tensile and torsion data obtained at a variety of temperature and strain rate combinations.

### 4:15 PM

#### Mechanical Properties and Casting Characteristics of the Secondary Aluminum Alloy AlSi9Cu3(Fe) (A226): Philip Pucher<sup>1</sup>; Holm Bötcher<sup>2</sup>; Helmut Kaufmann<sup>3</sup>; Helmut Antrekowitsch<sup>1</sup>; Peter J. Uggowitzer<sup>4</sup>; <sup>1</sup>University of Leoben; <sup>2</sup>AMAG Casting GmbH; <sup>3</sup>Austria Metall AG (AMAG); <sup>4</sup>ETH Zurich

Due to its excellent castability, good mechanical properties and cost-effectiveness the secondary alloy AlSi9Cu3 (A226) finds wide application for

the production of permanent mould castings and high pressure die castings (HPDC). Variations of the chemical composition within the tolerance limits cause pronounced changes in the mechanical properties and castability. For example the yield strength of permanent mold cast samples ranges from 100 MPa to 200 MPa, while the elongation varies between 0.3 % and 4 %. The present study was performed to investigate the mechanical properties and casting characteristics depending on the combined effect of the main alloying elements in the whole composition range. The results – based on 48 industry-oriented permanent mold casting experiments – are discussed on a systematic basis of thermodynamic calculations and metallographic investigations. These results were implemented in the software tool AMAG Top Cast® Alloy Designer (TCAD) for the prediction of mechanical properties and casting characteristics.

4:35 PM

#### Comparison of Different FEM Codes Approach for Extrusion Process

**Analysis:** *Lorenzo Donati*<sup>1</sup>; Luca Tomesani<sup>1</sup>; Noman Ben Khalifa<sup>2</sup>; A. Erman Tekkaya<sup>2</sup>; <sup>1</sup>University of Bologna; <sup>2</sup>Technische Universität Dortmund

The simulation of the extrusion process by means of FE codes has been applied in a great number of papers available in literature but its application in everyday production was limited due to several factors like computational times, user's skills as well as prediction accuracy. Indeed, the inner complexity of the process, characterized by extremely high deformations, strain rates and heat exchange phenomena, has led only in the last few years commercial FE codes to gain sufficient accurate solving capabilities. In the paper, five FEM codes based on different approaches were applied in the simulation of the same experiment: the results were compared in terms of set-up times, computational time as well as process prediction accuracy. Process load, profile speeds, die and profile temperatures were accurately monitored during the experiment in order to realize an effective comparison of the different FEM codes approaches.

4:55 PM

#### Numerical Prediction of Grain Shape Evolution during Extrusion of AA6082 Alloy

**Analysis:** *Antonio Segatori*<sup>1</sup>; Lorenzo Donati<sup>1</sup>; Luca Tomesani<sup>1</sup>; <sup>1</sup>University of Bologna

Extruded profiles applications require a strict control of the mechanical properties of the extrudates, in particular when undergoing severe loading conditions like in the transportation sector. Profile mechanical properties directly depend from its microstructure and texture, which are the result of multiple mechanisms based on precipitation mechanism or on grain shape evolution (grain refinement, recrystallizations, recovery and grain growth). In this direction the opportunity to predict the final profile microstructure under specific process parameters directly in the die design stage is of great relevance. The study involved experimental activity on grain size measurements during interrupted direct extrusion of an AA6082 round profile. The grain size measurements were coupled with the results of the simulation in order to regress analytical models based on effective strain, strain rate and temperature. Finally, the developed model was implemented in the numerical code through user subroutine so as to be used as microstructure prediction tool.

5:15 PM

#### Analysis of Charge Weld Evolution for a Multi-Hole Extrusion Die

**Analysis:** *Antonio Segatori*<sup>1</sup>; Lorenzo Donati<sup>1</sup>; Barbara Reggiani<sup>1</sup>; Luca Tomesani<sup>1</sup>; <sup>1</sup>University of Bologna

Extrusion process presents two types of welding mechanism inside the die: seam and charge weld. The first type is unavoidable in the production of hollow profiles while the second is generated during billet to billet transition. Differently from seam weld, charge weld represent an unacceptable defect that require profile discard. Nevertheless charge weld extent and location on extrudates is not evident, thus requiring scrap definition by means of time-consuming trials or to repetitive tests on each batch. In the paper an industrial four holes porthole die for hollow profile production was investigated during billet to billet transition. Extrusion of four billet was performed under strict parameter control. The profiles were microscopically analyzed in order to determine weld evolution: in particular start and end points of weld for

each profile were determined. Finally, weld evolution was studied through HyperXtrude code so as to evaluate weld prediction capabilities and accuracy.

### Aluminum Reduction Technology: Environment-Emissions/ Anode Effect I

2:00 PM

#### HF Measurements Inside an Aluminium Electrolysis Cell

**Analysis:** *Karen Osen*<sup>1</sup>; Thor Aarhaug<sup>1</sup>; Asbjørn Solheim<sup>1</sup>; Egil Skybakmoen<sup>1</sup>; Camilla Sommerseth<sup>2</sup>; <sup>1</sup>SINTEF Materials and Chemistry; <sup>2</sup>Norwegian Institute of Science and Technology, NTNU

HF emissions to the working atmosphere may still be a problem for the aluminium industry. The objective in the present work was to study how the HF evolution is distributed between feeder holes, other openings in the crust, gases diffusing through the crust, fumes from the secondary alumina residing on top of the crust etc. A movable "gas sniffer" connected to a Tunable Diode Laser was used to measure the HF concentrations at the above mentioned locations. The stationary HF level in an open flaming feeder hole was approximately 9000 ppm, when measured a few cm above the bath surface. In comparison, when the probe was positioned 5-10 cm above a crust area with good integrity, the HF concentration was in the range 5-10 ppm. The results support the notion that most of the HF evolves at the open flaming feeder holes and tap hole.

2:20 PM

#### LasIRTM -R – The New Generation RoHS-Compliant Gas Analyzers Based on Tunable Diode Lasers

**Analysis:** *Jean-Pierre Gagne*<sup>1</sup>; John Pisano<sup>2</sup>; Alak Chanda<sup>3</sup>; Gervase Mackay<sup>3</sup>; Keith Mackay<sup>3</sup>; Pierre Bouchard<sup>1</sup>; <sup>1</sup>STAS; <sup>2</sup>University of California at Riverside; <sup>3</sup>Unisearch Associates Inc.

The laser-based optical gas sensor using Tunable Diode Laser Absorption Spectroscopy (TDLAS) is rapidly gaining favor wherever high sensitivity, real time measurement and freedom from interferences are required, specifically for the measurement of HF in primary aluminium smelters. It eliminates the problems associated with extractive gas sampling techniques. A first generation of equipment designed by Unisearch Associates and based on the TDLAS appeared on the market in the mid 90s. It has since been improved significantly by employing fast scan measurement techniques. Now, the system is more robust, easier to operate and calibrate, and it can be simply audited. The utilization of fast scan measurement techniques not only provides enhanced stability and sensitivity but expands the dynamic range of the measurements. This new generation instrument is also very inexpensive compared to other TDLAS instruments. This paper describes the evolution of the new generation gas sensor.

2:40 PM

#### Use of Spent Potlining (SPL) in Ferro Silicomanganese Smelting

**Analysis:** *Paulo von Krüger*<sup>1</sup>; <sup>1</sup>Universidade Federal de Ouro Preto

In this work an evaluation on the possibilities of the employ of Spent Potlining (SPL), as a component of the burden of a Submerged Arc Furnace, producing Ferro Silicomanganese Alloy, is investigated. On this subject, a characterization of the SPL's most probable components as well as their interaction with the existing species in the ferroalloy furnace were carried out. Additionally relevant features of the ferroalloy smelting were identified and characterized. Those figures were introduced in a thermochemical

program where the SAF operational conditions were simulated in order to check the technical feasibility of that use. The simulation results showed that, on the technical point of view, the SPL carbonaceous fraction is a suitable component of the SAF burden, producing Ferro Silicomanganese alloys. Although some of the figures generated by simulation were confirmed in a couple of industrial exploratory tests, a more detailed test program is advisable.

### 3:00 PM

#### **Reduction of PFC Emissions at Pot Line 70 kA of Companhia Brasileira De Alumínio:** *Henrique Santos*<sup>1</sup>; Danilo Melo<sup>1</sup>; Jocimar Calixto<sup>1</sup>; Jefferson Santos<sup>1</sup>; João Miranda<sup>1</sup>; <sup>1</sup>Companhia Brasileira de Alumínio

Following world tendency Primary Aluminum Industry has been committed in the reduction of PFC's emissions in order to reduce the greenhouse effect. Anode Effect is the source for such emission. The CBA Pot Room 70kA VSS Montecatini technology from the end of 60's with side feed pots, has been making efforts and developing actions to improve process with the aim of reducing both the duration and frequency of anode effect. Projects were developed and implemented as follow: Liquids control, Resistance control, Feed control, Anode/Cathode control and mainly the team qualify through an operating training. In this paper, are shown achievements for projects cited, that caused significant impacts in reducing the duration and frequency of anode effect at the level of world reference. A reduction of 66 % of PFC's emissions was achieved from 1,2 to 0,4 t CO<sub>2</sub> eq./t Al.

#### **Towards Redefining the Alumina Specifications Sheet – The Case of HF Emissions:** *Linus Perander*<sup>1</sup>; Marco Stam<sup>2</sup>; Margaret Hyland<sup>1</sup>; James Metson<sup>1</sup>; <sup>1</sup>Light Metals Research Centre; <sup>2</sup>Aluminium Delfzijl B.V.

For smelting applications, alumina quality is typically defined in terms of chemical and physical properties, with emphasis on impurity elements, surface area, moisture content, particle size distribution and attrition index. However, these properties fail in prediction of the true HF generation potential, as well as the real capacity for HF removal in the dry scrubbers. Using plant measurements and additional laboratory characterization of a number of alumina samples a broadening of how alumina quality is specified is argued for. Measurements of the residual gibbsite/boehmite content and the pore size distribution, coupled with characterization of the alumina microstructure, can be used to predict and understand the generation of HF during feeding and dissolution as well as the ability to capture HF in the dry scrubbers.

### 3:50 PM

#### **Design of Experiment to Minimize Fluoride and Particulate Emissions at Alumar:** *Eliezer Batista*<sup>1</sup>; Paulo Miotto<sup>1</sup>; Edson Montoro<sup>1</sup>; Luciano Souza<sup>1</sup>; <sup>1</sup>Alcoa

Most of Aluminum plants have been struggling to minimize the fluoride and particulate emissions to reduce the environmental impacts. Nowadays, this challenge has been more difficult to be reached because of amperage increase, alumina quality deterioration and pot room expansions. Alumar, one of Alcoa's units, following a corporate vision, is continuously searching for alternatives to the environmental impact caused by its operations. This full factorial experiment 2k identified the main factors and their impacts on fluoride and particulate emissions. The statistical model indicates that the fluoride emission has been affected mainly by Pot Draft, Pot Dressing, and the Usage of Compressed air for Housekeeping with R2 at 82%, and for particulate at 58%. Based on the models, certain actions were recommended to minimize both of these emissions. In addition, this paper describes, step by step, how this kind of experiment can be applied to the Aluminum industry.

### 4:10 PM

#### **Innovative Distributed Multi-Pollutant Pot Gas Treatment System:** *Geir Wedde*<sup>1</sup>; Odd Bjarno<sup>1</sup>; Anders Sorhuus<sup>1</sup>; <sup>1</sup>Alstom

Gas Treatment Centers (GTC) are traditionally arranged in courtyard between pot rooms and handle vast quantities of pot gas (3- 4mill. m<sup>3</sup>/h) in large number of filter compartments (15-30) with demanding space

requirement and challenging control of operation. Arranging the gas treatment in decentralized installations as Distributed Decentralised Scrubbers (DDS) will obviously save on duct work, alumina handling, storage and civil work. In addition Alstom's DS integrates silos, heat exchangers, scrubbers, fans and stack into an extremely compact and efficient multi-pollutant control and recovery technology with incomparable footprint. The close integration with pots improves pot gas collection and simplifies the alumina distribution to pots. Module based design allows for short delivery time and early start-up. This paper discusses and reviews the new technologies, benefits and mitigation of the technical challenges of the DS solution.

### 4:30 PM

#### **Fluoride Emissions Management Guide (FEMG) for Aluminium Smelters:** *Nursiani Tjahyono*<sup>1</sup>; Yashuang Gao<sup>1</sup>; David Wong<sup>1</sup>; Wei Zhang<sup>1</sup>; Mark Taylor<sup>1</sup>; <sup>1</sup>Light Metals Research Centre

All smelters worldwide operate under strict fluoride emission limits and the reduction of fluoride emissions is further driven by health considerations. A Fluoride Emissions Management Guide (FEMG) has been written by the Light Metals Research Centre, on invitation of the Australian Aluminum Council, under the Asia-Pacific Partnership on Clean Development and Climate. The FEMG aims to provide better understanding of factors affecting fluoride evolution and emission in smelters, and further, to provide smelters with an operational guide for reducing and managing fluoride emissions. The guide uses practical examples with pictures of improvements that are applicable to operational, control and maintenance practices in potrooms, GTCs and other smelter systems. It is customizable to meet the need of any specific smelter. Along with incorporated audit guidelines and training packages, implementation of this guide can, in a short time, lead to significant reduction in fluoride emissions and improvement of operational standards in smelters.

### 4:50 PM

#### **Considerations Regarding High Draft Ventilation as an Air Emission Reduction Tool:** *Stephan Broek*<sup>1</sup>; Neal Dando<sup>2</sup>; Stephen Lindsay<sup>2</sup>; Alain Moras<sup>2</sup>; <sup>1</sup>Hatch Ltd; <sup>2</sup>Alcoa

High draft ventilation is an effective technique for reducing emissions from electrolysis cells while panel covers are removed to perform maintenance. In recent years, many new smelters have implemented high draft ventilation as one of the tools to further reduce air emissions from potrooms. In this paper the principles of high draft ventilation are discussed followed by a presentation on its impact on smelter performance. Comments are provided that concern implementation of high draft ventilation in greenfield and brownfield smelters.

## Approaches for Investigating Phase Transformations at the Atomic Scale: Transformations in Fe, Ni and Al based Systems I

*Sponsored by:* The Minerals, Metals and Materials Society, ASM International, TMS Materials Processing and Manufacturing Division, TMS/ASM: Computational Materials Science and Engineering Committee, TMS/ASM: Phase Transformations Committee  
*Program Organizers:* Neal Evans, Oak Ridge National Laboratory; Francisca Caballero, Spanish National Research Center for Metallurgy (CENIM-CSIC); Chris Wolverton, Northwestern University; David Seidman, Northwestern University; Rajarshi Banerjee, University of North Texas

Monday PM Room: 32B  
February 28, 2011 Location: San Diego Conv. Ctr

### 2:00 PM Invited

**Nano-scale Analysis of Precipitation in Nitrided Steels:** *Tadashi Furuhashi*<sup>1</sup>; Goro Miyamoto<sup>1</sup>; <sup>1</sup>Institute for Materials Research, Tohoku University

Microstructure formed during nitriding of steels is a quite complex phenomena because precipitation of fine alloy nitrides occurs in a chemically inhomogeneous matrix under continuous supply of nitrogen from the surface. In this presentation, the precipitation behaviors of nano-sized nitrides in various ferritic alloys are discussed based on the results of advanced analysis in atomic scale utilizing HREM and 3DAP. In the alloys containing strong nitride forming elements, precipitation of metastable nitrides occurs. Particularly, phase separation in ferrite is enhanced by strong interaction between the element such as Ti or V and nitrogen, resulting in uniform and fine dispersion of G.P zone like metastable clusters. Transition of those metastable phases to stable nitrides takes place gradually during further nitriding. Presence of excess nitrogen in ferrite is also recognized which might contribute to hardening by nitriding partly. A numerical approach to simulate the precipitation of alloy nitrides will be also presented.

### 2:25 PM Invited

**Atomic Structure of NbN GP Like Zones in a Model Fe-Nb-(C)-N Alloy:** *Frederic Danoux*<sup>1</sup>; Thierry Epicier<sup>2</sup>; David Tingaud<sup>3</sup>; Philippe Maugis<sup>4</sup>; <sup>1</sup>CNRS - Université de Rouen; <sup>2</sup>INSA de Lyon; <sup>3</sup>Université Paris 13; <sup>4</sup>Université Paul Cezanne - Marseille

The precipitation of GP like zones in a model Fe-Nb-(C)-N alloy is evidenced on the basis of atomic scale investigations using field ion microscopy (FIM), atom probe tomography (APT) and high resolution electron microscopy (HREM). These techniques support the existence of Nb and N rich monolayers, fully coherent, and lying in the {001} planes of the bcc ferrite ( $\alpha$ -Fe). HREM image simulations strongly suggest that Nb substitutes Fe in these monolayers. However, the position of N atoms, and therefore the elementary unit cell of these platelets, is still not fully understood. First-principle calculations, using the VASP software, were used to investigate the stability of possible unit cells, on the basis of the various NbX (X=C, N) bulk phases under strains similar to the coherency strains. The role of structural vacancies in the stabilisation of the NbN platelets is also investigated.

### 2:50 PM Invited

**Nanometric Scale Investigation of Phase Transformations in Advanced Steels for Automotive Applications:** *Josée Drillet*<sup>1</sup>; Thierry Lung<sup>1</sup>; Nathalie Valle<sup>1</sup>; <sup>1</sup>ArcelorMittal

The current trend towards vehicle lightening in the automotive industry is driven by the need to conform to the new exhaust emission control regulations. This objective presents a challenge to steel manufacturers. The difficulty lies in designing new alloys with the optimum strength/formability/

cost balance for the various components. Here, the key to success lies in controlling the steel microstructure and especially phase transformations at the finest possible scale. Among the different alloying elements, light elements as carbon and boron are of prime importance due to their major effects on the kinetics for phase transformations. Characterization tools combining high spatial and analytical resolution as NanoSIMS and FEG-TEM, have been used. In the paper, examples are presented concerning: • Local carbon distribution in advanced high strength steels, with a specific emphasis on martensite tempering, austenite stabilisation or low density Fe-Mn-Al-C steels. • Boron segregation and precipitation effects to control hardenability.

### 3:15 PM

**Precipitation Strengthening of a Nano-Cluster-Strengthened Ferritic Steel:** *Z. W. Zhang*<sup>1</sup>; Ai Serizawa<sup>2</sup>; C. T. Liu<sup>1</sup>; Xun-Li Wang<sup>2</sup>; M. K. Miller<sup>2</sup>; Bryan Chin<sup>1</sup>; <sup>1</sup>Auburn University; <sup>2</sup>Oak Ridge National Laboratory

The strength of Cu-rich nanocluster strengthened ferritic steels is derived mainly from nanocluster precipitation. This gives the ability to control the alloy's strength and ductility through the control of the precipitation process of nanocluster. The studies on the effects of composition and processing routes on the nature and development of these nanoclusters will enhance our understanding of the underlying mechanisms and to enhance the mechanical properties further. In this study, atom probe tomography (APT), small angle neutron scattering (SANS) have been used to study the nanocluster precipitation in FeCuNiAlMn and FeCuNiAlMnMoVTi steels thermally aged up to 500 h at 500°C. The microhardness results show a typical dependence on Cu-rich precipitate aging time. APT results show no precipitates in as-quenched specimens while Cu-rich clusters appeared and grew during aging for both steels. The results on cluster composition, number density, size distribution obtained by using APT and SANS were compared.

### 3:30 PM Break

### 3:45 PM Invited

**Atom Probe Tomography as a Tool to Advance Steels Design and Performance:** *Elena Pereloma*<sup>1</sup>; Ilana Timokhina<sup>2</sup>; <sup>1</sup>University of Wollongong; <sup>2</sup>Deakin University

Development of modern steels consisting of complex or nano-scale microstructures with advanced properties requires in-depth understanding of the mechanisms responsible for their microstructure/property relationships. The evolution of microstructure during processing is often associated with various changes taking place at atomic level. These include solute distribution between phases as a result of phase transformations, formation of atmospheres at dislocations, clustering and precipitation phenomena due to various thermo-mechanical processing schedules and/or heat treatments. Atom probe tomography (APT) is invaluable tool for gaining insight into events at atomic scale determining the steel properties. This technique also contributes to the fundamental understanding of phase transformations, which is essential for nano-scale engineering of modern steels and optimization of their performance. In this work application of APT to study solute segregation, clustering and precipitation in TRIP steels and nano-structured bainitic steels after isothermal heat-treatment and after thermo-mechanical processing will be discussed.

### 4:10 PM Invited

**Transformation of Martensite to Austenite During Aging in Steel Studied by Atom Probe Tomography and Simulation:** *Dirk Ponge*<sup>1</sup>; Olga Dmitrieva<sup>1</sup>; Gerhard Inden<sup>1</sup>; Julio Millán<sup>1</sup>; Pyuck-Pa Choi<sup>1</sup>; Jilt Sietsma<sup>2</sup>; Dierk Raabe<sup>1</sup>; <sup>1</sup>Max-Planck-Institut für Eisenforschung GmbH; <sup>2</sup>Delft University of Technology

We present atom probe tomography results on phase boundaries between martensite and retained austenite in steel after aging at 450°C. Due to partitioning of Mn and very different diffusibilities of Mn in martensite and austenite a strong accumulation of Mn at the interface is developed. The Mn profile can be explained in terms of the successive motion of the phase boundary into the martensite during aging owing to the formation of new austenite driven by diffusion of Mn into the austenite. This interpretation

is supported by dynamic diffusion calculations where we use the modeling method DICTRA to solve this coupled initial and boundary value problem, as well as the mixed-mode approach involving also the interface mobility. Good agreement between experiment and simulation is obtained by taking into account an increased mobility of Mn in martensite which is attributed to the high defect density of martensite.

**4:35 PM**

**Complementary Use of Transmission Electron Microscopy and Atom Probe Tomography for the Examination of Plastic Accommodation in Nanocrystalline Bainitic Steels:** *Francisca Caballero*<sup>1</sup>; Hung-Wei Yen<sup>2</sup>; Michael Miller<sup>3</sup>; Jer-Ren Yang<sup>2</sup>; Juan Cornide<sup>1</sup>; Carlos Garcia-Mateo<sup>1</sup>; <sup>1</sup>CENIM-CSIC; <sup>2</sup>National Taiwan University; <sup>3</sup>Oak Ridge National Laboratory

A displacive transformation involves the motion of a glissile interface. As in work-hardening, its motion can be halted by defects, such as dislocations, stacking faults or twins in the austenite. The defects are created when the shape deformation accompanying bainite growth is accommodated by plastic relaxation of the surrounding austenite. The growing plate stops before it collides with the austenite grain boundary. Because transformation from strong austenite leads to fine plates, alloys can be designed such that the bainite transformation is suppressed to low temperatures (200-350°C) leading to a nano-scale bainitic microstructure. Complementary high resolution transmission electron microscopy and atom tomography has provided new experimental evidence on the accommodation of transformation strain, subjects critically relevant to understand the atomic mechanism controlling bainitic ferrite growth. Research at the SHaRE User Facility was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

**4:50 PM Invited**

**Effect of Solute Atoms Distribution on the Phase Transformation in Steel:** *Genichi Shigesato*<sup>1</sup>; Shunsuke Taniguchi<sup>1</sup>; Taishi Fujishiro<sup>1</sup>; Masaaki Sugiyama<sup>1</sup>; <sup>1</sup>Nippon Steel Corporation

The phase transformation in steel is strongly affected by the distribution of solute elements. Boron is one of the most effective elements to hinder the diffusional transformation from austenite to ferrite. It has been considered that boron atoms segregate on grain boundaries in austenite phase and lower the grain boundary energy resulting in delaying the ferrite transformation. Manganese also impedes the phase transformation. The segregation of Mn atoms on the grain boundaries of austenite disturbs the nucleation of ferrite while the depletion of Mn around Ti oxide inclusions dispersed in austenite phase promotes the nucleation of ferrite transformation. The behavior of distribution of B and Mn atoms in the vicinity of the grain boundaries and the oxide-matrix interface examined with conventional and aberration corrected STEM will be presented and the influence on the phase transformation will be discussed.

**5:15 PM**

**Influence of Forging Conditions on Mechanical Properties of Ti and V-Bearing High Strength Forging Steels and Associated Precipitation Microstructure Characterized by TEM and 3D-Atom-Probe:** *Naoyuki Sano*<sup>1</sup>; Tatsuya Hasegawa<sup>2</sup>; <sup>1</sup>Sumitomo Metal Industries, Ltd.; <sup>2</sup>Sumitomo Metals (Kokura), Ltd.

Non-heat treated V-bearing high strength low alloy (HSLA) forging steels have been widely used for machine structural use. To improve mechanical properties further, other alloying elements are added in association with vanadium. It has been found that the addition of 0.15wt.% Ti to a V-bearing HSLA steel with the chemical composition of Fe-0.28C-0.55Si-0.75Mn-0.17V leads to lower the Charpy impact toughness and to increase tensile strength, however this effect is quite sensitive to processing conditions, i.e., hot forging temperatures and subsequent cooling rates. Precipitation microstructure evolved during forging process pronouncedly varied depending on the forging temperature range. At high finishing temperature, aligned fine coherent precipitates of (V, Ti)C carbides originated from interphase interface precipitation developed. However, lower finishing temperature induced coarsened and randomly-distributed precipitate

particles, which resulted in the increased impact energy and lower tensile strength.

**Gelation of Mucin Glycoproteins:** *Rama Bansil*<sup>1</sup>; <sup>1</sup>Boston University

In this talk, I will describe the unusual properties of mucin, a high molecular weight glycoprotein found in mucus, which prevents the stomach from being digested by the acidic gastric juices. Light scattering and rheological techniques show that purified pig gastric mucin solutions form a gel under acidic pH. Atomic Force Microscopy (AFM) of mucin solutions and gels as a function of pH provide direct visual evidence of aggregation. A model of gelation based on the interplay of hydrophobic and electrostatic interactions will be discussed. Molecular Dynamics simulation studies of folding and aggregation of mucin domains provide further support for this model. As an application I will describe how the motility of *H. Pylori*, the bacterium that causes ulcers, is influenced by the pH-dependent gelation of mucin, and conversely how the bacterium affects the gelation of mucin.

**2:30 PM**

**Synthesis of Vitrified Collagen Gels with Optimized Transparency and Mechanical Strength for Repair of Ocular Injuries:** Jennifer Breidenich<sup>1</sup>;

Daniel Mulreany<sup>2</sup>; Freddy Espinoza<sup>2</sup>; Yo-Rhin Rhim<sup>1</sup>; Xiomara Calderon-Colon<sup>1</sup>; Qiongyu Guo<sup>2</sup>; R.L. McCally<sup>1</sup>; *Morgan Trexler*<sup>1</sup>; Oliver Schein<sup>3</sup>; Jennifer Elisseff<sup>2</sup>; <sup>1</sup>Johns Hopkins University Applied Physics Laboratory; <sup>2</sup>Johns Hopkins University; <sup>3</sup>Wilmer Eye Institute

The frequency of ocular injuries on the battlefield has been steadily increasing during recent conflicts. Combat-related eye injuries are difficult to treat and solutions requiring donor tissue are not ideal. Vitrified collagen gels have been developed for repair of ocular injuries, but increased transparency and mechanical strength are desirable for improved vision and ease of handling, respectively. Synthesis of collagen vitrigels was optimized to yield the best combination of high transparency and high mechanical strength. Vitrification parameters that were investigated included temperature, humidity, and vitrification time. Transparency as well as tensile and tear strengths were characterized for each combination of synthesis conditions to evaluate the effects of the vitrification parameters on material properties. Changes in denaturing temperature and collagen fiber organization were also evaluated to correlate properties with structure. Preliminary results of ocular injury repair studies utilizing vitrigels with optimized properties will also be reported.

**2:50 PM Invited**

**Progress Towards Cartilage Engineering Using Peptide Hydrogels:** *Joel Schneider*<sup>1</sup>; <sup>1</sup>National Cancer Institute

Hydrogel materials are finding use for the encapsulation and delivery of mammalian cells for tissue regenerative therapy and cytomedical applications. We have designed a class of small peptides that undergo a triggered intramolecular folding event to form an amphiphilic beta-hairpin conformation that is prone to self-assembly. Self-assembly leads to the formation of a physically crosslinked network of beta-sheet rich fibrils that

MONDAY PM

constitute a mechanically rigid hydrogel. When peptide folding and self-assembly is triggered in the presence of cells, they are directly encapsulated in a uniform and cytocompatible manner. Peptide hydrogels, with or without cells, are shear thinning but have the capacity to quickly re-heal after the cessation of shear. This attribute allows hydrogel loaded with cells to be easily delivered from a syringe/catheter. Primary chondrocyte encapsulation and delivery is demonstrated and phenotype response studied, highlighting our efforts towards cartilage engineering.

### 3:20 PM

#### **Molecular Biomimetics Enables Biological Materials Science and Engineering:** *Mehmet Sarikaya*<sup>1</sup>; <sup>1</sup>University of Washington

Proteins enable biology to be viable through molecular interactions. Using biology as a guide, we biocombinatorially select, bioinformatically enhance and genetically tailor solid binding peptides and utilize them as molecular building blocks in carrying out molecular and nanomaterials science and engineering through biology. In this emerging field of molecular biomimetics, genetically engineered peptides for inorganic materials (GEPI) are used as bionanosynthesizers in biomaterialization, heterofunctional linkers to create thermodynamically stable interfaces between dissimilar materials, and as molecular assemblers for the targeted and directed assembly of nanomaterials towards addressable ordered architectures with genetically designed functions. Here, we will give an update of the utility of various kinds of GEPIs in nanoparticle formation for hybrid probe design and for bionanosensors; biomineral formation for tissue regeneration, and graphite-binding peptides for nano-electronics to demonstrate the power of the approach enabling nanotechnology and nanomedicine through materials science. Funded by NSF-MRSEC and NSF-BioMat programs.

#### **Hydrogels Formed by Inkjet Printing through Ionic Self-Assembly for Tissue Engineering and Drug Delivery:** Skander Limem<sup>1</sup>; Donald McCallum<sup>2</sup>; David Kaplan<sup>3</sup>; Marc in het Panhuis<sup>2</sup>; Gordon Wallace<sup>2</sup>; *Paul Calvert*<sup>1</sup>; <sup>1</sup>University of Massachusetts; <sup>2</sup>University of Wollongong; <sup>3</sup>Tufts University

Self-assembled ionic hydrogels are familiar when formed by the layer-by-layer method, which adds a monolayer of each polymer on every dipping cycle. We have been using inkjet printing to form similar gels at a rate 100x faster by printing anionic (polystyrenesulfonate) and cationic (polydimethylallylamine hydrochloride) polymers sequentially from a two-color printer. Gels of this type are not well understood because they have not previously been formed in bulk. We have characterized the swelling and dye-release properties and find that these change depending on the relative proportions of the two polymers and the extent of annealing of the structure. Similar gels can be formed from carboxylate polymers such as alginate and hyaluronic acid with chitosan and from polyglutamic acid with polylysine. Growth of cells on and in these gels is also being studied as a model for intercellular matrix.

### 4:20 PM

#### **Fabrication of 3D Hydrogel Matrices Containing Yeast and Human Cells:** *Paul Calvert*<sup>1</sup>; Swati Mishra<sup>1</sup>; Dapeng Li<sup>1</sup>; <sup>1</sup>University of Massachusetts Dartmouth

Acrylate hydrogels containing yeast and mammalian cells are formed by a blue-light activated polymerization that does not damage the cells. The viability and metabolic rate of the cells entrapped in the gel are determined and related to the thickness of the gel layers. Using a monomer paste thickened with nanoparticulate silica, 3D porous structures can be built. This is viewed as a route to tissue mimics and bioreactors but methods must be developed to control cell multiplication in order to avoid disruption of the gel layers.

### 4:40 PM

#### **Synthesis of Cellulose Hydrogels with High Strength and Transparency for Use as an Ocular Bandage:** *Morgan Trexler*<sup>1</sup>; Jenna Graham<sup>1</sup>; Jeffrey Maranchi<sup>1</sup>; Jennifer Breidenich<sup>1</sup>; Russell McCally<sup>1</sup>; Marcia Patchan<sup>1</sup>; Freddy Espinoza<sup>2</sup>; Jeremy Chae<sup>2</sup>; Iossif Strehin<sup>2</sup>; Oliver Schein<sup>3</sup>; Jennifer Elisseeff<sup>2</sup>; <sup>1</sup>Johns Hopkins University Applied Physics Laboratory; <sup>2</sup>Johns Hopkins University; <sup>3</sup>Wilmer Eye Institute

Cellulose is a biologically-derived material with excellent wound healing properties. The high strength of cellulose fibers and the ability to synthesize gels with high optical transparency makes these materials amenable for ocular bandage applications, which are becoming increasingly important in combat. Hydrogels were synthesized from cellulose derived from plant and bacterial sources. Material properties including mechanical strength, optical transparency, oxygen permeability, water content, and contact angle were evaluated, as these parameters are all critical for ocular applications, and compared with the natural cornea. Based on these materials characterization results and biocompatibility tests, cellulose types were down-selected for use in a temporary ocular bandage. The resulting cellulose gels were then functionalized with amine groups to achieve compatibility with a previously developed ocular adhesive. Results from preliminary in vivo tests will also be presented.

### 5:00 PM

#### **Fabrication of a Cellulosic Nanocomposite Scaffold with Improved Supermolecular Structure as a Potential Cardiovascular Tissue-Engineered Graft:** *Parisa Pooyan*<sup>1</sup>; Hamid Garmestani<sup>1</sup>; Rina Tannenbaum<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology

Cellulose nanowhiskers (CNWs) with its renewable and environmentally benign nature, and its abundance and excellent biocompatibility could potentially open a new avenue in cardiovascular tissue engineering for small caliber grafts. Inspired by this bioapplication, we have designed a fully bio-based nanocomposite of aligned CNWs embedded in a matrix of cellulose acetate possessing a controlled biodegradability, 3D porosity, and non-acidic byproducts as opposed to degradable PLA/PGA. To ensure uniform distribution, CNW were delicately extracted from a multi-stage process and dissolved in a solvent of choice prior to mixing with the matrix to inhibit whiskers flocculation. Comparable to Carbon Nanotubes and Kevlar, CNWs imparts significant strength and directional rigidity to the composite even at 0.2 wt% yet intensifies to about 40% within a controlled magnetic field of 0.3T. We believe our novel aligned nanocomposite could have groundbreaking features withstanding the physiological pressure and mimicking the topographical texture of the native extracellular graft.

### 5:20 PM

#### **Lessons from Nature: Biomimicry of Leaf Surfaces:** *John Nychka*<sup>1</sup>; <sup>1</sup>University of Alberta

The biological environment is vast yet the common denominator for life is water. While water is a requisite for most life on Earth too much water can be deleterious; for example plant leaf surfaces must remain dry to maintain gas exchange and prevent rotting. Various plant surfaces showing different wetting behavior will be described in this presentation; analysis of the structure of the epicuticular wax morphology on leaf surfaces will be discussed in the context of its effect on wetting behavior. Biomimicry of certain leaf surfaces using engineering materials will be described along with potential biomaterials applications of such technology.

## Bulk Metallic Glasses VIII: Alloy Development and Application II

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee

Program Organizers: Gongyao Wang, University of Tennessee; Peter Liaw, Univ of Tennessee; Hahn Choo, Univ of Tennessee; Yanfei Gao, Univ of Tennessee

Monday PM Room: 6D  
February 28, 2011 Location: San Diego Conv. Ctr

### 2:00 PM Invited

#### Ti-Based Bulk Metallic Glasses and Composites for Structural and Functional Applications: J. Eckert<sup>1</sup>; <sup>1</sup>IFW Dresden

Ti-based bulk glassy alloys and composites have potential for use in various fields due to the low density of the main constituent element Ti and high corrosion resistance. Their ultimate strength exceeds the values achievable for conventional microcrystalline alloys significantly. However, the strong monolithic amorphous/nanostructured alloys usually lack ductility, and an additional toughening phase is often needed to improve plasticity and to promote local shear events to be distributed more homogeneously. Recent results obtained for the structural and compositional analysis of the microstructures of Ti-based bulk metallic glasses and composites will be presented. The deformation behaviour and possible phase transitions during deformation and upon heating to elevated temperatures will be related to the structure of the glass in order to derive guidelines for the design of macroscopically ductile high-strength materials. The role of mechanically induced phase transitions and twinning of crystals for improving the ductility will be critically discussed.

### 2:20 PM

#### Evaluation of Physical and Mechanical Properties of Metallic Glasses in Micro/nano Scales: Jinn Chu<sup>1</sup>; Yen-Chen Chen<sup>1</sup>; Jason Jang<sup>2</sup>; Tsong-Ru Tsai<sup>3</sup>; Hidemi Kato<sup>4</sup>; <sup>1</sup>National Taiwan University of Science and Technology; <sup>2</sup>National Central University; <sup>3</sup>National Taiwan Ocean University; <sup>4</sup>Tohoku University

Recently, the process development of metallic glasses and the improvement of their mechanical properties have attracted considerable attention from the view point of potential applications. However, for industrial applications, the important issues that need to be overcome are their size limitation and room-temperature ductility. From this point of view, metallic glasses (MGs) exhibit viscous flow at high temperatures in the supercooled liquid region; thus they can be used to produce micro-devices via micro-/nano-imprinting. In this study, we demonstrate that various micro-/nano-patterns of Pd-based BMG can be imprinted from a mold in air. In addition, the physical and mechanical properties of the BMGs are evaluated. The obtained results suggest that the BMG is a suitable material for micro-/nano- imprinting, and is also a good mold material for imprinting.

### 2:30 PM Invited

#### Alloying Effects on Glass-Forming Ability and Soft Magnetic Properties of Fe-Based Bulk Metallic Glasses with a High Fe Concentration: H. X. Li<sup>1</sup>; J. E. Gao<sup>1</sup>; Z. B. Jiao<sup>1</sup>; Z. P. Lu<sup>1</sup>; <sup>1</sup>University of Science and Technology Beijing

Compared to the commercial silicon steels, Fe-based amorphous and nanocrystalline alloys which usually exhibit lower coercive force and core loss are attracting more and more attention as the transformer cores for high energy efficiency. However, the low glass-forming ability makes them available only as ribbons, powders or wires, as demonstrated by commercial products of FINEMET and NANOPERM alloys. In this talk, effects of metallic elements on the ferromagnetic system Fe-(P,C,Si,B) will be summarized and a group of newly developed soft magnetic Fe-C-Si-B-P-TM

(TM-transition metals) bulk amorphous alloys with a unique combination of super-high saturation magnetization (>1.5T), high glass-forming ability (=1mm) and high compressive fracture strength (= 3GPa) will be reported. Alloying effects on glass-forming ability and soft magnetic properties will also be discussed in detail.

### 2:50 PM Invited

#### Superplastic Deformation at Nanoscale in Metallic Glass: Scott Mao<sup>1</sup>; J. Luo<sup>1</sup>; Jianyu Huang<sup>2</sup>; <sup>1</sup>University of Pittsburgh; <sup>2</sup>Sandia National Lab

Metallic glasses are regarded as potential engineering materials for their high strength, hardness and large elastic strain. However, due to their high plastic instability, metallic glasses fail catastrophically once the shear band propagates throughout the specimen body, leading to near zero global plastic strain at room temperature. However, if the "brittle" metallic glass has extremely small dimensions at tens of nanometres, the shear bands will no longer operate, the flow and fracture mechanisms may change. Here we show that Al90Fe5Ce5 metallic glass with nanoscale size can undergo superplastic deformation with tensile elongation of ~200%. Finally necking occurred without shear bands in the nanoscale sample with the area reduction nearly 100%. Remarkably, even an atomic chain can be formed in the necking area approaching fracture, which is never found in metallic glass systems. Our discovery is fundamentally important for understanding the physics nature of metallic glasses in small scale.

### 3:10 PM

#### Atomic Mobility Inside Shear Bands and the Impact on Tracer Diffusion, Nucleation and Growth: Gerhard Wilde<sup>1</sup>; Joachim Bokeloh<sup>1</sup>; Gerrit Reglitz<sup>1</sup>; Harald Rösner<sup>1</sup>; Sergiy Divinski<sup>1</sup>; <sup>1</sup>University of Muenster

Although the occurrence of shear bands during plastic deformation of metallic glasses is well known, their actual physical properties remain fairly unknown. Here, experimental data on the rate of atomic diffusion within shear bands has been obtained using the radiotracer method on post-deformed specimens. The experimental results indicate unambiguously that the diffusivity is largely enhanced as compared to volume diffusion in metallic glasses. Moreover, nanocrystal formation has been observed in metallic glasses during different deformation processes. This finding has generated great interest as well as controversial discussions concerning the underlying mechanism. Here, different deformation methods with largely different strain and pressure levels have been applied on metallic glasses to investigate the deformation-induced nanocrystallization reaction with the strain as a metric for the transformation. The experimental results are discussed with respect to the underlying mechanism, utilizing also the first experimentally determined values of the diffusivity within a shear band.

#### Bending-Ductility Improvements of Bulk Metallic Glass by Surface Coatings: Jinn Chu<sup>1</sup>; Bo-Shian Houn<sup>1</sup>; Jason S. C. Jang<sup>2</sup>; Yin-Yu Chang<sup>3</sup>; Peter K. Liaw<sup>4</sup>; Yoshihiko Yokoyama<sup>5</sup>; Akihisa Inoue<sup>5</sup>; <sup>1</sup>National Taiwan University of Science and Technology; <sup>2</sup>National Central University; <sup>3</sup>Mingdao University; <sup>4</sup>The University of Tennessee; <sup>5</sup>Tohoku University

Room-temperature mechanical properties of bulk metallic glasses (BMGs) are characterized by excellent strength and elasticity with a lack of plasticity. Many attempts have been made to improve the ductility of BMGs, including surface modifications by shot peening. Our present study reports the use of Zr-based metallic-glass thin films as a promising coating to enhance the BMG bending ductility. The Zr-based BMG substrate is sputtered and coated with a 200 nm-thick Zr-based film and thin Ti adhesive layer. The coated sample has a maximum four-point bending loading of ~ 7 KN, a rise of ~ 75% from the uncoated one, with the 10-fold increased toughness to ~ 1,432 J and surface elongation reaching ~ 10%. Fractographic studies reveal that shear bands become highly populated for the coated BMG, suggesting that the ductility is closely related to the multiplication of the shear bands in the BMG substrate.

3:50 PM

**Characterization and Mechanical Response of Amorphous Fe<sub>45</sub>Ni<sub>45</sub>Mo<sub>7</sub>B<sub>3</sub> Honeycombs:** *Balaji Jayakumar*<sup>1</sup>; Jay Hanan<sup>1</sup>; <sup>1</sup>Oklahoma State University

The high yield strength and elastic modulus of metallic glasses implies that they could perform an important role in structural applications. In order to produce materials with a high strength-to-weight ratio and excellent energy absorption capabilities, it is advantageous to form amorphous alloys as cellular solids. Using the elastic property of slip cast amorphous Fe<sub>45</sub>Ni<sub>45</sub>Mo<sub>7</sub>B<sub>3</sub> ribbons, a metallic glass honeycomb was manufactured with a unique manufacturing approach. First prototypes were manufactured with a porosity of 96%, cell wall thickness of 0.028 mm and a cell size of 3 mm. We report ongoing studies of the mechanical properties of Fe<sub>45</sub>Ni<sub>45</sub>Mo<sub>7</sub>B<sub>3</sub> honeycombs. Experimentally measured mechanical properties are comparable to that of existing analytical models. Also, suggesting that potentially a 3X improvement in the strength properties in the out-of-plane direction are achievable when compared to that of crystalline Aluminum and Nomex honeycombs.

4:00 PM *Invited*

**Air-Oxidation of a [(Co<sub>50</sub>Cr<sub>15</sub>C<sub>15</sub>Mo<sub>14</sub>B<sub>6</sub>)<sub>97.5</sub>Er<sub>2.5</sub>]<sub>93</sub>Fe<sub>7</sub> Bulk Metallic Glass at 600 - 725 °C:** *Wu Kai*<sup>1</sup>; P.C. Lin<sup>1</sup>; Y.H. Wu<sup>1</sup>; W.S. Chen<sup>1</sup>; Z.Z. Liang<sup>1</sup>; H.L. Jia<sup>2</sup>; P.K. Liaw<sup>2</sup>; <sup>1</sup>Institute of Materials Engineering, National Taiwan Ocean University; <sup>2</sup>Department of Materials Science and Engineering, The University of Tennessee

The oxidation behavior of a [(Co<sub>50</sub>Cr<sub>15</sub>C<sub>15</sub>Mo<sub>14</sub>B<sub>6</sub>)<sub>97.5</sub>Er<sub>2.5</sub>]<sub>93</sub>Fe<sub>7</sub> bulk metallic glass (Co7-BMG) was studied over the temperature range of 600 – 725 °C in dry air. Nearly no oxidation was observed after oxidation at 625 °C for 36 h, indicative of an excellent oxidation resistance of the amorphous alloy. In addition, the oxidation kinetics of the Co7-BMG followed a two- to three-stage parabolic-rate law at T > 650 °C, having its steady-state parabolic-rate constants (kp values) increased with temperature. The scales formed on the Co7-BMG were very thin, consisting of an intermixed layer-structure mostly of CoMoO<sub>4</sub>, minor amounts of Cr<sub>2</sub>O<sub>3</sub>, CoCr<sub>2</sub>O<sub>4</sub>, and uncorroded Co<sub>3</sub>B at T > 650 °C. The formation of Co<sub>3</sub>B implied that a phase transformation of the amorphous substrate was occurred during oxidation at the temperature of interest.

4:20 PM

**Deformation Behaviour of Metallic Glasses:** *B Vishwanadh*<sup>1</sup>; R Tewari<sup>1</sup>; S Sharma<sup>1</sup>; R Kishore<sup>1</sup>; G K Dey<sup>1</sup>; <sup>1</sup>Bhabha Atomic Research Centre

The present paper reports on the influence of deformation on the structure and on mechanical properties of rapidly solidified ribbon (RSR) and bulk metallic glass (BMG) of the Zr<sub>52</sub>Ti<sub>6</sub>Al<sub>10</sub>Cu<sub>18</sub>Ni<sub>14</sub>(at%) alloy. The structure of as-solidified as well as deformed glasses has been probed by X-ray diffraction, transmission electron microscopy, positron annihilation, differential scanning calorimetry and nano indentation. Through these studies it has been established that the as-solidified structure is different at the different regions of BMG. For example, the peripheral region had lower medium range order (MRO) and higher free volume in comparison to the central region leading to higher hardness at periphery than in the central region. Through nano-indentation experiments, it has been demonstrated that subsequent to deformation BMG undergoes work softening whereas RSR undergoes work hardening. These behaviors have been explained in the present paper on the basis of change in free volume and MRO.

4:30 PM *Invited*

**Deformation Behavior and Deformation-Induced Nanocrystallization of Bulk Metallic Glasses:** *Tao Zhang*<sup>1</sup>; <sup>1</sup>Beihang University

For extensive applications of bulk metallic glasses (BMGs) with high strength as structural materials, development of BMGs with good plasticity and understanding the mechanism of their plastic deformation are of great importance, which have been widely studied in the last decade. We will review our recent work on the syntheses and deformation behavior of Cu-, Ti- and Zr-based BMGs with good plasticity. Especially, the Zr-based BMG exhibited remarkable work hardening besides plastic strain of ~20% in compression. For understanding the underlying mechanism of the deformation behavior of the present BMGs, the structural changes induced

by deformation as well as thermal stability of the BMGs were studied. It was found that deformation-induced nanocrystallites in glassy matrix as well as their crystalline defects could be responsible for the improved deformation behavior.

4:50 PM

**Dependence of Fracture Toughness on the Configurational State of a Metallic Glass:** *Glenn Garrett*<sup>1</sup>; Jin-Yoo Suh<sup>1</sup>; Michael Floyd<sup>2</sup>; Angeliki Kapoglou<sup>3</sup>; Marios Demetriou<sup>1</sup>; William Johnson<sup>1</sup>; <sup>1</sup>CalTech; <sup>2</sup>UC Berkeley; <sup>3</sup>European Space Agency

The fracture toughness of a metallic glass is thought to be determined by the ability of the glass to undergo extensive plastic shearing by hopping across a potential energy landscape while simultaneously resisting crack formation. Here, the fracture toughness of Zr<sub>35</sub>Ti<sub>30</sub>Cu<sub>8.25</sub>Be<sub>26.75</sub> relaxed at different configurational states in the potential energy landscape was measured using single-edge-notch bending specimens. Key potential energy landscape variables such as the elastic constants and stored enthalpy were measured at each configurational state, and correlated to fracture toughness. The fracture toughness is found to correlate more strongly with the shear elastic constant, thereby revealing that toughness is limited predominantly by the resistance of the glass to undergo plastic shearing.

5:00 PM *Invited*

**Dynamic Mechanical Behavior of Bulk Metallic Glass and Its Composite:** *Morgana Trexler*<sup>1</sup>; *Naresh Thadhani*<sup>2</sup>; <sup>1</sup>The Johns Hopkins University Applied Physics Laboratory; <sup>2</sup>Georgia Institute of Technology

The mechanical behavior of bulk metallic glass and its composite with tungsten particles is investigated as a function of dynamic uniaxial-stress and uniaxial-strain conditions. Anvil-on-rod impact tests instrumented with high-speed digital photography and velocity interferometry, were performed to determine the localized deformation and failure response, and elastic-plastic wave propagation characteristics. Imaging of transient deformation states and sample back surface velocity profiles obtained from the experiments were correlated with predictions from numerical simulations to validate the applicability of the Stassi-Drukker-Prager constitutive model used for describing the behavior of the BMG and the composite. Uniaxial-strain shock loading experiments were also performed to obtain evidence of shock-induced polymorphism which was observed to result in increase in strength and failure stresses. The state of the understanding of high-strain-rate deformation and shock compression response of bulk metallic glasses and their composites will be discussed in this presentation. [Research funding provided by U.S. Army Research Office].

5:20 PM

**Dynamic Compressive Behavior of Fe Based Amorphous Metal Honeycomb Cellular Structures:** *Advait Bhat*<sup>1</sup>; Jay Hanan<sup>1</sup>; Ganapathi Mahadevan<sup>1</sup>; <sup>1</sup>Oklahoma State University

Cellular solids like honeycombs have potential applications as energy absorbers. The typical applications are in dynamic stress environments. Quasistatic compression behaviors of honeycombs have been widely explored, however, their dynamic compression properties remain largely unknown. Also, no prior testing has been carried out on amorphous metal based honeycombs. The dynamic compressive behavior of a Fe<sub>45</sub>Ni<sub>45</sub>Mo<sub>7</sub>B<sub>3</sub> amorphous metal based honeycomb was investigated and mechanical properties were compared to those at quasistatic strain rates. The results indicate significant strain rate sensitivity. The observations can be compared to those seen in amorphous metal foams tested under similar conditions. The energy absorption capacity of this honeycomb is found to exceed that of aluminum counterparts of similar relative density.

5:30 PM *Invited*

**Atomic-Scale Structural Heterogeneity, Percolation and Unified Yielding Behavior in Metallic Glasses:** *Yong Yang*<sup>1</sup>; Jianchao Ye<sup>1</sup>; C.T. Liu<sup>1</sup>; Jian Lu<sup>1</sup>; <sup>1</sup>the Hong Kong Polytechnic University

Recent studies indicate that metallic glasses (MGs) can be viewed as atomic-scale composites containing soft free-volume zones and hard atomic clusters. In this study, the dynamic microcompression method developed recently was

utilized to characterize the atomic-scale structural heterogeneity of MGs and further to understand their yielding mechanisms. Based on the experimental findings, a percolation model was constructed to quantify the observed deformation-controlled yielding phenomenon in MGs. The experimental and theoretical results clearly show that the apparent universal yielding strain of ~2%, as measured from a wide range of MG alloys, originates from a percolation process that involves the destabilization of the sharing zones among solute-centered atomic clusters. The deformation mechanism proposed here is basically consistent with the spirit of the potential energy landscape (PEL) concept and provides an insight into the structure-property relationship in MGs, which has been remaining as a longstanding unresolved scientific problem for many years.

#### 5:50 PM

**The Oxidation Behavior of an FeCo-Based Bulk Metallic Glass at 600 - 700°C:** *Wu Kai*<sup>1</sup>; Pin-Chen Lin<sup>1</sup>; Yan-Hao Wu<sup>1</sup>; Z.Z. Liang<sup>1</sup>; P.K. Liaw<sup>2</sup>; <sup>1</sup>Taiwan Ocean University; <sup>2</sup>University of Tennessee

The oxidation behavior of an [(Fe<sub>50</sub>Co<sub>50-75</sub>B<sub>20-30</sub>Si<sub>3-96</sub>)<sub>100-x</sub>Nb<sub>x</sub> bulk metallic glass (FeCo5-BMG) was studied over the temperature range of 600 – 700 °C in dry air. The results showed that nearly no oxidation was observed for the FeCo5-BMG after oxidized at 600 °C for 36 h, indicative of a better oxidation resistance. In addition, the oxidation kinetics of this glassy alloy followed a two- to three-stage parabolic-rate law at higher temperatures, having its parabolic-rate constants ( $k_p$  values) increased with temperature. The scales formed on the FeCo5-BMG were very thin, consisting of an intermixed layer-structure of Fe<sub>3</sub>O<sub>4</sub>, Co<sub>3</sub>O<sub>4</sub>, B<sub>2</sub>O<sub>3</sub>, and uncorroded Fe<sub>3</sub>B. The formation of Fe<sub>3</sub>B further indicated that a phase transformation of the amorphous substrate was taken place during oxidation at the temperature of interest.

### Cast Shop for Aluminum Production: Casthouse Productivity and Safety

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee

*Program Organizers:* Geoffrey Brooks, Swinburne University of Technology; John Grandfield, Grandfield Technology Pty Ltd

Monday PM  
February 28, 2011

#### 2:10 PM

**New Casthouse Smelter Layout for the Production of Small Non-Alloyed Ingots: Three Furnaces/Two Lines:** Jacques Berlioux<sup>1</sup>; Arnaud Bourcier<sup>1</sup>; Jean-Louis Baudrenghien<sup>1</sup>; Christian Jonville<sup>1</sup>; Nicolas Tardy<sup>1</sup>; <sup>1</sup>Rio Tinto Alcan

This paper deals with a layout for a smelter casthouse producing small non-alloyed ingots. The layout of aluminium casthouses has important consequences with respect to safety, investment and operating cost. Traditional solution for casthouse producing non-alloyed ingots is two furnaces per one ingot line. In order to improve the economics and logistics the casthouse a detailed study was done, which required: detailed performance analysis, in particular relating to furnace/ingot line connections, impact on maintenance, operations, etc, hazard study, modeling of metal flow from tapping in the potline through to the end-product, including breakdowns and downgraded operation, thermal and flow modeling in the launder, in steady state and temporary operation and detailed determination of the launder. It was demonstrated that a layout based on such a configuration is superior in terms of full economic cost. This design is now part of our casthouse basic engineering package.

#### 2:35 PM

**Use of Process Simulation to Design a Billet Casthouse:** *Gwenola Jaouen*<sup>1</sup>; <sup>1</sup>Rio Tinto - Aluval

Designing a casthouse for billet is a complex activity. The billet casthouse must be properly sized to optimize the metal flow, and continuously feed the homogenization shop, while bearing in mind that oversizing adds no value and is costly. To solve this problem, it is necessary to accurately analyze the operations of the casthouse in real time and this requires a discrete simulation model. A model has been developed with a library that includes all the necessary equipment: conveyors, continuous and batch furnaces, finishing stations. The model was used to design an expended casthouse which requests the management of complex product mixes and which challenges the robustness and flexibility of the installation. By combining this model with the metal flow sizing model, it was possible to validate the performance of the design and its impact on casthouse operation. This resulted in a shop designed for customer needs, at optimal cost.

#### 3:00 PM

**Optimizing Scrap Reuse as a Key Element in Efficient Aluminium Cast Houses:** *Tom Schmidt*<sup>1</sup>; Jan Migchielsen<sup>1</sup>; <sup>1</sup>Otto Junker

In the last decades, the market share of secondary aluminium is slowly replacing primary aluminium. However, as the demand for aluminium is still considerable larger than the collection of used aluminium, primary aluminium will also be needed for the coming decades. This paper will address the current position of this development and the possibility to further increase the part of used aluminium scrap as the source for production of new aluminium to come to a durable production. The second part of the paper will concern the melting facilities for recycling used scrap.

#### 3:25 PM

**Implementation of an Effective Energy Management Program Supported by a Case Study:** *Roger Courchee*<sup>1</sup>; <sup>1</sup>K B Alloys, LLC

Effective energy management programs require commitment and leadership from Upper Management supported by an experienced Energy Manager. The vehicle for change is the Energy Management Working Party. The Working Party will be led by a Senior Manager and include other line managers under the technical guidance the Energy Manager. The first step is to use historical data to calculate an energy management performance indicator called Specific Energy Consumption [SEC] and then continue the calculations using real time data. The Working Party will initiate programs to achieve a continuous improvement in the SEC and in conjunction with Upper Management agree long term targets. Techniques will include evaluating base load data (energy consumed when not in production), projects targeted at energy inefficient equipment and a review of the various manufacturing processes to develop low energy solutions. This presentation is supported by a case study of the KB Alloys facility at Wenatchee WA.

#### 3:50 PM Break

#### 4:00 PM

**Molten Metal Safety Approach through a Network:** *Christian Pluchon*<sup>1</sup>; Bruno Hannart<sup>1</sup>; Laurent Jouet-Pastré<sup>1</sup>; <sup>1</sup>Alcan Engineered Product

Molten Metal explosion or splash is a major risk encountered in the aluminium casthouses. Alcan EP has had to face an accident in 2006, in one explosion in its casthouse. Unfortunately an employee had 2nd degree burns on the face. After expertise of the accident and implementation of corrective action in the plant, it appeared that we had a potential of improvement in management of Molten Metal risk by sharing experience coming from the merged companies, Alcan, Pechiney and Algroup. The EP management decided to create a network constituted of experienced managers of most of the casthouses. It was key to look deeply in the details and to think to the practical aspects of every decision. A novel approach of the management of Molten Metal risk was born in the company. The system was very powerful to align the whole organization on the objective to minimize risks.

4:25 PM

**Improved Monolithic Materials for Lining Aluminum Holding and Melting Furnaces:** *Andy Wynn*<sup>1</sup>; *John Coppack*<sup>1</sup>; *Tom Steele*<sup>1</sup>; *Ken Moody*<sup>1</sup>; <sup>1</sup>Thermal Ceramics

To remain competitive, aluminum producers continue to increase productivity through their Melt-Hold furnaces. Increasing heat input to the furnace using more powerful burners is common practice. But faster melting leads to increased metal losses from surface oxidation and to segregation from large heat gradients. These effects are countered by increased use of fluxes and increased stirring. Given the increasingly challenging environment within which the refractory lining has to work, traditional lining solutions can no longer be relied upon to provide the service lives that were previously achieved. Therefore, a new generation of furnace lining materials is required to cope with today's aluminum furnace. This work reports on a new monolithic material with improved performance, compared to existing materials, suitable for use in the critical metal contact areas of aluminum furnaces. Improved corundum growth resistance, salt resistance and thermal shock resistance are demonstrated in the laboratory using industry standard test methods.

4:50 PM

**Cost of Poor Quality in Aluminium Cast House Processes:** *Puliyur Krishnaswamy Narasimha Raghavan*<sup>1</sup>; <sup>1</sup>Bharat Aluminium Co. Ltd., (A Unit of Vedanta Resources Plc.), BALCO Nagar, Korba

Over 30 years aluminium casthouse technology has been driven by a number of factors such as, Competition from alternative materials, Lightweighting, Market requirements for enhanced properties affecting gas levels, impurities, inclusions, physical and chemical properties, ease of downstream processing, reduced cost and improved delivery, Reduction in conversion cost by various means including capacity increase, maximising asset utilization, minimizing scrap, reducing melt loss, labour, reduction in inspection with improved processes control activity, energy costs and need for improved safety performance. This paper will explore how these, and related considerations have provided the stimulus for improved casthouse technology by reducing Cost Of Poor Quality (COPQ). An attempt has been made to monitoring the COPQ and there by brining in improvement in the quality of the Aluminium Cast House products with a competitive reduction in Cost of production COP).

## Characterization of Minerals, Metals and Materials: Mineral Processing and Analysis

2:00 PM

**A Study on a Greensand Slate from Abaeté as a Source of Potassium: Thermal Treatment on Different Temperatures and Extraction on Acidic Media:** *Adriana da Silva*<sup>1</sup>; *Francisco Garrido*<sup>1</sup>; *Marta Medeiros*<sup>1</sup>; *João Sampaio*<sup>2</sup>; <sup>1</sup>UFRJ; <sup>2</sup>CETEM

Brazil is a great agricultural potential and its crop success is related to the soil's chemical and physical characteristics. The production of potassium fertilizers is a major concern because in 2009 Brazil produced only 10% of its needs and spent almost US\$ 2 billion on the purchase of this fertilizer. In this context, a potassium rock has been studied in order to evaluate its use as an alternative source of potassium to the Brazilian agriculture. This rock has been thermal treated with CaO (from 10 to 30%) at different temperatures

(from 800 to 1200°C) and its structural modifications have been supervised using x-ray diffraction and infrared spectroscopy. At the temperature of 1200°C and 10% of CaO, it was possible to observe the formation of new phases, such as spinel, that could improve the potassium availability that was quantified on acidic extractions using citric acid.

2:15 PM

**Application of High-Power Nanosecond Pulses to Flotation Separation of Sulfide Minerals:** *Igor Bunin*<sup>1</sup>; *Valentine Chanturiya*<sup>1</sup>; *Alexey Kovalev*<sup>1</sup>; *Irina Khabarova*<sup>1</sup>; *Elizaveta Kopolulina*<sup>1</sup>; <sup>1</sup>Research Institute of Comprehensive Exploitation of Mineral Resources RAS

The paper presents new theoretical and experimental results about mechanisms of disintegration of mineral complexes and structural transformations of the sulfide surface under high-power nanosecond electromagnetic pulses (HPEMP). The heated gas outflow from nanosecond breakdown channels of sulfide minerals under HPEMP is considered. It is shown that the gas outflow from channels can be an additional destructive factor in the processes of the electric pulse discharge disintegration of mineral complexes. It is shown that the effect of HPEMP changes chemical surface composition and, respectively, technological properties of pyrrhotite and pentlandite. Morphology and elementary composition of new micro- and nanoformations on mineral surface of pentlandite and pyrrhotite have been investigated using up-to-date methods of SEM/EDX and Scanning Probe Microscopy. Preliminary electropulse effect on mineral products before flotation allows producing optimal conditions for flotation separation of pentlandite and pyrrhotite owing to forming the new nanophases and defects on the surface of sulfides.

2:30 PM

**Sulfur Deposition Impact on Surface Morphology of Fly Ash-Based Adsorbent for Mercury Removal:** *Yaohua Chen*<sup>1</sup>; *Wei Gao*<sup>1</sup>; *Qingcai Liu*<sup>1</sup>; *Cunfang Lu*<sup>1</sup>; *Jian Yang*<sup>1</sup>; <sup>1</sup>University of Chongqing

Mercury is a toxic air pollution, and coal-fired utility plants are the largest anthropogenic emission source in China. Due to rapidly decreasing the cost and increasing the efficiency, it is becoming necessary to develop alternative technologies/materials for mercury removal. The adsorbents made from fly ash of coal-fired, and became spherical after sintering at temperature 500°C. Finally, it has been treated by thermal precipitation sulfur, to remove mercury in fuel gas. High temperature deposition furnace was applied to increase sulfur content in fly ash based adsorbents produced in lab. The experiments can increase its sulfur content of adsorbent, and found that sulfur attached to the surface, mesopore structure, microporous structure of fly ash-based adsorbents. So these treatments can increase their surface area and enhanced their adsorption capacity, while the sulfur was filled in interspace as small molecule S2 and S5. And the specific surface area increased by sulfur-loading and increasing temperature.

2:45 PM

**Sulfur Contents on the Distribution Characteristics of Mercury in Coals:** *Wei Gao*<sup>1</sup>; *Qingcai Liu*<sup>1</sup>; *Cunfang Lu*<sup>1</sup>; *Jian Yang*<sup>1</sup>; *Huimin Zheng*<sup>1</sup>; *Juan Wen*<sup>1</sup>; *Chunling Yao*<sup>1</sup>; <sup>1</sup>university of Chongqing

The coal samples were collected from coal fields in 12 provinces. There were studied on concentration, distribution, mode of occurrences and impact factors of mercury in Chinese coals. Sulfur and mercury in bituminous coals have been examined using X-ray fluorescence spectrometry, X-ray diffraction, and mercury spectrometer. Mercury levels in coal are related to the geographic location of the coals and types of the coals. A synthesis of result indicated that most likely occurrence modes of mercury in high-sulfur and high-mercury coals are in solid solution in pyrite. Coal samples showed that most values of mercury concentration in coal varied from 100 to 1000 ng/g with an average of approximately 500ng/g, and mathematical model about correlation between mercury and sulfur was gained by mathematical statistics. This is apparent that mercury and sulfur vary concomitantly from coal data, the high correlation between them at confidence of 95%( $\alpha=0.05$ ).

### 3:00 PM

**Characterization of Burrows from Mining District of Pachuca - Real Del Monte, in Hidalgo State and Viability Study to Use These Residues as Alternate Industrial Material:** Juan Hernández<sup>1</sup>; Eleazar Salinas<sup>1</sup>; Francisco Patiño<sup>1</sup>; Isauro Rivera<sup>1</sup>; Martín Reyes<sup>1</sup>; Miguel Pérez<sup>1</sup>; Eduardo Cerecedo<sup>1</sup>; <sup>1</sup>Universidad Autónoma del Estado de Hidalgo

A complete characterization of burrows from mining district of Pachuca - Real del Monte was done. These kind of residues had not been seriously characterized, and the results found lead to an average chemical composition of 79.43 % wt SiO<sub>2</sub>, 7.032 % wt Al<sub>2</sub>O<sub>3</sub>, 2.69 % wt Fe<sub>2</sub>O<sub>3</sub>, 0.70 % wt Mn, 3.98 % wt K<sub>2</sub>O, 3.34 % wt CaO, 2.50 % wt Na<sub>2</sub>O, 1.01 % wt MgO, 0.26 % wt TiO<sub>2</sub>, 0.04 % wt Zn, 0.026 % wt Pb, 56 g/t Ag and 0.6 g/t Au; showing as principal mineralogical phases: Quartz, Berlinite, Orthoclase, Feldspar, Anorthoclase and Calcite. By the other hand, joint with the big volume of these deposits and its chemical and mineralogical characteristics, this material can be used to the fabrication of ceramics, mixing it with agglutinants to produce, refractory bricks, in the industry of cement and to recover metallic values such as gold and silver.

### 3:15 PM

**Structural Characterization of Apatite Type Rare Earth Silicates:** Lii-Cherng Leu<sup>1</sup>; Sherin Thomas<sup>2</sup>; Mailadil Sebastian<sup>2</sup>; Rick Ubic<sup>1</sup>; Scott Mixture<sup>3</sup>; <sup>1</sup>Boise State University; <sup>2</sup>National Institute for Interdisciplinary Science and Technology; <sup>3</sup>Alfred University

Apatite-type rare-earth silicates have received much attention recently owing to their wide range of applications in microelectronics, solid-oxide fuel cells, solid-state lasers and phosphors. The crystal structure of Rare-earth apatite type Sr<sub>2</sub>RE<sub>8</sub>(SiO<sub>4</sub>)<sub>6</sub>O<sub>2</sub> (RE=La, Pr, Tb, Tm and Y) ceramics which were synthesized in a phase-pure form are characterized crystallographically via both electron and X-ray diffraction. The results show evidence of hexagonal crystal structure with space group P6<sub>3</sub>/m (No.176) for Sr<sub>2</sub>RE<sub>8</sub>(SiO<sub>4</sub>)<sub>6</sub>O<sub>2</sub> (RE=La, Pr, Tb and Y). The Rietveld structure refinement on X-ray diffraction data indicated a decrease in metaprimism twist angle for Sr<sub>2</sub>Tm<sub>8</sub>(SiO<sub>4</sub>)<sub>6</sub>O<sub>2</sub> and suggested that the hexagonal metric of apatite might not be sustained and the symmetry is reduced to monoclinic space group P2<sub>1</sub>/m (No.11) in order to compensate shorter bond length of the Tm ions.

### 3:45 PM Keynote

**Materials Characterization is the Key to Effective and Efficient Processing: Case Studies in Extractive Cu Leaching and Mineral Processing Post-Evaluation of Drywall:** Ann Hagni<sup>1</sup>; <sup>1</sup>Geoscience Consultant

Obtaining efficient and effective processing is a main component to profitability in materials processing and production environments. Materials characterization, in turn, is the key to understanding pre-processing and post-processed materials, which enables improvements in processing and increasing profits. Two case studies will be examined showing how the same materials characterization skills and abilities can be applied to very different real world scenarios in resolving processing dilemmas. Case 1 is an extractive copper leaching project at Johnson Camp Mine in Cochise County, Arizona, in which economic copper-bearing phases and deleterious clay phases are identified, quantified, and phase relationships imaged. Case 2 is a characterization study of one of the largest building construction materials problems ever to occur in the US of problematic drywall installed primarily during 2006 and 2007. Examining American-made versus Chinese-made drywall reveals clear distinctions between the two as post-mortem (after installation) evaluations.

### 4:25 PM

**The Influence of Ca on (Sr<sub>2-x</sub>Ca<sub>x</sub>)(MgTe)O<sub>6</sub> Double Perovskites:** Steven Letourneau<sup>1</sup>; Rick Ubic<sup>1</sup>; Sherin Thomas<sup>2</sup>; G. Subodh<sup>3</sup>; M. Sebastian<sup>2</sup>; <sup>1</sup>Boise State University; <sup>2</sup>National Institute for Interdisciplinary Science and Technology; <sup>3</sup>Physikalisches Institut

Complex perovskite oxides (A<sub>2-x</sub>A'<sub>x</sub>)(B<sub>2-y</sub>B'<sub>y</sub>)O<sub>6</sub> are ubiquitous in electronic applications, and a complete understanding of such structures

and the mechanisms which affect them is essential in predicting and controlling properties. Oxygen octahedral tilting and chemical ordering, in particular, are known to lower symmetry and influence dielectric properties. By investigating the appearance of superlattice reflections in electron and X-ray diffractograms, a summary of the octahedral tilting (tilt system) of the structure can be identified, cation ordering inferred, and space group symmetry established. In the case of the (Sr<sub>2-x</sub>Ca<sub>x</sub>)(MgTe)O<sub>6</sub> system, a phase transformation occurs from a tetragonal *I4/m* symmetry at *x* = 0 (Sr<sub>2</sub>MgTeO<sub>6</sub>) to monoclinic *P2<sub>1</sub>/n* symmetry for *x* = 0.5; however, B-site cation ordering causes ½{odd,odd,odd} type reflections in all compositions, complicating crystallographic characterization. The temperature coefficient of resonant frequency is negative throughout the series; permittivities were in the range 13.2-14.3, and quality factors varied from 27,500 to 81,000 (5-6GHz).

### 4:40 PM

**Technological Characterization of Phonolite Rock to Be Applied as Source of Nutrients to the Brazilian Agriculture:** Aline Maria Teixeira<sup>1</sup>; João Sampaio<sup>2</sup>; Francisco Garrido<sup>3</sup>; Marta Medeiros<sup>3</sup>; <sup>1</sup>IQ/UFRJ - CETEM; <sup>2</sup>CETEM-MCT; <sup>3</sup>IQ-UFRJ

The rocks for crops is a natural practice for soils fertilization and consists on adding rocks to the soil while the water by chemical weathering decomposes the rock and release the nutrients gradually to the soil solution. This practice can be considered an alternative to the low production of potassium fertilizers in Brazil. In this context, the phonolite rock will be characterized in order to evaluate its application as an alternative source of nutrients to the Brazilian agriculture. The phonolite that will be studied is an igneous, volcanic rock as alkaline character that chemically is composed by a high grade of potassium due to the presence of feldspar minerals. In order to quantify the minerals present in the sample the characterization will be carried out using several techniques such as X-ray diffraction, X-ray fluorescence and scanning electron microscopy.

### 4:55 PM

**Study on Thermal Stabilities of 2- Substituted Benzimidazoles Copper and Zinc Complex:** Yan Shi<sup>1</sup>; Dan Li<sup>1</sup>; Qingqiao Liu<sup>2</sup>; Zhongliang Xiao<sup>1</sup>; <sup>1</sup>Changsha University of Science and Technology; <sup>2</sup>Hunan Hualing Xiantan Steel Co. Ltd.

2-substituted benzimidazole-zinc and 2-substituted benzimidazole-copper complex were main components of organic solderability preservative (OSP) in PCB producing process and affect the thermal stability of OSP film. So these two complexes were prepared by 2-substituted-benzimidazole reacting with zinc ion and copper ion, the complex crystals were determined by IR, its thermal stabilities were studied by TG method. The results indicated that the thermal stability of 2-substituted benzimidazole-zinc is higher than the 2-substituted benzimidazole-copper, and the thermal decomposition mechanism was presented.

### 5:10 PM

**Investigation on Extracting Boric Acid from Saline Brine by Boron Specific Chelating Resin:** Xiang Xiao<sup>1</sup>; Baizhen Chen<sup>1</sup>; Xichang Shi<sup>1</sup>; Yunfeng Fu<sup>1</sup>; Hui Xu<sup>1</sup>; Xiyun Yang<sup>1</sup>; <sup>1</sup>Central South University School

Extracting boric acid from saline brine by boron specific ion-exchange resin was investigated. Effects of resin amount, temperature, time and stirring speed on boron adsorption rate were studied in the experiments. The results indicated that the XSC-700 resin showed excellent boron adsorbability and it performed better property for elution. The maximum boron adsorption capacity was 6.16 mg.ml<sup>-1</sup> in the optimum conditions: the resin concentration of 5ml/100ml (brine), the temperature of 60°C, the time of 5-6h and the stirring speed of 100r/min. Boron was eluted from the resin with HCl and boric acid was crystallized by evaporating the eluate. The product of boric acid was in pure form as confirmed by XRD and other analysis techniques.

5:25 PM

**Low Temperature Carbothermic Reduction of Panzhihua Low Grade Ilmenite after Ball Milling:** Ying Lei<sup>1</sup>; Yu Li<sup>1</sup>; Jinhui Peng<sup>1</sup>; Libo Zhang<sup>1</sup>; Shenghui Guo<sup>1</sup>; Wei Li<sup>1</sup>; <sup>1</sup>Key Laboratory of Unconventional Metallurgy, Ministry of Education

In this work, low temperature carbothermic reduction of Panzhihua low grade ilmenite after ball milling were investigated. The ball milling of ilmenite and graphite were processed in a ball mill. The milling process can attenuate the particle of ilmenite, and the ilmenite characteristic peak were broadened and weakened. The reduction temperature and behaviors are studied on the thermo gravimetric apparatus; lower temperature and higher reaction rate were obtained for the reduction of ilmenite with graphite after milled. The reduction temperature and times of ilmenite decreased to 1000~1025°C and 40~60min via milled for 4 or 8h; Low down the reduction temperature can eliminate the solution of Mg<sup>2+</sup> and FeTiO<sub>3</sub> in a certain degree; the reduced ilmenite has an obvious loose structure, can favored the subsequent procedure such as leaching.

## Chloride 2011: Practice and Theory of Chloride-Based Metallurgy: Pyrometallurgy and Acid Regeneration

*Sponsored by:* The Minerals, Metals and Materials Society, Canadian Institute of Metals, TMS Extraction and Processing Division, TMS: Magnesium Committee, TMS: Energy Committee  
*Program Organizers:* Dirk Verhulst, Consultant, Extractive Metallurgy; V.I. (Lucky) Lakshmanan, Process Research Ortech, Inc.

Monday PM  
February 28, 2011

Room: 19  
Location: San Diego Conv. Ctr

*Session Chairs:* Khamal Adham, Hatch Ltd.; Lisa Helberg, E.I. DuPont de Nemours

2:00 PM

**Chloride Metallurgy: Process Technology Development:** Edgar Peek<sup>1</sup>; <sup>1</sup>Xstrata Process Support

The two dominant metallurgical problems in treating most base metal (sulphide) concentrates in both the chloride and sulphate system are iron removal and sulphur elimination, respectively. In this paper the opportunities, limitations and fundamentals of the chloride metallurgy system are described against this background. Only the treatment of oxide and sulphide ores is considered. Both hydrometallurgical and pyrometallurgical unit process operations are highlighted, since most successful base metal processes are based on a combination of the two. Hence, an overview of the technical and also some economical aspects of chloride metallurgy are presented. This overview summarizes the successful applications of chloride metallurgy, but it will not give exhaustive process and plant descriptions. It predominantly focuses on the essential technical features of the metallurgical unit process operations, while providing numerous references separately.

2:25 PM

**Purification of Titanium Tetrachloride: A History:** Lisa Helberg<sup>1</sup>; <sup>1</sup>E.I. DuPont de Nemours

Titanium tetrachloride is produced through the chlorination of a variety of titanium bearing ores, some occurring in nature, and others enriched in titanium content by a variety of "beneficiation" processes. The chlorination step can produce a variety of metal chloride impurities, such as iron chlorides and vanadium chlorides, which must be removed from the TiCl<sub>4</sub> before it can be used to produce pigmentary TiO<sub>2</sub>, titanium metal or for any other commercial use. The requisite manipulations involve both physical and chemical separations in a multi-step process. The history of various purification strategies will be discussed.

2:50 PM

**Zirconium Chlorination Behavior: A Literature Review:** Donald Voir<sup>1</sup>; <sup>1</sup>Westinghouse

The reaction rate between zircon or zirconia, carbon, and chlorine is controlled by temperature, and the degree of contact intimacy between the carbon and the zirconium. Chlorination behavior observed in static beds (and pellets) is characterized by a thin reacting front that advances through the bed or pellet. Excess and unreacted material becomes an "ash layer" that limits chlorine access to the reacting front. The reaction rate for stoichiometric, well mixed, pelletized, sub-sieve zirconia is about 100 mmoles/cm<sup>2</sup>/hr at 800°C. The reaction rate for loosely packed, ~100μ carbon and zirconia is about 1 mmole/cm<sup>2</sup>/hr. Plug flow and fluid bed reactors, using much coarser zircon or zirconia and carbon particles, have a reaction rate of about 1 μmole/cm<sup>3</sup>/hr. The reaction rate is controlled by a slow reaction between carbon and zirconium species that results in an essentially zero order reaction rate dependency for the chlorine concentration.

3:15 PM

**HCl Leaching and Acid Regeneration Using MgCl<sub>2</sub> Brines and Molten Salt Hydrates:** Jan deBakker<sup>1</sup>; Joshua LaMarre<sup>1</sup>; Vladimiro Papangelakis<sup>2</sup>; Boyd Davis<sup>1</sup>; <sup>1</sup>Queen's University; <sup>2</sup>University of Toronto

HCl leaching using molten salt hydrates has the potential to improve the extraction of nickel from laterite ores. However, as in other HCl leaching applications, recovery of HCl is problematic. Spray pyrohydrolysis, which is used in current chloride-based flowsheets, represents a high energy cost. The authors have developed a proposed molten salt hydrate laterite leach circuit using an alternative HCl recovery route. The leach circuit envisions a leach by HCl gas in a MgCl<sub>2</sub> MSH medium, followed by Ni/Co recovery, iron hydrolysis, precipitation of magnesium from solution as magnesium hydroxychloride, and thermal decomposition of the hydroxychloride to produce HCl gas. The flowsheet will allow a chloride leach circuit to take place with simpler equipment requirements and lower energy cost than is currently available. The laboratory work investigates key aspects of the flowsheet, including precipitation of magnesium hydroxychlorides and their composition; magnesium hydroxychloride thermal decomposition; and iron control by selective pyrohydrolysis.

3:40 PM

**Precipitation of Hematite and Recovery of Hydrochloric Acid from Concentrated Iron Chloride Solutions by a Novel Hydrolytic Decomposition Process:** Levente Becze<sup>1</sup>; Sebastian Hock<sup>1</sup>; George Demopoulos<sup>1</sup>; <sup>1</sup>McGill University

Regeneration of HCl from chloride solutions is commercially practiced by high temperature (800-900°C) pyrohydrolysis associated with high energy consumption and capital cost. As an alternative to pyrohydrolysis a novel low temperature (<200°C) non-autoclave hydrolytic process has been studied in this research work, which comprises two steps. In the first step, ferrous chloride is oxidized by oxygen at T=150 °C, followed by hydrolytic decomposition of ferric chloride to coarse hematite particles and superazeotropic hydrochloric acid (8-9M) operated at approximately 180°C. This paper provides a summary of the laboratory results related to both oxidation and hydrolysis and presents a newly designed conceptual process flowsheet.

4:05 PM Break

4:20 PM

**Application of Oxygen Enrichment for the Pyrohydrolysis of Metal Chlorides:** Kamal Adham<sup>1</sup>; Cassandra Lee<sup>1</sup>; <sup>1</sup>Hatch Ltd.

Metal chlorides (e.g. iron and nickel) can be pyrohydrolysed at elevated temperatures to yield a HCl rich off-gas and an oxide product. Typically, the high energy requirement for pyrohydrolysis is provided by the combustion of a hydrocarbon fuel with air. Here, it is demonstrated that the use of oxygen-enriched air can result in lower fuel consumption and better HCl concentration. In addition, the oxygen enrichment can result in smaller quantity of off-gas and less expensive process equipment. This new concept can be applied to both the spray roaster and the fluidized bed reactor. Similar

to the air-combustion case, the O<sub>2</sub> enriched process can use a direct contact venturi scrubber, to recover energy from the roaster off gas, but at a higher efficiency. The new process also uses an absorption tower for capturing HCl from the roaster off-gas, but generates a stronger HCl solution, than is currently possible with air roasting.

4:45 PM

**Chlorine, Copper and “De Novo” Synthesis of Dioxins:** Alfons Buekens<sup>1</sup>; Shao Ke<sup>1</sup>; <sup>1</sup>Zhejiang University, Institute for Thermal Power Engineering (ITPE)

The de novo synthesis of dioxins involves a low temperature catalytic conversion of carbonaceous substrates in a flow of air. The theory as developed by Dr. Stieglitz (FZ Karlsruhe) involves copper as most potent catalyst. Tests on various sources of carbon (activated carbon, three types of soot, and graphite) conducted at 300°C allowed comparing native samples (without) with cupric chloride doped ones. Steam addition to the combustion air raises the rate of oxidation, which in turn is severely suppressed by sulphur dioxide. This paper presents thermodynamic calculations on the system Cu-Cl-O-S at the temperature of the experiments (300°C), as well as in a wider range of potential copper catalysed dioxin generation. For the sake of comparison, the results are compared with those obtained while using other transition metals as a catalyst. Some preliminary computations are presented.

5:10 PM

**Segregation Roasting of a Saprolitic Laterite Ore: An Experimental Investigation:** Munyaradzi Kwatara<sup>1</sup>; Juzer Tayabally<sup>1</sup>; Edgar Peek<sup>1</sup>; Ron Schonewille<sup>2</sup>; <sup>1</sup>Xstrata Process Support; <sup>2</sup>Xstrata Nickel

The potential recovery of nickel from a South-American saprolitic laterite ore using the segregation roasting technique was investigated. The ore was heated to temperatures that ranged between 900 and 1000°C in a rotary kiln. In all the tests, the laterite ore was first mixed with a predetermined amount of calcium chloride and either coal or coke. By varying the temperature, calcium chloride and reductant in the different tests, a preliminary set of optimal conditions was established for the specific laterite ore that was tested. A combination of chemical analysis and electron-probe-micro-analysis (EPMA) were used to determine and evaluate the effectiveness of segregation roasting on the recovery of nickel. The present paper describes the test procedure and the results that were obtained.

5:35 PM

**Mechanism of Selective Chlorination of Reduced Limonitic Nickel Laterite Using a Solid Chloride Agent:** Chuanlin Fan<sup>1</sup>; Xiujing Zhai<sup>1</sup>; Yan Fu<sup>1</sup>; Yongfeng Chang<sup>1</sup>; Binchuan Li<sup>1</sup>; Ting-an Zhang<sup>1</sup>; <sup>1</sup>Northeastern University

The mechanism of the selective chlorination of nickel and cobalt in reduced limonitic laterite was investigated. Reduced ores were obtained from the reduction roasting of a limonitic nickel laterite. The thermal decomposition of related chlorides and the selective chlorination of the reduced ore were carefully studied using Differential Thermal analysis – Thermogravimetry (DTA-TG), X-Ray Diffraction and chemical leaching methods. In the temperature range of 300 - 500 °C, aluminum chloride hexahydrate was chosen as chloride agent. During the selective chlorination, reduced ore was partly chlorinated by hydrogen chloride generated from the thermal decomposition of chloride agent. Then the oxydrolisis of ferrous chloride re-generated hydrogen chloride used to further the chlorination. Finally, iron was mostly rejected as hematite, while nickel and cobalt were selectively chlorinated. More than 91%Ni,90%Co and about 4%Fe in the chlorinated ore was extracted using a water leaching method.

**Megawatts and Petaflops:** Ian S. Anderson<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

A new generation of MW spallation neutron sources is providing unprecedented measurements of the dynamics of systems in, and away from, equilibrium. This ever-increasing experimental sophistication in synthesizing and interrogating matter at all levels is now taking place under the guidance of elaborate predictive models whose solution and simulation has been enabled by powerful cyber-capabilities and sophisticated mathematical and computational algorithms. Combining computational and experimental methods is increasingly important in materials science and engineering to extract critical information from data (e.g., intrinsic correlations between structure, processing, and properties/behavior), as well as being increasingly necessary for breakthroughs. Although numerous examples exist of successful combinations of modeling and experiment the question arises: how to make the most impact from the new capabilities?

2:35 PM Keynote

**High Temperature Thermodynamics and Atom Vibrations:** Brent Fultz<sup>1</sup>; <sup>1</sup>California Institute of Technology

The harmonic model often gives a good starting point for the vibrational thermodynamics of materials. The vibrational entropy is big, however, and at high temperatures relatively small non-harmonic effects can alter substantially the thermodynamics of alloy phases. One effect can be understood as standard “quasi-harmonic” behavior, where vibrational frequencies are lowered as a crystal expands against its bulk modulus. Most materials show a second effect from phonon-phonon interactions (PPI), and sometimes a third from how electronic excitations interact with vibrations (electron-phonon interaction, EPI). New results are presented from a study on the phonon lifetimes in aluminum, where we show with perturbation theory that the PPI from cubic anharmonicity accounts well for the lifetimes of the individual phonons. In other metals, the EPI can be important thermodynamically to temperatures approaching 1000 K. Rules of thumb for these effects are emerging from chemical and structural trends of electronic and phonon dispersions.

**Collective Behavior of Intrinsic Localized Modes Observed in the Vibrational Spectrum Of NaI:** Michael Manley<sup>1</sup>; <sup>1</sup>Lawrence Livermore National Laboratory

Intrinsic localized modes (ILMs) form in the lattice vibrations of both metallic uranium and ionic sodium iodide. These dynamic nonlinear hot

MONDAY PM

spots have been found to impact a variety of technologically important properties including thermal expansion, diffusion, mechanical behavior, phase transformations, and thermal conductivity. In this talk I will present recent discoveries on the ILMs in NaI that are challenging the independent local mode picture. First, the polarization of the ILMs collectively switch between  $\langle 111 \rangle$  and  $\langle 011 \rangle$  with very small temperature changes. Second, once an ILM polarization locks in the parent mode fragments into several distinct dispersive modes of different symmetry. This suggests that the ILMs are organizing into arrays or patterns that modulate the parent mode. Pattern formation by ILMs in anharmonic crystals was predicted more than a decade ago but never observed. Invited talk for symposium in honor of Brent Fultz

**Ab Initio above Zero: Alloy Thermodynamics from First Principles:** Axel van de Walle<sup>1</sup>; <sup>1</sup>Caltech

Although ab initio methods excel at calculating physical properties for any given atomic arrangements, proper modeling of the thermodynamic properties of solid-state alloys demands a sampling of the large number of states visited in thermal equilibrium, a task that is computationally intractable via a brute-force approach. This talk describes how this impasse can be resolved through a combination of automated computational techniques that are able to efficiently model electronic excitations, lattice vibrations and configurational disorder within a unified framework: the cluster expansion formalism in conjunction with a suitable coarse-graining of the partition function.

**Studies on Vibrational Entropy in Alloys Using Inelastic Neutron Scattering at ORNL:** Jack Robertson<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

Inelastic neutron scattering spectra and neutron diffraction patterns were measured for a verity of binary alloys using the triple-axis spectrometers at the High Flux Isotope Reactor (HFIR) at Oak Ridge National Laboratory. Phonon density-of-states curves were calculated from the inelastic scattering spectra, allowing estimates of the vibrational entropy in the harmonic and quasiharmonic approximations. A survey of studies done in collaboration with Professor Fultz and his students will be presented.

#### 5:00 PM Invited

**Time-of-Flight Inelastic Neutron Scattering Studies of Phonons and Magnetism in Polycrystalline Samples:** Robert McQueeney<sup>1</sup>; <sup>1</sup>Iowa State University

Neutron time-of-flight inelastic spectrometers with large area detectors provide complex data sets containing the wavevector and energy dependences of vibrational and magnetic excitations in solids. Extracting detailed information about the excitations continues to spur the development of more and more powerful calculations of the dynamics of solids. Over the last several years, our efforts have focused on the ability to analyze and interpret data from polycrystalline samples. In this talk, I summarize how the simultaneous development of new time-of-flight spectrometers and computation has furthered our understanding of the phonons and magnetism in several materials, most notably, our studies of cerium and plutonium metals and orthoferrite-based oxides. Although these materials appear quite dissimilar, in each case electronic valence fluctuations have profound effects on the structural phase diagrams and magnetic properties.

**Transformation-Induced Plasticity during Pseudo-Elastic Deformation in Ni-Ti Microcrystals:** Michael Mills<sup>1</sup>; Peter Anderson<sup>1</sup>; Matthew Bowers<sup>1</sup>; Sivom Manchiraju<sup>1</sup>; Peter Sarosi<sup>2</sup>; Michael Uchic<sup>3</sup>; <sup>1</sup>The Ohio State University; <sup>2</sup>General Motors R & D Tech Center; <sup>3</sup>Air Force Research Labs RXLM

Micromechanical testing of single crystal Ni-Ti based shape memory alloys is being performed in an effort to understand the effects of specimen size and crystal orientation on martensite-induced pseudoelastic and shape memory response. The primary goal in this investigation is to determine the means by which the matrix accommodates the large strain associated with the martensitic transformation. This information is critical in extending the working life of components under cyclic loading and/or heating. Micron-scale pillars of several crystallographic orientations have been prepared by FIB and tested in compression. Post-mortem TEM analysis has revealed the plasticity induced by the transformation. We demonstrate through this method that it is possible to directly study the mechanical response and defect generation associated with individual, isolated martensitic transformations. The experimental results are correlated with the predicted transformations and local stresses due to the crystallographic theory of martensite.

#### 2:30 PM Invited

**Some Unusual Aspects of the Deformation of FeAl and Fe<sub>2</sub>MnAl:** I. Baker<sup>1</sup>; <sup>1</sup>Dartmouth College

An overview of three unusual aspects of the behavior of the B2 compound FeAl and the L21 derivative Fe<sub>2</sub>MnAl is presented. First, both compounds show a yield anomaly. A model for the anomaly in FeAl, based on vacancy hardening (E.P. George and I. Baker, Phil. Mag. A, 77 (1998) 737), is outlined along with both data supporting and predictions of the model. The applicability of the model to describe the yield anomaly in Fe<sub>2</sub>MnAl is discussed. Second, both the room-temperature ductility and yield strength of these compounds are affected by water vapor. The phenomenology associated with this behavior is discussed along with a possible fracture mechanism. Finally, both compounds show a paramagnetic to ferromagnetic transition upon room-temperature deformation, which is reversed upon annealing. A model for this behavior (Y. Yang, I. Baker, and P. Martin, Phil. Mag. B, 79 (1999) 449), based on the formation of anti-phase boundary tubes, is presented.

**Recent Progress in High Temperature TiAl Alloys:** Guoliang Chen<sup>1</sup>; Junpin Lin<sup>2</sup>; <sup>1</sup>Univ. of Science and Technology Beijing; <sup>2</sup>univ. of Science and Technology Beijing

Conventional cast TiAl alloys have been used for the engine GENx. However, the conventional TiAl alloys are not strong enough for applications at higher temperatures. TiAl alloy have been developed into two categories: conventional TiAl and high temperature TiAl (high niobium containing)

alloys. These state-of-the-art alloys have great advantage that the service temperature is 60-100 oC higher than that of conventional TiAl alloys. The presentation discuss the relationships among composition, microstructure and properties for high temperature TiAl alloys, including the phase relationship with high Nb contents, the high temperature strengthening mechanisms of Nb, Al and other elements, excellent oxidation resistance at high temperature, especially focusing the new technology for the fabrication and processing of pilot ingots.

### 3:30 PM

**Atomistic Simulations of Cross-Slip Nucleation in L12 Ni3Al:** *Satish Rao*<sup>1</sup>; Dennis Dimiduk<sup>2</sup>; Jaafar El-Awady<sup>3</sup>; Triplicane Parthasarathy<sup>1</sup>; Michael Uchic<sup>2</sup>; Christopher Woodward<sup>2</sup>; <sup>1</sup>UES Inc.; <sup>2</sup>Air Force Research laboratory; <sup>3</sup>Johns Hopkins University

Using atomistic (molecular statics) simulations with embedded atom potentials, we evaluate the configurations for a dislocation to form the PPV lock by intersecting a forest dislocation in L12 Ni3Al. The activation energies were estimated by determining equilibrium configurations (energies) when variable pure tensile or compressive stresses are applied along the [111] direction on the intersection configurations. We show that the activation energy at the forest dislocation intersection is significantly lower than that for cross slip in bulk. These results suggest that cross-slip should be preferentially observed at selected screw dislocation intersections in L12 Ni3Al.

### 3:45 PM

**Effect of Lamellar Microstructure on Impact Toughness and Fracture Behavior in Wrought Gamma TiAl Alloy:** *Hirotoyo Nakashima*<sup>1</sup>; Toshikazu Kikugawa<sup>1</sup>; Shun Oinuma<sup>2</sup>; Masao Takeyama<sup>1</sup>; <sup>1</sup>Tokyo Institute of Technology; <sup>2</sup>Former graduate student (Currently Toshiba Corporation Power Systems Company)

Impact properties and fracture behavior of wrought  $\gamma$ -TiAl based alloys with various microstructures have been evaluated by means of an instrumented Charpy impact test and a specially designed three-point bend machine installed in SEM chamber, respectively. The alloy studied is Ti-42Al-8V (at.%) with a unique transformation pathway of  $\gamma$ -Ti  $\rightarrow$   $\gamma$ -Ti  $\rightarrow$   $\gamma$ -Ti  $\rightarrow$   $\gamma$ -Ti  $\rightarrow$   $\gamma$ -Ti. The alloy can easily be hot free-forged by 70% reduction in height by one stroke in the  $\gamma$ -Ti  $\rightarrow$   $\gamma$ -Ti two-phase region. The load-displacement curves of the impact test clearly detect the microstructure change, and the impact toughness increases with increasing the volume fraction of the lamellar grains. Further improvement was obtained in the specimens with fine  $\gamma$ -Ti particles within lamellae. *In-situ* observation and the corresponding load-displacement curves of the bend test revealed that the higher the lamellar angle with respect to the loading axis the larger the crack propagation resistance, thereby increasing the fracture toughness.

### 4:00 PM Break

### 4:10 PM

**The Role of Microtexture on Fatigue Lifetime Variability and Crack Initiation Mechanisms in Ti-6Al-4V:** *Christopher Szczepanski*<sup>1</sup>; James Larsen<sup>2</sup>; S. Lee Semiatin<sup>2</sup>; <sup>1</sup>UTC/AFRL; <sup>2</sup>AFRL/RX

To quantify the effect of microtexture on the fatigue behavior of  $\alpha$ + $\beta$  titanium alloys, Ti-6Al-4V material, initially containing bands of microtexture with a strong transverse texture was hot rolled to produce materials with varying levels of microtexture. These materials were heat treated to produce a range of microstructures: an equiaxed microstructure containing microtexture, a beta annealed structure containing microtexture and an equiaxed microstructure free of microtexture. The effect of test orientation on fatigue behavior for each of these microstructural variants was investigated by replicate testing of specimens along three different orientations; RD, TD, and 45° from the RD. Initial fatigue results indicate that specimens with their loading axis along the original plate TD tend to have the longest lifetimes. Orientation imaging microscopy and fractographic analysis were used to identify the mechanisms of fatigue crack initiation in these samples and to elucidate the role of microtexture.

### 4:25 PM

**Understanding of the Fracture Behavior of Titanium Alloy Ti-6Al-4V:** *Santhosh Koduri*<sup>1</sup>; Vikas Dixit<sup>1</sup>; Peter Collins<sup>2</sup>; Babu Viswanathan<sup>1</sup>; Hamish Fraser<sup>1</sup>; <sup>1</sup>The Ohio State University; <sup>2</sup>University of North Texas

A rigorous approach based upon integrated characterization and neural network modeling has resulted in the differentiation of the roles that microstructure, composition, and continuum variables (e.g., tensile properties, stress state at the crack tip) have on the fracture toughness for  $\alpha$ + $\beta$  processed Ti-6Al-4V. This approach has been applied to a high-fidelity database containing composition, microstructure and the resulting tensile and fracture toughness properties. The modeling tools have been used to isolate a key microstructural variable, which have been subsequently characterized in great depth using a suite of advanced characterization techniques. The details of one particular type of interface associated with crack initiation ahead of the moving crack tip will be discussed.

### 4:40 PM

**Extended Zonal Dislocations Mediating {11-22}<11-2-3> Twinning in Titanium:** *Bin Li*<sup>1</sup>; <sup>1</sup>Center for Advanced Vehicular Systems

We present atomistic simulation results on the mechanism for the {11-22}<11-2-3> twin growth in titanium (Ti) by analyzing the interfacial structure at the twin boundary (TB). The simulation results reveal interesting twin growth controlled by interfacial dislocations at the TB. The elementary twinning dislocations (bt) nucleate and glide in pairs but separately and sequentially on two neighboring twinning planes, distinctly different from that of conventional zonal dislocations with the core spreading over two or more twinning planes and each plane comprising one Burgers vector of an elementary twinning dislocation. These two separate elementary twinning dislocations add up to a net Burgers vector  $2bt \sim 0.2$  nm along the twinning vector, with the components in the in-plane direction perpendicular to the twinning vector canceled out. A reason for such an extended zonal dislocation will be discussed.

### 4:55 PM

**Characterization of {11-21} Twinning in  $\gamma$ -Ti:** *Leyun Wang*<sup>1</sup>; Rozaliya Barabash<sup>2</sup>; Yiyi Yang<sup>1</sup>; Thomas Bieler<sup>1</sup>; Martin Crimp<sup>1</sup>; Philip Eisenlohr<sup>3</sup>; Wenjun Liu<sup>4</sup>; Gene Ice<sup>2</sup>; <sup>1</sup>Michigan State University; <sup>2</sup>Oak Ridge National Laboratory; <sup>3</sup>Max-Planck-Institut für Eisenforschung GmbH; <sup>4</sup>Argonne National Laboratory

Activity of two tensile twinning systems, {10-12}<-1011>(T1) and {11-21}<-1-126>(T2), is observed in textured polycrystalline  $\gamma$ -Ti deformed by four-point bending. This work focuses on the relatively rare and less studied T2 twins. Owing to its large shear strain, T2 twins are often accompanied by accommodating T1 twins, surface ledges and in some cases, microcracks at grain boundaries. Using high resolution electron backscattering diffraction (EBSD), significant orientation gradients were observed in some T2 twins that were only several microns thick. The subsurface geometry of one T2 twin was examined by 3D X-ray diffraction. Streaking of Laue peaks indicates the presence of geometrically necessary dislocations (GNDs) in both the twin and the parent grain. Analysis of GND presence is used to identify a possible twin nucleation and propagation mechanism. This work is supported by NSF grant DMR-0710570 and DFG grant EI681/2-1.

## Dynamic Behavior of Materials V: Dynamic Behavior of Reactive Materials

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee

Program Organizers: Marc Meyers, UCSD; Naresh Thadhani, Georgia Institute of Technology; George Gray, Los Alamos National Laboratory

Monday PM Room: 5A  
February 28, 2011 Location: San Diego Conv. Ctr

Session Chair: Naresh Thadhani, Georgia Institute of Technology

### 2:00 PM Invited

**Behavior of Laminate Reactive Materials under Dynamic Loading**  
Conditions: Timothy Weihs<sup>1</sup>; Adam Stover<sup>1</sup>; David Lunking<sup>1</sup>; Jason Jouet<sup>2</sup>; Naresh Thadhani<sup>3</sup>; S Wu<sup>3</sup>; Kenneth Vecchio<sup>4</sup>; F Jiang<sup>4</sup>; Richard Lee<sup>2</sup>; <sup>1</sup>Johns Hopkins University; <sup>2</sup>Naval Surface Warfare Center; <sup>3</sup>Georgia Institute of Technology; <sup>4</sup>UC San Diego

Reactive materials are typically designed to produce rapid bursts of heat and light upon initiation of an exothermic reaction such as the formation of an intermetallic compound. The development of layered reactive materials offers the exciting opportunity to control the ignition threshold and propagation rates for these reactions. It also provides an ideal geometry, with uniform and consistent reactant spacing, for modeling material behavior. This presentation reviews results of dynamic studies of exothermic formation reactions in dense compacts of reactive laminate particles and it focuses on 3 separate dynamic impact studies performed using the same materials. This combination of studies provides information on ignition thresholds, pressure rises, degree of reaction and oxidation, and sample fragmentation following impact. Rapid thermal studies will also be reviewed to help explain the results of the dynamic impact experiments.

### 2:30 PM

**Dynamic Pressure Sensing during Rapid Combustion of Metal Powders in Bomb Calorimetry:** Adam Stover<sup>1</sup>; Nicholas Krywopusk<sup>1</sup>; David Lunking<sup>1</sup>; Timothy Weihs<sup>1</sup>; <sup>1</sup>The Johns Hopkins University

Reactive materials show promise for increasing the energy content of future weapon systems and many of these new materials rely on rapid and complete combustion of metal particles. However, many desirable metallic fuels such as aluminum, zirconium or titanium have potential drawbacks such as a high ignition temperatures or low stabilities. Bomb calorimetry coupled with dynamic pressure sensing is utilized to compare these metallic fuels to each other in various oxygen rich atmospheres to determine which produces the largest energy release and hence the largest pressure rise upon ignition. We will present results describing the ignition thresholds for each metallic fuel, the effects of average particle size and alloying on oxidation rates, and the use of reactive laminate particles to drive oxidation of the fuel particles in loose and dense compacts. In future applications the reactive laminate particles may serve as ignition sources for these fuels under dynamic loading conditions.

### 2:45 PM

**Fabrication and Properties of Hot Explosive Consolidation of Ni-Al Composites:** Laszlo Kecskes<sup>1</sup>; Akaki Peikrishvili<sup>2</sup>; Elguja Chagelishvili<sup>2</sup>; Zhiliang Pan<sup>3</sup>; Weihua Lin<sup>3</sup>; Qiuming Wei<sup>3</sup>; <sup>1</sup>US Army Research Laboratory; <sup>2</sup>Tsulukidze Institute of Mining and Technology; <sup>3</sup>University of North Carolina Charlotte

Clad and mechanical blends of Ni-Al powders were formed into cylindrical rods using a hot explosive consolidation process (HEC). A multi-stage loading of explosive consolidation was applied to fabricate highly dense billets having correct cylindrical geometry to form mostly Ni and Al with some intermetallic phases. The consolidation temperature was varied from ambient temperature up to 900°C; the shock loading intensity was as high as

10 GPa. The combination of high temperatures and explosive compression was beneficial to the consolidation of the both type of Ni-Al compositions, resulting in near theoretical densities and high hardness values. Right circular cylinders were cut from the HEC billets and were compressed at quasi-static and dynamic strain rates. Results show that there is a significant difference in the mechanical response of the Ni-Al specimens that were made from powder blends and those made from the Ni-coated Al particles. The results will be discussed.

### 3:00 PM

**Investigating Reaction Mechanisms in Ni+Al Configurations Using Laser-Accelerated Thin Foil Impact:** Sean Kelly<sup>1</sup>; Naresh Thadhani<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology

The reaction mechanisms in various Ni+Al binary metal configurations are being investigated using laser-accelerated thin foil set-up. Dynamic deformation (such as in an impact event) can allow rapid mixing of the components and lead to chemical reaction and release of energy in the form of heat, even with little or no porosity. Reaction mechanisms in these material systems must be characterized as a function of reactant configuration in order to control the initiation and the extent of reaction at various temporal and spatial scales. Experiments conducted using laser-accelerated thin foil impact of various Ni+Al configurations have been performed at a range of loading conditions to determine the process of deformation, flow, and mixing occurring up to the point of complete reaction. The results based on time-resolved interferometry measurements and microstructural characterization of recovered materials are used to isolate the reaction mechanisms for the various Ni+Al configurations.

### 3:15 PM

**Mesoscale Modeling of the Deconsolidative Burning in Polymer-Bonded Explosives:** H.Keo Springer<sup>1</sup>; <sup>1</sup>Lawrence Livermore National Lab

Polymer-bonded explosives (PBXs) can transition from conductive burning to more violent deconsolidative burning and subsequently detonate under heavy confinement. Previous studies have demonstrated that relatively more brittle PBXs with lower binder content have an increased propensity for deconsolidative burning. The initial stage of deconsolidative burning is characterized by the pressure-dependent infiltration of cracks and pores by product gases at the burn-front. However, the mechanism underlying the formation of this damage in (initially) intact PBX is poorly understood. The objective of this study is to use mesoscale simulations to investigate the role of energetic volume fraction and burn rate characteristics, as well as damage and fracture properties, on deconsolidative burning. The key metric of deconsolidative burning in these studies is the formation of damage at the burn-front. These modeling studies are important because they can enable the design of PBXs that do not escalate to violent burning modes.

### 3:30 PM Break

**Wave Propagation and Instabilities in "Soft" Heterogeneous Materials:** Vitali Nesterenko<sup>1</sup>; <sup>1</sup>University of California, San Diego

The wave propagation and dynamic behavior of "soft" heterogeneous materials (granular, granular composites, laminates composed from granular layers, forest of carbon nanotubes) in a broad range of impact conditions and types of deformation (shock, shear) will be discussed. The current interest on these materials is due to their efficiency as mitigators of blast/impact loading. These materials also combine high compressive strength with the ability to bulk distribute fracture resulting in a small size reactive fragments and even possible reaction on later stages of dynamic deformation. The behavior of granular metamaterials (with specially assembled mesostructure, e.g., random and periodic one or two mass low dimensional structures) under plane shock loading will be analyzed. Energy absorption and inertia based dispersive properties of these materials, crucial for intense stress wave mitigation, will be addressed. The support for this project provided by ONR MURI N00014-07-1-0740 (Program Officer Dr. Clifford Bedford).

4:20 PM

**Quasi-Static and Dynamic Response of Explosively Consolidated Reactive Mixtures:** *Chung-Ting Wei*<sup>1</sup>; Vitali Efrem<sup>2</sup>; Fengchun Jiang<sup>1</sup>; David Benson<sup>1</sup>; Kenneth Vecchio<sup>1</sup>; Naresh Thadhani<sup>3</sup>; Marc Meyers<sup>1</sup>; <sup>1</sup>University of California, San Diego; <sup>2</sup>Lawrence Livermore National Lab; <sup>3</sup>Georgia Institute of Technology

Five different nearly fully dense (> 95% TMD) reactive mixtures, Nb+Al, Ni+Al, Mo+Al, W+Al, Ta+Al, were produced by using double tube explosive shock consolidation. It is found that the elastic modulus of the compacts are not fully consistent with the theoretical predictions due to the soft matrix material (aluminum), imperfections of the compacts, and the different morphologies of the inclusions. The quasi-static behaviors are interpreted using Orowan and force chain mechanism and found that the differences of mechanical properties of the inclusions are not determinants. The dynamically mechanical and fracture behaviors are investigated using the split Hopkinson pressure bar, the high-speed camera (Phantom v12), and the simulation tool "RAVEN". It is found that the geometric properties of inclusions significantly influence the dynamic properties of the compacts. By conducting experimental and computational studies, it helps us understand the utmost importance of material factors to the explosively consolidated reactive mixtures.

4:35 PM

**The Role of Plastic Deformation in Initiating Intermetallic Formation Reactions:** *Brady Aydelotte*<sup>1</sup>; Naresh Thadhani<sup>1</sup>; <sup>1</sup>Georgia Tech

Rod-on-anvil experiments are conducted on uniaxially pressed and explosively compacted nickel+aluminum and tantalum+aluminum systems. The reactivity of these systems is compared and contrasted. Mesoscale simulations are conducted on real material microstructures to explore the role of plastic deformation in reaction initiation.

4:50 PM

**Numerical Modeling of Dynamic Deformation of Al/W Granular Composites:** *Karl Olney*<sup>1</sup>; Sophia Wang<sup>1</sup>; David Benson<sup>1</sup>; Vitali Nesterenko<sup>1</sup>; <sup>1</sup>UCSD

Aluminum/Tungsten granular composites are materials which combine high density and strength with bulk distributed fracture under impact or shock loading. They are processed using cold and hot isostatic pressing of W particles/rods in the matrix of Al powder. The presentation will describe modeling of these materials on the stage of cold isostatic pressing and under quasistatic and dynamic conditions. It will be demonstrated that morphology of W component and bonding between Al particles dramatically affects their strength and mode of fracture of Al matrix similar to observed in experiments. Funding was provided from the Grant: ONR MURI N00014-07-1-0740.

5:05 PM

**Investigation of Al-Metal Reactions Induced by High-Rate Mechanical Loading:** *Eric Herbold*<sup>1</sup>; Jennifer Jordan<sup>2</sup>; Naresh Thadhani<sup>1</sup>; <sup>1</sup>Georgia Tech; <sup>2</sup>AFRL

The reaction/combustion characteristics of compressed Al-metal powder combinations are presented in a modified rod-on-anvil Taylor impact-test set-up. The reaction threshold conditions for initiation of chemical reaction of these materials are discussed in terms of a critical energy and dynamic deformation requirement. These requirements depend on the pellet density, ratio and material properties of constituents, and level of pre-conditioning of the powders by ball-milling, which are shown to affect the sensitivity of the powders.

5:20 PM

**Processing and Dynamic Testing of Al/W Granular Composites:** *Po-Hsun Chiu*<sup>1</sup>; Vitali Nesterenko<sup>1</sup>; <sup>1</sup>UCSD

High density Al-W granular composites with an identical weight ratio between Al and W and with different porosities, size, shape and orientation of W component were investigated at strain rate 1000 1/s. Samples were fabricated by Cold Isostatic Pressing and also with subsequent Hot Isostatic Pressing. Size of particles and morphology of W inclusions had a strong effect on dynamic strength. Samples with W wires arranged in axial direction

(diameter 100 microns) had a highest dynamic strength and exhibited bulk distributed fragmentation of Al matrix. The support for this project provided by the Office of Naval Research Multidisciplinary University Research Initiative Award N00014-07-1-0740 (Program Officer Dr. Clifford Bedford).

5:35 PM

**Meso-Scale Simulations of Epoxy-Based Reactive Materials at High Strain-Rates:** *Bradley White*<sup>1</sup>; H. Keo Springer<sup>2</sup>; Jonathan Spowart<sup>3</sup>; Jennifer Jordan<sup>4</sup>; Naresh Thadhani<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology; <sup>2</sup>Lawrence Livermore National Laboratory; <sup>3</sup>AFRL/RXLMD; <sup>4</sup>AFRL/RWME

Particle reinforced polymer composites are increasingly being studied for use as structural energetic materials. This requires a greater understanding of the mechanisms of high strain-rate particle deformation and mixing, which influences chemical reactions occurring in reactive materials. To determine the effect that each composite constituent has on the bulk and particle level mechanical behavior at high strain-rates, meso-scale simulations were conducted on epoxy reinforced with nickel and aluminum particles. The composite was subjected to compressive strain-rates of  $10^3$ – $10^4$  /s. The constituent phases were then examined to determine the effects that highly contrasting material properties have on the stress transfer and deformation response of the particles. Preliminary results show that the stress-strain response of epoxy is highly influenced by the presence of particles and consequently its effect on the mechanical behavior of the particles. In this presentation results from simulations and experiments will be presented, including representative microstructures from each.

2:00 PM **Introductory Comments**

2:05 PM

**Determination of Coke Calcination Level and Anode Baking Level – Application and Reproducibility of  $L_c$  Based Methods:** *Stein Rørvik*<sup>1</sup>; Lorentz Petter Lossius<sup>2</sup>; Arne Petter Ratvik<sup>3</sup>; <sup>1</sup>SINTEF Materials & Chemistry; <sup>2</sup>Hydro Primary Metal Technology; <sup>3</sup>Norwegian University of Science and Technology (NTNU)

The average crystallite size ( $L_c$ ) is an important property of carbon materials for aluminium electrolysis;  $L_c$  is used for characterizing the petroleum coke calcination level, and sometimes also to estimate the baking level of anodes. The paper discusses problems when comparing  $L_c$  results from different laboratories with examples from round robins. The main cause are peak broadening errors introduced by the XRD instrument and sample preparation. The  $L_c$  standards ISO 20203 and ASTM 5197 neglect these errors, and two ways are demonstrated to minimize the effect and improve the standards, 1) by using thin sample thickness and 2) by embedding the coke in a high absorptive medium. Additionally ISO 17499, the equivalent baking level method for anodes is discussed and compared to  $L_c$  measurement for anode baking level. The equivalent baking level method completely bypass the peak broadening problem and is suited for baking level comparisons between anode plants.

2:30 PM

**Operation of an Open Type Anode Baking Furnace with a Temporary Crossover:** *Esteban Cobo*<sup>1</sup>; Luis Beltramino<sup>1</sup>; Juan Artola<sup>1</sup>; Jorge Rey Boero<sup>1</sup>; Pierre-Jean Roy<sup>2</sup>; Jean Bigot<sup>2</sup>; <sup>1</sup>Aluar Aluminio Argentino; <sup>2</sup>Rio Tinto Alcan

As part of the Puerto Madryn smelter expansion project, Aluar Aluminio Argentino has built and now operates an open type furnace designed with Rio Tinto Alcan AP Technology™. The furnace was built and started in two stages, each of them with 34 sections and 2 fires. In order to allow the construction of the second stage and the connection between both halves of the furnace, a method was used that had prior success on other projects with a temporary crossover to connect two sections at the extremity of the first stage. This paper describes the experience gained while operating in this mode and the procedural and process control modifications that were necessary to maintain quality anode baking. Footnote: AP Technology™ is a trademark of Aluminium Pechiney.

2:55 PM

**Recent Developments in Anode Baking Furnace Design:** Dagoberto Severo<sup>1</sup>; Vanderlei Gusberti<sup>1</sup>; Peter Sulger<sup>2</sup>; Felix Keller<sup>2</sup>; *Markus Meier*<sup>2</sup>; <sup>1</sup>CAETE Engenharia Ltda.; <sup>2</sup>R&D Carbon Ltd.

Today, furnace design still proceeds mainly by extrapolation from existing furnaces. Investigating existing furnaces shows the dangers of underestimating the impact of apparently small modifications: e.g., larger pits to accommodate higher anodes can result in furnaces with substandard performance. Side effects such as soot creation have then to be accepted. This paper presents an approach to bake furnace design which completely eliminates extrapolation from existing furnaces. The same approach can be used to estimate the optimization potential for existing furnaces.

3:20 PM

**Sohar Aluminium's Anode Baking Furnace Operation:** *Said Al Hosni*<sup>1</sup>; Jim Chandler<sup>1</sup>; Olivier Forato<sup>1</sup>; François Morales<sup>2</sup>; Christian Jonville<sup>2</sup>; Jean Bigot<sup>2</sup>; <sup>1</sup>Sohar Aluminium; <sup>2</sup>Rio Tinto Alcan

The Sohar Aluminium anode baking furnace was commissioned in 2008 and the furnace performance since has excellent in terms of gas consumption, baking level, fire productivity and firing cycle range. With 10 fluewalls per section, the furnace has productivity levels of 70 kt per fire. Gas consumption of less 1.9 GJ/t for a baking level (Lc) of greater than 33 angstrom has been maintained. Operation has been demonstrated across a fire cycle range from 24 to 36 hours. Refractory condition is excellent and first generation refractory life is likely to be > 175 fire cycles due to a thorough maintenance program and a very low anode sodium concentration of less than 150 ppm. These results have been achieved through a combination of design, process control and operation which places it amongst the benchmark operations of its type today. Some of the challenges in achieving these results are discussed.

3:45 PM Break

3:55 PM

**Meeting the Challenge of Increasing Anode Baking Furnace Productivity:** *François Ordronneau*<sup>1</sup>; Magali Gendre<sup>1</sup>; Luc Pomerleau<sup>1</sup>; Nigel Backhouse<sup>1</sup>; Adam Berkovich<sup>1</sup>; Xin Huang<sup>1</sup>; <sup>1</sup>Rio Tinto Alcan

The need to support amperage creep in smelters requires an increase in anode baking furnace productivity. The furnace operation must be adapted to provide more anodes while maintaining adequate baking performance, minimizing energy consumption and assuring anode quality. To do so, the essential factors to optimize include the firing strategy to ensure the appropriate baking level for a given fire cycle, fuel combustion efficiency and adequate cooling capability even at accelerated fire cycles and high ambient temperatures. Through the operation of 28 baking furnaces of differing technologies, tools have been developed to support this process. Simulations of firing and baking as a function of the fire cycle and key furnace design parameters such as anode size, pit width and flue design; injector combustion efficiency and cooling capability are now routinely

used. Industrial examples are shown from a number of sites using varying technology that demonstrate the gains achieved.

4:20 PM

**Wireless Communication for Secured Firing and Control Systems of Anode Baking Furnaces:** *Nicolas Fiot*<sup>1</sup>; Christian Coulaud<sup>1</sup>; <sup>1</sup>SOLIOS CARBONE

Anode baking requires firing and control systems which move every day as the fire progresses around the furnace. Wired connections between the moving equipment and the central control unit have always been an operation and maintenance concern. Wireless networks have become the modern solution with standard PLCs. However, modern furnace control requires new safety loops between the firing equipment. Wireless communication has encountered numerous drawbacks when used for secured control of the furnace via a safe communication between safety PLC's due to the nature of the safety communication protocol and interference with other wifi systems in the baking furnace area. Extensive development work has been completed with major PLC suppliers to find the right combination of modems and antenna and to fine tune the PLC's and wifi systems so that operational performance and safety requirements are fully met. Wifi is now available for the secured baking of anodes.

4:45 PM

**Full Control of Pitch Burn during Baking: It's Impact on Anode Quality, Operational Safety, Maintenance and Operational Costs:** *Detlef Maiwald*<sup>1</sup>; Domenico Di Lisa<sup>1</sup>; Peter Mnikoleiski<sup>1</sup>; <sup>1</sup>Innovatherm

Due to the physical design of the open top ring furnace the pitch burn development is not homogeneous in the individual flues of a section. As a primary result, the consistency of the anode quality will be affected. Secondary, other disadvantages will occur as well as there are unburned pitch fractions which are condensing downstream in the furnace and filter ducts, increase of emissions, higher operational costs, negatively impact on operational safety and a higher fuel consumption. The physics of the occurrence of the pitch burn is quite complex. Once the pitch burn process is started it behaves exothermal and is hard to control. This paper will describe the different control strategies which have been developed to gain full control of the pitch burn, and will show the results as remarkable improvements on anode quality, emissions, fuel consumption and running costs.

5:10 PM

**High Performance Sealing for Anode Baking Furnaces:** Pierre Mahieu<sup>1</sup>; Sébastien Neple<sup>1</sup>; Nicolas Fiot<sup>1</sup>; Ismael Ofico<sup>2</sup>; Manuel Eufrazio<sup>2</sup>; <sup>1</sup>Solios Carbone; <sup>2</sup>Mozaal

Anode baking requires important volumes of air and fumes for combustion and thermal exchange. Efficient refractory port sealing is an important condition required to reach rated flows inside flue walls. This function, apparently simple, has been facing many problems with conventional sealing techniques which can lead to process inefficiency and degraded operating conditions. A reliable and proven technology has been developed to enhance this sealing function: it is based on the use of advanced materials that combine flexibility, resistance to the extreme conditions in the furnace and offers a new potential of process improvement in anode baking furnaces. This patented system held between two rigid plates and surrounding the inner refractory port reduces drastically the incursion of cold air into the fume exhaust ramp. The most favorable outcomes of this technology are the limited condensation of exhausted fumes and increased furnace thermal efficiency.

#### Effects of Materials Strength on Very-High-Cycle Fatigue Behavior for Low Alloy Steels: *Youshi Hong*<sup>1</sup>; Aiguo Zhao<sup>1</sup>; <sup>1</sup>Institute of Mechanics, Chinese Academy of Sciences

The researches on the behavior of very-high-cycle fatigue (VHCF) for low alloy steels have become a new branch in the field of metal fatigue since 1980s. The behavior of VHCF for low alloy steels is evidently dominated by the strength level (yield strength and ultimate strength), which is dependent on the composition and the microstructure of the steel. The first part of this paper is a short review, summarizing a large number of experimental data from literature, and the second part is our experimental investigation on the VHCF behavior of a low alloy steel with four kinds of strength levels. All of these attempt to show the effects of materials strength on VHCF behavior for low alloy steels, including the effects on fatigue limit, on the difference of fatigue strength, on crack origination and on S-N curve characteristics.

### 2:20 PM

#### Effect of Porosity on the Mechanical and High Cycle Fatigue Behavior of Casting AM60B Magnesium Alloy: *Kee-Ahn Lee*<sup>1</sup>; Kyu-Sik Kim<sup>2</sup>; Jung-Cheol Park<sup>3</sup>; Chang-Dong Im<sup>4</sup>; <sup>1</sup>Andong National University; <sup>2</sup>Hanyang University; <sup>3</sup>RIST; <sup>4</sup>KIMM

The effect of casting defects on the high cycle fatigue behavior of magnesium alloy was investigated. Two AM60B magnesium alloys were manufactured by high pressure die casting with different processing parameters such as die morphology, melt and die temperature. One of AM60B alloys with relatively high porosity was called Alloy A(4.06%) and the other was called Alloy B(0.07%). Microstructures of both Alloy A and B were composed of primary dendrite a-Mg, Al rich a-Mg and Mg<sub>17</sub>Al<sub>12</sub> phases. Tensile properties of both alloys were showed that Alloy B had superior tensile, yield strength and elongation. Alloy A had significantly lower fatigue life than that of Alloy B. From the observation of the differences in porosities and fractography of two AM60B magnesium alloys, an attempt to explain the high cycle fatigue fracture behavior of casted magnesium alloys was made by using stress concentration factor  $K_{max}$ . [supported by "the program for Materials Bank", Korea]

### 2:40 PM

#### The Effect of Precipitate State on the Cyclic Deformation Behaviour of Al Alloys: Experiments and Modelling: Weizhong Han<sup>1</sup>; Alexei Vinogradov<sup>2</sup>; Christopher Hutchinson<sup>1</sup>; <sup>1</sup>Monash University; <sup>2</sup>Osaka City University

Fatigue deformation involves the repeated moving backwards and forwards of dislocations. A degree of irreversibility is inherent in the dislocation motion and it is generally thought that the greater the degree of reversibility, the better the fatigue properties of the material. A measure of the reversibility of deformation can be calculated from the shape change of the hysteresis loop during cyclic loading. In this work, the evolution of the hysteresis loop shape as a function of precipitate state and plastic strain amplitude has been studied at room temperature in a model Al-4Cu alloy containing shear-resistant theta prime precipitates only. An expression for

the slip reversibility is derived that explicitly includes the characteristics of the precipitate distribution. Coupling the expression for the slip reversibility to an expression for the strengthening response is shown to describe well the evolution of hysteresis loop shape with both microstructural changes and plastic strain amplitude.

### 3:00 PM Invited

#### Effect of Microstructure on Fatigue Behavior of Two Pipeline Steels: *Gongyao Wang*<sup>1</sup>; Muralidharan Govindarajan<sup>2</sup>; Douglas Stalheim<sup>3</sup>; Peter Liaw<sup>1</sup>; <sup>1</sup>University of Tennessee; <sup>2</sup>Oak Ridge National Laboratory; <sup>3</sup>DGS Metallurgical Solutions, Inc

In recent years, significant advances have been made in the microstructural design and inclusion control of advanced pipeline steels. A range of microstructures containing various amounts of polygonal ferrite, pearlite, bainite, and acicular ferrite can be achieved in pipeline steels with comparable tensile properties. Thus, there is a need to understand the effect of the presence/absence of these microstructural constituents on the fatigue and fracture behavior of these pipeline steels. In the current investigation, fatigue crack growth behavior in air and inert atmosphere of two X70/X80 grade pipeline steels with a mixture of polygonal ferrite/acicular ferrite microstructures has been evaluated. The effect of microstructures on the fatigue properties are compared and discussed. This work was funded by the US Department of Transportation Federal Aviation, under Grant No. USDOT-DTPH56-10-T-000001, with Dr. J. Merritt as contract monitor and by the Department of Energy, Office of Hydrogen, Fuel Cells and Infrastructure Technologies

### 3:20 PM

#### Fatigue and Fracture Performance of 500MPa Grade High Strength Bridge Steel: *Huaxin Hou*<sup>1</sup>; *Chengjia Shang*<sup>2</sup>; *Yuling Zhang*<sup>3</sup>; <sup>1</sup>Ansteel Company; <sup>2</sup>University of Science and Technology Beijing; <sup>3</sup>Institute of Railway Science and Technology

High strength bridge steel has a lot of advantages, not only with high strength, good toughness and weldability, but also with anti-weather resistance property. These years, a kind of low carbon low alloy steel is developing for bridge building. With the development of rail road and highway, tow long span bridges were built over Yangtze river with 420MPa grade low carbon bainitic steels. The thickness of plate has reached 80mm. Meanwhile, much higher strength bridge steel (yield strength 500MPa) is developing. In this paper, the performance such as fatigue, fracture, wide plate tensile properties of 500MPa grade plate steel and welding conjunction were invested. Moreover, a full size girder was also tested to invest the mechanical parameters of plastic deformation during loading.

### 3:40 PM Break

### 3:50 PM

#### Study the High-Cycle-Fatigue Behavior of a Nano-Precipitate Strengthened Alloy by In-Situ Neutron-Diffraction Experiments: *E-Wen Huang*<sup>1</sup>; Michael Hofmann<sup>2</sup>; Saurabh Kabra<sup>3</sup>; Sven Vogel<sup>4</sup>; Peter Liaw<sup>5</sup>; <sup>1</sup>National Central University; <sup>2</sup>Forschungsneutronenquelle Heinz Maier-Leibnitz (FRM II); <sup>3</sup>Australian Nuclear Science and Technology Organisation; <sup>4</sup>Los Alamos National Laboratory; <sup>5</sup>University of Tennessee

A tension-tension high-cycle-fatigue experiment was investigated to resolve the structural evolution of a nano-precipitate-strengthened alloy. A tension loading-unloading test was studied for comparison. Applying the in-situ neutron-diffraction experiments, the ensemble-averaged-diffraction results incorporating with the macroscopic stress-strain curves yield the deformation mechanisms of the alloy. In comparison with the fracture surfaces, the different deformation mechanisms of the alloy subjected to two types of loadings have been characterized by the evolution of the lattice-strain and peak-profile evolution. A complementary texture investigation was used to gauge its validity.

### 4:10 PM Invited

**Fatigue Crack Tip Mechanics Following a Tensile Overload:** *Soo Yeol Lee*<sup>1</sup>; Peter K. Liaw<sup>2</sup>; Hahn Choo<sup>2</sup>; Ronald B. Rogge<sup>3</sup>; Ke An<sup>4</sup>; Camden R. Hubbard<sup>4</sup>; <sup>1</sup>The University of British Columbia; <sup>2</sup>The University of Tennessee; <sup>3</sup>National Research Council Canada; <sup>4</sup>Oak Ridge National Laboratory

The improvement in lifetime of numerous engineering components exposed to fatigue is highly dependent on the accurate understanding of fundamental principles of the failure mechanism. One aspect that is still not completely understood is the overload-retardation micromechanism and crack-closure behavior in structural materials subjected to fatigue. Here we report in-situ neutron diffraction and electric potential investigations that allow us to observe the crack opening/closing processes and associated internal-stress distributions around the crack tip during real-time fatigue crack propagation following a tensile overload. The results provide insights into (i) the crack-tip deformation and fracture behaviors under applied loads, (ii) the overload-induced transient crack growth micromechanism, (iii) the applicability of the effective stress intensity factor range as the fatigue crack tip driving force, and (iv) the quantitative relationship between the crack tip driving force and crack growth behavior.

### 4:30 PM

**A Modified LEFM Approach for the Prediction of the Notch Effect in Fatigue:** *Masahiro Endo*<sup>1</sup>; Keiji Yanase<sup>1</sup>; Satoshi Ikeda<sup>2</sup>; Arthur McEvily<sup>3</sup>; <sup>1</sup>Fukuoka University; <sup>2</sup>Kawasaki Heavy industries, Ltd.; <sup>3</sup>University of Connecticut

Engineered designs usually contain stress-raising details such as holes, fillet, grooves and keyways which are known to have a deleterious effect on the fatigue limit and fatigue lifetimes because of the growth of fatigue cracks emanating from these details. A recent paper has dealt with the behavior of small cracks emanating from one type of stress-raiser, namely holes. In that paper, a modified LEFM approach was used and it involved consideration of elastic-plastic behavior, the Kitagawa effect, and the development of crack closure in the wake of a newly formed crack. The present paper extends this approach to deal with notches of elliptical shape. The proposed approach is validated by comparing predicted and experimental results.

### 4:50 PM

**Resistivity Based Evaluation of the Fatigue Behaviour of Cast Iron:** *Holger Germann*<sup>1</sup>; Peter Starke<sup>1</sup>; *Dietmar Eifler*<sup>1</sup>; <sup>1</sup>University of Kaiserslautern

Cast irons are used in particular for highly stressed components in the automotive and commercial vehicle industry, e.g. for crankcases and in the wind power industry, e.g. for rotor hubs. The microstructure of cast irons and consequently their mechanical properties are strongly influenced by graphite shape, micro-shrinkage cavities, micro-pinholes, micro-cracks etc. The measurement of the electrical resistance in the virgin state and its change during fatigue loading offers the possibility to get detailed information about the actual defect density and the cyclic deformation behaviour. In the scope of the present research work stress-controlled load increase tests and constant amplitude tests were carried out at ambient temperature with specimens of the perlitic cast irons EN-GJL-250 (ASTM A48 35B), EN-GJS-600 (ASTM 80-55-06) and EN-GJV-400. Beside electrical measurements scanning electron microscopy (SEM) was used to characterize the microstructure and to correlate microstructural details with cyclic properties.

### 5:10 PM

**Microstructure-Sensitive Probabilistic Fatigue Modeling of Notched Components:** *William Musinski*<sup>1</sup>; David McDowell<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology

Microstructure-sensitive, simulation-based strategies for modeling fatigue life reduction in cyclically loaded notched components offer a means to augment costly experiments and facilitate consideration of microstructures not yet processed. Using computational polycrystal plasticity and probabilistic arguments, a strategy is presented that links notch root microstructure heterogeneity to scatter in fatigue response and notch size effects. The notch root stress gradient field, grain size distribution, and

defect distribution (pores, nonmetallic inclusions) effects are considered for a polycrystalline PM processed Ni-base superalloy IN100. The probability of forming and propagating a crack from the grain scale to a transition crack length (LEFM applicable) is approximated using shear-based fatigue indicator parameters computed within the uncracked notched specimen. This model for crack formation and early growth is calibrated to existing smooth specimen experiments. Cumulative distribution functions and probabilistic strain life functions are constructed for various notch root radii and remote strain amplitudes.

### 5:30 PM

**Metallurgical Aspects of Stress Corrosion Cracking of X100 High-Strength Pipeline Steel:** *Frank Cheng*<sup>1</sup>; <sup>1</sup>University of Calgary

It is generally acknowledged that an elevated strength level of steels tends to decrease their resistance to stress corrosion cracking (SCC), particularly, hydrogen-induced SCC (HISCC). This work summarized the author's recent research in high-strength pipeline steel SCC phenomenon. The microstructure of X100 steel was characterized by scanning electron microscopy and energy-dispersive x-ray analysis, and various metallographic phases and inclusions were identified. Furthermore, micro-electrochemical measurement techniques and photo-electrochemical technique were combined to characterize the local activity of micro-defects, such as inclusions and grain boundaries, and the galvanic effect between the defect and the steel matrix. Micro-electrochemical measurements were also conducted on the X100 steel weld, where the typical microstructures and mechanical properties were introduced during welding. It is attempted to develop an essential insight into the effect of the welding metallurgy on local dissolution rate and the SCC susceptibility of X100 line pipe steel.

**Reliable Sealing of Copper Canisters through Cascaded Control of Power Input and Tool Temperature:** Lars Cederqvist<sup>1</sup>; Olof Garpinger<sup>2</sup>; Tore Haggglund<sup>3</sup>; Anders Robertsson<sup>3</sup>; <sup>1</sup>SKB/Lund University; <sup>2</sup>XDIN; <sup>3</sup>Lund University

The Swedish Nuclear Fuel and Waste Management Company (SKB) will join at least 12,000 lids and bottoms to the copper tubes containing Sweden's nuclear waste using friction stir welding (FSW). The paper shows how the 45 minute long weld cycle, with variable thermal boundary conditions, can be reliably controlled by an inner regulator loop controlling the power input and a slower outer regulator loop controlling the tool temperature. The results from recent, automatically controlled, welds are compared to those of early, manually controlled, welds. It is also shown how relatively small changes in the control strategy, depending on sequence in the weld cycle, can improve the overall performance and repeatability of the process. In addition to this, the controller is also compared to manual control when it comes to suppressing torque disturbances. The authors most definitely believe that the chosen, cascaded, controller structure can be successfully used in other applications in which the temperature signal reacts relatively slow to fast and distinct torque disturbances.

### 2:25 PM Invited

**Friction Stir Welding (FSW) of a Hardenable Alloy Steel in 'Dry' and 'Wet' Environments:** Norman Overfield<sup>1</sup>; Murray Mahoney<sup>2</sup>; Russell Steel<sup>3</sup>; Jon Babb<sup>3</sup>; Sarath Menon<sup>1</sup>; Terry McNelley<sup>1</sup>; <sup>1</sup>Naval Postgraduate School; <sup>2</sup>Consultant, Brigham Young University; <sup>3</sup>MegaStir Technologies

Recent advances in FSW tool material and design will facilitate numerous applications of this solid-state joining technology to steels. A single W-Re-CBN tool was used to conduct a series of bead-on-plate FSW traverses, approximately 1.5m in total length, on 6.3mm thick plates of a hardenable alloy steel. The first series of traverses involved various RPM/IPM combinations and a dry plate. A second series was carried out while a plate was immersed in water in order to assess potential for inducing hydrogen assisted cracking (HAC) during FSW of susceptible alloys. All traverses were defect-free. The FSW nuggets exhibited refined microstructures and increased hardness relative to the base plate. The influence of FSW parameters on nugget microstructure and mechanical properties will be summarized.

### 2:50 PM Invited

**Friction Stir Welding of Industrial Steels:** Jonathan Perrett<sup>1</sup>; Jonathan Martin<sup>1</sup>; Jeremy Peterson<sup>2</sup>; Russell Steel<sup>2</sup>; Scott Packer<sup>3</sup>; <sup>1</sup>TWI; <sup>2</sup>MegaStir Technologies; <sup>3</sup>Advanced Metal Products

Friction Stir Welding of steel has been in development for over a decade, but only in recent years have the strength and wear characteristics of tool materials improved extensively. Tool materials have been developed that have excellent high-temperature wear resistance, and consistently achieve weld lengths in excess of 50 meters in steel. These newly developed material characteristics comprise of a fine balance of high-temperature strength, hardness and ductility. Shipbuilding, bridge decking, pipe seam welding, or applications which require long uninterrupted steel welds, are now attractive

target markets for the friction stir process. It is the process's ability to create high-strength, low-distortion welds that make it potentially attractive to industry. This paper shows the results from welding and testing of five common industrial steels, as well tool wear profiles and demonstrative 6m length welds.

### 3:15 PM Invited

**Localized Mechanical Behavior Of Ti-5111 Friction Stir Welds:** Jennifer Wolk<sup>1</sup>; Marc Zupan<sup>2</sup>; Christopher Cheng<sup>2</sup>; <sup>1</sup>Naval Surface Warfare Center; <sup>2</sup>University of Maryland Baltimore County

Titanium (Ti) and titanium alloys have shown excellent mechanical, physical, and corrosion properties for marine applications. Friction stir welding (FSW) is being investigated as a possible joining alternative due to difficulties in conventional welding of Ti alloys. Due to the natural asymmetry of the FSW process, bulk mechanical properties may not be representative of the localized properties. This work focuses on direct measurement of the base metal, heat affected zone (HAZ), thermomechanically affected zone (TMAZ), and stir zone mechanical properties in friction stir welded Ti-5111. The localized mechanical properties are measured using micro scale tensile tests (~3 mm long by 1 mm wide with a cross-sectional gage section ~250  $\mu$ m square) extracted directly from the transverse cross-section of the weld. After testing, the mechanical response is correlated to the underlying material microstructure and texture for the different regions of the Ti-5111 friction stir weld.

### 3:40 PM

**Mechanical Properties of Thick Section Titanium 6Al-4V Friction Stir and Electron Beam Welds:** Paul Edwards<sup>1</sup>; Gary Coleman<sup>1</sup>; Marc Petersen<sup>1</sup>; <sup>1</sup>The Boeing Company

In this study, Friction Stir Welding of Ti-6Al-4V was developed in 1.0 inch thickness material. The microstructure and mechanical properties such as static, fatigue, fracture toughness and crack growth of these thick section Friction Stir Welds were evaluated and compared to Electron Beam Welds produced in the same thickness material. It was found that the Friction Stir Welds did possess a more wrought type structure than the Electron Beam Welds, leading to better ductility, fatigue life and fracture toughness. The solidified structure of the Electron Beam Welds resulted in higher strengths and showed slower crack growth rates. This screening data will allow design engineers to down select these processes, considering both cost and performance, for advanced aircraft structures.

### 4:00 PM

**Transformation and Deformation Texture Study in Friction Stir Processed API X80 Steel:** Majid Abbasi<sup>1</sup>; Tracy Nelson<sup>1</sup>; Carl Sorensen<sup>1</sup>; <sup>1</sup>Brigham Young University

The nature of deformation in FSW is very complex. This complexity becomes even more challenging when allotropic phase transformations are present. In this research, Electron Backscattered Diffraction is used as a means to reconstruct the prior austenite texture and grain structure. Considering the fact that the room temperature microstructure contains very little or no residual PA, the prior austenite microstructure was reconstructed from the room temperature ferrite utilizing transformation orientation relationships. Analysis shows that there is little evidence of shear deformation texture in the reconstructed PA, however; room temperature ferrite exhibits strong shear deformation texture components. This implies that extended plasticity mechanisms are occurring in prior austenite which weaken the shear deformation texture. The observed shear deformation texture in the room temperature microstructure implies that FSW imposes deformation during and after the phase transformation. The evolution of both elevated and room temperature textures in FSW HSLA steel will be presented.

##### **The Mechanisms of Microstructure Control and Homogenization in Multi-Pass Friction Stir Processing (FSP) of NiAl Bronze:** *Terry McNelley*<sup>1</sup>; *Sarath Menon*<sup>1</sup>; *Carolyn England*<sup>1</sup>; <sup>1</sup>Naval Postgraduate School

Multi-pass FSP of cast NiAl bronze provides a refined, homogeneous and isotropic surface layer in which both strength and ductility are doubled, relative to the as-cast condition. For large marine components this technology improves performance and reduces costs. The as-cast microstructure comprises primary and eutectoid constituents. The stir zone (SZ) microstructures reflect rapid transients and steep gradients in strain, strain rate and temperature. Field-emission scanning electron microscopy (FE-SEM) methods, including orientation imaging microscopy (OIM) have been applied to the evolution of thermomechanically affected zone (TMAZ) and SZ microstructures during single- and multi-pass FSP. A duplex  $\alpha$ (fcc)/ $\beta$ (bcc) microstructure develops in the TMAZ ahead of the tool and compatible deformation of these two phases enables estimation of strains and temperatures in this region. The development of the refined SZ microstructure in association with fragmentation of the duplex structure will be described.

#### 4:55 PM

##### **Wear Testing of Friction Stir Spot Welding Tools and Evaluation of Weld Performance as a Function of Tool Condition:** *Chris Ridges*<sup>1</sup>; *Michael Miles*<sup>1</sup>; *Yuri Hovanski*<sup>2</sup>; *Russell Steel*<sup>1</sup>; <sup>1</sup>BYU; <sup>2</sup>Pacific Northwest National Lab; <sup>3</sup>Megastir Technologies

Friction stir spot welding has been shown to be a viable method of joining ultra high strength steel, both in terms of joint strength and process cycle time. However, the cost of tooling must be reasonable in order for this method to be adopted as an industrial process. Several tooling materials have been evaluated in prior studies, including silicon nitride and polycrystalline cubic boron nitride (PCBN). Recently a new tool alloy has been evaluated, where a blend of PCBN and tungsten rhenium (W-Re) was used in order to improve toughness while maintaining an acceptable level of hardness and wear resistance. Wear testing and weld strength results will be presented for a PCBN tool as well as for tools that contain a blend of PCBN and W-Re, in the proportions of 60% PCBN, 70% PCBN, and 80% PCBN, where the balance in each case is W-Re.

#### 5:15 PM

##### **Tungsten Based Tool Material Development for the Friction Stir Welding of Hard Metals:** *Brian Thompson*<sup>1</sup>; <sup>1</sup>EWI

The Friction Stir Welding (FSW) of hard metals such as steel and titanium requires unique tool materials capable of achieving long linear lengths while minimizing tool degradation. W-based materials have demonstrated success as a FSW tool in resisting degradation while maximizing tool life. This presentation will review the development of current and future W-based tool materials for the FSW of hard metals. Results from the characterization of tool material microstructures identifying tool degradation mechanisms will be presented along with the evaluation of cutting edge tool materials for their performance in X-70 High Strength Steel and Titanium 6-4. In addition, resulting weld mechanical properties from these welds with corresponding stir zone microstructural characterization will be presented. This on-going work has resulted in a greater understanding of W-based tool materials and the development of improved W-based tool material compositions capable of achieving tool life in the hundreds of feet.

#### 5:35 PM

##### **Improving Heat-Affected Zone Liquefaction Cracking Resistance of Nickel-Base Alloys by Friction Stir Processing:** *James Rule*<sup>1</sup>; *Jeffrey Rodelas*<sup>1</sup>; *John Lippold*<sup>1</sup>; <sup>1</sup>Welding and Joining Metallurgy Group, The Ohio State University

Friction stir processing (FSP) was evaluated as a means to reduce the susceptibility of two solid-solution strengthened Ni-Base alloys, Alloy 625 and Hastelloy X, and a Ni-Base superalloy, Inconel 718, to heat-affected zone (HAZ) liquefaction cracking. FSP of the base metal resulted in

severe reduction in grain size (average grain diameter of less than 10 $\mu$ m). These grains contained highly tortuous grain boundaries with a very fine distribution of second phases. Cracking resistance was evaluated using the spot-varestraint test. Testing showed a reduction in cracking susceptibility relative to the baseline due to the reduction in HAZ grain size. Optical microscopy evaluation revealed that HAZ liquefaction cracking resistance is enhanced due to a higher density of grain boundaries resulting in finer, more discontinuous networks of low melting eutectic and second phases.

#### 5:55 PM

##### **Using Electron Backscatter Diffraction to Characterize the Texture and Microstructure of Friction Stir Welded AISI 304L Stainless Steel:** *Benjamin Nelson*<sup>1</sup>; *Carl Sorensen*<sup>1</sup>; <sup>1</sup>Brigham Young University

The crystallographic texture of friction stir welded (FSW) metals has been shown to resemble the torsional simple shear deformation (TSSD) texture of metals. In this study, electron backscatter diffraction (EBSD) was used to analyze the texture and microstructure of FSW AISI 304L stainless steel (304L). Locations at the retreating side, weld center, advancing side, and TMAZ were scanned and analyzed. For texture analysis, EBSD data was rotated to match the sample coordinate system of TSSD. Quantitative analysis of the texture showed that over 90% of the non-random textures correspond to TSSD; the remainder corresponds to a discontinuous dynamic recrystallization texture. EBSD microstructure analysis shows that dislocation cells are formed in the final microstructure of FSW 304L. Texture and microstructure analysis results suggest that dynamic recovery and continuous dynamic recrystallization (recovery phenomena) are active in the final microstructure of FSW 304L, while discontinuous dynamic recrystallization (nucleation phenomenon) is not.

##### **Heterogeneous Nucleation of Anisotropic Solids:** *Aurèle Mariaux*<sup>1</sup>; *Michel Rappaz*<sup>1</sup>; <sup>1</sup>EPFL

Surprisingly, the well-known theory of heterogeneous nucleation of a solid from a liquid phase on a foreign substrate did not consider anisotropic situations. Taking the case of zinc grains forming in thin coatings deposited by hot-dipping on steel sheets as a motivation to this study, the xsi-vector formalism of Cahn and Hoffman was first used to handle anisotropic nucleation situations. It can be shown that the ratio of the heterogeneous and homogeneous nucleation energy barriers is still given by the ratio of the corresponding volumes of the heterogeneous and homogeneous anisotropic nuclei. However, the function describing this ratio, which only depends on the ratio  $(\gamma_{lf} - \gamma_{sf})/\gamma_{sl0}$  for the isotropic case, where  $\gamma_{lf}$  and  $\gamma_{sf}$  are the liquid-foreign substrate and solid-foreign substrate interfacial energies, respectively, becomes a function of the orientation of the nucleus with respect to the substrate. In the case of zinc, it is shown that good wetting conditions, i.e.,  $(\gamma_{lf} - \gamma_{sf}) > 0$ , favor a basal orientation of the nucleus on the foreign substrate. Experimental evidence from several zinc-based systems will be presented to support this finding.

### 2:30 PM Invited

#### Phase-Field Simulations of Peritectic Growth in Ti-Al-B Including $TiB_2$ Inoculation: Markus Apel<sup>1</sup>; Janin Eiken<sup>1</sup>; Ulrike Hecht<sup>1</sup>; <sup>1</sup>Access e. V.

By varying the B content in a peritectic Ti45at%AlxB alloy the formation temperature of boride particles can be adjusted. For  $x > 1.47$ at%  $TiB_2$  is the first phase which forms during solidification. For  $0.58\text{at}\% < x < 1.47\text{at}\%$   $TiB_2$  becomes stable after  $\beta$ -Ti but before  $\alpha$ -Ti. In the first case boride particles can inoculate  $\beta$ -Ti, whereas in the latter case  $\alpha$ -Ti. We elucidate the effect of borides on microstructure formation by phase-field simulations coupled to a thermodynamic database. Nucleation and growth of small boride particles are explicitly taken into account on a scale below the phase-field interface thickness by using semi-analytical growth models. The simulation results show a variety of effects: grain refinement due to heterogeneous nucleation on  $TiB_2$  particles either of the  $\beta$  or  $\alpha$  phase, interactions between the growing Ti phases and the borides, as well as a pronounced dependency of the phase transformation rates on the dominant nucleation sites.

### 3:00 PM

#### Dispersion of Nanoparticles in Magnesium Using Contactless Electromagnetic Acoustic Transmission (EMAT) under High Magnetic Fields: Zachary Bryan<sup>1</sup>; Peiru Chen<sup>1</sup>; Hunter Henderson<sup>1</sup>; Orlando Rios<sup>2</sup>; Gail Mackiewicz-Ludtka<sup>2</sup>; Gerard Ludtka<sup>2</sup>; Michele Manuel<sup>1</sup>; <sup>1</sup>University of Florida; <sup>2</sup>Oak Ridge National Laboratory

Magnesium and its alloys have recently drawn significant attention due to their high specific strength. However, magnesium's inherently low ductility has prevented its wide spread integration into major engineering applications. It has been shown that the addition of ceramic nanoparticles to magnesium alloys can lead to dramatic increases in hardness, strength, and possibly ductility. This collaborative study focuses on the application of a novel contactless electromagnetic acoustical transmission (EMAT) technique to disperse dysprosium oxide nano-spheres and nano-rods in molten magnesium and throughout solidification. The magnesium and nano-particle composites, prepared at the University of Florida's Materials Design & Prototyping Laboratory, were induction melted using a custom apparatus developed at Oak Ridge National Laboratory (ORNL) in a 20 Tesla high magnetic field under controlled atmosphere at the National High Magnetic Field Laboratory (NHMFL). A detailed microstructural analysis characterizing the level and degree of nano-particle dispersion is presented and inferences will be provided regarding the nature of the solidification process. The authors acknowledge financial support from the US National Science Foundation award number DMR-0845868, Department of Energy DOE-EERE-ITP and Office of Science Graduate Fellowship Program administered by the Oak Ridge Institute for Science and Education, and General Motors Corporation.

### 3:20 PM

#### In-Situ Investigation of the Growth Dynamics of Floating and Locked Eutectic Grains during Thin-Sample Directional Solidification Using a Rotating Stage: Melis Serefoglu<sup>1</sup>; Sabine Bottin-Rousseau<sup>1</sup>; Silvère Akamatsu<sup>1</sup>; Gabriel Faivre<sup>1</sup>; <sup>1</sup>UPMC / CNRS

We investigated the directional-solidification dynamics of "floating" and "locked" eutectic grains (EGs) in a 12- $\mu\text{m}$  thick metallic samples (In-In2Bi) using a rotating stage. Our setup permits us to change the in-plane orientation of the crystals with respect to the thermal gradient continuously, while keeping the relative orientation of the two phases constant, and observing the solidification front in real time by videomicroscopy. We show that floating EGs correspond to the so-called regular eutectics generally observed in nearly isotropic systems with nonfaceted solid-liquid interfaces, i.e. the lamellae grow locally perpendicular to the front over the whole angular range. In contrast, in locked EGs, the lamellae keep, on average, a fixed orientation in the sample (i.e. crystal) reference frame during rotation. We usually observed a few locking orientations in a given EG. Assuming that they correspond to singular orientations, one can obtain valuable information on the gamma-plot of the interphase boundaries.

### 2:00 PM Invited

#### Assessment of Mobilities: Lars Hoglund<sup>1</sup>; <sup>1</sup>KTH

Simulations of diffusion controlled transformations have over the recent years become increasingly important for understanding the behaviour materials both in manufacturing and use. This applies both to new advanced material as well as materials that been long available. These simulations take advantage of the large availability of existing thermodynamic databases and software that with great accuracy can predict phase equilibria in a number of alloying systems. In order to perform accurate simulations of diffusion controlled processes, accurate descriptions of diffusion coefficients in the system must be assessed and stored in databases. The most convenient way in which to store this type of information is to assess and store the mobilities of the different diffusing components in databases. An overview on the methods used and the type of data that can be used to perform this task will be presented

### 2:30 PM Invited

#### Evaluation of the Uncertainty of Extrapolating Thermodynamic and Mobility Data in Temperature and Composition: Annika Borgenstam<sup>1</sup>; <sup>1</sup>KTH

It has for a very long time been debated if the bainitic transformation is formed by a diffusionless process or if it is controlled by carbon diffusion. If the transformation is controlled by carbon diffusion it should be possible to calculate the growth rate as controlled by carbon diffusion under paraequilibrium conditions. This has been done previously but must be done again for certain cases. When calculating the growth rate it is very important to have a proper thermodynamic description as well as correct mobility data. Since the bainitic transformation in steel takes place at rather low temperatures it is important that the extrapolations of both the thermodynamic and mobility data are correct. In the present work an attempt to evaluate the uncertainty in these extrapolations of temperature and composition are presented. It will be discussed from a general perspective and exemplified using new thermodynamic descriptions of Fe-C and Fe-Cr.

### 3:00 PM Invited

#### Development of a Reference Self-Diffusion Mobility Database: Carelyn Campbell<sup>1</sup>; <sup>1</sup>National Institute of Standards and Technology

Twenty years ago, John Ågren initiated the development of a CALPHAD-based approach to diffusion mobility databases. Since then, several multicomponent diffusion mobility databases have been developed for steels and Ni-base superalloys; however, the development of multicomponent diffusion mobility databases for other alloy systems has been slowed by the lack of standard references for the self-diffusion of the pure elements. In 2009, an international group began meeting at NIST to develop a set of standard reference diffusion mobilities. An overview of this group's work, including a set of initial recommendations for the self-diffusion in Al, Cu, Ni and Fe, will be presented. The recommendations are based on evaluation of the experimental data using a statistical meta-analysis, first principle calculations, and the use of previous assessments.

MONDAY PM

### 3:30 PM Break

### 3:50 PM Invited

**Atomistic and Meso-Scale Simulations of Diffusion in  $UO_{2+x}$ :** *David Andersson*<sup>1</sup>; Pankaj Nerikar<sup>1</sup>; Blas Uberuaga<sup>1</sup>; Michael Buksas<sup>1</sup>; Neil Carlson<sup>1</sup>; Cetin Unal<sup>1</sup>; Chris Stanek<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

Species transport is a critical process in nuclear fuels and due to fission gas redistribution and evolution of the  $UO_{2+x}$  stoichiometry it is an important performance characteristic. Xe transport is studied by calculating the activation energy using density functional theory (DFT) techniques. By analyzing the Xe solution thermodynamics, the relevant migration barriers and the interaction of dissolved Xe atoms with U vacancies we demonstrate that Xe diffusion occurs via a vacancy-mediated ring-like mechanism. The interaction of Xe with grain boundaries and dislocations has previously been investigated via atomistic simulations and we apply these results to formulate a thermodynamic and kinetic model for Xe segregation that account for the unique boundary characteristics. The resulting transport model for bulk and boundaries is then solved for both idealized and realistic microstructures within a finite element code. Finally, using DFT and kinetic Monte Carlo simulations we study the diffusion of O in non-stoichiometric  $UO_{2+x}$ .

### 4:20 PM

**Ab Initio Determination of Point Defect Kinetics in Fe-Based Alloys:** Tilmann Hickel<sup>1</sup>; Roman Nazarov<sup>1</sup>; *Niko Sandschneider*<sup>1</sup>; Joerg Neugebauer<sup>1</sup>; <sup>1</sup>Max-Planck-Institut fuer Eisenforschung GmbH

Aiming at a weight reduction of Fe-based products, there is currently a great interest in various alloying concepts such as Fe-Mn or Fe-Al. However, in order to reduce failure mechanisms in these materials, the understanding of their defect kinetics needs to be significantly improved. We therefore extensively studied the diffusion of hydrogen, a prominent interstitial atom connected to brittle fracture. In addition we considered vacancy driven self- and impurity diffusion, which is often responsible for strength reduction and creep. Density functional theory has been used to determine the energetics and structures of the involved defects (including the complex interplay with the local magnetic environment) and to obtain the complete information on the relevant transition states. These data are combined with kinetic Monte-Carlo simulations, in order to achieve temperature dependent diffusion constants. We observe characteristic dependencies on the concentration of alloying elements, their spatial distribution and the resulting local strain.

### 4:50 PM

**Oxygen Diffusion in  $\alpha$ -Titanium Alloys:** *Henry Wu*<sup>1</sup>; Dallas Trinkle<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign

Titanium alloys are limited in high temperature applications by oxidation. To understand and inhibit oxygen penetration, we determine the mechanisms of oxygen diffusion through  $\alpha$ -titanium with *ab initio* calculations. Diffusion in both the c-axis and basal directions proceeds between octahedral interstitial sites, through metastable hexahedral and crowdion configurations. From the mechanisms and energy barriers, we calculate the diffusion coefficient and anisotropy in the c-axis and basal directions that match well to experimental measurements. We use DFT to compute the interaction energy between oxygen in  $\alpha$ -titanium and substitutional solutes such as Al, V, and Sc. Solute reduce oxygen diffusion: attractive solutes act as traps, and repulsive solutes induce the labyrinth effect for non-dilute concentrations. We use the diffusion model to compare the effect of solutes on oxygen diffusion through pure Ti and Ti-6Al-4V.

### 5:20 PM

**Phase Stability of Mg<sub>2</sub>X Intermetallic Phases in the Mg-X-X' (X, X': Si, Ge, Sn) Systems:** *Jean Claude Tedenac*<sup>1</sup>; Isabelle Martin<sup>1</sup>; Elodie Ruiz<sup>1</sup>; Abel Haidoux<sup>1</sup>; <sup>1</sup>ICG

The materials based on the intermetallic compounds Mg<sub>2</sub>X (X = Si, Ge, Sn) are widely studied for applications in thermoelectric energy conversion. The ternary systems from which they derive are not very well known. It appears that the stabilities of the solid solutions are not as obvious as it sounds. We present in this communication an experimental study on the sections Mg<sub>2</sub>Si-Mg<sub>2</sub>Ge and Mg<sub>2</sub>Si-Mg<sub>2</sub>Sn of the ternary systems. The

stability of alloys of composition between 10 and 30 at% are studied by the way of the solid state methods. A thermodynamic study is given and the kinetic of decomposition is described. This study concerns an experimental approach which will be included a Calphad procedure. First results on the modelling of the system Mg-Ge-Si are given.

## Hydrogen Storage in Materials: Theory and Experiment: Session II

### 2:00 PM

**Controlling the Kinetics and Decomposition Pathway of LiBH<sub>4</sub> and Mg(BH<sub>4</sub>)<sub>2</sub> via Confinement in Highly Ordered Nanoporous Carbon:**

*Xiangfeng Liu*<sup>1</sup>; David Peaslee<sup>1</sup>; Christopher Jost<sup>1</sup>; Eric Majzoub<sup>1</sup>; <sup>1</sup>University of Missouri-St. Louis

In addition to conventional strategies for improving kinetics and thermodynamics of metal hydrides, including the use of catalyst dopants or destabilization, the effect of nanoscale size, through confinement in templates or frameworks, has attracted increasing attention. The decomposition thermodynamics and kinetics of LiBH<sub>4</sub> and Mg(BH<sub>4</sub>)<sub>2</sub> has been investigated in the presence of highly ordered nanoporous carbon (NPC) with a 2D-hexagonal geometry, a narrow size distribution, and different pore sizes. LiBH<sub>4</sub> confined within 2 nm highly-ordered columnar pores becomes amorphous. The nano-confinement results in the disappearance of the structural phase transition and the melting transition, a significant decrease of the onset desorption temperature, and suppresses diborane release. The reaction pathway is likely altered through a strong interaction with the carbon template. We illustrate the wetting behavior of LiBH<sub>4</sub> on infiltration NPC using differential scanning calorimetry, and discuss the implications of the wetting behavior on the decomposition pathways.

### 2:20 PM

**Direct Line-of-Site Gas Desorption Study of LiBH<sub>4</sub> in Nanoporous Carbons: The Influence of Surface Chemistry and the Size Effect:**

*David Peaslee*<sup>1</sup>; Xiangfeng Liu<sup>1</sup>; E. Majzoub<sup>1</sup>; T. Baumann<sup>2</sup>; <sup>1</sup>University of Missouri - St. Louis; <sup>2</sup>Lawrence Livermore National Laboratory

Thermodynamic and kinetic properties of metal hydrides may differ between bulk and nano-sized particles. Studies of nano-structured carbon materials infiltrated with LiBH<sub>4</sub> reveal differences in the decomposition pathway that depend on the nano-pore size and the surface chemistry. We present results of gas desorption using a direct line-of-site residual gas analyzer mass-spectrometer (RGAMS) to characterize gas desorption species, and decomposition temperatures, and differences in reaction pathways for a variety of LiBH<sub>4</sub>, Ca(BH<sub>4</sub>)<sub>2</sub>, and Mg(BH<sub>4</sub>)<sub>2</sub> infiltrated carbons. We present results for 9-14 nm carbon aerogels and 2-4 nm highly ordered nano-porous carbons consisting of columnar pores packed in a hexagonal geometry. RGAMS results, together with XRD, FTIR, and calorimetry studies, indicate that pore size, non-crystallinity, and surface chemistry all play a role in formation of diborane (B<sub>2</sub>H<sub>6</sub>) during the infiltration process and also during desorption of melt-infiltrated materials.

### 2:40 PM

**Energetics and Microstructures in Mg/Nb Multilayers:** *Anchalee Junkaew*<sup>1</sup>; Byoungsoo Ham<sup>1</sup>; Xinghang Zhang<sup>1</sup>; Raymundo Arroyave<sup>1</sup>; <sup>1</sup>Texas A&M University

Nb has been proposed for improving the hydrogen sorption kinetics in Mg thin films. Microscopy studies show the formation of metastable phases

at interfaces. In this presentation, we examine the microstructure of Mg/Nb multilayers through first-principles calculations based on Density Functional Theory. The interfacial energies of different interface configurations are reported and the effect of chemistry and strain energy on the interfacial energies is quantified. The resulting interfacial structures are then compared to experimental investigations. The structures of bulk distorted bcc/hcp lattices will also be compared to the structures resulting from interfacial relaxations, and the underlying physical basis for the formation of these metastable interfacial phases will be discussed. Finally, the electronic structure of these interfacial structures will be compared to that of hydrogen-carrying bulk phases in order to determine likely sites for hydrogen occupation in Mg/Nb multilayer films.

### 3:00 PM

**Exploration of Mg and Ca Based Laves Phases for Hydrogen Storage:** *Beau Biller<sup>1</sup>; Yuwen Cui<sup>1</sup>; J.-C. Zhao<sup>1</sup>; Leonid Bendersky<sup>2</sup>; William Boettinger<sup>2</sup>*; <sup>1</sup>Ohio State University; <sup>2</sup>National Institute of Standards and Technology

Laves phases are well-known compounds for forming interstitial hydrides. Lightweight Laves phase based on Mg and Ca are attractive since lighter elements may improve the gravimetric density of the hydrides, which is key for hydrogen storage. For transition metal based Laves phases, empirical rules have been developed to correlate the hydriding and dehydriding properties to the interstitial site sizes. We are studying the mutual solubility and the dependence of lattice parameters with compositions using a high-efficiency diffusion-multiple approach. Two diffusion multiples made up of CaMg<sub>2</sub>, CaAl<sub>2</sub>, CaZn<sub>2</sub>, MgNi<sub>2</sub> and MgCu<sub>2</sub> are studied to determine the stability and composition space for the C14, C15 and C36 Laves phases of the pseudo binary and pseudo ternary systems. Results on the phase equilibria, interstitial sizes and hydrogen storage properties of selected compositions will be reported.

### 3:20 PM

**Hydrogen Absorption/Desorption Behavior of the MgH<sub>2</sub>-Ni/Al<sub>2</sub>O<sub>3</sub> Composite Prepared by High Energy Ball Milling:** *Natsuki Yamasaki<sup>1</sup>; Manshi Ohyanagi<sup>1</sup>*; <sup>1</sup>Ryukoku University

The effect of Ni/Al<sub>2</sub>O<sub>3</sub> composite additive on the hydrogen absorption/desorption kinetics of the magnesium hydride (MgH<sub>2</sub>) was studied. The Ni/Al<sub>2</sub>O<sub>3</sub> composite was prepared by the oxygen reduction of the NiO/Al<sub>2</sub>O<sub>3</sub> composite using hydrogen. The MgH<sub>2</sub> and 50wt% Ni/Al<sub>2</sub>O<sub>3</sub> were mechanically milled using a gear driven planetary ball mill for 10 min. In the case of the specimen heated with 1 °C/min under helium flow, the onset temperature of hydrogen desorption of the MgH<sub>2</sub>-Ni/Al<sub>2</sub>O<sub>3</sub> was 180 °C, which is 40 °C lower than that of MgH<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub>. From the results of the hydrogen absorption measurement at 150 °C for 10 s, the Mg-Ni/Al<sub>2</sub>O<sub>3</sub> absorbed approximately 60% of the relative hydrogen desorption capacity, when the Mg-Al<sub>2</sub>O<sub>3</sub> absorbed only 10%.

### 3:40 PM Break

### 4:00 PM

**Improved Thermodynamics and Kinetics of Mg-based Hydrogen-Storage Materials Produced via Controlled Devitrification of a Metallic Glass:** *Eric Lass<sup>1</sup>*; <sup>1</sup>NIST

Mg-based hydrogen-storage materials are attractive because of their high gravimetric capacity and low cost. However, they exhibit poor kinetics and high absorption/desorption temperatures due to slow diffusion and a high formation enthalpy of the hydride. Ultra-fine grained materials show improved hydriding characteristics because of an increase in the density of short-circuit diffusion paths (i.e. grain/particle surfaces); and can destabilize the hydride phase when particle size is sufficiently reduced. In this work, nanocrystalline Mg-Ni based alloys for hydrogen-storage are produced via controlled devitrification of a metallic glass. The kinetics of hydriding/dehydriding are much improved compared to other bulk Mg-based materials. By adding small amounts of a ternary element, phase equilibria can be modified so that 4.5 to 5 wt. % H can be fully absorbed and desorbed at 473 K, about 100 K lower than other bulk Mg-based alloys.

### 4:20 PM

**Li-Mg Solid Solution Alloy for Reversible Hydrogen Storage:** *Bo Liu<sup>1</sup>; Zhigang Fang<sup>1</sup>; Jun Lu<sup>1</sup>; Peng Fan<sup>1</sup>*; <sup>1</sup>University of Utah

The search for onboard solid hydrogen storage materials have focused on complex metal hydride in recent years. The present work examines a new concept of hydrogen storage material based light metal solid solution alloys. Results of the experimental investigation of Li-Mg solid solution, which is a model system, are presented. Li-based solid solution can be prepared by using non-equilibrium processes such as rapid solidification and high energy mechanical alloying. The results showed that the temperature of dehydriding of the hydrogenated Li-Mg solid solution is much lower than that of monolithic LiH. The hydriding and dehydriding of the solid solution alloy of Li-Mg is reversible.

### 4:40 PM

**Nano-Chemo-Mechanics of Hydrogen Embrittlement of Metals under Extreme Conditions:** *Shan Huang<sup>1</sup>; David McDowell<sup>1</sup>; Ting Zhu<sup>1</sup>*; <sup>1</sup>Georgia Institute of Technology

Challenges associated with a hydrogen economy are substantial, ranging from hydrogen generation, storage and transportation. Hydrogen in high-pressure metallic containment systems causes the degradation that can result in sudden catastrophic fracture. A wide range of hydrogen embrittlement phenomena was attributed to the loss of cohesion of interfaces due to interstitially dissolved hydrogen. However, this concept has not been made sufficiently predictive, due to a lack of fundamental understanding of the chemo-mechanical processes of embrittlement. Here, by combining the atomistic simulation, thermodynamic theory of interfacial embrittlement, and electron theory of alloying, we analyze how the structure of grain boundaries influences the propensity of hydrogen chemisorption and consequent effects on embrittlement. Our results highlight the collective effects of multiple segregation sites in grain boundary embrittlement. Implications for efficient hydrogen storage are discussed by linking to a recent experiment showing that hydrogen embrittlement can be markedly reduced through grain boundary engineering.

### 5:00 PM

**Production and Characterization of Supported Transition Metal Nanoparticles on Multi-Walled Carbon Nanotubes Functionalized by Gamma Irradiation and Chemical Process:** *Jessika Rojas<sup>1</sup>; Carlos Castano<sup>1</sup>*; <sup>1</sup>Missouri University of Science and Technology

Recently, hydrogen has been the source of intense research and diverse methodologies to store it are being investigated. Single and multi-walled carbon nanotubes show promise as good options to achieve high storage. Although the current hydrogen storage capacity of CNTs does not fulfill the DoE requirements, further research is proposed about modifying the nanostructures to affect its properties. The main objective of this work is to evaluate mechanism of functionalization and purification by chemical and irradiation techniques to create functional groups in the surface and remove the caps at the end of the nanotubes to enhance the hydrogen storage capacity. Functional groups serve as a medium to attach metal nanoparticles to carbon nanotubes. SEM, STEM and XPS were used for morphological, chemical and structural characterization of the nanostructure.

### 5:20 PM Invited

**Thermodynamics of Nano-Cluster Complex Hydrides Using First-Principles Density Functional Theory:** *Eric Majzoub<sup>1</sup>; Vidvuds Ozolins<sup>2</sup>; Fei Zhou<sup>2</sup>*; <sup>1</sup>University of Missouri - St. Louis; <sup>2</sup>UCLA

While recent interest has focused on complex metal hydrides such as NaAlH<sub>4</sub> and Ca(BH<sub>4</sub>)<sub>2</sub>, these compounds are not as easily tunable as the interstitial metallic hydrides through alloying with other metal atoms. We investigate these materials at the nano-scale, where the ratio of surface to bulk atoms impacts the energetics. We present theoretical results for desorption energetics of nano-clusters of NaAlH<sub>4</sub>. Prototype geometries for the clusters were generated using a well-validated electrostatic ground state approach to a global optimization of the cluster total energy using a recently developed non-conventional Monte Carlo random walk in energy space. First-principles density functional theory applied to the prototype clusters

was used for full free energy calculations of the clusters and decomposition products. Results will be discussed with relation to recent experimental work on incorporation of complex hydrides in nanoporous framework materials, and the importance of the surface chemistry of the frameworks.

## ICME: Overcoming Barriers and Streamlining the Transition of Advanced Technologies to Engineering Practice -- The 12th MPMD Global Innovations Symposium: Modeling and Simulation Tools

### 2:00 PM Invited

**Open Source Calphad Software – Friend or Foe?:** *Ursula Kattner*<sup>1</sup>;  
<sup>1</sup>National Institute of Standards and Technology

In the early days of Calphad software was freely available, such as the Lukas' suite of programs or SOLGASMIX. Development of free packages has virtually stopped with Lukas' retirement and incorporation of SOLGASMIX into commercial software. Commercial software packages are constantly being extended and improved and have the benefit of the availability of support. Recently, Gibbs, a suite for the calculation and visualization, was introduced as open source software for thermodynamic calculations. A potential problem for developers of commercial Calphad software is the fairly small market size and that new products may have a negative impact on the sustainability of existing products. On the other hand, the advance cost of a license may deter newcomers from trying the method and/or restrict coupling of Calphad calculations with other calculations or simulations. The potential impact of open source software will be discussed using experience from thermodynamic databases for which similar issues apply.

### 2:25 PM Invited

**FiPy: PDE Performance in Python:** *Jonathan Guyer*<sup>1</sup>; *Daniel Wheeler*<sup>1</sup>;  
*James Warren*<sup>1</sup>; <sup>1</sup>NIST

FiPy is an open source, object oriented, partial differential equation (PDE) solver, written in Python. FiPy is particularly tailored to phase transformation simulations, focusing on the phase field and level set methods. The solution of coupled sets of PDEs is ubiquitous to the numerical simulation of science problems. Numerous PDE solvers exist, using a variety of languages and numerical approaches. Many are proprietary and difficult to customize. As a result, scientists spend considerable resources repeatedly developing limited tools for specific problems. FiPy takes advantage of Python's existing suite of open source tools for array calculations, sparse matrices and data rendering to provide a tool that is extensible, powerful and freely available. This talk focuses on our efforts to allow users to easily exploit parallel computing environments, sophisticated linear solvers, and advanced matrix preconditioners to obtain maximum performance without distracting them from their science.

### 2:50 PM

**Assessing Data Completeness and Predictive Potential in Magnesium Alloy Databases:** *Kim Ferris*<sup>1</sup>; *Dumont Jones*<sup>2</sup>; <sup>1</sup>Pacific Northwest National Laboratory; <sup>2</sup>Proximate Technologies, LLC.

Effective materials property databases need data completeness, which considers the range of property values and sufficiency of system

definitions. Property coverage and system definition are prerequisites for predictive structure-processing/property models. We have examined data completeness of Mg-alloy databases, finding current repositories do not exhibit full data completeness; however, their predictive capability can be substantially enhanced. Data completeness issues: 1) repositories do not completely specify individual alloy systems (e.g. processing); 2) reported Mg-alloy systems focus strongly on AZ series; and 3) measured properties show correlation in design and property spaces. Current information is sufficient to draw some conclusions for Mg-alloy design, and suggest design hypotheses. Improving predictive capability of repositories involves 1) better system definition (more detailed processing and post-treatment information), extracting basic mechanical measurements for "new" Mg-alloys, and testing hypotheses identified from current information. Authors acknowledge support from U.S. Department of Energy, Energy Efficiency and Renewable Energy, Office of Vehicle Technologies.

### 3:10 PM Invited

**Accelerated Insertion of Materials with Incomplete or Uncertain Information:** *Krishna Rajan*<sup>1</sup>; <sup>1</sup>Iowa State University

One of the critical barriers in transitioning new materials development into engineering practice is the uncertainty associated with the data that is used in the materials design process. While constitutive modeling strategies still form the foundations for computational materials design, uncertainty and incomplete information still pervades. Often intuition and/or heuristics experimentation is used to fill the gaps in evolving data needs. In this presentation we show how informatics methods helps to explore and analyze data where the information content and the taxonomy is not well defined. The talk aims to show that a formalism based on robust mathematical foundations, linked to materials engineering principles can be used to help in the design of materials in the context of their use in engineering practice. Suggestions on how this impacts the organization and use of databases to promote the philosophy of integrated computational materials engineering (ICME) are also discussed.

### 3:35 PM Break

### 3:50 PM Invited

**Code Validation and Qualification – The YMP Case:** *Patrice Turchi*<sup>1</sup>;  
<sup>1</sup>Lawrence Livermore National Laboratory

Having to tackle very challenging practical issues in an engineering-driven environment requires not only a quick solution but also in most cases code validation and qualification. For the purpose of illustration we will consider a series of studies conducted for the Yucca Mountain Project (YMP), although old and put on hold. One of the problems was to study the thermal integrity of the waste disposal canisters as a function of time with a combination of thermodynamic and kinetic modeling applied to complex multi-component alloys. After a brief review of the context of this project and the output of the materials study we will discuss the importance of code and results validation and qualification, and how it was done within this project. Then some general rules on how to qualify codes will be drawn. Work performed under the auspices of the U.S. DOE by LLNL under contract DE-AC52-07NA27344.

### 4:15 PM Invited

**A Phase Field Study on Static Strain Aging Kinetics of Dual Phase Linepipe Steel:** *Ning Ma*<sup>1</sup>; *Neeraj Thirumalai*<sup>1</sup>; *Nathan Nissley*<sup>2</sup>; *Rick Noecker*<sup>3</sup>; *William Lamberti*<sup>3</sup>; *Raghavan Ayer*<sup>1</sup>; <sup>1</sup>Corporate Strategic Research, ExxonMobil Research & Engineering Company; <sup>2</sup>ExxonMobil Upstream Research Company; <sup>3</sup>ExxonMobil Development Company

The increase of yield strength of steel during static strain aging is generally investigated following Cottrell's theory on Cottrell atmosphere formation. In the current study, we found that the time scale for strain aging of a dual-phase linepipe steel is several orders of magnitude longer than that needed for formation of "classical" Cottrell atmosphere. A Phase Field model was developed to study the kinetics of static strain aging considering the long range carbon diffusion. The observed strain aging kinetics can be rationalized by carbon diffusion across the ferrite grain from either trapped carbon in grain boundaries or neighboring carbon rich grains. The model was

extended to predict the increase in yield strength as a function of aging time and temperature. The predicted temperature dependence of yield strength produced by prolonged aging matches well with the experimental trend. Preliminary SIMS analysis in both aged and unaged samples will also be discussed.

#### 4:40 PM

**Determination of Microstructure-Property Correlations Using Phase Field Method:** *Saswata Bhattacharya*<sup>1</sup>; Tae Wook Heo<sup>1</sup>; Kunok Chang<sup>1</sup>; Ricardo Lebensohn<sup>2</sup>; Long-Qing Chen<sup>1</sup>; <sup>1</sup>Pennsylvania State University; <sup>2</sup>Los Alamos National Laboratory

Properties of materials, such as elastic stiffness, yield strength, dielectric and piezoelectric constants, diffusivity, thermal conductivity, etc. are affected by their microstructures. Therefore, establishment of microstructure-property relation is crucial for designing new materials and improving their performance. We developed an integrated computational framework based on phase field methodology to compute the effective properties of structurally inhomogeneous solids. We applied our technique to compute the effective properties of materials containing cavities or inclusions, composites, multiphase and polycrystalline microstructures. Moreover, our method can be used to calculate residual field distribution and the response behavior in inhomogeneous microstructures. As an example, we employed our method to computing the residual stress distribution and determining stress-strain relation in elastically and plastically anisotropic polycrystals undergoing deformation. Further, we studied grain growth and texture evolution under applied load and structural and diffusional phase transformations under applied field to demonstrate how the microstructural evolution affects the microstructure-property correlations.

#### 5:00 PM

**The Hierarchy of Fatigue Damage Accumulation:** *Sushant Jha*<sup>1</sup>; Christoph Szczepanski<sup>1</sup>; Craig Przybyla<sup>2</sup>; James Larsen<sup>2</sup>; <sup>1</sup>Universal Technology Corporation/Air Force Research Laboratory; <sup>2</sup>Air Force Research Laboratory

Fatigue damage is proposed to accumulate in an array of microstructural arrangements, which can be ranked in terms of the magnitude of deformation heterogeneity. These arrangements vary in size, combination of phases, and crystallographic orientations. This hypothesis rationalizes the dominance of crack growth lifetime (i.e., almost instantaneous crack-initiation) in the minimum fatigue behavior, which is often associated with an extreme microstructural arrangement. A computational study was conducted to explore the relationship between the occurrences of fatigue-critical microstructural arrangements and their rank, with the goal of predicting the probability of the life-limiting fatigue mechanisms. The analysis employed microstructures of a titanium alloy and a Ni-base superalloy simulated by an ellipsoid packing method. The computational study was complemented by detailed characterization of life-limiting microstructural configurations in both materials. The study also provided insights into the effect of microstructure, microtexture, and specimen volume on the probability of life-limiting failures in these materials.

#### 5:20 PM

**In-Situ Microscale Fatigue Study to Evaluate the Role of Microstructural Neighborhoods:** *Christopher Szczepanski*<sup>1</sup>; Sushant Jha<sup>1</sup>; Paul Shade<sup>1</sup>; Robert Wheeler<sup>2</sup>; James Larsen<sup>3</sup>; <sup>1</sup>UTC/AFRL; <sup>2</sup>UES/AFRL; <sup>3</sup>Air Force Research Laboratory/RX

A recent study of fatigue crack-initiation mechanisms and their relationship to lifetime variability in bulk samples of Ti-6Al-2Sn-4Zr-6Mo has revealed that crack initiation can occur in a variety of characteristic microstructural neighborhoods. These microstructural neighborhoods, which vary in size and frequency of occurrence, are observed at fatigue crack initiation sites through fractography. However, fractographic investigations do not allow one to identify the underlying nature of the fatigue damage accumulation and cracking mechanisms. To characterize these mechanisms under controlled conditions in a scanning electron microscope, an in-situ micro-scale tensile testing technique has been adapted to complete fatigue tests on micro-specimens extracted from representative fatigue-critical microstructural

neighborhoods. The results of these experiments will be presented, with an emphasis on identifying microstructurally driven cyclic damage accumulation processes leading to fatigue crack initiation. Additionally, the potential correlation between deformation severity and specific local microstructural configurations will be investigated to validate current mechanistic models.

#### 2:00 PM

**Simulation of Porosity and Hot Tears in a Squeeze Cast Magnesium Control Arm:** *Christoph Beckermann*<sup>1</sup>; Kent Carlson<sup>1</sup>; John Jekl<sup>2</sup>; R. Berkmortel<sup>2</sup>; <sup>1</sup>University of Iowa; <sup>2</sup>Meridian

Simulations are performed of the squeeze casting of AM60 and AZ91 automotive control arms. Advanced feeding flow and stress models are used within the casting simulation software to predict shrinkage porosity and hot tears. The simulations are validated through comparisons with observations made on experimental castings. Generally good agreement is obtained between the measured and predicted defect locations and extents. Design and process changes are introduced to mitigate the shrinkage and hot tear problems in these castings. The comparisons of the present study establish considerable confidence in the ability of casting simulation to predict shrinkage and hot tears in squeeze casting of magnesium alloys.

#### 2:20 PM

**Dendritic Microstructure in Directional Solidification of Magnesium Alloys:** *Morteza Amoorezaei*<sup>1</sup>; Sebastian Gurevich<sup>1</sup>; Nikolas Provatas<sup>1</sup>; <sup>1</sup>McMaster University

We demonstrate morphological transitions in Mg-Al alloy dendritic microstructure as the cooling conditions change during steady state and transient directional solidification. The effect of temperature gradient on the transition is investigated numerically using two-dimensional phase field simulations. The six-fold symmetry of Mg alloys leads to very different dendrite morphologies than those encountered in alloys exhibiting four-fold surface tension anisotropy. In particular, we find that at high temperature gradients primary dendrites become columnar in the direction of thermal gradient. In contrast, in the regions where surface energy anisotropy is dominant, primary stalks cross at 60-degree angles that characterize hexagonal crystal structure. Our modelling observations are compared to new Mg-Al experiments.

#### 2:40 PM

**Effect of Fraction Solid and Injection Speed on Microstructures and Casting Defects of Magnesium Alloy in New Type Semi-solid Injection Process:** *Yuichiro Murakami*<sup>1</sup>; Naoki Omura<sup>1</sup>; Mingjun Li<sup>1</sup>; Takuya Tamura<sup>1</sup>; Shuji Tada<sup>1</sup>; Kenji Miwa<sup>1</sup>; <sup>1</sup>Advanced Industrial Science and Technology

We have developed a new type semi-solid injection process, which can obtain high material yield of about 90% for magnesium alloy. In this process, generic magnesium billets are heated to the semi-solid temperature range in the injection cylinder without cover gasses and are injected into a mold. In this study, several billets were heated precisely in the cylinder to obtain desired fraction solid and the plate-like specimens were produced by injecting them under different injection speeds. The microstructures were observed by optical microscopy, and the casting defects were detected by

X-ray CT scanner. As increasing the injection speed, the shape and the size of alpha phase solid particles became more spherical, and smaller, and volume fraction of defects increased. Contrary, with higher fraction solid, volume fraction of defects decreased. Spheronization and miniaturization of solid particles was attributed to shear stress, and defects were affected by viscosity.

### 3:00 PM

**Macrostructure Evolution in Directionally Solidified Mg-RE Alloys:** Mario Salgado-Ordorica<sup>1</sup>; Willi Punessen<sup>1</sup>; Sangbong Yi<sup>1</sup>; Jan Bohlen<sup>1</sup>; Karl-Ulrich Kainer<sup>1</sup>; Norbert Hort<sup>1</sup>; <sup>1</sup>GKSS-Forschungszentrum

The mechanical properties of Mg-RE alloys, in particular their high strength at high temperatures, are well-known facts that make them promising materials for transport applications. However, since the quality of a specimen or the success of subsequent processing operations depends on the initial cast microstructure, an effort should be made on trying to understand and control the evolution of these alloy microstructures. To this end, Mg-RE alloys (where RE = Gd, Nd or Y) were cast by permanent mould direct chill casting. This process was performed in a specially optimized installation to ensure the obtention of ingots with homogeneous composition and free of porosity and inclusions. Different conditions were evaluated in order to better control the final grain size, orientation and distribution. The selection mechanisms operating during solidification, namely texturization and Columnar to Equiaxed Transition, were characterized and put into relation with the composition of the alloy and cooling conditions.

### 3:20 PM

**Microstructure and Mechanical Behavior of Cast Mg AZ31-B Alloy Produced by Magnetic Suspension Melting Process:** Nathan Rimkus<sup>1</sup>; Mark Weaver<sup>1</sup>; Nagy El-Kaddah<sup>1</sup>; <sup>1</sup>Univ of Alabama

Magnesium is the lightest of all structural metals and offers significant weight savings compared to traditional automotive materials. This paper describes macro/microstructure of Mg AZ31-B alloy produced via the Magnetic Suspension Melting (MSM) technique at a low superheat of 5°C. It was found that casting at this low superheat produced a fine cellular grain structure in comparison to a dendritic structure in conventionally cast alloys. The intermetallic phases were analyzed in detail and compared with the conventionally cast alloy. In the MSM cast alloy, the  $\gamma$ Mg17Al12 phase formed mainly at the grain boundaries, in contrast to typical dendritic entrapment of this phase within the grains in conventional castings. The formation of the Al-rich secondary- $\alpha$  phase during solidification was investigated. The effects of this morphology change on mechanical and fracture behavior of this material will be presented. These results will be discussed relative to conventionally cast Mg alloys.

### 3:40 PM

**Investigations on Hot Tearing of Mg-Zn-(Al) Alloys:** Le Zhou<sup>1</sup>; Yuanding Huang<sup>1</sup>; Pingli Mao<sup>2</sup>; Karl Ulrich Kainer<sup>1</sup>; Zheng Liu<sup>2</sup>; Norbert Hort<sup>1</sup>; <sup>1</sup>MagIC-Magnesium Innovation Centre, GKSS Research Centre; <sup>2</sup>Shenyang University of Technology

Mg-Zn alloys are widely used as wrought alloys such as ZM, ZK and ZE. It already had been reported that they are prone to hot tearing. The present work evaluates the hot tearing susceptibility (HTS) of binary Mg-Zn alloys using quantitative experimental methods and thermodynamic simulations based on Clyne's model. The results show that the curve of the HTS vs. the content of Zn has a typical "λ" shape. With increasing the content of Zn, the HTS increases firstly, reaches the maximum at 1.5% Zn and then decreases again. The addition of Al in Mg-Zn alloys influences the HTS. In the Mg-Zn-Al ternary system, the HTS decreases with the increase of Al content. The effect of Zn content on HTS in ternary Mg-Zn-Al systems is similar to that observed in binary Mg-Zn alloys.

### 4:00 PM Break

### 4:20 PM

**Proportional Strength-Ductility Relationship of Non-SF6 Diecast AZ91D Eco-Mg Alloys:** Shae K. Kim<sup>1</sup>; <sup>1</sup>Korea Institute of Industrial Technology

SF6 gas has been generally used for Mg alloys during melting and casting as a cover gas. The use of SF6 gas, however, will be limited owing to its

significant impact on global warming. Non-SF6 process during melting and casting in diecasting industry has been proved with Eco-Mg alloys, simple addition of small amount of CaO into AZ91D and AM60B Mg alloys. This paper will show non-SF6 diecasting procedures for AZ91D Eco-Mg alloys. Cold-chamber and hot-chamber diecasting mass productions were performed by using a Toshiba 135-ton cold chamber and a Frech 200-ton hot chamber diecasting machines under CO2 atmosphere without SF6 gas. An emphasis will be on proportional strength and ductility relationship of Eco-Mg alloys, in part, due to high-quality melt, refined grain size and Al2Ca second phase strengthening. Microstructures and mechanical properties of AZ91D Eco-Mg alloys will be evaluated in comparison with those of conventional AZ91D Mg alloy.

### 4:40 PM

**Estimation of Heat Transfer Coefficient in Squeeze Casting of Magnesium Alloy AM60 by Experimental Polynomial Extrapolation**

**Method:** Zhizhong Sun<sup>1</sup>; Xiaoping Niu<sup>2</sup>; Henry Hu<sup>1</sup>; <sup>1</sup>University of Windsor; <sup>2</sup>Promatek Research Centre, Cosma International

In this work, a different wall-thickness 5-step (with thicknesses as 3, 5, 8, 12, 20 mm) casting mold was designed and squeeze casting of magnesium alloy AM60 was performed in a hydraulic press. The casting-die interfacial heat transfer coefficient (IHTC) in 5-step casting was determined accurately based on thermal histories throughout the die and inside the casting which were recorded by fine type-K thermocouples. With measured temperatures, heat flux and IHTC were evaluated using the polynomial curve fitting method and numerical inverse method. For numerical inverse method, a solution algorithm is developed based on the function specification method to solve the inverse heat conduction equations. The IHTCs computed with these two techniques were compared. The results show that the peak values of IHTC at the thin steps are higher than those at the thick steps. However, the duration for IHTC remaining at the peak value increases as the step thickness increases.

### 5:00 PM

**Wide Strip Casting Technology of Magnesium Alloys:** Woo-Jin Park<sup>1</sup>; Jae-Joong Kim<sup>1</sup>; In-Joon Kim<sup>1</sup>; Dong-Kyun Choo<sup>1</sup>; <sup>1</sup>RIST

Extensive investigations relative to producing high performance and low cost magnesium sheet by strip casting have been performed for the applications to automotive parts and electronic devices. Research in order to develop magnesium sheet production technology has been begun from 2004 by RIST with support of POSCO. The POSCO has completed the plant to manufacture magnesium coil in the world's first. Big project in order to develop wide magnesium strip casting technology was started in succession. In this study, the recent results for wide magnesium strip casting are going to be presented. Wide magnesium coils of ~16 tons with 2,000mm width, 2,500mm diameter and 4~8mm thickness were successfully manufactured by strip casting process. Surface defects like inverse segregations could be minimized in the wide magnesium sheets by controlling adequately process parameters. As-strip cast microstructure consists of surface chill zone, dendritic columnar structure and central region.

### 5:20 PM

**Microstructural Analysis of Segregated Area in Twin Roll Cast Mg Alloy Sheet:** Jae Joong Kim<sup>1</sup>; Woo-Jin Park<sup>1</sup>; Dong Kyun Choo<sup>1</sup>; <sup>1</sup>RIST

Twin roll cast of magnesium alloy has been studied by various institutes since POSTECH started at the world first. RIST has done the R&D program of twin roll cast and reverse warm mill of magnesium sheet with 600 mm width. Presently, RIST is working on twin roll cast of magnesium sheet with 2,000 mm width. Twin roll cast magnesium alloy includes segregated area which is important due to controllable quality of final product. Here we present the microstructural analysis of segregated area of twin roll cast magnesium alloy to understand segregation phenomena. Especially, we studied on phase identification in segregated area, comparing the theoretical simulation. Our result shows that two kinds of phase morphologies are observed in the segregated area, not depending upon the position in the sheet. Phase identification shows that segregated area includes densely continuous or dispersed beta and phi phase, and dispersed Al<sub>3</sub>Mn<sub>3</sub> and Mg<sub>2</sub>Si.

5:40 PM

**Development of the Electromagnetic Continuous Casting Technology for Mg Alloys:** *Joonpyo Park*<sup>1</sup>; Myounggyun Kim<sup>1</sup>; Jong-Ho Kim<sup>1</sup>; Gyu Chang Lee<sup>1</sup>; U-Sok Yoon<sup>1</sup>; Woojin Kim<sup>1</sup>; <sup>1</sup>Research Institute of Industrial Science and Technology

Continuous casting technology for high-quality surface billets with fine-grained and homogeneous microstructure can be a solution for the cost barrier breakthrough. The latent heat of fusion per weight (J/g) of magnesium is similar to that of other metals. However, considering the heat emitted to the mould surface during continuous casting in meniscus region and converting it to the latent heat of fusion per volume, magnesium will be rapidly solidified in the mould during continuous casting, which induces subsequent surface defect formation. In this study, electromagnetic casting and stirring (EMC and EMS) techniques is proposed to control solidification process conveniently by compensating the low latent heat of solidification by volume and to fabricate magnesium billets of high quality surface. This technique was extended to large scale billets up to 300 mm diameter and continuous casting was successfully conducted. Then magnesium billet was used for the fabrication of prototype automobile pulley.

## **Magnesium Technology 2011: Primary Production; Characterization and Mechanical Performance**

2:00 PM

**The Development of the Multipolar Magnesium Cell: A Case History of International Cooperation in a Competitive World:** *Olivo Sivilotti*<sup>1</sup>; <sup>1</sup>Sigma Tau Technologies

The author conceived the first multipolar magnesium electrolytic cell in the late 1970s, in order to offset the impact of an 80kA monopolar cell being developed in cooperation with Osaka Titanium Company (OTC) being licenced by Alcan to a major competitor of OTC. During the 80s the commercial value of the multipolar magnesium cell technology was established. The 90s saw significant further progress in OTC, while attempts by Alcan to commercialize it in magnesium production plants met with technical difficulties and failure, due primarily to the lack of magnesium chloride feed of adequate quality. Now the author plans to commercialize a new multipolar cell design with a target productivity of 8.5-10 tons/day and a unit power consumption of 8.5-10 KWHR/kg of magnesium.

2:20 PM

**Effect of KCl on Liquidus of LiF-MgF<sub>2</sub> Molten Salts:** *Sh Yang*<sup>1</sup>; Fengli Yang<sup>1</sup>; Xianwei Hu<sup>2</sup>; Zhaowen Wang<sup>2</sup>; Zhingning Shi<sup>2</sup>; Bingliang Gao<sup>2</sup>; <sup>1</sup>Jiangxi University of Science and Technology; <sup>2</sup>School of Materials and Metallurgy117#, Northeastern University

Liquidus temperature of KCl-LiF-MgF<sub>2</sub> molten salts was determined based on cooling curve. The results proved the method of cooling curve was reliable and accurate by comparison liquidus temperatures of KCl. The measured value of KCl liquidus temperatures 769.27°C, and the documental value was 769.5°C. The different value was 0.23%, and the error ratio was 0.03%. The results were shown that effect of KCl on liquidus of molten salt was great for MgF<sub>2</sub>-LiF electrolyte. The liquidus temperatures were different with increasing of content of KCl in electrolyte. The liquidus temperature could be reduced 20°C with content of KCl in electrolyte from 0wt% to 50wt%. The experiments showed that the compound addition of

KCl into LiF-MgF<sub>2</sub> electrolyte not only reduced the liquidus temperature of electrolyte effectively but also decreased the aluminum-magnesium production cost and increased the economic benefits.

2:40 PM

**Efficiency and Stability of Solid Oxide Membrane Electrolyzers for Magnesium Production:** *Eric Gratz*<sup>1</sup>; Soobhankar Pati<sup>1</sup>; Jarrod Milshtein<sup>1</sup>; Adam Powell<sup>2</sup>; Uday Pal<sup>1</sup>; <sup>1</sup>Boston University; <sup>2</sup>Metal Oxygen Separation Technologies, Inc.

Solid oxide membrane (SOM) process has been successfully employed for the production of magnesium directly from its oxide. The process involves dissolving MgO in a fluoride based ionic flux and electrochemically pumping out the oxygen ions from the flux via an oxygen-ion-conducting SOM to the anode where they are oxidized, while reducing magnesium ions at the cathode. Understanding the long-term stability of the SOM in the flux is critical for the commercial success of this technology. This study utilizes electrochemical techniques such as impedance spectroscopy and linear sweep voltammetry to investigate key concepts related to MgO dissociation and current efficiency. Results show that the dissociation potential of MgO is dependent on the partial pressures at which magnesium is generated and the membrane stability is likely related to the current efficiency.

3:00 PM

**Magnesium Production by Vacuum Aluminothermic Reduction of a Mixture of Calcined Dolomite and Calcined Magnesite:** *Wenxin Hu*<sup>1</sup>; Naixiang Feng<sup>1</sup>; Yaowu Wang<sup>1</sup>; Zhihui Wang<sup>1</sup>; <sup>1</sup>Northeastern University

A new method of magnesium production was proposed that using a mixture of calcined dolomite and calcined magnesite with the molar ratio of MgO to CaO 6:1 as raw materials by vacuum aluminothermic reduction and extracted alumina from CaO·2Al<sub>2</sub>O<sub>3</sub>, the main phase of reduction slag analyzed by X-ray diffraction analysis. The results show that the reduction ratio of MgO was 86.18% at the conditions of 1414 K, 150 mins and was increased while reduction temperature and reduction time extended. The alumina leaching ratio of reduction slag reached 88% at the conditions of leaching temperature 95 °C and the concentration ratio of Na<sub>2</sub>CO<sub>3</sub> to NaOH was 100:75 in leaching Solution.

3:20 PM

**Multiphase Diffusion Study for Mg-Al Binary Alloy System:** *Young-Min Kim*<sup>1</sup>; Sazol Das<sup>1</sup>; Manas Paliwal<sup>1</sup>; In-Ho Jung<sup>1</sup>; <sup>1</sup>McGill University

Multiphase diffusion simulation and experimental studies are performed for Mg-Al binary alloy system at various temperatures. All simulations are based on the assumption that the inter-diffusion coefficients are composition independent and the interface always lies at equilibrium. Finite difference method (FDM) is used to solve diffusion equation and program is coded in FORTRAN with the evaluated self and inter diffusivity coefficients of Mg and Al. Annealing experiments of Mg-3wt% Al and Mg-6wt% Al were carried out at 330oC and 400oC for various times and the concentration profiles of Al were measured by Electron Probe Micro Analyzer (EPMA). The diffusion simulation results are in good agreement with both diffusion couple as well as annealing experiments.

3:40 PM

**Experiments and Modeling of Fatigue of an Extruded Mg AZ61 Alloy:** *J Jordan*<sup>1</sup>; J. Gibson<sup>1</sup>; M. Horstemeyer<sup>1</sup>; <sup>1</sup>Mississippi State University

In this study, structure-property relations with respect to fatigue of an extruded AZ61 magnesium alloy were experimentally quantified. Strain-life experiments were conducted in the extruded and transverse orientations under low and high cycle conditions. The cyclic behavior of this alloy displayed varying degrees of cyclic hardening depending on the strain amplitude and the specimen orientation. The fracture surfaces of the fatigued specimens were analyzed using a scanning electron microscope in order to quantify structure-property relations with respect to number of cycles to failure. Intermetallic particles were found to be the source of fatigue initiation on a majority of fracture surfaces. Finally, a multistage fatigue model based on the relative microstructural sensitive features quantified in this study was employed to capture the anisotropic fatigue damage of the AZ61 magnesium alloy.

#### 4:20 PM

**Low-Cycle Fatigue Behavior of Die-Cast Mg Alloy AZ91:** *Luke Rettberg*<sup>1</sup>; Warwick Anderson<sup>1</sup>; J. Wayne Jones<sup>1</sup>; <sup>1</sup>University of Michigan

An investigation has been conducted on the influence of microstructure and artificial aging response (T6) on the low-cycle fatigue behavior of super vacuum die-cast (SVDC) AZ91. Fatigue lifetimes were determined from total strain-controlled fatigue tests for strain amplitudes of 0.2%, 0.4% and 0.6%, under fully reversed loading at a frequency of 5 Hz. Cyclic stress-strain behavior was determined using incremental step test (IST) methods. Two locations in a prototype casting with different thicknesses and, therefore, solidification rates, microstructure and porosity, were examined. In general, at all total strain amplitudes fatigue life was unaffected by microstructure refinement and was attributed to significant levels of porosity. Cyclic softening and a subsequent increased cyclic hardening rate, compared to monotonic tests, were observed, independent of microstructure. These results, fractography and damage accumulation processes, determined from metallographic sectioning, are discussed.

#### 4:40 PM

**Small Fatigue Crack Growth Observations in an Extruded Magnesium Alloy:** *J. Bernard*<sup>1</sup>; J. Jordon<sup>1</sup>; M. Horstemeyer<sup>1</sup>; <sup>1</sup>Center for Advanced Vehicular Systems- Mississippi State University

The purpose of this paper is to quantify the microstructurally small/physically small crack growth behavior in an extruded AZ61 magnesium alloy. Fully-reversed, interrupted load control tests were conducted on notched specimens that were taken from the transverse direction with respect to the extrusion direction. In order to measure crack growth, replicas of the notch surface were taken at periodic intervals. Scanning electron microscopy analysis of the replica surfaces revealed multi site crack initiation and subsequent crack coalescence. The crack growth behavior of the small fatigue cracks was shown to have a strong dependence on the material microstructure as the crack was submitted to a tortuous growth path along grain boundaries and crystallographic slip planes. A multi-stage microstructurally dependent crack growth model that was previously calibrated for FCC metals was further developed by this research for HCP materials.

#### 5:00 PM

**Applicability of Mg-Zn-(Y, Gd) Alloys for Engine Pistons:** *Kazutaka Okamoto*<sup>1</sup>; Masato Sasaki<sup>2</sup>; Norikazu Takahashi<sup>2</sup>; Qudong Wang<sup>3</sup>; Yan Gao<sup>3</sup>; Dongdi Yin<sup>3</sup>; Changjiang Chen<sup>3</sup>; <sup>1</sup>Hitachi, R&D; <sup>2</sup>Hitachi Automotive Systems; <sup>3</sup>Shanghai Jiao Tong Univ

Commercial magnesium alloys have a great potential for structural applications in automotive due to their significant weight saving. However, they have poor creep resistance at temperature over 125°C, thus making them inadequate for power train applications such as engine pistons, which are operated at temperature up to 300°C. Recently, creep resistant magnesium alloys with rare earth elements and Zn have been developed, hence the applicability of Mg-Zn-(Y, Gd) alloys for engine pistons was investigated in this paper. Gravity casting was performed with Mg-Zn-(Y, Gd)-Zr ingot, followed by T6 treatment. High cycle fatigue tests were carried out and results were compared to the current aluminum cast alloy of A336 (JIS AC8A) for pistons. At room temperature, the fatigue strength is 27% lower than A336, while it is 35% higher at 300°C. The effects of microstructure on the mechanical properties will be discussed in the presentation.

#### 5:20 PM

**Compressive Creep Behaviour of Extruded Mg Alloys at 150°C:** *Michelle Fletcher*<sup>1</sup>; Lukas Bichler<sup>1</sup>; Dimitry Sediako<sup>2</sup>; Robert Klassen<sup>3</sup>; <sup>1</sup>University of British Columbia; <sup>2</sup>NRC-Canadian Neutron Beam Centre; <sup>3</sup>University of Western Ontario

Wrought Mg alloy bars, sections and tubes have been extensively used in the aerospace, nuclear and automotive industries, where component weight is of concern. The operating temperature of these components is typically limited to below 100°C, since appreciable creep relaxation of the alloys

takes place above this temperature. This study was focused on a selected wrought magnesium alloys developed for high temperature applications. Compressive creep behaviour of AE, ZE, AJ, AX and EZ rods was studied at room temperature and at 150°C using the microindentation creep technique. Measurements were obtained in the radial and transverse directions to observe the effect of texture on creep strain, hardness and elastic modulus. Microscopic examination of the alloys revealed that the distribution of second phases was critical to the alloy's creep resistance. Selected results were also related to in-situ compressive creep experiments carried out using neutron diffraction techniques.

#### 5:40 PM

**The Effect of Thermomechanical Processing on the Creep Behavior and Fracture Toughness of Thixomolded® AM60 Alloy:** *Zhe Chen*<sup>1</sup>; Amit Shyam<sup>2</sup>; Jane Howe<sup>2</sup>; Jack Huang<sup>3</sup>; Ray Decker<sup>3</sup>; Steve LeBeau<sup>3</sup>; Carl Boehlert<sup>1</sup>; <sup>1</sup>Michigan State University; <sup>2</sup>Oak Ridge National Laboratory; <sup>3</sup>Thixomat Inc.

The effect of thermomechanical processing and subsequent heat treatment on the small fatigue crack growth behavior of a nanoMAG AM60 magnesium alloy will be reported. The investigated alloys have a finer grain structure and higher levels of yield strength compared to similar alloys with conventional processing treatment. The effect of maximum stress and load ratio on the growth rate of cracks emanating from artificial notches will be characterized and modeled. The notches were of the same size scale as natural defects in these materials and were fabricated by electro-discharge machining. Microstructure and fracture surface characterization will be performed by electron microscopy to develop the microstructure-fatigue property relationships in this class of lightweight alloys.

### Magnetic Materials for Energy Applications: Magnetocaloric Materials

*Sponsored by:* TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Energy Conversion and Storage Committee, TMS: Magnetic Materials Committee; JSPS 147th Committee on Amorphous and Nanocrystalline Materials; Lake Shore Cyrotronics, Inc.; AMT&C

#### 2:00 PM Keynote

**Towards Better Magnetocaloric Materials:** *Vitalij Pecharsky*<sup>1</sup>; Karl Gschneidner<sup>1</sup>; <sup>1</sup>Iowa State University

Recent achievements in the design of robust near room temperature magnetic cooling devices signify paradigm shift in refrigeration, liquefaction and freezing technologies, and call for a much broader base of advanced magnetocaloric materials to support the quick realization of this environmentally friendly, energy efficient technology in a variety of markets. The latest materials discoveries and current trends in design of advanced magnetocaloric compounds will be reviewed. Work at the Ames Laboratory is supported by the U.S. Department of Energy – Basic Energy Sciences under contract No. DE-AC02-07CH11358.

#### 2:40 PM Invited

**Interplay between Structure and Magnetism in Gd<sub>5</sub>(Si<sub>x</sub>Ge<sub>1-x</sub>)<sub>4</sub>:** *Daniel Haskel*<sup>1</sup>; <sup>1</sup>Argonne National Laboratory

The connection between atomic structure and magnetism in giant magnetocaloric effect (MCE) material Gd<sub>5</sub>(Si<sub>x</sub>Ge<sub>1-x</sub>)<sub>4</sub> is explored using synchrotron radiation techniques. The element selectivity of x-ray absorption fine structure (XAFS) and additional orbital selectivity of x-ray magnetic circular

dichroism (XMCD) allow probing the magnetic polarization of conduction states responsible for mediating exchange interactions between localized Gd 4f electrons in the context of the magneto-structural phase transition. Furthermore, extension of these measurements to the diamond anvil cell allows a detailed comparison of the effects of chemical pressure (Si doping) and physical pressure upon the strength of magnetic interactions providing valuable insight into the role that Si/Ge p- Gd 5d hybridization plays in regulating the ferromagnetic ordering temperature of these materials. Work at Argonne is supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

### 3:05 PM Invited

#### **Novel Design of Magnetic Refrigerant Materials towards High Refrigeration Performance:** *Julia Lyubina*<sup>1</sup>; <sup>1</sup>Imperial College London

Materials showing a large magnetocaloric effect around room temperature are of increasing interest due to their possible application in magnetic refrigeration. Very attractive in this respect are materials with a first order transition, since the latter results in a large (giant) entropy change. However, these materials usually possess magnetic and thermal hysteresis and are prone to fracture due to crystal symmetry and/or volume change accompanying the transition that reduces the efficiency or even makes the refrigeration cycle impossible. Here, we discuss how the magnetic and mechanical properties can be improved by special processing. It is shown that the design of porous microstructure in La(Fe,Si)<sub>13</sub> materials is advantageous for the reduction of hysteresis and substantially improves mechanical stability. Practical implementation issues for the integration of La(Fe,Si)<sub>13</sub> in cooling engines are discussed. This research is in part supported by a Marie Curie Intra European Fellowship within the 7th FP of EC.

### 3:30 PM

#### **Adiabatic Temperature Change, Entropy Change and Magneto-Volume Effect in La-Fe-Si Alloys: A Study of Thermal and Magnetic Hystereses:** *Konstantin Skokov*<sup>1</sup>; James Moore<sup>1</sup>; Jian Liu<sup>1</sup>; Maria Krautz<sup>1</sup>; Oliver Gutfleisch<sup>1</sup>; <sup>1</sup>Leibniz Institute for Solid State and Materials Research

Compounds with the first-order ferromagnetic-paramagnetic transitions seem to be very promising for magneto magneto-cooling technique due to very high values of the magnetic entropy change. However in comparison with the second-order transition, the first-order transition is unavoidably accompanied by field- and temperature-hystereses as well as latent heat transfer. During operational field or temperature cycling this irreversibility appears as an undesirable heating of the magnetocaloric material. Thus, the study on the issue of hysteresis is extremely important for development of an efficient magnetic refrigerator prototype. A comparative study of the magnetic hysteresis from isothermal M-H loops, the magnetic entropy change, the adiabatic temperature change and the volume change of LaFe<sub>13-x</sub>Si<sub>x</sub> alloys undergoing the first-order magnetic transition has been carried out. Also, effects of temperature and field cycling on the magnetocaloric effect were investigated. By building the S-T diagram, a thermodynamic analysis of the first-order transition in LaFe<sub>13-x</sub>Si<sub>x</sub> alloys has been performed.

### 3:45 PM

#### **Magnetocaloric Study of Mechanically Alloyed LaFeSi:** *Mathieu Phejar*<sup>1</sup>; *Loffi Bessais*<sup>1</sup>; Valérie Paul-Boncour<sup>1</sup>; <sup>1</sup>CNRS

The room temperature magnetic refrigeration based on the magnetocaloric effect (MCE) is an alternative to conventional cooling. Much interest have been carried on La(Fe,Si)<sub>13</sub> compounds since the discovery of their giant MCE associated with low cost. These compounds is hardly formed by a peritectic reaction between the liquid La and the solid solution of Fe,Si resulting in a inhomogeneous microstructure. We have synthesized those compounds by ballmilling which until now haven't been used for this kind of samples. While a heat treatment of one month is necessary to obtain the crystallization of the NaZn<sub>13</sub> type structure for bulk alloys only 30 minutes is sufficient for ballmilled samples because of their finer microstructure. The magnetic properties of these compounds have been improved by substitution of Fe for Si and by insertion of hydrogen or carbon.

### 4:00 PM Break

#### **Field Effect on Martensitic Transition and Magnetocaloric Effect in Ni<sub>50</sub>Mn<sub>35.5</sub>In<sub>14.5</sub> and Ni<sub>45.5</sub>Mn<sub>43</sub>In<sub>11.5</sub> Ribbons:** *Wagner Rosa*<sup>1</sup>; *Tatiana Sánchez*<sup>1</sup>; *Javier García*<sup>1</sup>; *Victor Vega*<sup>1</sup>; *Victor Prida*<sup>1</sup>; *Lluisa Escoda*<sup>2</sup>; *Joan Suñol*<sup>2</sup>; *Blanca Hernando*<sup>1</sup>; <sup>1</sup>Universidad de Oviedo; <sup>2</sup>Universidad de Girona

Ferromagnetic shape memory Ni-Mn-In Heusler alloys undergo a thermoelastic martensitic transformation (MT) from parent austenitic phase to a martensitic one on cooling [1]. The sensitivity of MT to the applied magnetic field becomes this material very suitable for alternative energy technologies due to magnetocaloric effect (MCE) [2]. We report on structural and magnetic properties for Ni-Mn-In melt-spun ribbons. Samples microstructure was checked by XRD and SEM together with their chemical composition by EDS. Magnetic properties were measured with a VSM in the temperature range of 50K-400K and up to 3 T. MT was characterized from the thermomagnetic measurements (ZFC-FC-FH) in different applied fields. MT behaves highly sensitive to the applied field and alloy composition. Direct and inverse MCE near Curie point and MT point, have been clearly revealed. [1] Z.D. Han, et al, Solid State Communications 146 (2008) 124. [2] B. Hernando, et al, Appl. Phys. Lett. 94 (2009) 222502.

### 4:30 PM

#### **In-Situ High-Energy X-Ray Studies of Magnetic-Field-Induced Functional Behaviors in Ferromagnetic Shape-Memory Alloys:** *Zhihua Nie*<sup>1</sup>; *Yandong Wang*<sup>1</sup>; *Yang Ren*<sup>2</sup>; <sup>1</sup>Beijing Institute of Technology; <sup>2</sup>Argonne National Laboratory

A large magnetic-field-induced strain (MFIS) found in ferromagnetic shape-memory alloys (FSMAs) has stimulated much attentions. The large MFIS can be achieved through (1) the rearrangement of martensite variants via twin boundary motion, such as NiMnGa, or (2) the phase transition from a phase with lower magnetization to a phase with higher magnetization, such as NiCoMnIn. Synchrotron-based high-energy X-ray diffraction (HEXRD) techniques provide an in-situ tool for tracing the microscopic evolution of structures under various environments. This talk will present our in-situ HEXRD studies of magnetic-field-induced functional behaviors in FSMAs. An internal-stress of ~8 MPa was uncovered in a NiMnGa single crystal after thermo-magnetic training, showing a new training mechanism by introducing internal-stress in FSMAs which aims to lower the twinning stress. In polymer-bonded NiCoMnIn composites, the magnetic-field not only induced an inverse martensitic phase transformation accompanied with a MFIS of ~1.76%, but also affected the phase fraction at low temperatures.

### 4:45 PM

#### **Room Temperature Magneto-caloric Effect In Fe Substituted Ni-Mn-Sn Alloy:** *Rahul Das*<sup>1</sup>; *Perumal Alagarsamy*<sup>1</sup>; *Ananthakrishnan Srinivasan*<sup>1</sup>; <sup>1</sup>Indian Institute of Technology Guwahati

Ferromagnetic shape memory alloys exhibiting high magnetic entropy change ( $\Delta S_M$ ) near room temperature are being developed for magnetic refrigeration application. Ni<sub>49</sub>Mn<sub>37</sub>Fe<sub>1</sub>Sn<sub>13</sub> (Ni<sub>47</sub>Mn<sub>37</sub>Fe<sub>3</sub>Sn<sub>13</sub>) exhibit highest  $\Delta S_M$  of ~6 Jkg<sup>-1</sup>K<sup>-1</sup> (11 Jkg<sup>-1</sup>K<sup>-1</sup>) for 2 T field change at 241 K (177 K) [1]. In this work, we altered the composition of Ni-Mn-Sn-Fe system and obtained  $\Delta S_M$  of 5.2 Jkg<sup>-1</sup>K<sup>-1</sup> for 2 T field change in Ni<sub>50</sub>Mn<sub>36</sub>Sn<sub>13</sub>Fe<sub>1</sub> alloy at 304 K.  $\Delta S_M$  obtained is larger than those reported for Fe substituted Ni-Mn-Sn alloys near room temperature for the same field change. Since the properties of these alloys are strongly influenced by the composition and processing conditions, it is possible to improve the  $\Delta S_M$  of these alloys further. Details of experiments and results obtained would be presented.[1] T. Krenke *et al. J. Appl. Phys.* 102 (2007) 033903.

### 5:00 PM

#### **The Magnetocaloric Effect in Ni-Mn-Ga Heusler Alloys:** *Mikhail Drobosyuk*<sup>1</sup>; *Vasily Buchelnikov*<sup>1</sup>; *Sergey Taskaev*<sup>1</sup>; <sup>1</sup>Chelyabinsk State University

In this work we study experimentally the positive magnetocaloric effect (MCE) in Ni<sub>2-x</sub>Mn<sub>1-x</sub>Ga (x = 0.02, 0.03, 0.04, 0.07, 0.09) Heusler alloys. The MCE have been measured by the direct method. For the magnetic field change

$\Delta H = 2$  T, the maximal adiabatic temperature change  $\Delta T_{ad}$  in  $Ni_{2-x}Mn_{1-x}Ga$  alloys is larger than 0.6 K. The results show that the studied Heusler alloys may be interesting from the practical application point of view.

5:15 PM

**Calorimetric and Magnetic Measurements of Magnetic Entropy Change in Pr<sub>0.5</sub>Sr<sub>0.49</sub>Ca<sub>0.01</sub>MnO<sub>3</sub>:** *Ramanathan Mahendiran*<sup>1</sup>; <sup>1</sup>National University of Singapore

Perovskite manganites are considered to be one of the likely candidates for magnetic refrigeration due to significant magnetic entropy change exhibited by them. Majority of the existing work focussed on extracting magnetic entropy change from magnetization isotherms using Maxwell's relation. However, application of Maxwell's equation overestimates magnetic entropy in first order transition and independent verification of magnetic entropy by thermal method is essential. We investigated magnetocaloric effect in Pr<sub>0.5</sub>Sr<sub>0.5-x</sub>CaxMnO<sub>3</sub> series (x = 0 to 1) using differential scanning calorimeter and magnetization isotherms. While magnetic measurement gave a large magnetic entropy change (= +10.9 J/kg K for a field variation of 5 T, calorimetric data gave smaller value (= +6.5 J/kg K) around the Neel temperature (TN = 140 K) but comparable values (= 4 J/kg K) around the Curie temperature (TC = 260 K). The large magnetic entropy around TN found by calorimetric method is promising for application.

5:30 PM

**Influence of Heat Treatment on the Structure and Magnetic Properties of Gd<sub>5</sub>Sn<sub>4</sub> Alloy for Magnetic Refrigeration:** *Xichun Zhong*<sup>1</sup>; H Zhang<sup>2</sup>; M Zou<sup>2</sup>; Zhongwu Liu<sup>1</sup>; Dechang Zeng<sup>1</sup>; K.A. Gschneidner Jr.<sup>2</sup>; V.K. Pecharsky<sup>2</sup>; <sup>1</sup>South China University of Technology; <sup>2</sup>The Ames Laboratory, Iowa State University

The effects of heat treatment on the structure and magnetic properties of Gd<sub>5</sub>Sn<sub>4</sub> alloy were investigated. In as-cast alloy, the main phase is orthorhombic Gd<sub>5</sub>Sn<sub>4</sub>, and two secondary phases are monoclinic Gd<sub>5</sub>Sn<sub>4</sub> and hexagonal Gd<sub>5</sub>Sn<sub>3</sub>. After 1300°C annealing, the content of main phase increased from 85.39% to 98.47% and the monoclinic Gd<sub>5</sub>Sn<sub>4</sub> phase disappeared. For as-cast alloy, an antiferromagnetism-ferromagnetism transition near 60K caused by Gd<sub>5</sub>Sn<sub>3</sub> phase was evident. Two magnetic transitions near 82K and 130K are caused by the Gd<sub>5</sub>Sn<sub>4</sub> main phase and monoclinic phase, respectively. For the annealed sample, the phase transitions near 60 and 130K are not significant due to the reduced secondary phases and the Tc of Gd<sub>5</sub>Sn<sub>4</sub> phase decreases from ~82 to ~80K. The maximum magnetic entropy change in a low field of  $\square H=20$ kOe increases from 21.5 to 24.65J/kgK after heat treatment. The results demonstrated that Gd<sub>5</sub>Sn<sub>4</sub> alloy is a good magnetocaloric material for refrigeration.

5:45 PM

**Bonded Magnetocaloric Powders for the Refrigeration Application:** *Spomenka Kobe*<sup>1</sup>; Benjamin Podmiljšak<sup>1</sup>; Marko Soderžnik<sup>1</sup>; Boris Saje<sup>1</sup>; Paul McGuinness<sup>1</sup>; <sup>1</sup>Jožef Stefan Institute

Magnetocaloric materials (MCM) based on Gd<sub>5</sub>Si<sub>2</sub>Ge<sub>2</sub> with Fe as an additive show that the refrigeration capacity (RC) can be optimized with processing methods and substitution of various atoms in the lattice. Modified alloy can be used at room temperature. The hysteresis losses are drastically decreased with small decrease of net refrigeration capacity (NRC). The final product for refrigeration application should not be in the powder form and the idea is to use the discs, which will rotate in the applied magnetic field. The discs should be mechanically hard, but the amount of the bonding material should be as low as possible to prevent the dilution of the active magnetocaloric material. We used MCM with the best properties achieved, and various bonding materials. With the systematic experimental work we determined the composition, which enabled us the highest density with simultaneously good mechanical strength and magnetocaloric properties.

**Status of the ReaxFF Reactive Force Field: Development and Applications:** *Adri van Duin*<sup>1</sup>; <sup>1</sup>Penn State

The ReaxFF method enables large-scale (>>1000 atoms) molecular dynamics simulations on chemically reactive systems. The method combines a bond order/bond distance concept with a polarizable charge method and employs relatively long-range bond orders, enabling an accurate description of transition state energies. While initially developed for hydrocarbons and first-row element chemistry, the method has currently been applied to a significant section of the periodic system, including covalent, metallic, ionic and ceramic materials. Furthermore, the ReaxFF program has been distributed to over 125 academic groups. In this presentation we will provide a status-report on the currently available ReaxFF force fields, the program environments that currently support ReaxFF, including a number of parallel options, and the plans for further method development. This includes recent extensions of ReaxFF to aqueous-phase chemistry, enabling applications to biochemical reactions, extensions and applications to combustion chemistry, applications to material failure and simulations on catalytic materials.

2:25 PM Invited

**LIGGGHTS – Open Source Discrete Element Simulations of Granular Materials Based on LAMMPS:** *Christoph Kloss*<sup>1</sup>; <sup>1</sup>JKU Linz

In this work, we present the development of an open-source software for modeling granular material by means of the Discrete Element Method. LIGGGHTS ([www.liggghts.com](http://www.liggghts.com)) stands for 'LAMMPS Improved for General Granular and Granular Heat Transfer Simulations' and is based on LAMMPS ('Large Atomic and Molecular Massively Parallel Simulator'), a successful open source Molecular Dynamics code written and distributed by Sandia National Laboratories for massively parallel computing on distributed memory machines. We first give a brief overview of implemented models and features. These comprise CAD geometry import, features for particle insertion and packing, contact models, wallstress analysis, moving mesh capability, a 6 DOF feature and non-spherical particle handling. Finally, we would like to focus on the simulation of coupled granular-fluid systems with the CFD-DEM approach.

**Parallel Parameterization of Models Using Noisy Simulation Data:** *Steven Stuart*<sup>1</sup>; Dheeraj Chahal<sup>1</sup>; Sebastien Goasguen<sup>1</sup>; <sup>1</sup>Clemson University

Although massively parallel simulations of materials are becoming increasingly routine, parallelization of the optimization of the potentials needed in those simulations generally lags far behind. This talk describes some advances in automated parameterization methods that make efficient use of large-scale parallel processing environments. Rather than performing a deterministic minimization of a noise-free objective function, as with most automated parameterization methods, this approach acknowledges the stochastic nature of the data obtained from finite-duration dynamics and sampling simulations. Consequently, potentials can be successfully fit to physically relevant thermodynamic data, rather than relying too heavily on zero-temperature quantum mechanical energetic and structural data. Each stage in the parameterization process terminates as soon as it can be

determined that the parameters are non-optimal, but continues sampling as long as the parameters remain viable, rather than terminating at an arbitrary cutoff. The parameterization approach interfaces easily with massively parallel simulation engines, including LAMMPS.

#### **Effect of the Stress Field of an Edge Dislocation on Carbon Diffusion in $\alpha$ -Iron: Coupling Molecular Statics and Atomistic Kinetic Monte Carlo:** *Michel Perez*<sup>1</sup>; <sup>1</sup>Université de Lyon - INSA de Lyon

Carbon diffusion near the core of a [111](101) edge dislocation in  $\alpha$ -iron has been investigated by means of an atomistic model that brings together molecular statics and atomistic kinetic Monte Carlo (AKMC). Molecular statics simulations with a recently developed embedded atom method potential have been carried out in order to obtain atomic configurations, carbon-dislocation binding energies, and the activation energies required for carbon hops in the neighborhood of the line defect. Using information gathered from molecular statics, on-lattice AKMC simulations have been performed for temperatures in the 300–600 K range, so as to study the behavior of a carbon atom as it interacts with the edge dislocation stress field. This model can be seen as a very first step toward the modeling of the kinetics of carbon Cottrell atmosphere formation in iron during the static aging process.

#### **Molecular Dynamics Simulation of Cavitation in Metallic Glass:** *Michael Falk*<sup>1</sup>; Shuo Lu<sup>2</sup>; Pavan Valavala<sup>1</sup>; Michael Spector<sup>1</sup>; <sup>1</sup>Johns Hopkins University; <sup>2</sup>Beihang University

Experimental investigations indicate that cavitation may play a critical role in determining the fracture toughness of amorphous solids such as metallic glasses. We have undertaken a series of molecular dynamics simulations of cavitation under hydrostatic tension in a binary metallic glass analog using pair-wise potentials. We compare the rate of cavity nucleation directly to homogeneous nucleation theory to extract the role of irreversible deformation in the cavitation process. In doing so we are able to estimate the effective free energy for cavitation. Our simulations indicate that the barrier to cavitation is several orders of magnitude lower than that expected in the liquid. The implication of these measurements for the observed fracture behavior in metallic glasses will be discussed.

### 4:15 PM

#### **Large Scale Simulation of 3D Nanocrystalline Mg by Molecular Dynamics:** *Dong-Hyun Kim*<sup>1</sup>; M. V. Manuel<sup>1</sup>; F. Ebrahimi<sup>1</sup>; S. R. Phillpot<sup>2</sup>; <sup>1</sup>Department of Materials Science and Engineering, University of Florida

So far, comparing with f.c.c metals, very little has been done in large scale simulation of mechanical behaviors of h.c.p. metals. To understand nucleation and interaction of dislocations by slip and twinning, here we take Mg as a prototypical nanocrystalline h.c.p. metal. Atomistic process of slip and twinning created by a tensile stress was observed in fully dense 3D structure with nano-grain sizes. We address a length-scale dependence of twinning and slip in plastic deformation of nc-Mg. This work was supported by DOE NERI contract DE-FC07-07ID14833 and by the DOE-BES Computational Materials Science Network (CMSN).

### 4:35 PM

#### **Large-Scale Molecular Dynamics Simulations of Tribology in Metallic Contacts:** *Michael Chandross*<sup>1</sup>; <sup>1</sup>Sandia National Laboratories

Materials that perform well in electrical contacts usually exhibit high adhesion during frictional contacts. An excellent example of this phenomenon is pure gold, which has extremely low electrical contact resistance, but generally has a high friction coefficient. The exception to this, however, is nanocrystalline gold alloyed with minute amounts of Ni or Co, which in addition to its low contact resistance can also show low friction. The mechanism for this remains poorly understood. We will present the results of large scale molecular dynamics (MD) simulations which study the tribological response of both single crystal and nanocrystalline gold films in contact with curved probe tips under a variety of sliding conditions. Results

from simulations of adhesion and friction in metallic alloys will also be presented.

### 4:55 PM

#### **Molecular Dynamics Simulations of Nanoindentation of Si/SiO<sub>2</sub> Systems using the Charge Optimized Many-Body (COMB) Potential:** *Tzu-Ray Shan*<sup>1</sup>; Simon Phillpot<sup>1</sup>; Susan Sinnott<sup>1</sup>; <sup>1</sup>University of Florida

Oxides such as SiO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub> and HfO<sub>2</sub>, are widely used together with Si in many high-performance electronic devices, including metal-oxide-semiconductor (MOS) devices/junctions and gate stacks. Since nanoindentation has been established as a primary tool for investigating the mechanical behavior of small volumes of materials, classical molecular dynamics simulation is used to examine the nanoindentation of Si/SiO<sub>2</sub> interfacial systems. Because these systems consist of heterogeneous interface with significant changes in bonding as one crosses from one side of the interface to the other, the empirical charge optimized many-body (COMB) potential as implemented in LAMMPS is used to model the structural evolution, mechanical response and charge transfer of Si/SiO<sub>2</sub> systems under the influence of a nanometer-scale spherical indenter. The SiO<sub>2</sub> layers considered include  $\alpha$ -quartz and amorphous silica with various thicknesses. Aspects of the Si/SiO<sub>2</sub> interface during nanoindentation, including dislocation formation and the mechanisms by which fracture occurs, will also be addressed.

### 5:15 PM Invited

#### **Shear Transformation Zone Dynamics Modeling of Metallic Glasses:** *Christopher Schuh*<sup>1</sup>; Eric Homer<sup>1</sup>; <sup>1</sup>MIT

A thorough understanding of deformation in metallic glasses has proven elusive as a result of the disparate time and length-scales that span between the unit processes of deformation and the macroscopic flow localization events that are experimentally observed. We attempt to model the deformation of metallic glasses using a meso-scale model that treats the “shear transformation zone” (STZ) as a fundamental unit of deformation. STZ dynamics combines finite element mechanics, to solve for the stress redistribution when STZs operate, with a kinetic Monte Carlo algorithm, to model the kinetics of their activation sequence. The method allows processing and deformation to be simulated on larger length-scales and longer time-scales than, e.g., atomistic simulations. The method can be implemented in two or three dimensions, and can provide insight on deformation in complex experimental situations, such as in the formation of shear bands or the development of microplasticity around stress concentrators.

### 5:40 PM Invited

#### **Modeling Shear Band Formation and Propagation in Bulk Metallic Glasses and Nanoglasses:** *Daniel Soper*<sup>1</sup>; Yvonne Ritter<sup>1</sup>; *Karsten Albe*<sup>1</sup>; <sup>1</sup>TU Darmstadt

Plastic deformation in metallic glasses is highly localized in shear bands and there is a broad consensus that shear transformation zones (STZs) are the basic units of plastic deformation. In this work, we study plastic deformation of bulk metallic glasses and nanoglasses by molecular dynamics simulation using LAMMPS. We investigate homogeneous shear band nucleation by simulating tensile deformation of a 3-dimensional-periodic metallic glass sample and compare it to shear band nucleation in the presence of free surfaces and interfaces as present in nanoglasses. In contrast to earlier studies, our results show only little influence of surfaces and interfaces on the shear band nucleation process and the stress-strain-behavior. We conclude that shear band formation involves the condensation of a critical number of STZs along a feasible shear path. Finally, we compare structural features present in shear bands to those found in internal interfaces present in nanoglasses.

## Materials for the Nuclear Renaissance II: Irradiation Effects

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Corrosion and Environmental Effects Committee, TMS/ASM: Nuclear Materials Committee

*Program Organizers:* Raul Rebak, GE Global Research; Brian Cockeram, Bechtel-Bettis; Peter Chou, Electric Power Research Institute; Micah Hackett, TerraPower, LLC

Monday PM Room: 4  
February 28, 2011 Location: San Diego Conv. Ctr

*Session Chair:* Micah Hackett, KAPL

### 2:00 PM Introductory Comments

#### 2:05 PM

**Evaluation of Scale Bridging Methodology for Performance Prediction:** *Dongsheng Li<sup>1</sup>; Yulan Li<sup>1</sup>; Fei Gao<sup>1</sup>; Ram Devanathan; Xin Sun<sup>1</sup>; Moe Kahleel<sup>1</sup>; <sup>1</sup>Pacific Northwest National Laboratory*

Effective property prediction is the cornerstone for performance evaluation of materials under irradiation condition. Molecular dynamics method is used to calculate atomic-level properties of materials, while phase field model is used to predict the microstructure evolution. Different methods have been developed to bridge low scale models with polycrystalline level models. Finite Element Analysis (FEA), microstructure informed FEA, self consistent models, Taylor models, Sachs models and statistical continuum mechanics are evaluated. Cost, efficiency and accuracy were compared for these methods. Pros and cons, depending on the problems studied, are discussed. While open to discussion, general recommendation on bridging methodology is presented based on different scenarios.

#### 2:25 PM

**Localized Deformation in Proton and Heavy Ion Irradiated Austenitic Stainless Steels:** *Zhijie Jiao<sup>1</sup>; Gary Was<sup>1</sup>; Terumitsu Miura<sup>2</sup>; Koji Fukuya<sup>2</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>Institute of Nuclear Safety System*

Recent studies have shown that among the various features of the irradiated microstructure, localized deformation correlates most strongly with irradiation-assisted stress corrosion cracking (IASCC). The degree of localized deformation is influenced by irradiated microstructure and possibly by the irradiation depth if that depth is less than the grain size. In this study, two austenitic stainless steels, 304SS and 316SS, were irradiated to 5 dpa using 1.2 and 2 MeV protons and to 100 dpa using 2.8 MeV Fe<sup>++</sup> at 300/176C. Constant extension rate tensile tests were conducted on the irradiated samples to 2% strain in both argon and water environments. The degree of localized deformation (the weighted average dislocation channel height) was characterized using atom force microscopy and crack initiation was examined using scanning electron microscopy. The effect of the degree of localized deformation on IASCC and the influence of irradiation depth on localized deformation will be presented and discussed.

#### 2:45 PM

**Toward a Better Understanding of Heat-to-Heat Variations in Irradiation-Assisted Stress Corrosion Cracking:** *Peter Chou<sup>1</sup>; Raj Pathania<sup>1</sup>; Bob Carter<sup>1</sup>; <sup>1</sup>Electric Power Research Institute*

There are marked heat-to-heat variations in the susceptibility of materials to environmentally-assisted cracking in LWR environments. Although, in time, all heats will be affected by EAC, it is the "early" failures of a minority of heats in the field that consume attention and resources of the industry. Heat-to-heat variations imply a gap in knowledge between microstructure/microchemistry and materials performance; and better understanding will influence how the industry should approach testing, screening, and development of existing and new materials. This presentation will describe ongoing EPRI-sponsored research on the application of atom-probe

tomography to irradiated stainless steels and discuss how the observations serve as motivation for future research to support existing and new plants.

#### 3:05 PM

**Multiscale Simulation of the Effect of Irradiation-Induced Microstructure Evolution on Reactor Fuel Performance:** *Michael Tonks<sup>1</sup>; Paul Millett<sup>1</sup>; Derek Gaston<sup>1</sup>; Bulent Biner<sup>1</sup>; Anter El-Azab<sup>2</sup>; <sup>1</sup>Idaho National Laboratory; <sup>2</sup>Florida State University*

Fuel performance in nuclear reactors is highly dependent on irradiation-induced microstructure evolution. Therefore, a fuel performance code must consider atomistic and mesoscale effects in order to provide a predictive capability. In this work, we present the multiscale fuel performance modeling approach currently being employed at Idaho National Laboratory (INL). Atomistically-informed mesoscale phase field simulations are used to determine the effect of irradiation-induced microstructure evolution on bulk properties, such as thermal conductivity and density. Continuum expressions describing the effect of irradiation on the bulk properties as a function of temperature are then determined from the mesoscale simulations. Finally, these expressions are used in INL's BISON fuel performance code to model fuel pellet behavior.

#### 3:25 PM Break

#### 3:35 PM

**Mechanical Properties of Fresh and Neutron Irradiated U-Mo Fuels for the RERTR Application:** *Ramprasad Prabhakaran<sup>1</sup>; D Burkes<sup>1</sup>; A Robinson<sup>1</sup>; J-F Jue<sup>1</sup>; A DeMint<sup>2</sup>; J Gooch<sup>2</sup>; D Keiser<sup>1</sup>; D Wachs<sup>1</sup>; I Charit<sup>3</sup>; <sup>1</sup>Idaho National Laboratory; <sup>2</sup>Y-12 National Security Complex; <sup>3</sup>University of Idaho*

The Reduced Enrichment for Research and Test Reactors (RERTR) program was initiated to develop new nuclear fuels to enable the research and test reactors to use low-enriched uranium fuels instead of high-enriched uranium fuels, without significant loss in performance. Hence, a new monolithic fuel type that possesses the greatest possible uranium density in the fuel region is being developed, where the fuel region consists of a single foil encased inside an aluminum alloy cladding. Currently, efforts are ongoing to evaluate the mechanical properties and microstructure of fresh and irradiated fuels as a function of molybdenum content, carbon content, burn up and fabrication method (Friction Bond and Hot Isostatic Pressing). Small-scale specimen testing techniques, such as sub-size tensile testing, microindentation hardness testing and shear punch testing are being performed. Other materials characterization techniques, such as optical microscopy, XRD and SEM are being used in conjunction with the small-scale mechanical test methods.

#### 3:55 PM

**Micro-Displacement Measurement for Small Samples in the Advanced Test Reactor (ATR) National Scientific User Facility (NSUF):** *Anthony Santo Domingo<sup>1</sup>; Mitchell Meyer<sup>2</sup>; Denis Beller<sup>1</sup>; <sup>1</sup>Univ. of Nevada, Las Vegas; <sup>2</sup>ATR National Scientific User Facility*

The ATR NSUF at the Idaho National Laboratory (INL) provides a high-flux environment for long-term irradiation experiments. Battelle Energy Alliance (BEA) and the Electric Power Research Institute (EPRI) are fielding an experiment that will obtain data on the growth rate of zirconium alloys versus hydrogen content. This project will be conducted to investigate a postulated hydrogen-assisted irradiation growth rate mechanism that may be operative in zirconium alloys and that is associated with channel bowing in BWRs. In the project described herein, University of Nevada, Las Vegas faculty and students and INL personnel collaborated in an ATR NSUF Faculty-Student Research Project to design, build, and test a device that will accurately measure the micro-displacement of pre-irradiated and post-irradiated specimens of zirconium alloy. The design, fabrication, and operation of the micro-displacement measurement device will be described.

4:15 PM

**MC Calculation of Optimal Gd and B Containing Composition for Effective Protection from Gamma and Neutron Irradiation:** *Nikoloz Chikhradze*<sup>1</sup>; Leri Kurdadze<sup>2</sup>; Guram Abashidze<sup>1</sup>; <sup>1</sup>Mining Institute/Georgian Technical University; <sup>2</sup>G. Tsulukidze Mining Institute

The radiation materials have different applications, including: working in nuclear reactors, localization of uncontrolled radiation sources, safety storage of radiation wastes and etc. Accordingly, it is actual to create composite materials having the appropriate ratio mixtures of constituents, which can produce stable physical-chemical and radiation-resistant properties and characterized with abilities of inactivated absorption of various types of neutron and gamma irradiation. In the paper the results of calculation of sorption properties of Me-Gd and Me-B composite materials with various ratio of B and Gd are discussed. Calculations was performed by the Monte-Carlo method with a program package GEANT3 including a special package GCALOR for the simulation of the interaction of thermal and fast neutrons within the sample. During the neutron passage through the sample all main processes of the interaction of neutrons with matter are considered including: elastic and inelastic scattering, neutron fission of nuclei, radiation capture, etc.

4:35 PM

**Microstructure and Mechanical Properties of Irradiated Friction Stir Welded ODS Alloys:** *Ramprashad Prabhakaran*<sup>1</sup>; J Wang<sup>2</sup>; I Charit<sup>3</sup>; J Cole<sup>1</sup>; KL Murty<sup>4</sup>; R Mishra<sup>2</sup>; <sup>1</sup>Idaho National Laboratory; <sup>2</sup>Missouri University of Science and Technology; <sup>3</sup>University of Idaho; <sup>4</sup>North Carolina State University

Conventional fusion welding of oxide dispersion strengthened (ODS) alloys causes various undesirable effects, such as coalescence of oxide dispersoids and significant porosity. In this study, MA956 and MA754 alloys were friction stir welded in a bead-on-plate configuration. Microhardness, shear punch and mini-tensile testing of the base and processed materials were carried out to evaluate the mechanical properties. Optical microscopy and transmission electron microscopy were used to study the changes in the grain size and particle characteristics across the weld zone. Efforts are ongoing to study the effect of neutron irradiation (at the Advanced Test Reactor, Idaho Falls) on the friction stir welded MA956 and MA754 alloys. Microhardness and shear punch tests are being carried out on the irradiated samples (1 and 2 dpa), and will be compared with the properties of the unirradiated materials.

## Materials in Clean Power Systems VI: Clean Coal-, Hydrogen Based-Technologies, and Fuel Cells: Materials for Gasification and Turbines I

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division, TMS/ASM: Corrosion and Environmental Effects Committee, TMS: Energy Conversion and Storage Committee, TMS: High Temperature Alloys Committee  
*Program Organizers:* Xingbo Liu, West Virginia University; Zhenguo "Gary" Yang, Pacific Northwest National Laboratory; Jeffrey Hawk, U.S. Department of Energy, National Energy Technology Laboratory; Teruhisa Horita, AIST; Zi-Kui Liu, The Pennsylvania State University

Monday PM  
February 28, 2011

2:00 PM Keynote

**Meeting the Materials Challenges to Enable Clean Coal Technologies:** *Cynthia Powell*<sup>1</sup>; <sup>1</sup>Office of Research and Development, National Energy Technology Laboratory, US Department of Energy

Realization that the environmental impact of energy production must be reduced on a global scale, combined with an increased desire in this country to reduce dependence on foreign energy sources, is driving significant

change in the way the United States will derive and produce power in the future. While renewable energy resources will continue to grow in importance, environmentally responsible fossil energy production will be necessary to provide a bridge to the next energy revolution. This drive to increase efficiencies and reduce environmental impact in fossil-based energy production will lead to increased operating temperatures and pressures and increasingly aggressive operating environments. The practical result is a requirement for affordable and reliable high-performance materials and materials systems to enable these next-generation fossil energy systems. This talk will focus on the research being performed at the National Energy Technology Laboratory to meet this requirement for high performance yet affordable materials.

2:30 PM Keynote

**Mechanistic Understanding of Materials Degradation Processes in Solid Oxide Fuel Cell (SOFC) Power Generation Systems: From Bulk to Interfacial Reactions:** *Prabhakar Singh*<sup>1</sup>; <sup>1</sup>University of Connecticut

High temperature operation of solid oxide fuel cells (600-1000C), exposure of cell components to dual atmosphere, and the presence of complex gas environment have been associated with severe surface and bulk corrosion and structural degradation conditions in cell and the balance of plant (BOP) components. This presentation provides an overview of materials degradation and corrosion processes operating in cell stack and BOP. Role of bi-polar exposure condition on accelerated corrosion has been investigated. Oxide evaporation in oxidizing and reducing atmospheres has also been investigated and its influence on the catalytic and electrocatalytic poisoning will be reported. Pertinent electrode structural changes and interfacial compound formation will be examined and discussed. Current research trend will be presented.

3:00 PM Invited

**The Impact of Mixed Carbon Feedstock on High Cr2O3 Refractory Liners Used in Commercial Gasifiers:** *James Bennett*<sup>1</sup>; Kyei-Sing Kwong<sup>1</sup>; Seetharaman Sridhar<sup>2</sup>; Jinichiro Nakano<sup>3</sup>; <sup>1</sup>NETL, US DOE; <sup>2</sup>Carnegie Mellon University; <sup>3</sup>URS Corp.

Gasifiers are high temperature/pressure reaction vessels used to contain interactions between a carbon feedstock, water, and oxygen (reducing environment); producing CO and H2 used in power generation or chemical production. Carbon feedstock includes coal and/or petcoke, with biomass considered a candidate to produce a carbon neutral process. Impurities in carbon feedstock materials vary from about 1-10 pct and liquefy during gasification (1325-1575°C, 10-8 O2 partial pressure), forming slags that interact with the high chrome oxide refractory liner by chemical corrosion and spalling, causing unpredictable and premature shutdown of a gasifier. Mixtures of carbon feedstock that include biomass will have an unknown impact on slag properties and refractory liners, and are the focus of ongoing research. Slag properties and slag/refractory interactions are being evaluated by post mortem analysis of commercial gasifier samples, in laboratory simulations, and by thermodynamic modeling. Results of these studies to date will be presented.

3:25 PM Break

3:40 PM

**Stability of Mullite and V2O3 in Synthetic Slags Based on Molten Coal/Petcoke Ash Mixtures:** *Jinichiro Nakano*<sup>1</sup>; Seetharaman Sridhar<sup>2</sup>; Kyei-Sing Kwong<sup>1</sup>; James Bennett<sup>1</sup>; Thomas Lam<sup>1</sup>; <sup>1</sup>NETL; <sup>2</sup>Carnegie Mellon University

In gasifiers, non-volatiles such as SiO2 in coal and petcoke carbon feedstock form slags that can impact gasifier efficiency and increase refractory corrosion. In this study, synthetic slags simulating coal-petcoke ash mixtures were evaluated for phases existing in a gasification environment at 1500°C and Po2=10-8atm. VxOy-bearing phases are of particular interest because their stabilities are governed by Po2. Slag mixtures of SiO2-Al2O3-Fe2O3-CaO-V2O5 containing 0-10wt.% of V2O5 were equilibrated at 1500oC and rapidly quenched to freeze high temperature phases. XRD analyses identified mullite (in Al2O3-rich slags) and V2O3 (in V2O5-rich slags) as stable

MONDAY PM

phases. TEM and EPMA analyses indicated that the mullite contained V and V<sub>2</sub>O<sub>3</sub> contained Al. Concentration depended on starting slag composition. XRD indicated that lattice parameters of the two crystalline phases were found to vary with elemental substitution. The presence of the solid phases is discussed in light of its impacts on slag fluidity and refractory erosion.

#### 4:00 PM

**Effect of Temperature Gradient on Slag Infiltration into Porous Refractory Material:** *Tetsuya Kaneko*<sup>1</sup>; *Junichiro Nakano*<sup>2</sup>; *Seetharaman Sridhar*<sup>1</sup>; *Kyei-Sing Kwong*<sup>2</sup>; *Rick Krabbe*<sup>2</sup>; *Hugh Thomas*<sup>2</sup>; *James Bennett*<sup>2</sup>; <sup>1</sup>Carnegie Mellon University; <sup>2</sup>US Department of Energy National Energy Technology Laboratory

Entrained-flow slagging gasifiers produce syngas (CO and H<sub>2</sub>) using coal, petcoke, and/or biomass as a carbon feedstock. The high operating temperatures (1325-1575°C) of these gasifiers, along with corrosive gases and slags from the carbon feedstock pose material challenges in the gasifier. Slags originating from mineral impurities in the carbon feedstock liquefy, corrode, and penetrate the porous refractory liner. The penetration characteristics of coal slag into alumina refractory have been studied using a temperature gradient along the slag's penetration direction, which are compared to those obtained under isothermal conditions. The studies were conducted with a hot face temperature of 1450°C and a CO/CO<sub>2</sub> ratio of 1.8 (corresponding to an oxygen partial pressure of approximately 10-8 atm). Slag-infiltrated refractory samples were studied using SEM-EDS to identify primary phases and to track the slag's changing chemical composition. Primary phases and slag compositions were compared to those calculated in using FactSage™ software.

#### 4:20 PM Invited

**Creep Strength Property of Advanced Ferritic Creep Resistant Steels for Fossil Energy Applications:** *Kazuhiro Kimura*<sup>1</sup>; *Kota Sawada*<sup>1</sup>; <sup>1</sup>National Institute for Materials Science

An overestimation of long-term creep strength was pointed out on creep strength enhanced ferritic (CSEF) steels and premature failure due to Type IV cracking and remarkable drop in creep rupture ductility were also recognized. Microstructural evolution is influenced by stress and that is different in the high- and low-stress regimes divided by a macroscopic elastic limit where successive plastic deformation of polycrystalline material initiates which corresponds to 50% of 0.2% offset yield stress. A region splitting analysis method was proposed for a reliable life prediction of CSEF steels and allowable stress was reduced. Creep rupture ductility drop is caused by a combination of high creep strength and stress dependence of creep deformation. In order to ensure strength and soundness, upper limit of aluminum was reduced from 0.04mass% to 0.02mass% and maximum level of 0.01mass% was specified on titanium and zirconium, as well as weld strength reduction factor.

#### 4:45 PM

**A Comparison of Creep-Rupture Tested Cast Alloys HR282, IN740 and 263 for Possible Application in Advanced Ultra-supercritical Steam Turbine and Boiler Components:** *Neal Evans*<sup>1</sup>; *Philip Maziasz*<sup>2</sup>; *Yukinori Yamamoto*<sup>2</sup>; *Paul Jablonski*<sup>3</sup>; <sup>1</sup>University of Tennessee, Knoxville; <sup>2</sup>Oak Ridge National Laboratory; <sup>3</sup>National Energy Technology Laboratory

Cast forms of traditionally wrought Ni-base precipitation-strengthened superalloys are being considered for service in the ultra-supercritical conditions (760°C, 35MPa) of next-generation steam boilers and turbines. After casting and homogenization, these alloys were given heat-treatments typical for each in the wrought condition to develop the gamma-prime phase. Specimens machined from castings were creep-rupture tested in air at 800°C. In their wrought forms, alloy 282 is expected to precipitate M<sub>23</sub>C<sub>6</sub> within grain boundaries, alloy 740 is expected to precipitate several grain boundary phases including M<sub>23</sub>C<sub>6</sub>, G Phase, and η phase, and alloy 263 has M<sub>23</sub>C<sub>6</sub> and MC within its grain boundaries. This presentation will correlate the observed creep-life of these cast alloys with the microstructures developed during creep-rupture tests, with an emphasis on the phase identification and chemistry of precipitated grain boundary phases. The suitability of these cast

forms of traditionally wrought alloys for turbine and boiler components will also be discussed.

#### 5:05 PM

**Mesososcopic Finite Element Analysis of Interfacial Failure in High Temperature Alloys:** *Changsoo Kim*<sup>1</sup>; *Keeyoung Jung*<sup>2</sup>; *Frederick Pettit*<sup>2</sup>; *Gerald Meier*<sup>2</sup>; <sup>1</sup>University of Wisconsin-Milwaukee; <sup>2</sup>University of Pittsburgh

A numerical model has been developed employing mesoscopic finite element analysis (FEA) to study interfacial failure in high temperature alloys and coatings. Using this model, the impacts of mesoscopic details on the thermo-mechanical performance such as different oxide compositions, types, sizes and shapes of encapsulated particles, and geometries of scales can be quantitatively estimated. The developed algorithm was applied to the scale buckling phenomena in an outward-growing thermal oxide that may occur in syngas-fired gas turbines assuming that brittle interfacial fracture occurs in Mode II. Experimentally observed microstructures with measured thermo-mechanical parameters were incorporated in the model. The presentation will discuss and elucidate the potential scale decohesion mechanism observed in experiments. This FEA model can be readily expanded to thermo-mechanical issues in other high temperature material applications that are integrated with clean energy systems such as scale spallation from metallic SOFC interconnects.

### Materials Processing Fundamentals: Process Modeling

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Process Technology and Modeling Committee

*Program Organizers:* Prince Anyalebechi, Grand Valley State University; Srikanth Bontha, Temple University

Monday PM

February 28, 2011

*Session Chair:* Prince Anyalebechi, Grand Valley State University

#### 2:00 PM

**Computational Modeling of Field-Assisted Sintering:** *Cristina Garcia Cardona*<sup>1</sup>; *Eugene Olevsky*<sup>1</sup>; *Veena Tikare*<sup>2</sup>; <sup>1</sup>San Diego State University; <sup>2</sup>Sandia National Laboratories

A three-dimensional multi-scale model of Field-Assisted Sintering is presented. The model captures the complexity of the multiphysics phenomena involved in field-assisted sintering by coupling: electrical, thermal, stress-strain and densification components. The calculations are based on the finite-element (macroscopic scale) and kinetic Monte-Carlo (mesoscopic scale) codes. Specimen's macroscopic behavior is described through a non-linear viscous constitutive relation. The simulation of the densification is based on local conditions, and micro-scale factors as grain growth are also taken into account. Thus not only distributions of current density, temperature and strain fields can be obtained but also a spatial density and grain size evolution can be computed. The sintering constitutive parameters are determined through Monte-Carlo simulations of the grain-pore structure evolution. This corresponds to a true 3D, multi-scale, multiphysics modeling of sintering. The modeling predictions are discussed via several examples and calculation results are compared with experimental data available.

#### 2:15 PM

**Simulation of Macroseggregation Due to Melt Convection and Grain Sedimentation in Steel Ingots Using a Mixture Model:** *Wensheng Li*<sup>1</sup>; *Houfa Shen*<sup>1</sup>; *Baicheng Liu*<sup>1</sup>; <sup>1</sup>Tsinghua University

In order to understand the formation of macroseggregation in steel ingots, a mixture solidification model has been developed which accounts for coupled mass, momentum, species, and energy transport and notably describes the sedimentation of free equiaxed grains. In this model, the mushy zone

is divided into the slurry and porous regimes according to a solid packing fraction. Settling velocity of equiaxed grains in the slurry regime is given by an explicit expression. The solidification of a binary steel ingot (Fe-0.36 wt pct C) with a two-dimensional geometry is numerically simulated. It is demonstrated that the predicted macrosegregation patterns agree to some extent with classical experimental results. Further refinement of this model is still necessary for realistically simulating steel ingot solidification.

**2:30 PM**

**Effect of Casting Speed on Temperature Difference between Copper Plate and Solidifying Shell in Meniscus of Slab Continuous Casting Mold:** *Xiangning Meng*<sup>1</sup>; <sup>1</sup>Northeastern University

A three-dimensional finite-element heat-transfer model was established to predict temperature of hot copper plate in a slab continuous casting mold and effect of casting speed on temperature difference between copper plate and solidifying shell was simulated in combination with process data. The results show that centre temperature of hot copper surface at casting speed 1.8 m·min<sup>-1</sup> and 2.0 m·min<sup>-1</sup> are higher than that of 1.6 m·min<sup>-1</sup> casting speed 4.7-5.2 °C and 11.2-12.2 °C respectively and temperature is not increased linearly with casting speed. Temperature difference in meniscus between mold wall and shell surface is influenced obviously by casting speed and increased 4.0-6.0 °C with increment of casting speed 0.2 m·min<sup>-1</sup>. Fluctuation of temperature difference in meniscus is a main reason to deteriorate casting effectiveness as increasing casting speed.

**2:45 PM**

**Numerical Simulation of Decarburization Reaction on the Surface of Liquid Iron:** *Hyunjin Cho*<sup>1</sup>; Sangjoon Kim<sup>1</sup>; Haegon Lee<sup>1</sup>; <sup>1</sup>POSTECH

Decarburization phenomena on the surface of liquid iron have been simulated by numerical method and the results were compared to the experimental data. During the DeC process in a converter, a large amount of splashed droplets are generated from the top surface of the bath and consequently the reaction surface area is increasing tremendously. Since the decarburization mainly occurs at the interface, it is important to understand the reactions on the liquid iron droplets. The flow and species concentration fields around liquid droplets taking into account the reaction of carbon with oxygen at the interface were calculated by a commercial CFD code FLUENT which solving multiphase Navier-Stokes equation with Volume Of Fluid method. The initial carbon concentration was fixed to 4 wt% and the concentrations of oxygen in the atmosphere were varied from 5 to 50 wt%. This numerical approach could allow predicting the decarburization rate of liquid iron.

**3:00 PM**

**3D Simulation of the Melting during an Electro-Slag Remelting Process:** *Abdellah Kharicha*<sup>1</sup>; <sup>1</sup>University of Leoben

The droplet formation during the melting of a 400 mm diameter electrode is simulated with a multiphase-MHD approach. The computational model includes a layer of slag and a layer of liquid steel. A VOF approach is used for the interface tracking, and a potential formulation is used for the electric and the magnetic field. The Lorentz force and the Joule heating is recalculated at each time step in function of the phase distribution. The first results provided by this model are presented.

**3:15 PM Break**

**3:30 PM**

**An Analysis of Electromagnetic Field and Joule Heating of Electroslag Remelting Processes with Two Series-Connected Electrodes:** *Fang Wang*<sup>1</sup>; *Baokuan Li*<sup>1</sup>; <sup>1</sup>Northeastern University

Comparing with single electrode in electroslag remelting processes, two series-connected electrodes have the advantage of small inductive, low power consumption and high efficiency, which was widely used to produce large scale steel. In the present work, a 3D finite element model was developed for the magnetic field, electromagnetic force, current density and Joule heating field of electroslag remelting processes (electrode, slag and ingot) with two series-connected electrodes using Maxwell equation, Lorentz law and Joule law. It was found through comparison that the modeling results

is in accord with the experimental results, thus verifying the reliability of the model developed and relevant computation program. The results show that the current distribute on internal surfaces of electrode is smaller than on external surfaces; the maximum electromagnetic force is at the upper surface of slag nearby the electrode and the maximum joule heating is at the middle bottom of two electrodes.

**3:45 PM**

**Modeling of Copper Converter Foamover and Operational Improvements:** *Pengfu Tan*<sup>1</sup>; <sup>1</sup>Xstrata Copper

The foamed converter charges were up to 38 per month in Xstrata Copper Smelter at Mount Isa. The issue of high converter foamover frequency had remained unsolved for many decades in Mount Isa. A thermodynamic model of copper P-S converter and a viscosity model of converter slag have been developed to simulate the slag blow and copper blow, in order to understand the mechanism of converter foamover. The model predicts the chemistry and viscosity of slag during slag blow and copper blow. The effects of oxygen potential, charge of dirty reverts, slag carry-over, under-blowing, over-blowing, and temperature on the foamover and viscosity of slag in copper blow have been discussed. A theory has been developed to understand the mechanism of converter foamover. The practical solutions have also been developed and implemented in Mount Isa Copper Smelter. Some improvements of the industrial operations have been presented. After a series of improvements, the number of foamed charges per month in the converter operations has been decreased significantly from 35 in Aug 2008 to only one per month in 2009/2010.

**4:00 PM**

**Modeling and Control of Copper Loss in Smelting Slag: Part I and Part II:** *Pengfu Tan*<sup>1</sup>; <sup>1</sup>Xstrata Copper

Xstrata Copper Smelter at Mount Isa in Australia had experienced the technical issue of high copper losses in smelting slag (or RHF slag) before 2008. The copper losses in RHF slag was more than 3% in 2006 and 2007. The thermodynamic models, viscosity model have been developed to simulate the process control, slag chemistry, slag viscosity, and matt-slag separations. The theory of RHF KPIs has also been developed to reduce the copper losses in RHF slag. The RHF KPIs Theory has been applied in Mount Isa Copper Smelter. The copper losses in RHF slag have been dropped from 3.1% in 2007 to 0.76% in Apr 2009. The average copper loss in RHF slag in 2009 and 2010 is about 0.9%.

**In-Situ TEM Study on Elastic Interaction between a Prismatic Dislocation Loop and a Gliding Dislocation:** *Yoshi Matsukawa*<sup>1</sup>; Grace Liu<sup>1</sup>; Ian Robertson<sup>1</sup>; <sup>1</sup>University of Illinois

Due to its glissile character the prismatic dislocation loop is expected to be either swept or arrested by the strain-field of gliding dislocations, and the latter is believed to be a key mechanism whereby locking of dislocation source occurs in neutron-irradiated metals. In this talk we show the first successful in-situ TEM observation capturing trap and de-trap processes

MONDAY PM

of the prismatic loop to/from a gliding dislocation. The critical capture distance measured on a micrograph was ~8 nm, which was smaller than the loop diameter (~10 nm). The gliding dislocation was originally a mixed dislocation; however, its line direction changed to a screw configuration upon interaction. The dislocation eventually bypassed the loop via cross-slip to a plane with a resolved shear stress ~40% smaller than that of the original slip plane. The prismatic loop was certainly an obstacle for dislocation-slip though a single loop was insufficient to completely lock the dislocation.

#### 2:40 PM

**In-Situ Investigation of Microstructure Evolution in NF616 and HCM12A Alloys under Heavy Ion Irradiation:** *Cem Topbası<sup>1</sup>*; Arthur Motta<sup>1</sup>; Mark Kirk<sup>2</sup>; <sup>1</sup>Pennsylvania State University; <sup>2</sup>Argonne National Laboratory

The NF616 and HCM12A ferritic-martensitic alloys are candidate cladding and duct materials for Generation IV nuclear energy systems. In-situ investigation of radiation damage was conducted for these alloys using the IVEM-Tandem at Argonne National Laboratory, which is a transmission electron microscope interfaced with ion accelerators allowing observing the development of irradiation damage as it occurs. The alloys were irradiated in situ to 15 dpa with 1 MeV Kr<sup>++</sup> ions at temperatures between 50K and 673K. The number density and size distribution of irradiation induced defects were determined as a function of dose and temperature. Nano-sized defects (~1-2 nm) first appeared as white dots in dark-field TEM images between 0.5 to 1 dpa and later develop into resolvable loops. Dynamic observations show that black dots constantly appear and disappear under irradiation indicating a steady state of defect density. At high doses, complex defect superstructures including loop alignment were observed.

#### 3:00 PM

**Thermal Annealing Recovery Behavior of HT-9 Steel Irradiated to High Doses in FFTF:** *Thak Sang Byun<sup>1</sup>*; William Lewis<sup>1</sup>; Stuart Maloy<sup>2</sup>; <sup>1</sup>Oak Ridge National Laboratory; <sup>2</sup>Los Alamos National Laboratory

The Fuel Cycle R&D Program is investigating methods of burning minor actinides in a transmutation fuel, for which the fast reactor core materials must be able to withstand very high doses (>200 dpa). To investigate operating strategies to reduce the buildup of radiation-induced defects, thermal annealing behavior has been studied for irradiated HT-9 steel. Samples were taken from representative locations of the ACO-3 duct of Fast Flux Test Facility: their irradiation doses were in the range of 3 – 148 dpa and irradiation temperatures in the range of 379 – 503 °C. The samples were tested after each isochronal anneal for 1 hour at 300 – 650 °C or after each isothermal anneal at 510 or 550 °C. The radiation-induced hardening was nearly completely recovered by one-hour isochronal annealing above 550 °C or by isothermal annealing at 510 °C for about 20 hours or at 550 °C for 2 hours.

#### 3:20 PM

**Microstructural Study of Pure Iron and Fe-Cr Model Alloys Ion Irradiated within the Jannus Platform (In- and Ex-Situ Mode):** *Daniel Brimbal<sup>1</sup>*; Estelle Meslin<sup>1</sup>; Brigitte Décamps<sup>2</sup>; Jean Henry<sup>1</sup>; Alain Barbu<sup>1</sup>; <sup>1</sup>C.E.A. Saclay; <sup>2</sup>CNRS

Damage displacement cascades and helium production by transmutation reactions will result from the intense neutron irradiation in structural materials of future Fusion and GenIV reactors. In order to predict in-service properties of such materials, the microstructural evolution under irradiation of model materials (high purity iron and Fe-Cr alloys) has been studied using the JANNUS platform. Single- and dual-beam irradiations (Fe and Fe/He) have been performed ex-situ and in-situ (TEM) at high temperature. The TEM analysis leads to the following results: - In both materials irradiated ex-situ at 500°C up to 6 dpa, a coarse microstructure of large <100> dislocation loops, located in {100} planes, was formed. - Single-beam in-situ irradiations show a difference between iron and Fe-5at.%Cr: dislocation loops formed during irradiation display back-and-forth motion in iron but not in the alloy. They interact with dislocations in the alloy. - Dual-beam in-situ and ex-situ experiments are being analysed.

#### 3:40 PM

**Multiple-Beam Irradiation Effects in Ferritic Steels:** *Naoyuki Hashimoto<sup>1</sup>*; Norihito Yamaguchi<sup>1</sup>; Hiroshi Oka; Hiroshi Kinoshita<sup>1</sup>; Somei Ohnuki<sup>1</sup>; <sup>1</sup>Hokkaido University

Reduced-activation ferritic/martensitic steel F82H has been developed as one of prime candidate materials for experimental fusion reactors. To estimate irradiation effects in fusion reactor components, multiple-scale modeling has been studied. Modeling activities for irradiation induced microstructural change is quite effective to enhance the capability to predict mechanical properties of the materials during irradiation. Defect activation energies such as vacancy and interstitial migration energies should be estimated to obtain fundamental parameters for the modeling. And also, some of the key issues are the effects of helium and hydrogen on the microstructure evolutions such as swelling, and on the mechanical properties such as fracture toughness or embrittlement. In this study, TEM specimens of F82H, Fe-8Cr model alloy, and Pure Fe have been irradiated by electron and helium ion beams using a High Voltage Electron Microscope (HVEM) as the experimental evaluation of the modeling and simulations.

#### 4:20 PM

**The Effects of Mn on Microstructure and Hardness in A533B and Model Alloys:** *Hideo Watanabe<sup>1</sup>*; Naoaki Yoshida<sup>1</sup>; <sup>1</sup>RIAM, Kyushu University

It is well known that radiation hardening and embrittlement of A533B steels are very sensitive to minor solutes (namely, P, Cu, Ni, Si etc.) containing in the steels. To investigate the effect of these solutes on microstructural evolution and hardness changes due to irradiation, A533B steels and some model alloys were irradiated by neutron, Fe ion and electron at 290°C. After the irradiation, the microstructure of the specimens was observed by transmission electron microscopy. The recovery behavior of the hardness by post-irradiation annealing at 450°C was related with the disappearance of these dislocation loops. The study revealed that the formation of interstitial type dislocation loops, which can be seen by conventional weak-beam technique, was essential for irradiation hardening of these samples. In this study, microstructure and hardness of these samples were compared with the results of Fe ion and electron irradiation at room temperature and 290°C.

#### 4:40 PM

**Microstructural Changes by Thermal Aging and Neutron Irradiation in Stainless Steel Weld Overlay Cladding of Nuclear Reactor Pressure Vessels:** *Tomoaki Takeuchi<sup>1</sup>*; Jun Kameda<sup>2</sup>; Yasuyoshi Nagai<sup>3</sup>; Takeshi Toyama<sup>3</sup>; Yutaka Nishiyama<sup>1</sup>; Kunio Onizawa<sup>1</sup>; <sup>1</sup>Japan Atomic Energy Agency; <sup>2</sup>National Institute for Materials Science; <sup>3</sup>The Oarai Center, Institute for Materials Research, Tohoku University

Microstructural changes in thermally aged and neutron-irradiated stainless steel weld overlay cladding applied to the inner surface of nuclear reactor pressure vessels were investigated using three-dimensional atom probe (3DAP). The cladding material was composed mainly of austenitic phase and partly of ferritic phase. In the as-received cladding material, a slight fluctuation of Cr concentration probably due to spinodal decomposition was observed only in the ferritic phase. Moreover in the ferritic phase, thermal aging at 400°C for 10,000 h caused the precipitation of G phase with chemical composition of Ni:Si:Mn = 16:7:6 as well as increased spinodal decomposition. Significant hardening of the ferritic phase was induced by the thermal aging. A correlation between hardening and the microstructural changes will be discussed. The neutron irradiation effects will be also shown in this presentation.

#### 5:00 PM

**Dependence of Radiation Induced Segregation on Grain Boundary Structure in a 9 wt.% Cr Model Ferritic/Martensitic Steel:** *Kevin Field<sup>1</sup>*; James Bentley<sup>2</sup>; Chad Parish<sup>2</sup>; Jeremy Busby<sup>2</sup>; Todd Allen<sup>1</sup>; <sup>1</sup>University of Wisconsin - Madison; <sup>2</sup>Oak Ridge National Laboratory

Ferritic/Martensitic (F/M) steels containing 9 wt.% Cr, are candidate materials for structural components in the next generation of advanced nuclear and fusion reactors. Although it is known that these alloys exhibit

radiation induced segregation (RIS) at grain boundaries (GBs) while in-service, little is known about the mechanism behind RIS in F/M steels. Current understanding of RIS in F/M steels presents a model of point defect migration to GBs, which are considered perfect sinks. Changes in grain boundary character may influence the sink nature and migration processes. Proton irradiated 9 wt.% Cr model steel was investigated using STEM/EDS spectrum imaging and GB misorientation analysis to determine the role of GB structure on RIS at different GBs. This preliminary investigation found Cr preferentially segregates to specific GB structures. The preferential segregation to specific GB structures suggests a need to alter the understanding of how point defects interact at GBs in F/M steels.

**5:20 PM**

**Kinetic Lattice Monte Carlo Simulations of Radiation Induced Segregation of Chromium in Ferritic-Martensitic Steels:** *Brian Frisbie*<sup>1</sup>; Brian Wirth<sup>1</sup>; <sup>1</sup>University of California at Berkeley

Ferritic-martensitic steels with 8-12% Cr are leading candidates for advanced nuclear applications because of their superb thermal properties and swelling resistance. Irradiation of these steels introduces microstructural and microchemical changes in the material that can lead to degradation of their structural properties through processes such as radiation-induced embrittlement. In this work, we present a kinetic lattice Monte Carlo model intended to simulate the segregation behavior of Cr to grain boundaries in these ferritic-martensitic steels while under irradiation. The simulations confirm that the enrichment or depletion of Cr at grain boundaries is dependent on its diffusivity relative to that of Fe. While variations in input parameters including the temperature and local energy barriers influence the direction and rate of Cr enrichment, all simulation results display a tendency towards saturation in Cr content at the grain boundaries after a sufficiently high dose.

**5:40 PM**

**Application of Modified Inverse Kirkendall Model of Radiation-Induced Segregation to Ferritic-Martensitic Alloys:** *Janelle Wharry*<sup>1</sup>; Zhijie Jiao<sup>1</sup>; Gary Was<sup>1</sup>; <sup>1</sup>University of Michigan

Ferritic-Martensitic (F-M) alloys are leading candidates for fast reactor cladding and structural materials. This study is a combined experiment-modeling effort to understand radiation-induced segregation (RIS) of Cr in these alloys. Alloys T91 (9wt%Cr), HT9 (12wt%Cr), and HCM12A (11wt%Cr) were irradiated with 2.0 MeV protons at 400°C to 3, 7, and 10 dpa, and with 5.0 MeV Fe<sup>2+</sup> ions to 100 dpa at an equivalent temperature. Prior austenite grain boundary (PAGB) compositions were measured with scanning transmission electron microscopy using energy-dispersive X-ray spectroscopy (STEM/EDS). Results show Cr depletion at PAGBs in HT9 and HCM12A, and enrichment in T91. The modified inverse Kirkendall (MIK) model, which has successfully predicted RIS in austenitic alloys, was modified for the Fe-Cr system and used to predict the direction and magnitude of RIS in F-M alloys. Model results are compared to experimental results and are discussed in the context of the RIS mechanism in F-M alloys.

**6:00 PM**

**Ab Initio-Based Rate Theory Modeling of Radiation Induced Segregation in Ni-Cr Alloys:** *Leland Barnard*<sup>1</sup>; Samrat Choudhury<sup>2</sup>; Dane Morgan<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison; <sup>2</sup>Los Alamos National Lab

The fcc Ni-Cr alloy system forms the basis of an important class of structural materials in the nuclear power industry, both in existing reactors and for future reactor designs. Point defect diffusion under irradiation in this alloy results in a phenomenon known as radiation induced segregation (RIS), whereby Cr is depleted near grain boundaries, voids, and surfaces. Cr is essential to the corrosion resistance of these alloys, and depletion near these critical microstructural features potentially results in a vulnerability to corrosion damage. In this study, we construct a rate theory model to simulate RIS in Ni-Cr alloys parameterized entirely with data obtained through ab initio calculations. Our results indicate that details pertaining to the fate of radiation produced defects that are neglected in conventional RIS modeling, such as defect sink bias, production bias, and energetic defect trapping, may play a critical role in the evolution of Cr RIS.

**2:00 PM Keynote**

**The Metallurgy of Sn Whisker and Hillock Growth:** *William Boettinger*<sup>1</sup>; <sup>1</sup>National Institute of Standards and Technology

Pb-free pre-tinned electronic components are subject to the spontaneous growth of Sn whiskers at room temperature. These whiskers are known to have caused shorts in various high reliability circuits. The metallurgical factors affecting whisker growth will be described. The columnar grain structure of Sn deposits combined with biaxial in-plane compressive stress cause either whiskers or hillocks to grow due to a grain boundary creep-type mechanism. Hillocks appear to grow when the grain boundaries of the Sn in the substrate are mobile whereas whiskers grow when the Sn grain boundaries in the substrate are pinned. The biaxial stress is due to the plating process as well as the growth of Cu<sub>3</sub>Sn<sub>5</sub> intermetallic particles. Remaining questions related to the location of nucleation sites for hillocks and whiskers as well as the details of the stress generation mechanisms will be discussed.

**2:40 PM Invited**

**Kinetic Mechanisms Controlling IMC Growth, Stress Evolution and Whisker Formation:** *Eric Chason*<sup>1</sup>; Nitin Jadhav<sup>1</sup>; Eric Buchovecky<sup>1</sup>; Fei Pei<sup>1</sup>; Allan Bower<sup>1</sup>; Sharvan Kumar<sup>1</sup>; <sup>1</sup>Brown University

Understanding the mechanisms controlling tin whisker formation is necessary for developing reliable mitigation strategies and for developing predictive models. Although stress is widely accepted as the driving force

MONDAY PM

for whisker growth, there are still many questions about how the stress is generated, what controls its evolution and how it leads to whisker formation. To address these issues, we present results from real-time studies that explore the correlation between the kinetics of IMC growth, stress evolution and whisker nucleation in films with different microstructures and layer morphologies. Comparisons among different measurements (e.g. varying layer structures, grain sizes, surface oxide layers and Pb content) help identify the different kinetic processes that play a role in their evolution. These mechanisms are used to develop a finite element analysis (FEA) model combining IMC growth, plastic deformation and grain boundary diffusion to simulate how the stress evolves and how it leads to whisker growth.

### 3:05 PM Invited

**Role of Stress and Oxidation on Metallic Whisker Growth:** *Elizabeth Hoffman*<sup>1</sup>; Yong Sun<sup>2</sup>; Poh-Sang Lam<sup>1</sup>; Xiaodong Li<sup>2</sup>; <sup>1</sup>Savannah River National Laboratory; <sup>2</sup>University of South Carolina

Preventing metallic whisker growth leading to electronic failures is particularly important in microelectronic circuits where devices are separated by spacings as small as tens of nanometers. Historically, lead has been added to solders to suppress whisker growth and to improve the manufacturing processes. With the understanding of lead's harmful effects on the environments and human health, this is no longer an acceptable solution. It is generally acknowledged that internal stresses arising in low melting point metals, such as Sn, promote whisker growth based on a creep-like process. Compressive stress resulting from metal oxidation is one of the theories that have been suggested to play a role in the growth of whiskers. To investigate the influence of oxidation on whisker formation and growth, a series of experiments are underway to correlate the oxygen uptake, the measured internal stress, and the whisker density that forms on specimens with particular thin film/substrate combinations.

### 3:30 PM

**Evidence of Plastic Deformation Adjacent to Sn Whiskers:** *John Osenbach*<sup>1</sup>; Robert Hilty<sup>2</sup>; <sup>1</sup>LSI Corporation; <sup>2</sup>Tyco

In this paper the results of indentation induced plastic deformation and Sn whisker growth is reported. Sn plating on a number of different substrate materials were subjected to indentation stresses. Post indentation, the microstructure and presence or absence of whiskers was evaluated using scanning and transmission electron microscopy. In all cases, independent of substrate alloy, plastic deformation as observed as evidenced by grain elongation and compression with no whiskers in the indentation region. Adjacent to the plastically deformed region whiskers are observed. Whiskers were typically found within 500um of the plastically deformed region. We interpret the results as being consistent with a theory that one of the authors has recently published "Creep and It's Affect on Sn Whisker Growth Whisker Formation".

### 3:50 PM Break

### 4:00 PM

**Whisker Formation Induced by Component and Assembly Ionic Contamination:** *Polina Snugovsky*<sup>1</sup>; Stephan Meschter<sup>2</sup>; Zohreh Bagheri<sup>1</sup>; Eva Kosiba<sup>1</sup>; Marianne Romankys<sup>1</sup>; <sup>1</sup>Celestica; <sup>2</sup>BAE Systems

The paper will describe the results of an intensive whisker formation study on Pb free assemblies with different level of cleanliness. Thirteen types of as-received surface mount (SMT) and pin-through-hole (PTH) components were cleaned and intentionally contaminated with solutions containing chloride, sulfate, bromide, and nitrate. Then the parts were assembled on double sided boards that were also cleaned or intentionally contaminated with three fluxes having different halide contents – ROL0, ROL1, and ORH1. The assemblies were subjected to high temperature/high humidity testing (85°C/85%RH). Periodic examination found that contamination triggers whisker formation on both exposed tin and solder fillets. Whisker occurrence, morphology, and length parameters depending on the type and level of contamination will be discussed. Sequential cross-sections were used to assess the metallurgical aspects of whisker formation and the microstructural changes occurring during corrosion.

### 4:20 PM

**Microstructure Formation and Whisker Growth in SAC105 Solder Joints with Rare Earth Elements:** *Polina Snugovsky*<sup>1</sup>; Zohreh Bagheri<sup>1</sup>; Stephan Meschter<sup>2</sup>; Leonid Snugovsky<sup>3</sup>; John Rutter<sup>3</sup>; Doug Perovic<sup>3</sup>; <sup>1</sup>Celestica; <sup>2</sup>BAE Systems; <sup>3</sup>University of Toronto

Rare earth elements (REE) such as Y, Ce, and La being added to Sn-Ag-Cu alloys may improve mechanical properties of solder joints. It was shown in literature that the addition of 0.2% REE refines the microstructure positively effecting drop/shock behavior. Unfortunately, it has also been demonstrated that Sn-Ag-Cu solders with REE are prone to whisker formation. In the present work, microstructure of SAC105 solder with 0.1 – 0.4 % Y, Ce, or La reflowed on the Cu substrate, is examined. The results of high temperature/high humidity testing that may trigger whisker formation is discussed. The similarities and differences in microstructure and whisker growth of SAC105 solder joints with different REE is examined from a metallurgical perspective using sequential microsectioning. The influence of flux type and cleanness on propensity of whiskering is discussed.

### 4:40 PM

**Tin Whisker Growth on the Surface of Sn-3.8Ag-0.7Cu-RE Solder Alloys:** *Hu Hao*<sup>1</sup>; Fu Guo<sup>1</sup>; Yonglun Song<sup>1</sup>; Guangchen Xu<sup>1</sup>; Yaowu Shi<sup>1</sup>; <sup>1</sup>Beijing University of Technology

Alloying approach by adding trace amount of rare earth (RE) elements in Sn-3.8Ag-0.7Cu solder alloy has been widely reported to show its ability on the improvement of processing and reliability properties. However, bulk RE-Sn phases, when adding excessive RE elements, can be observed inside the solder matrix. This study systematically investigated the tin whiskers growth (including the incubation time, growth rate, quantity, morphology, size, etc.) on the surface of CeSn<sub>3</sub>, LaSn<sub>3</sub>, (La<sub>0.4</sub>Ce<sub>0.6</sub>)Sn<sub>3</sub>, ErSn<sub>3</sub>, and YSn<sub>3</sub> by adding excessive Ce, La, La/Ce mixture, Er and Y, respectively, in the Sn-3.8Ag-0.7Cu solder. Most important, the finding of tin whiskers with a non-constant cross-section provided a better understanding to the spontaneous growth equation of tin whiskers. In addition, a hypothesis of "double stress zones" was proposed to demonstrate the underlying mechanism for tin whiskers growth on the bulk RE-Sn phases.

### 5:00 PM

**Effect of Sn Layer on Whisker Growth Kinetics: Modifying the Surface, Microstructure, Composition and Heat Treatment:** *Fei Pei*<sup>1</sup>; Gordon Barr<sup>2</sup>; Eric Chason<sup>1</sup>; Nitin Jadhav<sup>1</sup>; <sup>1</sup>Brown University; <sup>2</sup>EMC Corporation

Though it is well understood that compressive stress due to intermetallic (IMC) formation is the main driving force for whisker formation, the underlying mechanisms that control the stress distribution and cause whiskering are not clear. We present the results of studies done to understand how modification of the Sn layer (surface treatment, thickness, grain size, Pb-alloying, heat treatment) affects the growth and morphology of the IMC and the corresponding stress development in the Sn layers. We have quantified the whisker nucleation kinetics using an optical method so that we can relate the whisker growth to the underlying stress evolution. Changes in the Sn surface and bulk alter the mechanical properties and stress relaxation behavior and thus result in various whisker growth rates. The study also shows that a grain with a weaker oxide layer will not necessarily whisker, indicating that the underlying Sn microstructure plays a crucial role in whiskering.

### 2:00 PM Invited Structure and Thermomechanical Behavior of NiTiPt Shape Memory Alloy Wires: Ken Gall<sup>1</sup>; <sup>1</sup>Georgia Tech

The objective of this work is to understand the structure property relationships in polycrystalline NiTiPt (Ti 42.7 at.% Ni 7.5 at.% Pt) with a composition showing pseudoelasticity at ambient temperatures. Structural characterization of the alloy includes grain size determination and texture analysis while the thermomechanical properties are explored using tensile testing. Variation in heat treatment is used as a vehicle to modify microstructure. The results are compared to experiments on Ni-rich NiTi alloy wires (Ti-51.0 at.% Ni), which are in commercial use in various biomedical applications. With regards to microstructure, both alloys exhibit a <111> fiber texture along the wire drawing axis; however, the NiTiPt alloy grain size is smaller than that of the Ni-rich NiTi wires, while the latter materials contain second-phase precipitates.

### 2:20 PM Training and the Two-Way Shape Memory Effect in TiNiPd and TiNiPdX High Temperature Shape Memory Alloys: Kadri Atli<sup>1</sup>; Brian Franco<sup>1</sup>; Ibrahim Karaman<sup>1</sup>; Ronald Noebe<sup>2</sup>; <sup>1</sup>Texas A&M University; <sup>2</sup>NASA Glenn Research Center

The relationship between thermomechanical cycling (training) and the two way shape memory effect (TWSME) was investigated for a number of shape memory alloy (SMA) systems including equiatomic TiNi, a ternary Ti<sub>50.5</sub>Ni<sub>24.5</sub>Pd<sub>25</sub> high temperature SMA (HTSMA), and its quaternaries TiNiPd<sub>25</sub>X (X = Sc, Ta replacing Ti). Training consisted of thermal cycling under various constant stress levels and stable and reproducible TWSME behavior was obtained for all materials after 100 thermal cycles. It was shown that training stress dictated the level of TWSME strain and thermal hysteresis behavior, which were in turn significantly affected by the strength of the material and the compatibility of the transforming phases. The work output capability of the TWSME was evaluated by constraining the "cold shape" under external stress-free conditions and heating above the transformation temperature. Improvements in TWSME strains and thermal hysteresis were found after microalloying TiNiPd<sub>25</sub> with Sc and Ta.

### 2:35 PM Thermomechanical Testing of NiTiPdPt High Temperature Shape Memory Alloy Springs: Douglas Nicholson<sup>1</sup>; Santo Padula<sup>2</sup>; Ronald Noebe<sup>2</sup>; Raj Vaidyanathan<sup>1</sup>; <sup>1</sup>UCF; <sup>2</sup>NASA GRC

Stroke in high temperature shape memory alloys (HTSMAs) can be limited in cases where stability and repeatability at elevated temperatures are required. However, these alloys can still be used in actuator applications that require large strokes, by fabricating them in the form of springs. Thus there is value in evaluating the thermomechanical performance of HTSMA helical actuators. Towards that goal, a test setup was designed to acquire stroke, moment, and temperature data during thermomechanical cycling of NiTiPdPt springs under load. The role of grip constraints was also systematically

investigated, i.e., by allowing the springs to freely rotate during actuation or fixing the ends of the springs. The experiments assessed the contributions of material behavior (i.e., microstructural evolution) and geometry (i.e., helical angle) to overall actuator performance. With appropriate assumptions, the mechanics of the spring behavior was approximately captured using spring theory and finite element analysis.

### 2:50 PM Structure-Property Relationships in a Ni-Rich Ni-25Pd-48Ti (at.%) High Temperature Shape Memory Alloy: Taisuki Sasaki<sup>1</sup>; B. C. Hornbuckle<sup>1</sup>; Glen Bigelow<sup>2</sup>; Ronald Noebe<sup>2</sup>; Mark Weaver<sup>1</sup>; Gregory Thompson<sup>1</sup>; <sup>1</sup>University of Alabama; <sup>2</sup>NASA Glenn Research Center

Ni-rich NiTi alloys, when properly processed, display relatively stable shape memory and superelastic behavior. However, their potential applications are severely limited because of low transformation temperatures. Recent efforts have focused on using ternary additions to raise the transformation temperatures, while simultaneously improving stability through nanoscale precipitation. In this work, we have investigated the effect of aging on the structure and shape memory behavior of an extruded Ni-48Ti-25Pd (at.%) alloy. After aging at 400°C, nanoscale precipitates formed within the matrix, resulting in an increase in transformation temperatures. Electron diffraction studies and atom probe analysis showed that the structure and the chemistry of the precipitate are similar to the P-phase seen in NiTiPt alloys. The mechanical responses of this aged alloy were tested via superelastic and load biased thermomechanical testing, demonstrating the stabilizing effect of the fine precipitate phase.

### 3:05 PM Structure-Property Relationships for Ni-Ti-Pt High Temperature Shape Memory Alloys: Grant Hudish<sup>1</sup>; Glen Bigelow<sup>2</sup>; Ronald Noebe<sup>2</sup>; Michael Kaufman<sup>1</sup>; <sup>1</sup>Colorado School of Mines; <sup>2</sup>NASA-GRC

Alloys of Ni and Ti in near equal amounts are commercially prevalent shape memory alloys (SMA's), but are limited to use near room temperature. Increasing the transformation temperature of traditional Ni-Ti SMAs, through ternary alloying of Pd, Pt, Au, Hf or Zr, would allow for their use in various higher temperature applications and industries including aerospace, automotive, and down hole energy exploration, to name a few. Pt is currently one of the most promising ternary additions for stable and predictable high temperature SMA's (HTSMA's), but little is understood about the effects of Pt on the microstructure and mechanical properties of Ni-Ti alloys. Using various techniques including scanning and transmission electron microscopy (SEM and TEM), differential thermal analysis (DTA), and load-biased thermally cycled compression tests, the current research explores the link between alloy microstructures and the shape memory properties of several Ni-Ti-Pt alloys.

### 3:20 PM Break

### 3:30 PM Invited A New Precipitate Phase in High-Temperature TiNiPt and Its Effect on Shape Memory Properties: F. Yang<sup>1</sup>; L. Kovarik<sup>1</sup>; Y. Wang<sup>1</sup>; P. M. Anderson<sup>1</sup>; A. Garg<sup>2</sup>; R.D. Noebe<sup>3</sup>; Michael Mills<sup>1</sup>; <sup>1</sup>The Ohio State University; <sup>2</sup>University of Toledo - and - NASA Glenn Research Center; <sup>3</sup>NASA Glenn Research Center

The effects of aging on mechanical and shape memory properties of the high-temperature shape memory alloy Ti<sub>50</sub>Ni<sub>30</sub>Pt<sub>20</sub> (at.%) were investigated in order to understand aging effects on transformation strain, work output and dimensional stability under cyclic load biased tests. Aging results in precipitation of a previously unidentified phase. The precipitate phase has been analyzed with electron diffraction and high-resolution STEM HAADF imaging. The precipitates are closely related to the high temperature cubic B2 phase, but have a unique structure due to their non-periodic character along one of the primary crystallographic directions. The importance of these precipitates in other high temperature shape memory alloys and their role in achieving optimal shape memory properties will be discussed.

3:50 PM

**Grain Size Distribution Effects on Phase Transformation Behavior of NiTi Thin Films:** *Xu Huang*<sup>1</sup>; David Wu<sup>2</sup>; Ainissa Ramirez<sup>3</sup>; <sup>1</sup>Yale University; <sup>2</sup>Institute of High Performance Computing

This presentation demonstrates the role of grain size and its distribution on phase transformations in sputter-deposited NiTi thin films. Two-step heat treatments—where growth and nucleation are both active in the first step, and nucleation is suspended in the second—narrow the grain size distribution, as determined by transmission electron microscopy. The associated transformation temperatures and actuation properties departed significantly from the Hall-Petch-like relationship of conventionally (one-step) annealed films. A change in texture was also apparent with two-step heat treatments. This presentation demonstrates a method for tailoring microstructures and illuminates the role of grain size distributions on properties.

4:05 PM

**Shape Memory Characteristics of Time Gradient Annealing Treated Ti-50.9 at.% Ni Alloy:** *Jae Il Kim*<sup>1</sup>; Su Ho Park<sup>1</sup>; Jun Hee Lee<sup>1</sup>; Yun-Jung Lee<sup>2</sup>; Tae-Hyun Nam<sup>3</sup>; <sup>1</sup>Dong-A University; <sup>2</sup>Gyungbook National University; <sup>3</sup>Gyungsang National University

In this study shape memory characteristics and superelasticity of a time gradient annealing treated Ti-50.9at%Ni alloy have been investigated by means of differential scanning calorimetry (DSC), thermal cycling tests under constant load and tensile tests. This method is an anneal within a time gradient after cold work, thus creating a structural gradient within the matrix of the alloy. By annealing 30% cold worked alloy under the time gradient from 3min to 20min at 773 K, 44K variation in R phase transformation interval (Rs - Rf) were obtained along the length of sample (80mm). Temperature dependence of R-phase transformation elongation (de/dT) of time gradient annealing treated sample at 773 K was 0.0068%/K. Also, it was found that the time gradient-anneal resulted in varying thermal transformation behavior along its length and a unique Lüders-type deformation behavior with a positive stress gradient. Such behavior provides improved controllability for actuation applications.

4:20 PM

**Crystal Structures, Phase Transformations and Microstructures of Rapidly Solidified Heusler Type CoNiGa(Al) Ferromagnetic Shape Memory Alloys for Micro-Actuator Applications:** *Shampa Aich*<sup>1</sup>; M. Vijaykumar<sup>2</sup>; I. Al-Omari<sup>3</sup>; M. Chakraborty<sup>4</sup>; D. Sellmayr<sup>3</sup>; <sup>1</sup>Indian Institute of Technology; <sup>2</sup>JSW Steel Ltd.; <sup>3</sup>University of Nebraska-Lincoln; <sup>4</sup>Indian Institute of Technology - Bhubaneswar

A series of arc-melted ingots of Heusler type  $\text{Co}_{50}\text{Ni}_{25}\text{Ga}_{25-2x}\text{Al}_{2x}$  ( $x = 0, 1, 2, 3,$  and  $4$ ) alloys were rapidly solidified by melt-spinning onto a copper wheel with a linear velocity of 25 m/s. The melt-spun ribbons were heat-treated at 800°C-1200 °C for 4 hours followed by water quenching. The occurrence of  $\text{L1}_2$  ordered structure and disordered  $\square$ -phase has been confirmed by XRD analysis in the as-spun and annealed alloys. The martensitic transformation temperature ( $T_m$ ) increases with annealing temperature and Al addition in all alloys with deterioration of ductility due to replacement of Ga with Al. The microstructural observations performed by HRTEM and FESEM reveal the martensitic twin bands at higher concentration of Ga in the as-spun as well as in heat-treated ribbons. High  $T_m$  (~ 390 K-440 K) and high Curie temperature  $T_c$  (~ 400K) make those alloys good enough to be used as Ferromagnetic Shape Memory Alloys.

4:35 PM

**Studies on Effect of Aging on Shape Memory Characteristics of Cu-Al-Fe Alloys:** *Sampath Vedamanickam*<sup>1</sup>; Raju T.N.<sup>1</sup>; <sup>1</sup>Indian Institute of Technology Madras

The most popular SMAs based on Ni-Ti cannot be used in service at  $T > 100^\circ\text{C}$ . In addition, they are difficult to produce and process and are also expensive. There is therefore a need for producing SMAs for high temperature actuator applications. With this as the background and impetus, Cu-Al-Fe shape memory alloys in the range of 10-12 wt% of Al and 0-2 wt % of Fe, exhibiting  $\beta$ -phase at high temperatures and manifesting shape memory effect upon quenching to lower temperatures, were prepared through

ingot metallurgy. The alloys were aged at 300°C and 500°C, respectively. The effect of ageing on the transformation temperatures and shape memory properties has been studied. The alloys aged at 300°C show an increase in the transformation temperatures. The results are presented and discussed in the paper.

4:50 PM

**Stoichiometry and Aging Effects on the Microstructure and Properties of NiTiHf Shape Memory Alloys:** *Daniel Coughlin*<sup>1</sup>; Ronald Noebe<sup>2</sup>; Glen Bigelow<sup>2</sup>; Anita Garg<sup>2</sup>; Michael Mills<sup>1</sup>; <sup>1</sup>Ohio State University; <sup>2</sup>NASA Glenn Research Center

Certain alloys belonging to the NiTiHf ternary system exhibit attractive high temperature shape memory properties, including relatively high transformation temperature, moderate transformation strain, and very small irrecoverable strain during load-biased, thermal-cycling tests at moderate to high stresses. Alloy compositions that span "stoichiometry", consisting of 20at.% Hf and varying Ti concentrations (from 29 to 30.5at.%) have been analyzed using SEM and TEM in the as-extruded condition. The phase constituents will be reported as a function of composition. The effect of aging on the Ni-29.7Ti-20Hf composition has also been explored using isothermal, constant strain rate testing above the austenite finish temperature. The results indicate that significant strengthening occurs upon aging due to the formation of a distribution of fine precipitates. The structure of these precipitates and their interaction with dislocations in the B2 phase will be discussed with relationship to the desirable shape memory properties.

5:05 PM

**Magnetic Shape Memory Effect in NiMnCo-Based Meta-Magnetic Shape Memory Alloy Micropillars:** *Nevin Ozdemir*<sup>1</sup>; Ibrahim Karaman<sup>1</sup>; Nathan Mara<sup>2</sup>; Douglas Pete<sup>3</sup>; <sup>1</sup>Texas A&M University; <sup>2</sup>Los Alamos National Laboratory; <sup>3</sup>Sandia National Laboratories

Magnetic Shape Memory Alloys (MSMAs) have recently emerged as an alternative to conventional Shape Memory Alloys (SMAs) due to their faster response, which is a consequence of the magnetic field-induced reversible shape change. NiMnCo-based SMAs show great promise for functional materials applications due to an order of magnitude higher actuation work output than other active materials and their potential for use in MEMS/NEMS devices. To the best of our knowledge, there is no work on the magnetic field-induced shape change via field-induced phase transformation on sub-micron structural length scales. Here, we studied the magnetic field-induced martensitic transformation on NiMnCoIn MSMAs at this size scale. The pillars were obtained from NiMnCoIn single- and polycrystals and deformed to various strain levels. Magnetic field was applied to recover the deformation via field-induced reverse martensitic transformation. The recovery strain levels and phase transformation characteristics were determined as a function of pillar size.

5:20 PM

**In-Situ Phase Transformation Behavior of Ni-Rich NiTi Shape Memory Alloys:** *Suresh Santharam*<sup>1</sup>; Dong-Ik Kim<sup>2</sup>; Subir Kumar Bhaumik<sup>3</sup>; Satyam Suwas<sup>1</sup>; <sup>1</sup>Indian Institute of Science; <sup>2</sup>Korea Institute of Science and Technology; <sup>3</sup>National Aerospace Laboratory (CSIR)

Ni-rich NiTi Shape memory alloy, characterized by room temperature austenite (B2) phase, was deformed in-situ in a Scanning Electron Microscope. The characteristic crystallographic features pertaining to B2 (austenite) to B19' (martensite) transformation were examined using Electron Back Scattered Diffraction. From the results, it has been shown that during stress induced transformation, different martensite variants appear within a single austenite grain. The Schmid factor calculations for different martensite variants indicate that in addition to the variants possessing the highest Schmid factor, certain variants with lower Schmid factor also get activated during stress induced martensitic transformation. The authors attribute the activation of different martensite variants with lower Schmid factor values as semi-coherent austenite-martensite interface. This proposition has been substantiated through transmission electron microscopic study.

#### Information Volumes in Diffraction Techniques for Strain Analysis: I Noyan<sup>1</sup>; <sup>1</sup>Columbia University

In this presentation we discuss how the modality (dynamical or kinematic) of scattering determines the volumes from which the information is obtained. In addition, this modality also impacts the uniqueness of the stress state measured. We use rigorous diffraction modeling to show that diffraction data obtained from weakly deformed crystals that scatter in the dynamical limit should not be used for validating continuum models. The "mean" strain obtained from polycrystalline continua and how this compares to the orientation-specific strain and mean-strain computed by mean-field models of deformation will also be discussed.

### 2:25 PM Invited

#### EPSC Modeling and Neutron Diffraction Measurements: Bjoern Clausen<sup>1</sup>; Donald Brown<sup>1</sup>; Levente Balogh<sup>1</sup>; Carlos Tomé<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

Dr. Carlos Tomé has been one of the major contributors in developing and implementing the Elasto-Plastic Self-Consistent (EPSC) model throughout the years. Although the EPSC scheme was introduced in the 60's and 70's, the first publically released code implementing the EPSC model with full elastic and plastic anisotropy on both grain and polycrystal level originated in the 1994 Turner and Tomé paper. From the start, the predictions of the EPSC model were correlated with neutron diffraction measurements of internal strains and texture. In the following years there were many publications showing how internal strain measurements using diffraction can be used to verify the predictions of the EPSC model, and vice versa, how the EPSC model predictions can be used to interpret and deconvolute measured diffraction data. This symbiotic relationship between diffraction measurements and the EPSC model and how it has influenced the development of both techniques will be discussed.

#### Texture and Type-2 Strains in Rolled Zircaloy-2 and Their Relevance to In-Reactor Growth: Thomas Holden<sup>1</sup>; <sup>1</sup>Northern Stress Technologies

Zr-2 calandria tubes in CANDU reactors can grow by 0.1% in a fast neutron fluence thus creating an engineering problem. Neutron diffraction was used to measure the strain state of Zr-2 rolled plate, an analog for the tubes, in the late 1980's. The type-2 strains plus the texture determine the growth behaviour. The strong texture permits a practical estimate of the strain tensor of the material. With the aid of the elasto-plastic self-consistent model (EPSC), developed by C.N Tomé and his collaborators, one can compare experiment and theory for the strains in as-prepared or tensioned Zr-2 and incorporate this into the in-reactor growth model as set out by C. H. Woo. Carlos Tomé's contributions to the ever-improving EPSC, as well

as the problem of in-reactor growth, and his enthusiastic encouragement of experimentalists to test the polycrystal models are the mark of an outstanding scientist. His friendship is highly valued.

### 3:15 PM

#### Internal Stresses and Microstructure by Neutron Diffraction Profile Analysis: Comparison with Other Techniques: Vadim Davydov<sup>1</sup>; Petr Lukáš<sup>2</sup>; Helena Van Swygenhoven<sup>1</sup>; Martin Petrenc<sup>3</sup>; Ondrej Man<sup>4</sup>; Pavel Strunz<sup>2</sup>; Radomír Kužel<sup>5</sup>; <sup>1</sup>Paul Scherrer Institut; <sup>2</sup>Nuclear Physics Institute; <sup>3</sup>Institute of Physics of Materials; <sup>4</sup>Brno University of Technology; <sup>5</sup>Charles University

The neutron and X-ray diffraction techniques combined with electron microscopy methods has been used to study the internal microstresses and microstructure in low carbon steel. Since the real structure features affect the width and shape of the neutron or X-ray diffraction pattern, and, as these real structure aspects are very numerous and mutually superposed, diffraction effects in terms of real structure characteristics are not simple to interpret. Using the recently modified single-line profile analysis method, the dislocation content was addressed and compared in terms of dislocation density parameter with the results obtained by other microscopy methods. The single-line neutron diffraction profile analysis performed at NPI was extended using full diffraction patterns collected in time-of-flight mode on POLDI.

#### On the Evolution of Crystal Stresses during the Elastic-Plastic Transition in FCC Polycrystals: Paul Dawson<sup>1</sup>; Su Leen Wong<sup>1</sup>; <sup>1</sup>Cornell University

Simulations based on crystal-scale elastoplasticity have proven to be a valuable tool for interpreting data measured by diffraction techniques. Diffraction measurements provide lattice strain data on subsets of the grains within the diffraction volume and offer insight into grain interactions. With finite element models the spatial arrangement of grains is included and interactions among the grains arise naturally in simulating an experiment. We discuss the roles of elastic and plastic anisotropies on grain interactions with attention to changes in the crystal stress distributions as the loading progresses through the elastic plastic transition. The simulations offer an explanation for the differences in lattice strain behaviors at the onset of yielding observed between metals of low and high elastic anisotropy under monotonic loading. We will show the implications of elastic and plastic anisotropies, as quantified by the directional strength-to-stiffness, on lattice strains during cyclic loading.

### 4:15 PM Invited

#### High Pressure Plastic Properties of Hcp Metals: Experiments and Elasto-Plastic Models: Sebastien Merkel<sup>1</sup>; <sup>1</sup>Universite Lille 1

Over the last few years, we developed new techniques for the study of plastic properties of materials under high pressure and temperature. Their physical properties are analyzed in-situ using x-ray diffraction to extract quantitative texture information and average elastic strains within the sample. Thanks to the contribution of Carlos Tomé, we now use EPSC models to relate the experimental observations and the plastic properties of the sample. In this presentation, I will show results on the hcp phase of Co deformed at 300 K between 0 and 42 GPa and results on the hcp phase of Fe deformed at pressures and temperatures reaching 19 GPa and 600 K. I will highlight how the combination of x-ray diffraction and EPSC modeling can be used to infer important information, such as the average stress within the sample, identify and constrain the plastic deformation activated, and evaluate stress heterogeneity with the sample.

### 4:40 PM Invited

#### A Decade Plus of Making Carlos Tomé Sweat: Donald Brown<sup>1</sup>; Bjoern Clausen<sup>1</sup>; Thomas Sisneros<sup>1</sup>; <sup>1</sup>Los Alamos National Lab

The Self-Consistent plasticity models developed by Carlos and his team are in the (un)enviable position of being readily, and robustly, validated by diffraction measurements, meaning the simulations can be easily tested. Since its inception, the SMARTS team has worked closely with Carlos to

“exercise” the models. Toward this end, we have moved to ever increasing complexity in the form of lower symmetry crystal structures (cubic to hexagonal to orthogonal) and more complicated thermo-mechanical histories (cycling, strain path changes, annealing, etc). Concomitantly, we have collected more diffraction data (e.g. during compression and tension) analyzed the data more aggressively, providing increased microstructural information to be used to constrain the model. This talk will use beryllium as an example material to discuss the evolution of both the modeling and experimental efforts toward improving the fidelity between the SC models and the actual physics occurring at the grain level during deformation.

5:05 PM

**Finite Element Diffraction Model for Spatially Resolved Strain Measurements in the Bulk of (Poly-) Crystals:** *Peter Reischig*<sup>1</sup>; Wolfgang Ludwig<sup>2</sup>; Andrew King<sup>3</sup>; Tilo Baumbach<sup>4</sup>; <sup>1</sup>TU Delft; <sup>2</sup>GEMPPM-MATEIS, INSA de Lyon; <sup>3</sup>GKSS-Forschungszentrum Geesthacht GmbH; <sup>4</sup>Institute for Synchrotron Radiation, Karlsruhe Institute of Technology

Measuring local strain state in the bulk of polycrystalline materials or single crystals is key to understanding their deformation processes and damage phenomena. We propose a linear model to spatially resolve the complete deformation tensor, i.e. 3 rotational and 6 elastic strain components, inside individual grains (diffraction contrast tomography) or a single crystal (rocking curve imaging) from full beam diffraction data. Practical implementation of the model comprises the concepts of finite elements, ray-tracing and kinematical diffraction. The linear approach of the crystal diffraction behavior under deformation enables fast and efficient computation and a rigorous analysis of the well-posedness of the inverse problem. The model allows for direct coupling with crystal plasticity simulation, hence for the verification of such models. Preliminary results on simulated and measured data will be presented.

5:25 PM

**The Bauschinger Effect in Austenitic (317L) Stainless Steel: Validating a Slip-System Based Non-Linear Kinematic Hardening Model with In-Situ Neutron Diffraction:** *James Wollmershauser*<sup>1</sup>; Bjørn Clausen<sup>2</sup>; Carlos Tome<sup>2</sup>; Sean Agnew<sup>1</sup>; <sup>1</sup>University of Virginia; <sup>2</sup>Los Alamos National Laboratory

Accurate prediction of the Bauschinger effect is considered a litmus test for the validity of strengthening theories. The effect is known to arise from ‘backstresses’ having intergranular and intragranular sources. Self-consistent polycrystal models inherently capture intergranular effects but typically fail to account for intragranular (dislocation-based) sources. This inadequacy is illustrated by comparisons of model predictions with in-situ neutron diffraction measurements of the hysteresis and internal stresses within a sample subjected to tension-compression fatigue. A single non-linear kinematic hardening rule, similar to the Armstrong-Frederick model, is implemented at the slip system level. With this simple adaptation, the polycrystal model accurately predicts the hysteresis loops and internal strains observed during the aforementioned in-situ low cycle fatigue tests, as well as monotonic stress strain curves and texture evolution after larger strain deformation. The physics-based polycrystal plasticity approach obviates the need for multiple kinematic hardening terms used in phenomenological models.

5:45 PM

**Study of Lattice Strain Based on the Finite Strain Elastic-Viscoplastic Self-Consistent Model for Polycrystalline Materials:** *Huamiao Wang*<sup>1</sup>; Peidong Wu<sup>1</sup>; Carlos Tome<sup>2</sup>; <sup>1</sup>McMaster University; <sup>2</sup>Los Alamos National Laboratory

The recently developed large strain elastic-viscoplastic self-consistent (EVPSC) model for polycrystalline materials is used to study the lattice strain measurements for conventionally extruded magnesium alloy AZ31 under uniaxial tension and compression. The EVPSC model is a completely general elastic-viscoplastic, fully anisotropic, self-consistent polycrystal model, applicable at large strain and to any crystal symmetry. At single crystal level, both the rate sensitive slip and twinning are included as the plastic deformation mechanisms, while elastic anisotropy is accounted in the

elastic moduli. The transition from the single crystal plasticity to polycrystal plasticity is based on a completely self-consistent approach. In the present study, effects of texture evolution, twinning activity and stress relaxation on lattice strain are interpreted by the EVPSC model. It is found that the stress relaxation has a significant effect on the lattice strain measurements.

6:05 PM

**High Pressure Deformation of Zirconium:** James Wilkerson<sup>1</sup>; *Sven Vogel*<sup>1</sup>; Donald Brown<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

Uni-axial deformation of pure Zirconium and Zircaloy-2 was performed with the D-DIA apparatus at the APS. The transformation from  $\alpha$ -Zr to  $\omega$ -Zr during hydrostatic compression was observed at  $\sim 4.5$  GPa at room temperature with the applied pressure derived from the unit cell volume of  $\alpha$ -Zr and the known equation of state. A combination of texture analysis of the diffraction data and energy minimization-based variant selection during texture modeling allows to establish the orientation relationship between the two phases for the first time from a large number of grains. We found that both published orientation relationships, derived from TEM data, are needed to describe the texture change during the phase transformation. From the uni-axial deformation at applied pressure of Zircaloy-2 we found that the twin activity at elevated pressure is increased compared to deformation at ambient pressure, confirming predictions by Lebensohn & Tomé.

## Processing and Properties of Powder-Based Materials: Sintering Science and Technology

**Process Simulation of Cold Pressing and Sintering of Armstrong CP-Ti Powders:** Sarma Gorti<sup>1</sup>; *Adrian Sabau*<sup>1</sup>; William Peter<sup>1</sup>; Stephen Nunn<sup>1</sup>; Yukinori Yamamoto<sup>1</sup>; Wei Chen<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

A computational methodology is presented for the process simulation of cold pressing and sintering of Armstrong CP-Ti powders. Since the powder consolidation is governed by specific pressure-dependent constitutive equations, solution algorithms were developed for the ABAQUS user material subroutine, UMAT, for computing the plastic strain increments based on an implicit integration of the nonlinear yield function, flow rule, and hardening equations. Sintering was simulated using a model based on diffusional creep using the user subroutine CREEP. The initial mesh, stress, and density for the simulation of sintering were obtained from the results of the cold pressing simulation, minimizing the errors from decoupling the cold pressing and sintering simulations. Numerical simulation results are presented for the cold compaction followed by a sintering step of the Ti powders. The numerical simulation results for the relative density were compared to those measured from experiments before and after sintering, showing that the relative density can be accurately predicted.

2:25 PM

**Hot Isostatic Pressing of Beta Titanium Alloy Powders:** *Xinjiang Hao*<sup>1</sup>; Nicholas Wain<sup>1</sup>; Xinhua Wu<sup>1</sup>; <sup>1</sup>University of Birmingham

Hot isostatic pressing (“HIPping”) of Ti alloy powders is an effective near net-shape technique to produce complex parts which can have similar or even superior mechanical properties to wrought alloys. Ti alloy powders (such as Ti-6Al-4V) are normally HIPped at temperature below beta-transus to avoid excessive grain coarsening. However, the beta-transus of metastable beta or

beta titanium alloys is lower than alpha-beta alloys and this makes HIPping of beta alloys a challenge to produce a good bonding between powders and therefore good properties. In this work, powder bonding mechanisms in several beta titanium alloys (Ti-5553, Ti-6246 etc) were investigated and the HIPping parameters were optimized.

#### 2:45 PM

**Effect of Particle Size Particle Surface Modification Pressing Pressure and Sintering Temperature on Microstructure and Mechanical Properties P/M Al-B4C Composites:** *Fatih Toptan*<sup>1</sup>; *Isil Kerti*<sup>1</sup>; *Sibel Daglilar*<sup>1</sup>; *Ahmet Sagin*<sup>1</sup>; *Taner Hacioglu*<sup>1</sup>; <sup>1</sup>*Yildiz Technical University*

Al-Ti-B grain refiners are widely used as aluminium grain refiners despite the problems in application Al-Ti-C refiners have an increasing demand in recent years. In the present work, Al-Ti-C grain refiners with different Ti:C ratios were produced by in-situ method with the addition of elemental carbon into the Al-Ti master alloy and addition of K2TiF6 and elemental carbon powder mixture into the commercially pure aluminium. Microstructures were characterised by optic microscope and scanning electron microscope equipped with energy dispersive spectroscopy. The effects of production method and Ti:C ratio on the grain refinement process was investigated with Alcoa Coldfinger Test and optimum conditions were determined. Commercial Al-Ti-B grain refiners also tested with Alcoa Coldfinger Test in identical conditions and it has been stated that, in-situ Al-Ti-C refiners are more effective than commercial Al-Ti-B grain refiners in grain refining.

#### 3:05 PM

**Microstructure and Mechanical Properties of TiNbSn-HA Biocomposite Fabricated by Mechanical Alloying and Sintering:** *Xiaopeng Wang*<sup>1</sup>; *Yuyong Chen*<sup>1</sup>; *Kee-Do Woo*<sup>2</sup>; <sup>1</sup>*Harbin Institute of Technology*; <sup>2</sup>*Chonbuk National University*

Ti-based alloys have been used as biomaterials, due to their excellent properties. Recently nontoxic elements  $\beta$  type Ti-based alloys cause researchers' interest because of their lower elastic modulus. But poor bioactivity of Ti-based alloys becomes a problem. Hydroxyapatite(HA) has tightly combination ability with bones tissue. However, poor mechanical properties limit their application. In present paper,  $\beta$  type TiNbSn-HA composites were fabricated by mechanical alloying and sintering. These composites are expected to integrate advantages of TiNbSn alloy and HA. Elastic modulus, compression strength, wear resistance and microstructure of composites were investigated. XRD and DSC results showed that Ti was suggested to be fully transformed from  $\alpha$  phase to  $\beta$  phase after 12h milling, transform temperature was 380.06°C. TEM results indicated that nanostructure was obtained. With the increase of Sn content, composites' microstructure changed. Compression test and wear test results indicated that composites had lower elastic modulus and superior mechanical properties.

#### 3:25 PM

**Physical Principles and Technological Tools for the Control of Densification, Shape and Diffusion Bonding during HIP of Metal Powders And Ceramics:** *Charles Barre*<sup>1</sup>; *Viktor Samarov*<sup>1</sup>; *Dmitry Seliverstov*<sup>1</sup>; *Evgeny Khomyakov*<sup>1</sup>; *Roman Haykin*<sup>1</sup>; <sup>1</sup>*Synertech PM Inc.*

The process to manufacture complex-shaped homogeneous or diffusion bonded products using Hot Isostatic Pressing (HIP) of powder materials is utilizing a suit of the advanced technologies related to this consolidation process. The most essential of them is advanced computer modeling that enables to provide very complex shapes and a significant reduction of development and manufacturing costs. The suit also includes design of the HIP tooling to provide cost efficient manufacturing solutions and non-destructive inspection for complex shape parts with cavities. The paper analyses, the physical principles and technological tools for the control of densification, shape, mechanical properties and diffusion bonding of large and complex shape parts during HIP of various metal powders and ceramics.

#### 3:55 PM

**Effect of HCl Concentration on ZrB<sub>2</sub> Separation from a Self-Propagating High-Temperature Synthesis (SHS) Product:** *Burcu Akkas*<sup>1</sup>; *Murat Alkan*<sup>1</sup>; *Bora Derin*<sup>1</sup>; *Onuralp Yucel*<sup>1</sup>; <sup>1</sup>*Istanbul Technical University*

The self-propagating high-temperature synthesis (SHS) of zirconium diboride followed by hydrochloric acid leaching was carried out in this study. In the SHS stage, the initial mixture of B<sub>2</sub>O<sub>3</sub>, ZrO<sub>2</sub> and Mg powders were ignited and then a mixture of the ZrB<sub>2</sub>, MgO, Mg<sub>3</sub>B<sub>2</sub>O<sub>6</sub> and Mg<sub>2</sub>B<sub>2</sub>O<sub>5</sub> were formed. In the leaching step, the SHS product was leached in the acid solution to remove impurities i.e. MgO, Mg<sub>3</sub>B<sub>2</sub>O<sub>6</sub> and Mg<sub>2</sub>B<sub>2</sub>O<sub>5</sub>. The effects of temperature and acid concentration on the selective leaching were investigated. The obtained products were characterized by using X-ray diffraction and SEM techniques.

#### 4:15 PM

**Microwave Sintering of Different Aluminum Alloy Powders and Their Characterization:** *Padmavathi Chandran*<sup>1</sup>; *A Upadhyaya*<sup>1</sup>; *Dinesh Agrawal*<sup>2</sup>; <sup>1</sup>*Indian Institute of Technology, Kanpur, India*; <sup>2</sup>*The Pennsylvania State University*

Microwave processing has been emerged as a well recognized processing technique due to its advantages such as rapid heating rates, time savings, reduction in processing temperature, energy, and environmental friendly. The present work investigates the densification behaviour, microstructural and phase evolution during microwave sintering of various grades of aluminum alloy powders using multimode furnace operating at 2.45GHz. The microwave sintering resulted in approximately 55% reduction in processing time as compared with conventional sintering. The microwave sintered samples exhibited the higher densification response and absence of intermetallic phases as when compared with conventional counterparts. Keywords: P/M Al alloy, multimode-microwave sintering, densification behavior, microstructural aspects, phase transformation.

#### 4:35 PM

**Die-Press and Sinter Processing of Armstrong Process® CP-Ti and Ti-6Al-4V Powders for Near-Net-Shape Manufacturing:** *Wei Chen*<sup>1</sup>; *Yukinori Yamamoto*<sup>1</sup>; *Stephen Nunn*<sup>1</sup>; *Jim Kiggans*<sup>1</sup>; *Michael Clark*<sup>1</sup>; *Sarma Gorti*<sup>1</sup>; *Adrian Sabau*<sup>1</sup>; *William Peter*<sup>1</sup>; *Craig Blue*<sup>1</sup>; *Brian Fuller*<sup>2</sup>; *Kamal Akhtar*<sup>2</sup>; <sup>1</sup>*Oak Ridge National Laboratory*; <sup>2</sup>*Cristal US, Inc. / International Titanium Powder*

This work investigates the die-pressing and sintering processes of new titanium and titanium pre-alloyed powders made by Armstrong Process® technology. The CP-Ti and Ti-6Al-4V powders were uniaxially die-pressed at designated pressures up to 100 ksi to form disk samples with varying aspect ratios (thickness to diameter). Samples with high aspect ratios tended to exhibit non-uniform green density along the pressing axis. This led to non-uniform shrinkage after sintering, forming disks of an hourglass shape. In addition, the sintering shrinkage of diameter tended to be higher than that of thickness for all samples. Effects of multiple different die-pressing techniques such as holding and repeated pressure strikes were performed to obtain desired sample shape after sintering. In-situ and ex-situ sintering were also performed to record the powder morphology change. This research was sponsored by the U.S. DOE, Office of EERE Industrial Technologies Program, under contract DE-AC05-00OR22725 with UT-Battelle, LLC.

## Recent Developments in the Processing, Characterization, Properties and Performance of Metal Matrix Composites: Multimodal, Processing and Microstructure

**2:00 PM**  
**Effect of Al+B4C Agglomerate Size on Mechanical Properties of Trimodal Aluminum Metal Matrix Composites:** *Bo Yao*<sup>1</sup>; Travis Patterson<sup>1</sup>; Yongho Sohn<sup>1</sup>; Matthew Shaeffer<sup>2</sup>; Cory Smith<sup>3</sup>; Mark van den Bergh<sup>3</sup>; Kyu Cho<sup>4</sup>; <sup>1</sup>University of Central Florida; <sup>2</sup>The Johns Hopkins University; <sup>3</sup>DWA Aluminum Composites; <sup>4</sup>U. S. Army Research Laboratory

Trimodal aluminum (Al) metal matrix composites (MMCs) consisting of a nanocrystalline Al (ncAl) phase, B4C reinforcement particles, and a coarse grain Al (cgAl) phase contain multiscale microstructure and interfacial features that contribute to exceptional mechanical properties. One of the hierarchical microstructural features within the composite, namely the ncAl+B4C agglomerates formed during cryomilling, is an important feature whose size can range from tens of micro-meters to millimeters. This paper reports a study on the influence of the ncAl+B4C agglomerate size on the dynamic compressive strength of the trimodal Al MMCs. A desired hierarchical microstructure for high-strength of Al MMCs is identified to contain uniformly distributed relatively small ncAl+B4C agglomerates. Commercial-scale fabrication process to achieve this microstructure includes size classification by sieving the cryomilled ncAl+B4C agglomerates.

**2:20 PM**  
**Alternate Processing of Trimodal Aluminum Composites:** *Joseph Paras*<sup>1</sup>; Deepak Kapoor<sup>1</sup>; Tony Zahrah<sup>2</sup>; Rod Rowland<sup>2</sup>; <sup>1</sup>U. S. Army ARDEC; <sup>2</sup>Matsys Inc.

The Trimodal Aluminum 5083-Boron Carbide (Al5083-B4C) system has generated much military interest due to the composite's light weight and high strength. The system has traditionally been processed through powder metallurgy means via cryomilling, resulting in long processing times. In an effort to make the process more efficient, we have explored dry high energy milling as an alternate process. Preliminary results indicate that there is very little difference between cryomilled Bimodal Al5083-B4C and dry milled Bimodal Al5083-B4C. It was also observed that poor bonding can exist between the bimodal composition and the coarse-grained Al5083 when consolidated. This was remedied by light milling of the coarse-grained Al5083 to break the nascent oxide layer and provide a clean metallurgical interface. Evidence of the increased bonding is seen in the fracture surfaces, and mechanical testing has shown a 10% increase in compressive strength and a 30-50% increase in ultimate failure strain.

**2:40 PM**  
**Effect of Layered Interface on Mechanical Behaviors in TiO2 Nano-Particle Reinforced Aluminum Matrix Composites:** *Jaehyuck Shin*<sup>1</sup>; Hyunjoon Choi<sup>1</sup>; Donghyun Bae<sup>1</sup>; <sup>1</sup>Yonsei University

Interface characteristics, with their mechanical behaviors, have been investigated for aluminum based composites reinforced with titanium dioxide nano-particles (TiO<sub>2</sub>, 20 nm). The composites are produced by hot rolling the ball-milled mixture of Al powders and TiO<sub>2</sub> nano-particles. During a milling process, TiO<sub>2</sub> nano-particles are gradually dispersed and embedded within the Al powders. After the subsequent annealing process, an interface layer composed of TiO and □-Al<sub>2</sub>O<sub>3</sub> has newly formed between the TiO<sub>2</sub>

nano-particles and the aluminum matrix. The composites show significant increase in yield strength with increasing volume fraction of TiO<sub>2</sub> nano-particles (514 MPa with 5vol.% TiO<sub>2</sub> nano-particle), and the semi-coherent interface layer between the Al matrix and the TiO<sub>2</sub> nano-particle enables the nucleation of dislocation at the particle/matrix interface during the plastic deformation. Mechanical properties with the variation of volume fraction of TiO<sub>2</sub> nano-particles and their deformation behaviors will be presented.

**3:00 PM**  
**Fabrication of Extruded Aluminum Composites Reinforced by Vapor Grown Carbon Nanofibers and Characterization, Modeling of Their Properties:** *Fumio Ogawa*<sup>1</sup>; Toshiyuki Nishimura<sup>2</sup>; Chitoshi Masuda<sup>1</sup>; <sup>1</sup>Waseda University; <sup>2</sup>National Institute for Materials Science

Aluminum composites reinforced by vapor grown carbon nanofibers (VGCNF) are expected to be used as thermal management devices and structural parts due to high strength and thermal conductivity of VGCNF e.g. about 2000W/mK along fiber direction. However, because of transverse anisotropy of VGCNF e.g. about 30W/mK transverses to fiber direction, it is expected their properties strongly depend on fiber orientation. In this study, composites were fabricated by powder metallurgy and extruded to control fiber orientation. Microstructure such as orientation, length of VGCNF, porosity in matrix was investigated. And relation of them with extrusion condition was discussed. Strength, thermal conductivity along and transverse to extrusion direction were measured and effect of orientation, anisotropy of VGCNF on them was studied. Modeling of their properties as function of fiber anisotropy, fiber aspect ratio, matrix and interface was conducted and mechanism of reinforcing and heat transfer in composites was discussed.

**3:20 PM**  
**Multi-Scale Modeling on the Mechanical Behavior of Aluminum-Based Metal-Matrix Nano Composites (MMNCs):** *Changsoo Kim*<sup>1</sup>; Pradeep Rohatgi<sup>1</sup>; Amirreza Sanaty-Zadeh<sup>1</sup>; <sup>1</sup>University of Wisconsin Milwaukee

A systemic, multi-scale computational model has been developed to describe mechanical behavior of metal-matrix nano composites (MMNCs). The modeling begins by using nano-scale (molecular dynamics, MD) simulations for the quantitative evaluation of material properties and dislocation movements. The results from MD simulations are then incorporated as a basis for the meso-scale (finite element analysis, FEA) simulations to predict mechanical performance and failure of MMNCs. Pseudo-plastic failure has been approximated for the fracture of MMNCs. Using this model, the influence of microstructural features such as fine, coarse grain sizes, fine-to-coarse heterogeneous multi-modal phase ratio, and the type, shape, contents of reinforcement particles on the macroscopic mechanical performance can be quantitatively characterized. The developed algorithm has been applied to Aluminum-based (Al) fine/coarse multi-modal MMNCs that are reinforced with SiC and/or B4C particles. The presentation will elucidate the potential failure mechanisms and propose optimized microstructures of these Al MMNC systems.

**4:00 PM**  
**Strain Induced Grain Growth of Cryomilled Nanocrystalline Al in Tri-Modal Al Composites during Forging:** *Bo Yao*<sup>1</sup>; Cory Smith<sup>2</sup>; Mark van den Bergh<sup>2</sup>; Bhaskar Majumdar<sup>3</sup>; Yongho Sohn<sup>1</sup>; <sup>1</sup>University of Central Florida; <sup>2</sup>DWA Aluminum Composites; <sup>3</sup>New Mexico Institute of Mining and Technology

This report presents our study on the grain growth of nanocrystalline aluminum (NC-Al) in tri-modal Al metal-matrix-composites (MMCs) under forging process. The NC-Al phase formed through cryomilling in liquid nitrogen atmosphere exhibits an excellent thermal stability when annealed without applied stress. However, grain growth was observed when the Al MMCs were forged at temperatures where the NC-Al grain growth might have remained stable without applied stress. The influence of strain and temperature on the NC-Al grain growth during forging is presented. The grain growth activation energy with forging is lower than that without any

applied stress. The role of pinning effect by dispersoids and impurities at grain boundaries is presented and discussed.

#### 4:20 PM

**Origin of High Strength in a Micro-Alloyed Ferritic Steel:** *Hesamaldin Askari*<sup>1</sup>; Yong Shen<sup>2</sup>; C. Wang<sup>2</sup>; Xin Sun<sup>3</sup>; Hossein Zbib<sup>1</sup>; <sup>1</sup>Washington State University; <sup>2</sup>Northeastern University; <sup>3</sup>Pacific Northwest National Laboratory

The strengthening role of carbide precipitates in a high strength ferritic steel with finely dispersive precipitates was investigated using a combined experimental and modeling approach. Using EDXS and TEM, fine carbides with an average diameter of 10 nm were observed in the ferrite matrix of the 0.08%Ti steel, as well as some cubic M23C6 precipitates at the grain boundaries. The dual precipitate structure provides combined matrix and grain boundary strengthening. The increase in strength due to precipitation is 2-3 times higher than the conventional high strength steels depending on the average size and distance of the nanoscale precipitates. The effects of the particle size and density on the strength have been investigated through Dislocation Dynamics simulations. The DD simulations and experimental analysis showed that the finely dispersive precipitates can strengthen the steel by pinning the dislocations up to a critical shear stress and retarding the recovery and annihilation of dislocations.

#### 4:40 PM

**Synthesis of MWCNT Reinforced Al Based Nanocomposite Via Spark Plasma Sintering:** *Tapas Laha*<sup>1</sup>; Lakshmikanth Reddy<sup>1</sup>; Anup Keshri<sup>2</sup>; Devrupa Lahiri<sup>2</sup>; Anway Maiti<sup>1</sup>; <sup>1</sup>Indian Institute of Technology; <sup>2</sup>Florida International University

A trend has been perceived in the field of composite materials to employ carbon nanotubes as reinforcement in synthesizing composites of unique properties. In this endeavor, Al-based nanostructured composite with carbon nanotubes, as second phase particles, has been synthesized by combination of two novel processing techniques, viz. Cryomilling and Spark Plasma Sintering. Scanning electron microscopy and quantitative image analysis has been performed to understand the microstructural evolution and to verify the retention of carbon nanotubes. Nanoindentation and microhardness test have been carried out to obtain the effective elastic modulus and hardness of the consolidated samples. Tribological study on the nanocomposites has been done in order to understand the effect of CNT reinforcement on the mechanical properties. The characterization affirms the retention of carbon nanotubes in the nanocomposites. Raman spectroscopy revealed that the MWCNTs were partially damaged during cryomilling.

#### 5:00 PM

**Effects of SPS Parameters on the Mechanical Properties and Microstructures of Titanium Reinforced with Multi-Wall Carbon Nanotubes Produced by Hot Extrusion:** *Thotsaphon Threrujirapong*<sup>1</sup>; Katsuyoshi Kondoh<sup>1</sup>; Junko Umeda<sup>1</sup>; Bunshi Fugetsu<sup>2</sup>; <sup>1</sup>Osaka University; <sup>2</sup>Hokkaido University

The effects of spark plasma sintering (SPS) temperature and time on the mechanical properties and microstructures of titanium (Ti) reinforced with multi-wall carbon nanotubes (MWCNTs) were investigated. The Ti powders were coated with MWCNTs via a wet process using a zwitterionic surfactant solution containing 2.0 wt.% of MWCNTs. The coated Ti powders were consolidated by SPS process at various temperatures and times. All sintered billets were subsequently extruded at 1000°C. The mechanical properties responses of these extruded Ti composites showed the decrease of yield and tensile strength when higher consolidation temperatures were used. The microstructures of those Ti composites were observed using optical microscopy and scanning electron microscopy. All of the results were used to select the suitable condition for fabrication of Ti/MWCNTs composite materials.

#### 5:20 PM

**On the Methods for Grain Size Analysis and Grain Growth Kinetic Studies for a Thermally Stable Al 5083 Nanocomposite:** *Leyla Hashemi-Sadraei*<sup>1</sup>; S. E. Mousavi<sup>1</sup>; Rustin Vogt<sup>1</sup>; Ying Li<sup>1</sup>; Zhihui Zhang<sup>1</sup>; Enrique Lavernia<sup>1</sup>; Julie Schoenung<sup>1</sup>; <sup>1</sup>University of California Davis

A nanocomposite of Al 5083 and B<sub>4</sub>C was fabricated by cryomilling the powders for 24 hours. Powders annealed at temperatures as high as approximately 0.9 T<sub>m</sub> were investigated for grain growth and were found to exhibit superior thermal stability compared to Al 5083 powders without B<sub>4</sub>C that were cryomilled for shorter durations. The high thermal stability was attributed to the pinning effect of ultrafine secondary dispersoids residing on grain boundaries. Several approaches were evaluated, on the basis of X-ray diffraction and transmission electron microscopy, in order to determine average grain sizes. Grain size results from alternative X-ray-based methods were utilized in order to study grain growth mechanisms by fitting grain growth curves to established equations. Two distinct temperature-dependent grain growth regimes were observed. By comparing the kinetic results achieved when using different grain size calculation methods, the relevance and applicability of each method is described.

### Size Effects in Mechanical Behavior: Size Effects in Multilayer Structures

**A Quantized Crystal Plasticity Finite Element Model for Nanoindentation: Size Effect from Discrete Plasticity:** *Lin Li*<sup>1</sup>; Myoung-Gyu Lee<sup>2</sup>; Peter Anderson<sup>1</sup>; <sup>1</sup>The Ohio State University; <sup>2</sup>Pohang University of Science and Technology

Quantized crystal plasticity (QCP) simulations are employed to study a distinctive observation from an in-situ nanoindentation test on nanocrystalline Al. This displacement controlled indentation test shows that the sample surface recedes even faster than the rate of indenter as a consequence of incipient dislocation events. This direct experimental observation emphasizes the discrete nature of dislocation slip in a confined volume. The QCP model incorporates such a feature showing that the plastic shear strain can jump by discrete amounts that scale as 1/grain size. This unique feature is motivated by recent molecular dynamics results, showing that the grain averaged shear strain jumps ~1% as a dislocation unstably traverses a grain. This quantized aspect enables the QCP model to simulate the load-displacement trace and the underlying slip pattern during indentation. Also, the grain size effect on indentation response can be assessed through a comparison of the conventional and quantized simulations.

#### 2:20 PM

**Size Effects in Fatigue of Cu/Ta Multilayers:** *Guangping Zhang*<sup>1</sup>; Xiaofei Zhu<sup>1</sup>; Jiawei Yan<sup>1</sup>; Jin Xu<sup>1</sup>; <sup>1</sup>Chinese Academy of Sciences

Although strengthening and deformation mechanisms of metallic multilayers with different length scales ranging from microns to nanometers are investigated extensively, fatigue behavior of the metallic multilayers is known little. Here we present a systematic investigation of fatigue properties of Cu/Ta multilayers deposited on a flexible polyimide substrate. We will show that fatigue resistance of the multilayers gradually increases with decreasing individual layer thickness from 500 nm to 20 nm. Microscopic characterization reveals an evident transition of fatigue damage from typical

bulk-like extrusions/intrusions to boundary-localized behavior. Such size effects in fatigue are evaluated and compared with recent findings of fatigue of thin metal films constrained by a substrate as well as unconfined small-volume metals.

**2:40 PM**

**Microstructure and Strengthening Mechanisms of Highly Textured Cu/Ni Multilayers:** *Yue Liu*<sup>1</sup>; Dan Bufford<sup>1</sup>; Haiyan Wang<sup>1</sup>; Cheng Sun<sup>1</sup>; Xinghang Zhang<sup>1</sup>; <sup>1</sup>Texas A&M University

We report on the synthesis of sputtered, highly (111) and (100) textured Cu/Ni multilayers with individual layer thickness, *h*, varying from 1 to 200 nm. At greater *h*, XRD patterns of Cu and Ni (100) (or (111)) peaks are clearly separated indicating that the existence of semi-coherent interface. When *h* decreases to 10 nm or less, XRD spectra show significant peak distortions due to coherency stress. High resolution TEM studies confirm the coexistence of twin and coherent layer interfaces in highly (111) textured Cu/Ni multilayers. Multilayer hardnesses increase with decreasing *h*, approach a maxima at *h* of 2.5-5 nm, and show softening thereafter. A detail comparison between (111) and (100) textured Cu/Ni is made in both microstructure and strengthening mechanisms. The influences of both coherent layer interfaces and twin interfaces on strengthening mechanisms are discussed.

**3:00 PM**

**Hardening in He Ion Implanted V/Ag Multilayers:** *Qiangmin Wei*<sup>1</sup>; Nathan Mara<sup>1</sup>; Michael Nastasi<sup>1</sup>; Amit Misra<sup>1</sup>; <sup>1</sup>LANL

Hardness before and after irradiation as a function of layer thickness on sputter-deposited V/Ag multilayers, as well as pure Ag and V, was measured by nano-indentation. Radiation-induced hardening was found to decrease with decreasing individual layer thickness. No significant radiation hardening was observed at layer thickness less than 6 nm within the error limit of equipment. A model describing radiation effects on the hardness of multilayers with length scale from micrometer to less than one nanometer was developed on the basis of Freidel model and confined layer slip (CLS) model. At layer thickness larger than 50 nm, hardening from He bubbles dominates. With decreasing layer thickness, hardening from the interfaces becomes dominant with less contribution from He bubbles.

**3:20 PM Invited**

**Deformation Mechanisms of Nanoscale Multilayers:** *Jian Wang*<sup>1</sup>; Amit Misra<sup>1</sup>; <sup>1</sup>LANL

Nanoscale metallic multilayer composites exhibit relatively high flow strengths in comparison with bulk polycrystalline materials due to the presence of the high density of interfaces in composites. The flow strength of composite materials produced in this way increases as decreasing the thickness of individual layers. The systematic study regarding deformation mechanisms of layered composites from experimental measurements to theoretical and numerical studies, suggests that crossing of dislocations across interfaces becomes an important unit process at layer thicknesses in the range of a few nanometers, in turn, implying that interface structures and the resultant properties of interfaces play a vital role in determining material strength. The difficulty of crossing of dislocations across interfaces is ascribed to different mechanisms with respect to interface types. Using atomistic simulations, deformation mechanisms in nanolayered materials, such as Cu/Nb layered composites are discussed. Weak interface strengthening mechanisms are developed and examined.

**3:50 PM Break**

**4:20 PM**

**Fundamental Investigation of Deformation Using Spherical Indentations and 3D X-Ray Microscopy:** *Bennett Larson*<sup>1</sup>; Jon Tischler<sup>1</sup>; Yanfei Gao<sup>2</sup>; <sup>1</sup>Oak Ridge National Laboratory; <sup>2</sup>Oak Ridge National Laboratory, University of Tennessee Knoxville

3D x-ray microscopy measurements of the spatially confined lattice distortions under spherical indentations provide an opportunity for fundamental investigations of deformation on mesoscopic length scales and detailed testing of finite element crystal plasticity simulations of deformation in crystalline materials. Direct comparisons of 3D x-ray microscopy

measurements of deformation below 100 mN, 100 micron radius spherical indents in (100), (110), and (111) oriented Cu with crystal plasticity simulations have shown remarkable overall agreement. However, both qualitative and quantitative differences are found to exist between measured and simulated local rotational distortion components and geometrically necessary dislocation density patterns. Strong, depth dependent dislocation patterning under indents provides a further fundamental challenge to deformation simulations. Research sponsored by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, U.S. Department of Energy.

**4:40 PM**

**Structure and Hardness of Aged Ti-W Multilayer Films:** *Ross Economy*<sup>1</sup>; Marian Kennedy<sup>1</sup>; <sup>1</sup>Clemson University

Metallic multilayer film systems are being studied for potential use in microelectromechanical systems and freestanding high-strength structures. Control of layer thickness has been shown to influence the mechanical response by controlling dislocation slip. Only a few groups, however, have looked at the influence of aging and porosity on the mechanical properties of these multilayer systems. As a result, this study will look at the influence of film porosity and thermal aging on the properties of Ti-W multilayer systems. 500nm Ti, W, and nano-porous Ti thin films, as well as multilayer Ti-W systems (20nm layers), were deposited onto Si(100) via magnetron sputtering. SEM and AFM were used to characterize film morphology and microstructure. Hardness was characterized using nanoindentation. Initial data shows that multilayer film systems exhibit an increase in hardness of ~200% when compared with bulk W and a slight decrease when compared to the W films.

**5:00 PM**

**Flow Stress Partitioning in Two-Phase Metallic Composites at Decreasing Phase Length Scales:** *Rainer Hebert*<sup>1</sup>; Girija Marathe<sup>1</sup>; <sup>1</sup>University of Connecticut

Repeated cold-rolling and folding of metallic multilayers generates two-phase composite materials with continuously decreasing length-scales in the layer thickness direction. Within a few rolling and folding passes, the layer thickness decreases for systems such as Cu-Ni from the micrometer to the nanometer scale. Instrumented indentation measurements are used to probe the hardness and flow stresses of the individual layers at increasing strain levels. During the initial stages, i.e. at the micrometer scale for the layer thickness, the indentation measurements allow for studies of the impact of the strain compatibility between the layers on the flow stress evolution. The strain compatibility between the layers modifies the work-hardening behavior and the observed changes in the flow stress evolution are discussed in light of crystal plasticity models based on geometrically necessary dislocations. The results reveal a mutual impact between the mechanical properties of the individual layers and the geometry of the layer arrangement.

**5:20 PM**

**Film Thickness Effects on Interfacial Failure in Polymer Metal Thin Film Structures:** *Neville Moody*<sup>1</sup>; Markus Ong<sup>2</sup>; E. David Reedy Jr.<sup>1</sup>; Edmundo Corona<sup>1</sup>; David Adams<sup>1</sup>; John Yeager<sup>3</sup>; David Bahr<sup>3</sup>; <sup>1</sup>Sandia National Laboratories; <sup>2</sup>Whitworth University; <sup>3</sup>Washington State University

Interfaces are the critical feature governing performance of polymer-metal thin film structures where differing properties between adjacent films can induce strong interlaminar stresses and catastrophic failure. We are studying these effects in a model system created by spin coating 10 to 650nm thick PMMA films onto copper coated silicon substrates followed with a sputter deposited overlayer of highly stressed tungsten. The high film stresses triggered spontaneous delamination and buckling along the PMMA-tungsten interface accompanied by intense deformation in the PMMA layers that varied markedly between each system studied and from model elastic behavior. In this presentation we will use crack growth simulations and comparison to metal film structures to show that film compliance provides a lower bound to behavior for all samples while constrained yielding accounts for the pronounced differences in behavior between samples. This work was

supported by Sandia National Laboratories through USDOE NNSA Contract DE-AC04 94AL85000.

#### 5:40 PM

**Size Effect in Cleavage Cracking in Polycrystalline Thin Films:** *Yu Qiao*<sup>1</sup>; Weiyi Lu<sup>1</sup>; <sup>1</sup>University of California San Diego

As a cleavage crack front propagates across a wide high-angle grain boundary, it would first penetrate across a number of break-through points, and the persistent grain boundary areas would then be separated through shear fracture or ligament bending. Therefore, as the film thickness is smaller than the characteristic distance between the break-through points, which is often in the range of 1-5 microns, the crack front transmission can be significantly confined by the film surfaces leading to an either beneficial or detrimental size effect. That is, the fracture toughness of the polycrystalline thin film is not a material constant; rather, it highly depends on the film thickness. This concept was recently validated in our bicrystal thin film testing.

### Surfaces and Heterostructures at Nano- or Micro-Scale and Their Characterization, Properties, and Applications: Growth, Characterization, and Devices II - and - Coatings, Surfaces, and Interfaces I

**On the Role of Interface Engineering in Future Technology Applications:** *Aarthi Venkateshan*<sup>1</sup>; Rajendra Singh<sup>2</sup>; <sup>1</sup>Canon Anelva Corporation; <sup>2</sup>Clemson University

The global need for high performance, low power computing continues as a major driver of the semiconductor industry. A decade ago, Moore's Law scaling meant oxide thickness, transistor length and width were scaled by factor (1/k) to provide delay improvement 1/k at constant power density. In subsequent generations, performance enhancers were added to drive the transistor roadmap forward. The continued decrease in feature sizes means management of interfaces will play an important role in future scaling. High quality ZrO<sub>2</sub> high-k films were grown, EOT 1.4 nm 1V leakage current density 1.83 10<sup>-11</sup> A/cm<sup>2</sup> was observed. For Al<sub>2</sub>O<sub>3</sub> of EOT 1.04 nm at 1 V leakage current density 5.71 10<sup>-11</sup> A/cm<sup>2</sup> was achieved. We report results of EOT 0.39 nm HfO<sub>2</sub> with leakage current density 1.0 10<sup>-12</sup> A/cm<sup>2</sup> for gate voltage -3 to +3 V. Based on DOE and process variation data, process is robust and will transfer from laboratory to manufacturing environment.

**Role of Rapid Photothermal Processing in Providing Homogenous Nanostructure of Silica Clad Silicon Fibers:** *Rajendra Singh*<sup>1</sup>; Nishant Gupta<sup>1</sup>; T. Wade Hawkins<sup>1</sup>; Paul Foy<sup>1</sup>; Colin McMillen<sup>1</sup>; Stephanie Morris<sup>1</sup>; Robert Rice<sup>2</sup>; Kelvin Poole<sup>1</sup>; John M. Ballato<sup>1</sup>; <sup>1</sup>Clemson University; <sup>2</sup>Northrop Grumman Space Technology

The recent realization of silicon core optical fibers has the potential for rack-to-rack optical interconnects in integrated optoelectronic applications. Incoherent light source based rapid photothermal processing was used to carry out ex-situ annealing on the as-drawn silicon core optical fibers. The

dark current-voltage characteristics of annealed silicon fibers diodes showed lower leakage current than the diodes based on as drawn fibers. X-ray diffraction examination of the crystal structure of as-drawn fiber of 5 mm length showed 3 mm stretch of single crystal Si and 2 mm of polycrystalline material. On the other hand, the entire 10 mm length of the annealed sample was crystalline. The role of rapid photothermal processing in obtaining homogenous nanostructure of the silica clad silicon fiber will be presented. Structural, electrical, and optical characterization of annealed and as-drawn fibers will be presented. This work is supported by Northrop Grumman Corporation.

#### 3:00 PM

**High Surface Metal/Metal Nano-Microstructured Porous Monoliths:** *Martin Bakker*<sup>1</sup>; Franchesca Maddox Saylor<sup>1</sup>; Amy Grano<sup>1</sup>; Keana Graves<sup>1</sup>; <sup>1</sup>The University of Alabama

Porous metal electrodes are of interest in a wide range of electrochemical processes. We report here on a versatile process for making a range of such electrodes using a porous silica template. The porous silica monoliths are produced by a sol-gel process with PEO polymer and cationic surfactant added to give porosity at nanometer and micrometer length scales. Metal nitrates are infiltrated into the silica monolith either as a saturated solution or as a melt. Decomposition under hydrogen results in formation of metal replicas. By controlling the number of infiltration cycles, the extent of replication can be controlled. By changing the metal salt used between infiltration cycles, heterostructures consisting of nanostructures of one metal on a continuous microstructure of a second metal can be produced. Typical surface areas are 40-90 m<sup>2</sup>/g. Significant variations in pore size distributions are found for different metals and for different methods of producing the metals.

**Microstructural Evolution in NiAlCrHf and NiAlCrZr Coated Superalloys:** *Mark Weaver*<sup>1</sup>; Joel Alfano<sup>1</sup>; <sup>1</sup>The University of Alabama

Coated Ni based superalloys are used for power generation due to their ability to function in oxidative and corrosive environments. However, it is well known that the microstructures of these coated systems change in service due to interactions with the environment and interdiffusion with the underlying substrate. In this study, NiAlCr-(Hf,Zr) overlay coatings were produced via dc magnetron sputtering. Post-deposition annealing in a mixture of Ar+5%H<sub>2</sub> and oxidation in laboratory air produced microstructural and chemical changes within the coating/substrate systems which significantly influenced their performance. The purpose this presentation is to describe the results of a study to quantify the microstructural changes occurring in NiAlCrHf and NiAlCrZr coated superalloys in comparison with (Ni,Pt)Al coated superalloys tested under the same conditions.

#### 4:00 PM Invited

**Nature of the B2 Phase in Sputter-Deposited 304 Stainless Steel + 10 wt.% Al Coatings:** U.M.R. Seelam<sup>1</sup>; C. Suryanarayana<sup>1</sup>; T. Ohkubo<sup>2</sup>; Kazuhiro Hono<sup>2</sup>; N. S. Cheruvu<sup>3</sup>; <sup>1</sup>University of Central Florida; <sup>2</sup>National Institute for Materials Science; <sup>3</sup>Southwest Research Institute

A Fe-18Cr-8Ni-10Al (wt.%) coating was deposited on a 304-type austenitic stainless steel substrate by magnetron sputtering technique using SS304 and Al targets. The as-deposited coatings were characterized by XRD, SEM, TEM, and 3DAP techniques. The coating consists of columnar grains with alpha-ferrite and B2 phase particles uniformly distributed. It also has a deposition-induced layered structure with two alternate layers (of 3.2 nm wavelength), one rich in Fe and Cr, and the other rich in Al and Ni. Conventional TEM techniques were able to provide the general microstructural features of the coating, but it was not able to determine the exact nature and chemistry of the B2 phase; 3DAP studies helped in unambiguously identifying that the B2 phase is NiAl. Based on the above

results, it was concluded that NiAl is the preferred phase over FeAl, further correlated with the heats of mixing among Fe, Ni, and Al elements.

**The Solution Precursor Plasma Spray Process for Depositing Multi-Functional, Nanoscale Coatings:** *Maurice Gell*<sup>1</sup>; Eric Jordan<sup>1</sup>; <sup>1</sup>University of Connecticut

The Solution Precursor Plasma Spray Process (SPPS) is a highly flexible process that can deposit single- or multi-phase oxide coatings for functional applications. The coating microstructure is on the nanoscale and is compositionally homogeneous. In this presentation, the SPPS process and its utility to fabricate multi-functional materials will be described. Comparisons will be made to alternate plasma spray processing methods, including those using powder and suspensions. The applications include: (a) thermal barrier coatings with a unique strain-tolerant microstructure, (b) coatings with in-situ sensors on the atomic scale, and (c) two-phase transparent ceramics that meet stringent optical and elevated temperature mechanical properties.

#### 5:00 PM

**Tribological Behavior of Spark Plasma Sintered Iron-Based Bulk Amorphous Alloys:** *Ashish Singh*<sup>1</sup>; Sandip Harimkar<sup>1</sup>; <sup>1</sup>Oklahoma State University

Amorphous alloys (BMG's) exhibit high-micro hardness, fracture toughness, and yield strength at ambient temperature. These properties result in good tribological behavior of BMG's and make it a potential material for high performance wear resistance applications. Spark plasma sintering technique is used to fabricate fully amorphous and in-situ bulk amorphous matrix composites near crystallization temperature of the alloy. Sintered samples exhibited heterogeneous microstructure which involves nano crystallized phases embedded in-between amorphous matrix. Frictional and wear behavior of spark plasma sintered iron based BMG's are investigated under dry sliding conditions. Wear behavior of sintered specimens are analyzed at different normal loads and rotational speeds. The surface roughness, coefficient of friction, and wear loss of the wear tested samples are studied.

**Willingness to Recycle Electronic Waste: Results from a National Survey of U.S. Households:** *Jean-Daniel Saphores*<sup>1</sup>; Oladele Ogunseitan<sup>1</sup>; Andrew Shapiro<sup>2</sup>; <sup>1</sup>University of California Irvine; <sup>2</sup>Jet Propulsion Laboratory, California Institute of Technology

The fate of used electronic products (e-waste) is of increasing concern because of the toxicity of e-waste, its growing volume, and the environmental and public health consequences of its inadequate handling. The U.S. EPA estimates that e-waste has become the main contributor of lead (Pb) to landfills. Households also store large volumes of e-waste, yet little is known

about their willingness to recycle e-waste at the national level. This paper starts filling this gap based on a 2006 survey of U.S. households. Using multivariate models, we find that gender, education, convenience, moral considerations, environmental beliefs, and knowledge of e-waste toxicity, but neither income nor political affiliation, are key factors explaining people's willingness to drop off e-waste at recycling centers. Our results suggest targeting e-waste public education programs at younger adults and making recycling more convenient for older adults.

#### 2:30 PM

**Development of Technology for Recycling Valuable Metals from Electronic Wastes in Korea:** *Jae-chun Lee*<sup>1</sup>; Byung-Su Kim<sup>1</sup>; Min-seuk Kim<sup>1</sup>; Jinki Jeong<sup>1</sup>; Banshi Pandey<sup>2</sup>; <sup>1</sup>Korea Institute of Geoscience and Mineral Resources (KIGAM); <sup>2</sup>National Metallurgical Laboratory, CSIR

The generation of electronic wastes in Korea has been increasing significantly over the years. These wastes viewed previously as the source of contaminants for environment due to the hazardous materials are now recognized as the new resources termed as "urbane ore" because of presence of the valuable metals. The development of a sustainable recycling technology for electronic wastes is urgently required with the aim of environmental protection and secured supply of resources simultaneously. The commercial recycling technology of electronic wastes uses pyrometallurgical process to recover copper, gold and silver partially in the existing smelters. This paper elaborates the development of a combined process involving mechanical pretreatment and hydrometallurgical reclamation which has the advantage to recover not only copper but most rare metals as well. The research focus is on the development of the liberation technology using various pulverization methods along with the eco-friendly and energy-saving metal extraction – separation technology.

#### 3:00 PM

**State of the Art in the Recycling of Waste Printed Wiring Boards:** *Lifeng Zhang*<sup>1</sup>; <sup>1</sup>Missouri University of Science and Technology

Printed Wiring Board (PWB) is a platform upon which microelectronic components such as semiconductor chips and capacitors are mounted. It is also called printed circuit board (PCB). In the PWBs, the organic substances are approximately 72%. The main composition of organic substances in PWBs is ethoxylated resin bromide or ethoxylated resin chlorinate. Depending on the different application and design of the PWB, various metals may be used in the manufacturing process, including precious metals such as copper, lead, silver, gold, platinum, and toxic metals such as mercury, cadmium, barium, gallium, cadmium, lead, bismuth. The current paper reviewed the recycling process for waste PWB materials, including mechanical recycling, combustion for energy recovery and different pyrolysis processes, such as vacuum pyrolysis, atmospheric inert pyrolysis and flux pyrolysis process, and hydrometallurgical recycling process.

#### 3:30 PM

**Overview of Electronics Waste Management in India:** *Sandip Chatterjee*<sup>1</sup>; Krishna Kumar<sup>1</sup>; <sup>1</sup>Department of Information Technology

Growth of electronics waste (e-waste) and lack of appropriate disposal mechanism are the great concern for developing countries like India. The domestic generation of e-waste in India is rapidly growing with the development. The imported substance is also substantially contributing to the e-waste inventory. Recycling of e-waste is mainly carried out in unorganized units in India. The primitive recycling technique used by the unorganized sector is a great threat to the environment and the health of the operators involved in these profession. Therefore, improvement of technology used by these units towards a cost effective, environmental friendly alternative could be the solution to the present crisis. Few initiatives of recycling have, however, come up in recent years in organized units. The precious metals are still recycled in the developed countries. This report discusses the inventory, technology status, legal legislative and existing practices of e-waste management in India.

#### 4:00 PM Break

#### 4:10 PM

**Prospective Scenario of E-Waste Recycling in India:** Manis Kumar Jha<sup>1</sup>; Abhishek Kumar<sup>1</sup>; Vinay Kumar<sup>1</sup>; Jae-chun Lee<sup>2</sup>; <sup>1</sup>National Metallurgical Laboratory; <sup>2</sup>Korea Institute of Geoscience and Mineral Resources (KIGAM)

However, India is rich in ores and minerals, but e-waste recycling is necessary due to the report of national and international studies, which cautioned on the generation, treatment and accumulation of e-waste in India. Current data indicate that the total domestic e-waste generation, including imports, is around 382979 MT. However, waste available for recycling and actually recycled are 144143 MT and 19000 MT, respectively, in which recycling by non-formal and formal sector are 95% and 5%, respectively. On the other hand, India has developed an expertise in handling varieties of metallic wastes in an organized and safe manner. The development of individual processes or combined processes for handling the e-waste is underway. Eco- friendly and energy-saving processes are necessary to comply with stringent environmental regulations. The paper includes the recent trend of e-waste generation, recycling process and its future prospects particularly in India.

#### 4:40 PM

**From a Technical Marvel to a Hazardous Box: An Estimate of the Volumes of Potentially Toxic Materials in Obsolete TVs Stored by US Households Based on National Survey:** Natalia Milovantseva<sup>1</sup>; Jean-Daniel Saphores<sup>1</sup>; <sup>1</sup>University of California, Irvine

The increasing popularity of consumer electronics continues to present tough challenges for policy makers concerned with the risks for human health and the environment of improperly disposing of electronic waste (e-waste). In 2007, the EPA estimates that approximately 26.9 million TVs were discarded in the US alone, yet only 18 percent by weight was recycled; unfortunately, these numbers are very uncertain. Discarded cathode ray tube (CRT) TVs contain large amounts of lead but flat panel TVs contain some mercury and present new recycling challenges. It is important for public policy to get better estimates of the number of TVs currently in storage and of the quantity of potentially toxic materials they contain. This paper relies on count models to analyze the data from a national survey (n=3165) of US households. Our models estimate the number and the size of obsolete TVs stored by US households using a set of behavioral, socio-economic and demographic variables, and we then approximate the volumes of potentially toxic materials they contain. Our findings provide information to support future state and national policy decisions on the management of hazardous materials.

#### 5:10 PM

**Methodology for Recovery Precious Metals: Gold, Silver and Platinum Group from Electronic Waste:** Oscar Restrepo<sup>1</sup>; Honorio Oliveros<sup>1</sup>; <sup>1</sup>National University of Colombia

Colombia produces nine tons of electronic waste per year and there are approximately 60 tons accumulation generated in the last nine years. This work aims to establish a general methodology in the laboratory to recover gold, silver and platinum groups present in electronic waste and also to explore other forms of recovery of metals contained in electronic waste. We selected seven types of electronic cards present in the computers, which have their parent desoldering electronic components. Initially, we characterized the components of the cards through x-ray diffraction and SEM to identify the metal species and composition. Tests were conducted in laboratory hydrometallurgical recovery of metals. This paper proposes a methodology for laboratory-scale work.

#### 5:40 PM

**WEEE: Obsolete Mobile Phones Characterization Aiming at Recycling:** Viviane Moraes<sup>1</sup>; Denise Espinosa<sup>1</sup>; Jorge Tenório<sup>1</sup>; <sup>1</sup>Escola Politécnica da Universidade de São Paulo

The development of mobile phone technology has increased the replacement of outdated equipment for more modern models, transforming the disposal of such devices into a serious environmental problem. Recycling

appears as an attractive alternative to minimize the environmental impact of disposing such large quantities. Recycling can be accomplished by treating the printed circuit boards of used mobile phones with the same techniques used in ore treatments with hammer mill: magnetic separation, electrostatic separation and grain size range. Before performing the recycling process, a PCB characterization was performed to identify the fraction with the higher metals concentration/content. This study demonstrated that the electrostatic separation was not the best metals concentration of PCB aiming the recycling, while the non-magnetic residue had presented a more significant metal concentration. Furthermore, after the magnetic separation, it was possible to separate the metals iron and nickel.

**Grain Boundary Diffusion: From Nearly Perfect Bicrystals to Severely Deformed Polycrystalline Materials:** Sergiy Divinski<sup>1</sup>; <sup>1</sup>University of Münster

An overview of recent advances in grain boundary (GB) diffusion and segregation in bi-crystalline, tri-crystalline, and poly-crystalline metals is presented with an emphasize on the relationship between the structure and kinetic properties. GB diffusion is strongly affected by the structural state of interfaces and segregation of residual impurities. The so-called 'non-equilibrium' GBs are introduced by severe plastic deformation of metals using deferent routes. These GBs are characterized by an increased free volume, larger excess free energy and, as a result, enhanced diffusivities. The kinetic and structure properties of the 'non-equilibrium' GBs are investigated for several pure metals (Cu, Ni, Ti) and Cu-based alloys severely deformed by equal channel angular pressing. The relaxation behavior of interfaces in ultra-fine grained metals is investigated by radiotracer diffusion measurements and differential scanning calorimetry.

#### 2:30 PM Invited

**Experimental Measurements of the Shear-Coupled Stress Driven Grain Boundary Migration in Al Bicrystals:** Dmitri Molodov<sup>1</sup>; Tatiana Gorkaya<sup>1</sup>; Günter Gottstein<sup>1</sup>; <sup>1</sup>RWTH Aachen University

Recent results of experimental research into stress induced grain boundary migration in aluminum bicrystals will be briefly reviewed. Boundary migration under a shear stress was observed to be coupled to a lateral translation of the grains for planar symmetrical <100> tilt boundaries. This coupling proved to be the typical migration mode of any <100> tilt boundary, no matter whether low- or high angle, low  $\Sigma$  CSL coincidence or non-coincidence boundary. The measured ratios of the normal boundary motion to the tangential displacement of the grains were in an excellent agreement with theoretical predictions. Measurements of the temperature dependence of coupled boundary migration revealed that there is a specific misorientation dependence of migration activation parameters. The experimental observations provide evidence that the investigated boundaries can act during their migration under stress as sources of lattice dislocations that results in the formation and growth of new grains in the boundary region.

### 3:00 PM Invited

#### **Evolution of the Grain Boundary Character Distribution during Grain Growth:** *Gregory Rohrer*<sup>1</sup>; Herbert Miller<sup>1</sup>; <sup>1</sup>Carnegie Mellon University

The grain boundary character distribution is the relative area of grain boundaries as a function of the lattice misorientation and grain boundary plane orientation. This paper will focus on experiments undertaken to assess the evolution of the grain boundary character distribution as a function of thermal annealing that leads to grain growth. The analysis is based upon electron backscatter diffraction (EBSD) data, which allows the crystallography and relative areas of all of the grain boundaries to be measured. Data from SrTiO<sub>3</sub> taken a range of grain sizes indicates that the grain boundary character distribution changes as the grains grow. Measurement of the relative grain boundary energies indicates that as grain growth proceeds, higher energy boundaries are preferentially eliminated from the distribution.

#### **Grain Growth in 4D: A Comparison between Simulation and Experiment:** E. Lauridsen<sup>1</sup>; I. McKenna<sup>2</sup>; S. Poulsen<sup>1</sup>; W. Ludwig<sup>3</sup>; *Peter Voorhees*<sup>2</sup>; <sup>1</sup>Riso Laboratory for Sustainable Energy; <sup>2</sup>Northwestern University; <sup>3</sup>European Synchrotron Radiation Facility

The evolution of polycrystalline materials is examined using 3D imaging tools based on phase- and diffraction- contrast X-ray tomography and phase field simulations. Since the techniques are nondestructive, it is possible to record the morphological and topological evolution of an individual grain and compare this to the predictions of simulations using the experimentally measured structure as an initial condition. Through this comparison, we find that the phase field model can reproduce quite accurately grain morphology and topology in regions of the Ti-21S sample with isotropic grain boundary properties. However, in other regions, we find grain boundary mobilities that are orders of magnitude larger than the average, mobilities that depend strongly on the grain boundary normal, and clear influence of grain boundary energy anisotropy on the morphological evolution of grains.

### 4:15 PM

#### **A Comparison between Creep in Molybdenum and Iron toward Understanding Dynamic Abnormal Grain Growth:** *Phi Thanh*<sup>1</sup>; Daniel Worthington<sup>2</sup>; Cory Guebels<sup>1</sup>; J. P. Delplanque<sup>1</sup>; Joanna Groza<sup>1</sup>; <sup>1</sup>University of California Davis; <sup>2</sup>University of Texas

Dynamic abnormal grain growth (DAGG) is a phenomenon which produces abnormal grains during straining above a critical temperature. DAGG has been observed in molybdenum but not in iron at similar homologous temperatures ( $T = 0.4 TM$ ) and strain rates (strain-rate  $\square 10^{-3}$  to  $10^{-5} s^{-1}$ ). We compare high-temperature plastic deformation data of molybdenum and iron via creep and activation area analyses. Experiments for both materials were conducted under displacement-controlled tensile deformation. We utilize the present analyses to discuss the occurrence of DAGG in body-centered cubic metals.

### 4:35 PM Invited

#### **Quantum Dynamical Effects in Thermally-Activated Dislocation Glide: Origin of the Discrepancy between Experimental and Simulated Peierls Stresses:** *David Rodney*<sup>1</sup>; Laurent Provaille<sup>2</sup>; <sup>1</sup>INP Grenoble; <sup>2</sup>CEA Saclay

The Peierls stress is one of the most fundamental properties of a dislocation. In BCC crystals for example, it is appreciably high, causing a strongly temperature-dependent plasticity at low temperatures. Atomic-scale simulations are known to overestimate the Peierls stress. Indeed, calculations based on electronic structure theories and interatomic potentials predict Peierls stresses two to three times larger than experimental values. We show here that this discrepancy arises from quantum effects in atomic motion (zero-point motion and tunneling) so far neglected in atomistic calculations although the experiments were performed well below the Debye temperature. We used a Quantum Transition State Theory based on Path Integrals to evaluate how quantum dynamics alter the Peierls potential of several high-Peierls stress dislocations and find that the free energy barrier

against motion disappears at low temperatures for applied stresses below half the "classical" Peierls stress, thus in the experimental range.

### 5:05 PM

#### **Core Properties of Screw Dislocations in Fe and W Based Materials:** *Lisa Ventelon*<sup>1</sup>; François Willaime<sup>1</sup>; Emmanuel Clouet<sup>1</sup>; <sup>1</sup>CEA

A quantitative description of straight and kinked screw dislocations in iron and tungsten based materials from first principles is presented. We show that standard convergence criteria for relaxation in DFT calculations are not sufficient for a quantitative determination of the onset of glide and hence of the Peierls stress. We propose an alternative method, which consists in calculating the Peierls barrier for various strains, using a constrained minimization method. The calculation has been repeated for several crystal orientations to determine the deviation from Schmid law. We have also performed DFT simulations on the effect of rhenium on screw dislocations in tungsten using the VCA approximation, which confirm a recent prediction of the unexpected transition from symmetric to asymmetric core upon alloying. More insight into the stability of the core structure in tungsten alloys for different rhenium concentrations has been gained by looking at the response of the core polarization.

### 5:25 PM

#### **Thermal Activation in BCC Metals: Linking Local Atomistic Information to the Mesoscale:** *Kinshuk Srivastava*<sup>1</sup>; Daniel Weygand<sup>1</sup>; Peter Gumbsch<sup>1</sup>; <sup>1</sup>Karlsruhe Institute of Technology

High yield and flow stress in bcc metals is attributed to the large intrinsic resistance called Peierls stress experienced by the  $\langle 111 \rangle$  screw dislocations. This is because of the non-planar nature of the dislocation core. However, at finite temperatures, the screw dislocations overcome the intrinsic energy barriers at less than the theoretical stresses due to stress-assisted thermal activation of kink-pairs on screw dislocations and their subsequent migration along them. In this work, the activation enthalpies of kink-pair nucleation are obtained directly from atomistic data incorporating the effect of local non-glide stresses and orientation dependence of the Peierls barrier of the  $1/2\langle 111 \rangle$  screw dislocation. The effects of non-glide stresses and their importance on dislocation mobility in a three-dimensional discrete dislocation dynamics framework is presented. Simulations on micro-meter sized Tungsten pillars under bending show the effects of tension-compression asymmetry on dislocation micro-structure.

### 5:45 PM

#### **Thermally Activated Motion of $1/2\langle 111 \rangle$ Screw Dislocation in BCC Iron:** *Zhiming Chen*<sup>1</sup>; Matous Mrovec<sup>2</sup>; Peter Gumbsch<sup>2</sup>; <sup>1</sup>Karlsruher Institut für Technologie (KIT); <sup>2</sup>Fraunhofer-Institute Für Werkstoffmechanik IWM

The plastic deformation of body-centered cubic metals is governed by  $1/2\langle 111 \rangle$  screw dislocations. We perform atomistic computer simulations of the response of the  $1/2\langle 111 \rangle$  screw dislocation to various applied loadings in iron. The calculations have been made using tight-binding based bond-order potential, which also correctly accounts for magnetic effects. We study the orientation dependence of the critical resolved shear stress for pure shear stresses as well as the effect of non-glide stresses, which have a profound influence on the dislocation core structure. Our simulations show that iron possesses a significant twinning-antitwining and tension-compression asymmetries like other bcc metals and does not follow the Schmid law. The atomistic results are transferred to macroscopic level by formulating single crystal yield criteria which can be applied in discrete dislocation dynamics or continuum approaches.

## 2011 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: Fabrication of Nanomaterials I

##### Atomic Layer Deposition for the Functionalization of Nanoporous Materials: Jeffrey Elam<sup>1</sup>; <sup>1</sup>Argonne National Laboratory

Atomic layer deposition (ALD) is a thin film growth technique that uses alternating, self-limiting chemical reactions to deposit materials in an atomic layer-by-layer fashion. Although this process is already used commercially for microelectronics manufacturing, ALD promises to have a much broader impact extending far beyond microelectronics. In particular, the capability to infiltrate and coat nanoporous substrates coupled with a broad palate of available materials make ALD a versatile technique for synthesizing nanostructured materials. At Argonne we are pursuing a variety of new applications for ALD including photovoltaics, catalysis, and energy storage. A central theme in these efforts is that we use ALD to apply precise, conformal coatings onto nanostructured scaffolds to impart the desired optical, electrical, or chemical properties to advance these technologies.

#### 9:05 AM Invited

##### One Dimensional Nanomaterials Synthesis Using Atomic Layer Deposition: Hyungjun Kim<sup>1</sup>; <sup>1</sup>Yonsei University

Atomic layer deposition (ALD) has been considered as a promising thin film deposition technique for nanoscale semiconductor device fabrication. Recently, however, the exclusive benefits of ALD make it viable tool for nanotechnology. In this presentation, I will present several examples on the one dimensional nanomaterials synthesis using ALD. Due to its excellent conformality, ALD is an ideal technique to produce nanomaterials with combination of nanopatterning techniques. Utilizing highly conformal Ru and ZnO ALD with nanotemplates, 1 D nanomaterials were fabricated. Moreover, by adding SiH<sub>4</sub> to the NH<sub>3</sub> plasma reactant during Co plasma-enhanced ALD process, Co nanorods array was formed on Si substrates without using nanotemplates. Also, by applying highly conformal ALD processes for transition metals followed by annealing, silicide nanowires were synthesized. The physical and structural properties of these nanomaterials were investigated by various analysis techniques.

#### 9:35 AM

##### Recent Progress on Synthesis and Characterization of Boron-based One-Dimensional Nanostructures: Terry Xu<sup>1</sup>; XiaoXia Wu<sup>1</sup>; Zhe Guan<sup>1</sup>; Youfei Jiang<sup>1</sup>; <sup>1</sup>UNC Charlotte

Boron-based (i.e., boron and metal boride) one-dimensional (1D) nanostructures have recently attracted much attention due to their predicted superior electrical and mechanical properties. Combining with other properties such as low density and high chemical stability, boron-based 1D nanostructures are appealing candidates for applications such as thermoelectric energy conversion, nanocomposites and nanoelectronics. In this presentation, our recent progress on synthesis and characterization of boron-based nanomaterials, such as  $\alpha$ -tetragonal boron, MB<sub>6</sub> (M=Ca, Sr and Ba), and B<sub>4</sub>C-type 1D nanostructures will be reviewed. Special discussion

will be on (1) the need of carbon to achieve high volume fabrication of  $\alpha$ -tetragonal boron nanostructures, (2) Young's modulus measurement of MB<sub>6</sub> 1D nanostructures and  $\alpha$ -tetragonal boron nanostructures, and (3) thermal stability of  $\alpha$ -tetragonal boron nanostructures. The thermoelectric property of these boron-based nanostructures will also be briefly discussed.

#### 9:50 AM

##### Superhydrophobicity of Boron Nitride Nanotubes Structures: Chee Huei Lee<sup>1</sup>; Jaroslav Drellich<sup>1</sup>; Yoke Khin Yap<sup>1</sup>; <sup>1</sup>Michigan Technological University

Boron nitride is a chemically inert, resistive to oxidation up to 900/176C, and transparent to visible-UV light, potentially attractive insulating material for applications under rigorous chemical and thermal conditions. Recently, we also demonstrated (Langmuir 25(9), 2009, 4853-4860) that boron nitride nanotubes can be structured into a superhydrophobic coating. Dense structures of partially vertically aligned boron nitride nanotubes demonstrate excellent water repellency, with advancing and receding contact angles exceeding 150 and 140 degrees, respectively. Boron nitride nanotubes demonstrate superhydrophobicity in both air environment and oil phase. Our results also show that the pH value of water does not affect wetting characteristics of boron nitride nanotubes. On a contrary, lowering the surface tension of liquid by adding ethanol to water reduces the receding contact angle to nearly zero value.

##### Solution-Synthesized ZnO Nanomaterials for Hybrid Solar Cells: Julia Hsu<sup>1</sup>; <sup>1</sup>University of Texas at Dallas

There has been great interest in hybrid organic:inorganic solar cells due to their potential for large-scale, cost-effective solar cells. These devices commonly use zinc oxide (ZnO) as the electron acceptor and a conjugated polymer, e.g. poly(3-hexylthiophene), as the electron donor. ZnO nanomaterials are readily synthesized using solution methods. In this talk, I will review using various ZnO nanomaterials for hybrid solar cells. For example, by changing the pyrolysis temperature in the sol gel process, we are able to reduce the size of ZnO crystallites. Consequently, the band gap of the ZnO acceptor is increased due to greater quantum confinement, leading to a larger donor-acceptor energy level offset. We find that a direct correlation between the increase in ZnO Eg and device open-circuit voltage. Nanomaterials enables larger donor-acceptor interfacial area. I will also discuss the gain in device performance by using ZnO nanomaterials in the active layer.

#### 10:50 AM

##### Unipolar Assembly of ZnO Rods: Polarity Driven Collective Luminescence: Ujjal Gautam<sup>1</sup>; Masataka Imura<sup>1</sup>; Xiaosheng Fang<sup>1</sup>; Yoshio Bando<sup>1</sup>; Dmitri Golberg<sup>1</sup>; <sup>1</sup>National Institute for Materials Science

Crystal assemblies are omnipresent and are useful for many devices. Nature too has shown phenomenal control over biomineralization processes to produce exquisite looking crystal assemblies. We have discovered a new phenomenon associated with concentric assemblies of ZnO rods. Usually, a ZnO rod always has an intrinsically positive and a negative polar end induced by the non-centrosymmetric arrangement of Zn and O atoms. We found two distinct types of assemblies wherein all the rods in a single assembly emanate out of a central core maintaining a single polar direction. Due to growth along the two polar surfaces with different atomic arrangements, these assemblies are distinct in their intrinsic properties and exhibit strong UV luminescence in the exterior of Zn-polar assemblies, unlike the O-polar assemblies. While novel applications can be envisioned, these observations suggest that hierarchical organization with respect to internal asymmetry such as polarity might be widespread in natural crystal assemblies.

#### 11:05 AM

##### Hierarchical Graphene Nanomaterials and Applications: Cengiz Ozkan<sup>1</sup>; <sup>1</sup>University of California

I will first describe the patterning of DNA molecules and block copolymers on CVD grown large-area graphene layers to modulate their

TUESDAY AM

electronic properties. DNA molecules are found to act as negative potential gating agents that increase the hole density in single layer graphene. Highly sensitive and cost-effective field effect transistor biosensors are fabricated based on large area graphene layers. Next, I will describe new classes of CVD grown hierarchical graphene nanomaterials in the form of three dimensional architectures called pillared graphene nanostructures (PGN), which are combinations of graphene floors and carbon nanotube pillars. The dependence of the morphology of large-area PGN on the process conditions was investigated by Raman spectroscopy, SEM, TEM, and HRTEM techniques. The successful transfer of the large area PGN onto arbitrary substrates while keeping the 3D architecture intact is demonstrated. Hierarchical graphene nanomaterials are envisioned for future applications in fuel cells, ultracapacitors and hydrogen storage.

#### 11:20 AM Invited

**Atomic Layer Deposition of Al<sub>2</sub>O<sub>3</sub> and ZnO at Atmospheric Pressure in a Flow Tube Reactor:** Gregory Parsons<sup>1</sup>; Jesse S. Jur<sup>1</sup>; <sup>1</sup>North Carolina State University

Atomic layer deposition typically proceeds at ~ 1 Torr because the pressure is high enough to minimize precursor/reactant gas mixing, and the pressure is sufficiently low so that precursors with moderate vapor pressure can be delivered directly into the growth zone. Recently, to investigate capabilities of continuous ALD processes at under atmospheric pressure, our group developed a unique flow tube ALD reactor that operates at pressures between ~1 and 760 Torr. We have characterized ZnO and Al<sub>2</sub>O<sub>3</sub> film growth versus pressure, and used it on several soft material substrates, including polypropylene, nylon-6 and cellulose cotton. We find that ALD growth can be readily achieved for ZnO, whereas some excess growth is observed consistent with ALD+CVD for Al<sub>2</sub>O<sub>3</sub> growth under similar conditions. We will discuss likely mechanisms for these differences, and present possible new applications of ALD performed at atmospheric pressure.

#### 11:50 AM

**Boron Carbide-Nanowires/Carbon-Microfiber Hybrid Structures and Composites from Cotton T-shirts:** Xinyong Tao<sup>1</sup>; Lixin Dong<sup>2</sup>; Xinnan Wang<sup>1</sup>; Wenkui Zhang<sup>3</sup>; Bradley Nelson<sup>2</sup>; Xiaodong Li<sup>1</sup>; <sup>1</sup>University of South Carolina; <sup>2</sup>ETH Zurich; <sup>3</sup>Zhejiang University of Technology

Boron carbide-nanowire/carbon-microfiber hybrid structures have been fabricated using a cotton T-shirt as both the template and carbon source. The boron carbide nanowires exhibit a high elastic modulus of 428.1 GPa and elastic recovery after multiple high-strain bending cycles without brittle failure or obvious residual deformation for the strain up to 45%. The boron carbide-nanowire/carbon-microfiber hybrid structures can block 99.8% UV irradiation and achieve a superior reinforcing effect in their epoxy composites. The boron carbide-nanowire formation mechanisms and corresponding synthesis techniques presented here can be extended to other carbide nanowires such as SiC, TiC, MoC, and WC by introducing suitable carbide-sources and catalysts.

#### 8:30 AM

**Study on Preparation of High-Quality Synthetic Rutile from Titanium Slag by Activation Roasting Followed by Acid Leaching:** Yufeng Guo<sup>1</sup>; Shuishi Liu<sup>1</sup>; Tao Jiang<sup>1</sup>; Guanzhou Qiu<sup>1</sup>; <sup>1</sup>Central South University

The preparation of high-quality synthetic rutile from electric furnace titanium slag was systematically investigated by activation roasting followed by acid leaching method. The results showed that impurities such as Ca and Mg in titanium slag can be effectively removed by roasting with phosphoric acid followed by acid leaching and TiO<sub>2</sub> grade of the product was markedly improved. High-quality synthetic rutile containing 88.54% TiO<sub>2</sub>, 0.42% (CaO+MgO) was obtained under the conditions that roasted with 7.5% (wt) H<sub>3</sub>PO<sub>4</sub> at 1000 \176C for 2h, two-stage leached in sulfuric acid of boiling for 2h. Mechanism studies showed that anosovite solid solution and silicate minerals were reacted with phosphoric acid in the roasting process, as a result, titanium components in titanium slag turned into rutile TiO<sub>2</sub>, impurities turned into acid-soluble phosphate and quartz, therefore, the structures of anosovite solid solution and silicate minerals were destroyed, which is favorable for impurities' removing.

#### 8:50 AM

**Calculation of Phase Equilibria Relations in CaO-SiO<sub>2</sub>-FeOx-MgO System:** Cuihuan Huang<sup>1</sup>; <sup>1</sup>Northeastern University

SiO<sub>2</sub>, CaO, Al<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, Na<sub>2</sub>O and MgO account for more than 90% by weight of the bottom ash slag from municipal solid waste incineration. These compositions have direct effect on the harmless disposal and efficient utilization of bottom ash slag. The phase transformation and phase relations of sub-systems in CaO-SiO<sub>2</sub>-FeOx-MgO system was considered to be important to provide essential data for the thermodynamic properties of the CaO-Al<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub>-FeOx-MgO-Na<sub>2</sub>O system. Based on FactSage software, a set of optimized parameters for the thermodynamic properties of CaO-SiO<sub>2</sub>-FeOx-MgO system was obtained, and the phase equilibria relations were calculated for different temperatures and oxygen partial pressures. Spinel solid solution emerged with the increase of partial pressure of oxygen, which changed the phase relations in FeOx-rich area, and the liquid phase region moved to the poor-FeOx area in MgO-SiO<sub>2</sub>-FeOx system. At 1873K and 10-8atm oxygen partial pressure, MgO solid phase can be found in CaO-SiO<sub>2</sub>-FeOx-MgO system.

#### 9:10 AM

**Dissolution Behavior of Rhodium into Molten Slag:** Chompunoot Wiraseranee<sup>1</sup>; Toru Okabe<sup>1</sup>; Kazuki Morita<sup>1</sup>; <sup>1</sup>The University of Tokyo

Due to very limited resources, recycling of rhodium becomes essential so that rhodium can be sustainably used. By the pyrometallurgical recycling process, rhodium can be separated from various impurities. However, the rhodium dissolution behavior in the process is not yet clarified; thus rhodium loss into slag cannot be estimated. Aiming at the development of more effective recycling processes, rhodium dissolution behavior into molten slag was investigated. Using a pure rhodium crucible and Na<sub>2</sub>O-SiO<sub>2</sub> slag system, equilibration experiments carried out for 18 h at 1423-1573 K, under oxygen

partial pressure 0.001-1 atm, and varying slag basicity. Rhodium solubility increases with increasing oxygen potential, slag basicity and temperature, and the dissolution reaction is determined as  $Rh + 3/4O_2 + 1/2O^{2-} = [RhO_2]$ . From this study, the correlations of rhodium solubility, the newly-defined rhodate capacity and optical basicity are discussed; and rhodium loss in the pyrometallurgical recycling process can be estimated.

**9:30 AM**

**“One Step” Technology to Separate Copper, Zinc, Lead from Iron in Metallurgical Slag and Pyrite Cinder: Part 2- Pilot Test:** *De-qing Zhu*<sup>1</sup>; Dong Chen<sup>1</sup>; Jian Pan<sup>1</sup>; Yu Cui<sup>1</sup>; Tie-jun Chun<sup>1</sup>; <sup>1</sup>Central South University

A study of processing pyrite cinder and metallurgical slag using “one step” technology in strand grate - rotary kiln is presented, which aims to efficiently recover valuable metals of iron, lead, zinc and copper. The effect of chlorination roasting parameters including roasting time and temperature on the nonferrous metal removal rate was investigated. It is shown that copper and zinc are low removed and lead is removed more easily. Then the preheated pellets were reduced in rotary kiln, which indicates zinc and lead can be removed easily and high iron grade and good metallurgical performance prereduced pellets can be obtained. Furthermore, the chlorination and reduction mechanisms of copper, lead and zinc are discussed. It is revealed that the phases of copper, lead and zinc in slag are complex and ferrite and silicate of metals are hardly removed.

**9:50 AM**

**Effect of Oxygen to Alumina Ratio on the Viscosity of Aluminosilicate and Aluminate Systems:** *Jifang Xu*<sup>1</sup>; Jieyu Zhang<sup>1</sup>; Chang Jie<sup>1</sup>; Fei Ruan<sup>1</sup>; Kuochih Chou<sup>1</sup>; <sup>1</sup>Shanghai Key Laboratory of Modern Metallurgy and Material Processing, Shanghai University

Viscosity is an important physical parameter of slag in metallurgical process. Most of studies of aluminosilicate and aluminate systems assume that aluminum occurs in tetrahedral coordination. In this case the O/Al value was utilized to describe the slag structure in terms of the network character of aluminosilicate and aluminate systems. Data of composition and viscosity were come from the literatures, and the trends have been analyzed according to the O/Al value and temperature. It is shown that the O/Al value can be used to explain the trends in more than ten systems successfully, containing more than 200 data points. In aluminosilicate system, the trend that viscosity value changed with the O/Al value implied that alumina works as network modifier such as basic oxides or works as network former. In aluminate system, irrespective of the system and temperature, viscosity would decrease steadily when O/Al value increasing.

**10:10 AM Break**

**10:20 AM**

**Blast Furnace Burdens Preparation from Blast Furnace Burdens Preparation from Metallurgical Dusts and Sludges with Composite Binder:** *Kecheng Zhang*<sup>1</sup>; *Yuanbo Zhang*<sup>1</sup>; Tao Jiang<sup>1</sup>; Guanghui Li<sup>1</sup>; Zhucheng Huang<sup>1</sup>; <sup>1</sup>Central South University

With rapid development of Iron and Steel industry, plenty of metallurgical dusts & sludges are generated, which have not been effectively utilized because of their poor hydrophilicity and bad ballability. Agglomeration and roasting of metallurgical dusts & sludges with a new-type composite binder are studied in this paper. The results indicate that the dosage of the new binders can be decreased to 2.5% from 3.5% when using the wet-grinding process. Under the optimal conditions of briquetting pressure 2070 N/cm<sup>2</sup>, briquetting moisture content 13%, roasting temperature 1000° and roasting time 40 min, the qualities of the green, dry and roasted briquettes meet the requirements of the industry production. The finished products have the compression strength of more than 2000 N/cm<sup>2</sup>, which can be used as high-quality burdens for blast furnaces.

**10:40 AM**

**Determination of FeO Containing Liquid Slag Surface Tensions Using the Sessile Drop Method:** *Clemens Schmetterer*<sup>1</sup>; Patrick Masset<sup>1</sup>; <sup>1</sup>TU Bergakademie Freiberg

Surface and interfacial tensions are important properties of slags for the virtualization of the blast furnace process, since they influence the interactions between the components in the blast furnace, e.g. at the slag – Fe interface. In this work the dependence of the surface tension of Al<sub>2</sub>O<sub>3</sub> – CaO – SiO<sub>2</sub> mixtures with varying Fe<sub>x</sub>O content and oxygen partial pressure was determined at different temperatures using the sessile drop technique with boron nitride (BN) as a substrate material under partial oxidation conditions. In addition, structural investigations using powder X-ray diffraction and Mössbauer spectroscopy (Fe<sup>3+</sup>/Fe<sup>2+</sup> ratio) on quenched specimens were performed as a start in developing a model combining the slag structure, the surface tension and its thermodynamic properties. The obtained experimental data will be discussed with respect to the slag structure and will be compared to results reported in the literature and obtained from modelling.

**11:00 AM**

**Preparation of Partially Stabilized Zirconia and Interface Structure Analysis:** *Dong Bo Li*<sup>1</sup>; Sheng Hui Guo<sup>1</sup>; Li Jun Liu<sup>1</sup>; Jin Hui Peng<sup>1</sup>; Li Bo Zhang<sup>1</sup>; Cheng Dong He<sup>1</sup>; <sup>1</sup>Kunming University of Science & Technology

In present study, partially stabilized zirconia (PSZ) was prepared from CaO doped fused zirconia heated by Microwave furnace at the temperature of 1450° and holding time of 120 min. The characterization of XRD results show that untreated fused zirconia mainly consists of crystalline compounds of cubic ZrO<sub>2</sub> phase; while the roasted one mainly composed of crystalline compounds of cubic ZrO<sub>2</sub> phase and monoclinic ZrO<sub>2</sub> phase. It is shown through the optimization of structures of two phases that structure of cubic ZrO<sub>2</sub> and monoclinic ZrO<sub>2</sub> reject, revealing its difficulty of forming coinciding interface and linkage of two phases being of Ca atom.

**11:20 AM**

**Characteristic of Mineralization of Specularite Iron Ores during Composite Agglomeration Processing:** *Helei Zhang*<sup>1</sup>; Heng Yu<sup>1</sup>; *Guanghui Li*<sup>1</sup>; Yuanbo Zhang<sup>1</sup>; Qian Li<sup>1</sup>; Tao Jiang<sup>1</sup>; <sup>1</sup>Central South University

Large reserves of specularite iron ores had been found all over the world, which is characterized as high total iron grade, low gangues content, as well as low commercial price. However, it has not been widely used in sinter or pellet production due to its inferior sintering and roasting characters. It has shown that the proportion of specularite ores reaches as high as 40%~50% and achieves good results by using Composite Agglomeration Process (CAP), an innovative agglomeration process invented by Central South University. But the mineralization of specularite is still unknown during composite agglomeration processing. In this paper, the induration characteristics of specularite ore is studied by simulating CAP in laboratory, as well as phase and microstructure analysis of CAP product. The results show that specularite pellet is mainly indurated through recrystallization of Fe<sub>2</sub>O<sub>3</sub>, calcium ferrite within high basicity sinters matrix interweaves with the recrystallized Fe<sub>2</sub>O<sub>3</sub> on the surface of the pellet, which forms an integral microstructure, and ensures high strength of CAP product for ironmaking.

**11:40 AM**

**Enrichment Behavior of Phosphorous in CaO-SiO<sub>2</sub>-FetO-P<sub>2</sub>O<sub>5</sub> Based Slag:** *Yingying Shen*<sup>1</sup>; <sup>1</sup>Northeastern University

As a by-product of steelmaking, not only environmental pollution can be removed, but also huge economical benefits can be created if reutilization of steel slag can be developed deeply. In order to enhance the reuse of convert slag to the metallurgical flowsheet, it's need to promote the enrichment of phosphorous to phosphorous-containing phase and separate the phosphorous-containing phase from steel slag to avoid the deterioration of refining process caused by the accumulation of phosphorous. In this paper, the enrichment behavior of phosphorous to CaO-SiO<sub>2</sub> particle in CaO-SiO<sub>2</sub>-FetO-P<sub>2</sub>O<sub>5</sub> based slag was studied and the phosphorous contents in the molten bulk slag, as well as the interior and surface of 2CaO·SiO<sub>2</sub> particle for different temperatures were also investigated. The enrichment process of phosphorous in CaO-SiO<sub>2</sub>-FetO-P<sub>2</sub>O<sub>5</sub> based slag can be considered to be mix-controlled

TUESDAY AM

by the two steps of diffusion in molten bulk slag and internal diffusion through  $2\text{CaO}\cdot\text{SiO}_2\text{-3CaO}\cdot\text{P}_2\text{O}_5$  solid solution reactant layer.

## Advances in Science-Based Processing of Superalloys for Cost and Sustainment: Residual Stress and NDE Technologies for Components

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS Structural Materials Division, TMS/ASM: Computational Materials Science and Engineering Committee, TMS: High Temperature Alloys Committee, TMS: Advanced Characterization, Testing, and Simulation Committee

*Program Organizers:* Donna Ballard, US Air Force; David Furrer, Pratt & Whitney; Paul Jablonski, US Department of Energy; Christopher Woodward, Air Force Research Laboratory; Jeff Simmons, AFRL; Mark Blodgett, Wright-Patterson AFB

Tuesday AM  
March 1, 2011

### 8:30 AM Introductory Comments

#### 8:35 AM Invited

#### Predicting and Managing Bulk Residual Stresses within Superalloys: Ronald Wallis<sup>1</sup>; <sup>1</sup>Wyman Gordon Forgings

The residual stresses developed in superalloy forgings during heat treatment result in a number of potential problems during subsequent manufacturing. They may lead to distortion of the forging which results in extra material being needed to ensure a part may be manufactured from it. The residual stress pattern may also lead to issues in machining the final component from the forging (the part moving during machining as the stresses attain a new equilibrium). A brief history of the numerical calculation of residual stresses during heat treatment (data needed and validation) is presented together with some examples of typical results obtained. The paper also gives examples where modifications to the manufacturing process have resulted in alleviating the problems. Finally the paper discusses more recent developments where models together with more versatile production equipment has been adopted to control the magnitude and distribution of residual stresses developed in a forging.

#### 9:05 AM Invited

#### Microstructural Effects on Electrical Resistivity in Comparison to Residual Stresses and the Implications for Eddy Current Methods in Measuring Residual Stress in IN718: Triplicane Parthasarathy<sup>1</sup>; Pavel Mogilevsky<sup>1</sup>; Sonya Boone<sup>1</sup>; Satish Rao<sup>1</sup>; Peter Nagy<sup>2</sup>; Mark Blodgett<sup>3</sup>; <sup>1</sup>UES, Inc.; <sup>2</sup>Univ. of Cincinnati; <sup>3</sup>Air Force Research Laboratory

As part of a sustainment program, the ability to measure residual stresses on the surface of turbine disks using eddy current methods has been of great interest. In IN718, a widely used disk alloy, initial results have shown that complex metallurgical phenomena interfere with this approach yielding an anomaly in eddy current measurements. The objective of this work was to determine the various possible metallurgical factors that might affect electrical resistivity and to identify the one that is responsible for the anomaly. A systematic investigation was carried out to evaluate and model the effects of chemistry, heat treatment, plastic deformation and recovery after cold work during annealing on the electrical resistivity of an IN718 alloy. The results were analyzed using semi-empirical models. The experimental results were fit to analytical models for use in calibrating eddy current methods for measuring residual stress in shot-peened or LPB treated engine parts.

#### Modeling and Simulation of Residual Stresses Resulting from Superalloy Processing: Wei-Tsu Wu<sup>1</sup>; Ravi Shankar<sup>1</sup>; Alex Bandar<sup>1</sup>; Byung-Kwan Chun<sup>1</sup>; <sup>1</sup>Scientific Forming Technologies Corp

To meet the demands of increasing thrust and higher operating temperatures, sophisticated nickel based superalloy turbine disks are processed with spatially varying properties. Dual Microstructure Heat Treatment (DMHT) induces fine grained, high strength, fatigue resistant microstructure at the bore, while creating coarser grained, creep resistant microstructure at the rim. Accurate modeling of disks under thermal-mechanical loading require appropriate initial conditions, including variation of microstructure and properties resulting from forging, heat treatment, and machining. Current approach is to couple the multi-physics phenomena: heat transfer, non-linear deformation, and micro-structure evolution. The mechanical properties, such as flow stress, Young's modulus, creep property, etc evolve due to changes in microstructure during the thermo-mechanical processes. The microstructure evolution is impacted by changes in temperature and deformation history, and precipitation kinetics. To demonstrate the methodology, a dual microstructure heat treatment process (DMHT), followed by machining (material removal), and spinning process were simulated and presented.

#### Probabilistic Fatigue Life-Prediction of Turbine Engine Materials: Reji John<sup>1</sup>; Sushant Jha<sup>2</sup>; Michael Caton<sup>1</sup>; James Larsen<sup>1</sup>; Patrick Golden<sup>1</sup>; <sup>1</sup>Air Force Research Laboratory; <sup>2</sup>Universal Technology Corporation

Physics-based probabilistic methods are essential in appreciably reducing the uncertainty in fatigue life prediction. Towards this objective, the role of competing mechanisms in producing dual-fatigue variability behavior in turbine engine materials is discussed. The competing modes could be related to randomly occurring microstructural configurations, differing in the degree of heterogeneous deformation accumulation in fatigue. The fatigue variability is described as a sequence of mechanisms, probabilistically originating from these configurations, in the order of decreasing heterogeneity level. These mechanisms separated into two primary contributions to the lifetime probability density: (i) the mean-lifetime response and (ii) the crack-growth-controlled, life-limiting behavior. A model incorporating this dual behavior was developed and provided reasonable predictions of the influence of material and extrinsic variables on the lifetime density and the probabilistic lifetime-limit.

#### 10:50 AM Invited

#### Advancements in NDE Technologies to Support Superalloy Component Lfing: R. Thompson<sup>1</sup>; Norio Nakagawa; Lisa Brasche<sup>1</sup>; <sup>1</sup>Iowa State University

NDE has a well established role in managing the lives of superalloy components such as the rotating disks in aircraft engines. Historically, this has been based on the detection of flaws, a capability that is quantified by the Probability of Detection. NDE techniques often employed for this purpose and the lifing strategies employed by the U.S. Air Force and Federal Aviation Agency, based on this strategy will be briefly reviewed. Attention will then turn to emerging NDE techniques that are intended to detect more subtle microstructural features that also influence component lifing, such as grain structure, dislocation density, inclusions, texture and residual stress. The current status of such techniques will be discussed. Finally, potential Bayesian strategies for integrating this information with the predictions of failure models to make lifetime predictions will be outlined.

#### 11:20 AM

#### Nondestructive Evaluation of Microstructure in Super Alloy Disk Material: James Blackshire<sup>1</sup>; Enrique Medina<sup>1</sup>; Jeong Na<sup>2</sup>; <sup>1</sup>Air Force Research Laboratory; <sup>2</sup>University of Dayton Research Institute

Nickel-based super alloy materials with dual-microstructure characteristics are being engineered to increase both fatigue and creep resistance properties in turbine engine disks. Nondestructive evaluation methods are needed to assess grain structure and size distributions, and for estimating material property

changes due to thermal and mechanical loads. Ultrasonic measurements represent one of the most promising candidates for characterization, where sound velocity, attenuation, and backscatter are known to be sensitive to microstructure in polycrystalline materials. The feasibility of three ultrasonic measurement approaches is investigated for grain size estimation in dual-microstructure materials including contact ultrasound, scanning immersion ultrasound, and scanning laser vibrometry detection of ultrasound energy. Finite element models are also used to study the ultrasonic forward problem, where the characteristic response of ultrasonic waves propagating through coarse and fine grain microstructures is investigated. Results indicate that qualitative measurements of coarse grain, transition, and fine grain regions are possible in realistic geometry samples.

#### 11:40 AM

**Application of Model-Based Inversion to Materials Characterization:** Harold Sabbagh<sup>1</sup>; R. Murphy<sup>1</sup>; Elias Sabbagh<sup>1</sup>; John Aldrin<sup>2</sup>; <sup>1</sup>Victor Technologies, LLC; <sup>2</sup>Computational Tools

Model-based inversion (MBI) is of increasing importance in eddy-current nondestructive evaluation (NDE). We apply MBI to two important problems: characterizing ferritic stainless steels and characterizing thermal barrier coatings. Ferritic stainless steels are being increasingly used in heat-exchanger tubes because of the increased resistance to chloride stress corrosion and intergranular attack. This presents interesting modeling opportunities for the eddy-current NDE of these tubes because their magnetic permeability is quite large, being of the order of 950 for low stress, decreasing to 500 for a state of shear stress. We will present examples of direct and inverse problems involving such tubes, using the proprietary code VIC-3D(c). The application of NDE to high-temperature coatings is one of the important factors in achieving a high level of structural integrity in advanced gas turbines. We will demonstrate that sophisticated eddy-current inverse techniques can be utilized to measure the thickness and remaining life of high-temperature coatings.

#### 12:00 PM

**Conductivity Profile Determination via Model-Based Inversion of Swept Frequency Eddy Current Data and Its Use for Near-Surface Material Characterization:** Norio Nakagawa<sup>1</sup>; Chester Lo<sup>1</sup>; Anatoli Frishman<sup>1</sup>; <sup>1</sup>Iowa State University

This paper reports on a nondestructive residual stress characterization methodology for superalloy components having residual stresses ranging in depth between tens of micrometers and an order of a millimeter. Using high frequency eddy current (EC) instrumentations, we measure the near-surface conductivity deviation profiles and relate them to the residual stress profiles via the piezoresistivity. We have been examining precipitation hardened superalloys such as Inconel 718, while recently adding other types of superalloys in the scope of applications. When inverting swept frequency impedance data into conductivity deviation profiles, we utilize the lift-off normalized vertical component signals for direct comparison with model predictions without being adversely affected by instrumentation and lift-off noise. The critical step is to convert conductivity profiles into residual stress profiles, where the apparent piezoresistivity is strongly affected by the specific material conditions. We will present recent findings regarding precipitation hardening and other material effects on residual stress characterization.

### Alumina and Bauxite: Bayer Process I

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee

*Program Organizers:* James Metson, University of Auckland; Carlos Suarez, Hatch Associates Consultants Inc

Tuesday AM  
March 1, 2011

Room: 17A  
Location: San Diego Conv. Ctr

*Session Chair:* To Be Announced

#### 8:30 AM

**Application of Operation Integrity Management to the Alumina Industry:** Carlos Suarez<sup>1</sup>; Daniel Welshons<sup>1</sup>; John McNerney<sup>2</sup>; Jim Webb<sup>2</sup>; <sup>1</sup>Hatch Associates Consultants Inc; <sup>2</sup>Warren-Fortought Inc

In today's economic environment the Safety of our industry assets – People, Equipment and Processes – have become even more demanding. This paper attempts to provide means to apply Operation Integrity Management System (OIMS) to the Alumina Industry. It discusses what OIM is about, its implementation parameters such as cost and time, as well as an effective way to integrate such a system into refineries day to day operations. A series of Key Process Performance Indicators (KPPIs) are presented as well as an Electronic Knowledge Support System (EKSS) Mockingbird ® as a tool to support the implementation of OIM.

#### 8:55 AM

**Influence of Solid Concentration, Particle Size Distribution, pH and Temperature on Yield Stress of Bauxite Pulp:** Carla Barbato<sup>1</sup>; Márcio Nele<sup>2</sup>; Silvia França<sup>3</sup>; <sup>1</sup>EQ/UFRJ/CETEM; <sup>2</sup>EQ/UFRJ; <sup>3</sup>CETEM

In Northern Brazil, bauxite pulp is transported through pipelines to the plant where alumina is produced. In slurry transportation through pipelines, knowing the yield stress value is essential for pumps and pipeline design. Yield stress is the minimum shear stress and corresponds to the first evidence of flow. This rheological property is influenced by some factors, such as: particle form, temperature, particle size distribution and interaction among the particles. Within the context above, the objective of this work is to verify the influence of solid concentration, particle size distribution, temperature and pH on the yield stress of bauxite pulp. It was verified that the yield stress of bauxite slurry increases as solid concentration goes up, decreases with particle size, temperature and pH.

#### 9:20 AM

**A New Method of Organics Removal in Bayer Process:** Bai Yingwei<sup>1</sup>; Gao Zhenwen<sup>1</sup>; Shen Mingliang<sup>1</sup>; Yi Xiaobing<sup>1</sup>; <sup>1</sup>CHALIECO

This article introduces briefly main organics sources at Bayer process alumina production and the harms due to accumulation during process flow, specifies the organics removal methods applied generally in world alumina refineries, and explains briefly advantages & disadvantages of each method. The article stresses the new super-concentrated organics removal method developed successfully by CHALIECO GAMI with Guizhou University together, which not only has good organics removal effect (total removal rate of 57~67%), but also removes the carbonates in the process flow.

#### 9:45 AM

**Alunorte Expansion 3 – The New Lines Added to Reach 6.3 Million Tons per Year:** Daryush Khoshnevis<sup>1</sup>; Luiz Corrêa<sup>2</sup>; Joaquim Ribeiro Alves Filho<sup>1</sup>; Hans Marius Berntsen<sup>3</sup>; Ricardo Carvalho<sup>2</sup>; Daryush Albuquerque Khoshnevis<sup>1</sup>; <sup>1</sup>Alumina do Norte do Brasil S.A.; <sup>2</sup>Vale S.A.; <sup>3</sup>Hydro Aluminium AS

Alunorte started operation in 1995 with a design production capacity of 1.1 Mtpy. Since then the plant was expanded three times and consists today of seven production lines with a total production capacity of 6.3 Mtpy. Expansion 3 was commissioned in 2008 and consists of process lines 6 and 7. Their nominal production capacity was reached after a short start-up phase. In Expansion 3 a number of new technology developments were

implemented. The impact of the process modifications applied in lines 6 and 7 compared to the previous lines are discussed with regard to effects on production volume, productivity, alumina quality and availability. However, a number of challenges are associated with the operation of a plant of the size of Alunorte which has grown very fast: the management of seven process lines, the operation of the plant with a very young organization and strong demand for training.

#### 10:10 AM Break

#### 10:20 AM

**One Green Field Megaton Grade Large Alumina Refinery with Successful Engineering and Operation Experience:** *Luo Xianqing*<sup>1</sup>; Yang Xiaoping<sup>1</sup>; Yi Xiaobing<sup>1</sup>; <sup>1</sup>CHALIECO

Phase I alumina project (1.6million tons/a metallurgical grade alumina) of Guangxi Huayin Aluminum Corporation Limited is one green field construction project with largest disposable investment in China alumina industry, and its diaspora bauxite is difficult to be ground and dissolved with high aluminum and low silicon content. Now two year's operation practice shows that the comprehensive energy consumption per ton alumina production is only 10.51GJ. This article introduces the process scheme and technical measures adopted in the engineering and operation stage for the features of this project.

#### 10:45 AM

**Advanced Process Control in the Evaporation Unit:** *C. Satish Kumar*<sup>1</sup>; Uttam Giri<sup>1</sup>; Rosalin Pradhan<sup>1</sup>; Tonmoy Banerjee<sup>1</sup>; Ramu Saha<sup>1</sup>; Pratichi Pattnaik<sup>1</sup>; <sup>1</sup>Vedanta Aluminium limited

Energy consumption is a significant constituent of production cost in an Alumina refinery. Indian refineries are striving to reach global benchmarks and have made conscious efforts to minimize energy consumption. Evaporation plays a significant role in conserving energy and is responsible for 30% of the thermal energy consumption. In the Evaporation unit, due to a large number of interacting processes, frequent disturbances and the presence of single line equipment, it is necessary to maximize the utilization of assets to ensure the production volumes at targeted efficiencies. The need for reduction in process variability resulting in optimizing operations, challenged by plant constraints, was derived by adopting Advanced Process Control (APC) application in the Evaporation unit. APC incorporates a matrix of modeled dynamic process responses with an optimizer to maintain the unit at the most profitable vertex of the allowable operating envelope. This paper will discuss the area selection criteria, activities carried out during the project tenure and post benefit analysis.

#### 11:10 AM

**Reduction in Metallic Impurities by Improvement in Process Control:** Ruth Headlam-Shaw<sup>1</sup>; <sup>1</sup>Alcoa Minerals of Jamaica

Alcoa's Clarendon Alumina Works recorded a significant improvement in the control of and reduction of impurities in its smelter grade alumina (SGA). This marked improvement came about as a result of a change in green liquor filter technology from gravity sand filtration to short cycle pressure filtration and improvement in process management systems.. This paper discusses the impact the change had on Iron,Chromium, Titanium, Phosphorous and Calcia in alumina product.

## Aluminum Alloys: Fabrication, Characterization and Applications: Solidification

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Processing Committee

#### 8:30 AM

**Simulation of the Deformation of a Flexible Combo Bag in a DC Aluminium Casting:** *Abdellah Kharicha*<sup>1</sup>; <sup>1</sup>University of Leoben

In the latest years combo bags were introduced in the DC aluminium casting to give better production results. In order to understand why this is the case, hydrodynamic simulations are performed. The movement of the Combo bag surface is modelled though the introduction of particles markers. The particles are allowed to move according to a dynamic law using an assumed flow-bag drag interaction. An additional artificial elastic force is introduced between neighbour particles in order to keep the total bag surface constant. The specificity of the present liquid/bag drag is not only its dependence on the relative movements, but also on the relative liquid velocity/bag surface angle. This kind of fluid/structure approach allows a full coupling between the liquid flow hydrodynamic and the bag shape movement. The results will focus on the quantification of the impact of the bag on the global heat transfer and solidification pool shape.

#### 8:50 AM

**Solidification Analysis of Al-Si Alloys Modified with Addition of Cu Using In-Situ Neutron Diffraction:** *Dimitry Sediako*<sup>1</sup>; Wojciech Kasprzak<sup>2</sup>; Ian Swainson<sup>3</sup>; Ovidiu Garlea<sup>4</sup>; <sup>1</sup>National Research Council Canada ; <sup>2</sup>CANMET-MTL, Natural Resources Canada; <sup>3</sup>National Research Council Canada; <sup>4</sup>Oak Ridge National Lab

The potential of application of in-situ neutron diffraction for studies of solidification of Al alloys were earlier reported by the authors for the binary hypereutectic Al-Si system. This illustrated the potential of neutron diffraction for high resolution melt analysis at near-liquidus temperatures required for advanced studies of grain refining, eutectic modification, etc. The solid and liquid volume fractions were determined based on the change of intensity of neutron diffraction peaks over the solidification interval. The path of non-equilibrium solidification for the alloy modified with addition of copper and magnesium is very complex. Phase diagrams and FactSage-based computations give only approximate kinetics of solid phase(s) evolution during cooling and solidification. On the other hand, in-situ neutron diffraction, coupled with the results of thermal analysis, provided non-biased experimental data on phase evolution; for example, on formation of FCC Al-Cu-Si, diamond silicon, and Al-Cu theta phase during solidification of hypereutectic Al-Si-Cu alloy.

#### 9:10 AM

**Development of Novel Grain Refiner for Al-Si Alloys:** *Magdalena Nowak*<sup>1</sup>; Hari Babu Nadendla<sup>1</sup>; <sup>1</sup>BCAST

A novel effective grain refiner for aluminium alloys has been developed. The composition of the grain refiner has been optimised to produce a fine grain structure for Al-Si alloys. Effectiveness of grain size under various cooling conditions has also been investigated to simulate various practical casting conditions. For comparative purposes, a wide range of Al alloys have been produced with the addition of commercially available Al-5Ti-B master alloys. The results show that the addition of novel grain refiner reduces the grain size significantly when compared to that of the commonly used Al-5Ti-B grain refiner addition. As a result of fine grains, the porosity in the

solidified alloys is notably lower. A remarkable improvement in mechanical properties has also been observed.

#### 9:30 AM

**Application of Neutron Diffraction in Analysis of Residual Stress Profile in the Cylinder Web Region of As-Cast V6 Aluminum Engine Block with Cast-In Iron Liners:** *Dimitry Sediako*<sup>1</sup>; Ravi Ravindran<sup>2</sup>; Camden Hubbard<sup>3</sup>; Francesco D'Elia<sup>2</sup>; Anthony Lombardi<sup>2</sup>; Alan Machin<sup>2</sup>; Robert Mackay<sup>4</sup>; <sup>1</sup>National Research Council Canada ; <sup>2</sup>Ryerson University; <sup>3</sup>Oak Ridge National Laboratory; <sup>4</sup>Nemak of Canada

Nowadays aluminum alloys are widely used for production of gasoline engine blocks. In this study 319 aluminum is sand cast around Fe-liner cylinder inserts, then undergoes the T7 heat treatment process. One of the critical factors determining the quality of the final product is the type, level, and profile of residual stresses along the Fe liners (or extent of liner distortion) that are always present in a cast component. In this study neutron diffraction was used to characterize residual stresses along the Al and the liners in the web region of the cast engine block. The strains were measured both in aluminum and iron in hoop, radial, and axial orientations and stresses were determined using generalized Hook's law. The study gives invaluable insight on anticipated service properties of the engine block and demonstrates that neutron strain mapping is an efficient tool for optimization of manufacturing technologies.

#### 9:50 AM

**Surface Modification of Aluminum Alloys by Electrolytic Plasma Processing:** *Mark Liu*<sup>1</sup>; Xijin Li; Ben Li Luan<sup>1</sup>; <sup>1</sup>National Research Council Canada

Aluminum alloys are widely used as lightweight materials in the transportation industry. For applications in aggressive wear and corrosive environments, proper surface treatment and protection of aluminum alloys are required. Electrolytic plasma processing is a relatively new surface coating technology that offers an environmentally friendly and cost effective solution for the surface protection of lightweight materials. In this presentation, the effect of electrolyte chemistry and various processing parameters on the microstructure, phase constituents, and the properties of the surface coating of aluminum alloys is discussed.

#### 10:10 AM Break

#### 10:25 AM

**Solidification Characteristics of Aluminium Alloys under Electron Beam Fabrication Conditions:** *Ma Qian*<sup>1</sup>; Dacian Tomus<sup>2</sup>; <sup>1</sup>The University of Queensland; <sup>2</sup>Monash University

Wire-based electron beam direct manufacturing (EBDM) is a novel layer additive near-net shape metal fabrication technique. The process can be advantageous for aluminium alloys if new compositions can be created that leverage the near rapid solidification conditions inherent to the process. As most structural aluminium alloys utilize some form of precipitation strengthening, to capitalise on the EBDM attributes, it is important to understand the as-solidified microstructural characteristics under electron beam fabrication conditions. This paper describes the results of an investigation of the microstructures of electron beam processed AA 2219 and AA 6061 alloys and binary Al-Sc and Al-Ti alloys. Electron beam processing led to unique microstructural features in each alloy. The experimental observations are compared with Thermo-Calc predictions for metastable solidification. It will be demonstrated that electron beam processing offers promising alloy design opportunities for advanced aluminium alloy development.

#### 10:45 AM

**Formation of Intermetallic Compound Layer between A356 Al Alloy and Cast Iron in Isothermal Condition.:** *Kwang Suk Son*<sup>1</sup>; Sungmin Kang<sup>1</sup>; Jinsu Kim<sup>1</sup>; Donggyu Kim<sup>1</sup>; <sup>1</sup>Dong-A university

A356 alloy and cast iron have many advantages for industrial purpose despite of insufficient properties. Bonding of dissimilar materials which would compensate their weaknesses, could increase its applicability to the industrial usages. But some problems have been remained in bonding

these alloys by casting due to the role of graphite and the complexity of intermetallic compound layer of Al-Fe-Si system. This work, the interactions between liquid A356 alloy and cast iron, and the structural investigation of compound layer were performed with the variables of contact temperature and time by hot dip aluminizing. Microstructure of interlayer was investigated by TEM, FESEM and EDS. Intermetallic compound layer showed two growth steps, during and after dipping. Poly crystalline compound layer consisting of t1(Al<sub>10.42</sub>Fe<sub>0.39</sub>Si<sub>0.15</sub>) and □(FeAl<sub>2</sub>) was formed during dipping and columnar ternary phase of □(FeAl<sub>3</sub>) and t5(Al<sub>10.72</sub>Fe<sub>0.18</sub>Si<sub>0.10</sub>) was formed after dipping. In addition, the growth mechanisms of compound layer was also discussed.

#### 11:05 AM

**Effects of Al-8B Grain Refiner on the Structure, Hardness and Tensile Properties of a New Developed Super High-Strength Aluminum Alloy:** Mohammad Alipour<sup>1</sup>; Masuod Emamy<sup>1</sup>; Jafar Rassizadehghani<sup>1</sup>; Mostafa Karamouz<sup>1</sup>; Mortaza Azarbarmas<sup>1</sup>; <sup>1</sup>University of Tehran

In this study the effect of Al-8B grain refiner on the structural characteristics, hardness and tensile properties of Al-12Zn-3Mg-2.5Cu aluminum alloy was investigated. The results show that by adding 3.75 wt.% Al-8B grain refiner in the cast alloy, the grains can be refined to a fine degree. T6 heat treatment was applied for all specimens before tensile testing. In heat treated condition, the average tensile strength of 500 MPa was found to be increased to 590 MPa for sample refined with 3.75 wt.% Al-8B (0.3 wt.% B). SEM fractography of the fractured faces of several castings showed an overall macroscopically brittle appearance at low magnifications. At higher magnifications, unrefined specimens showed cracking along the grains, whereas B-refined specimens showed cracks in individual intermetallic compounds.

### Aluminum Reduction Technology: Environment-Emissions/ Anode Effect II

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee

#### 8:30 AM

**On Continuous PFC Unrelated to Anode Effects:** *Xiping Chen*<sup>1</sup>; Wangxing Li<sup>1</sup>; Jerry Marks<sup>2</sup>; <sup>1</sup>Zhengzhou Research Institute of Chalco; <sup>2</sup>J Marks & Associates

It was investigated what result in continuous PFC emission unrelated to anode effects in two smelters. Anode current distribution was measured in QY smelter, no obvious correlation was observed between non-homogenous anode current and continuous PFC emission. Bath temperature and alumina concentration were synchronously measured during PFC monitoring in LX smelter, no continuous PFC emit when cells are operated at stable bath temperature and alumina concentration. But no clear relationship among them was concluded and further survey need to be made in other smelters. The effect of feeding mechanism was also investigated. Metal tapping and anode exchange can disturb cells' balance, which result in cell voltage rising, then may cause continuous PFC emission. It is found out that continuous PFC emission only occurs in some particular cells and is different from cell to cell even with the same line current. It is only a small portion in total PFC emission.

8:50 AM

**Reduction of Anode Effect Duration in 400kA Prebake Cells:** *Wei Zhang*<sup>1</sup>; David Wong<sup>1</sup>; Michel Gilbert<sup>1</sup>; Yashuang Gao<sup>1</sup>; Mark Dorreen<sup>1</sup>; Mark Taylor<sup>1</sup>; Alton Tabereaux<sup>2</sup>; Melinda Soffer<sup>2</sup>; Xiaopu Sun<sup>2</sup>; Changping Hu<sup>3</sup>; Xuemin Liang<sup>4</sup>; Haitang Qin<sup>4</sup>; Jihong Mao<sup>5</sup>; Xuehui Lin<sup>5</sup>; <sup>1</sup>Light Metals Research Centre; <sup>2</sup>Institute for Governance and Sustainable Development; <sup>3</sup>China Nonferrous Metals Industry Association; <sup>4</sup>Henan Zhongfu Industrial Co. Ltd.; <sup>5</sup>Northeastern University

In order to improve energy efficiency and reduce green house gas emissions, the aluminum smelting industry has been continuously working on reducing both anode effect frequency (AEF) and duration (AED). However, there is still a long way to go to achieve zero anode effect (AE) on very high amperage, low specific power consumption cells due to the added complexity of the process. A new program to quickly terminate AEs has been developed by Light Metals Research Centre, the University of Auckland, in conjunction with the efforts of the Asia Pacific Partnership on Clean Development and Climate (APP) to facilitate investment in clean technologies and to accelerate the sharing of energy efficient best practices. A pilot project was initiated to test an automatic Anode Effect Termination (AET) program on 400kA cells in Zhongfu, China. This paper demonstrates the success of the new anode effect termination (AET) program in killing AEs on this cell technology without conflicting with normal cell operations. The resulting decrease in average anode effect duration (AED) is demonstrated.

9:10 AM

**Sustainable Anode Effect Based Perfluorocarbon Emission Reduction:** *Neal Dando*<sup>1</sup>; Lise Sylvain<sup>1</sup>; Janice Fleckenstein<sup>1</sup>; Ciro Kato<sup>1</sup>; Vince Van Son<sup>1</sup>; Laura Coleman<sup>1</sup>; <sup>1</sup>Alcoa

Alcoa has been performing plant-specific perfluorocarbon (PFC) emission testing at operating smelters for over 15 years and has the largest Tier 3 data base in the aluminum industry. From 2005-2009, Alcoa smelters have reduced anode effect (AE) based PFC emissions by over 0.48 T CO<sub>2</sub>e/T Al produced, resulting in an absolute annual reduction of 2.3 million tonne CO<sub>2</sub>e over this same time period. These PFC reductions were the result of 1) continuous local optimization at operating locations 2) focused monthly reporting on anode effect performance, 3) internal workshops regarding shared AE reduction efforts and 4) technology improvements. This paper will discuss examples of key enablers employed for sustaining AE-based PFC reductions of 15.9 million tonnes over the period 1990 to 2009.

9:30 AM

**The Initiation, Propagation and Termination of Anode Effects in Hall-Heroult Cells:** *Gary Tarcy*<sup>1</sup>; Alton Tabereaux<sup>2</sup>; <sup>1</sup>Alcoa; <sup>2</sup>Consultant

Anode effects in Hall-Heroult cells have been the subject of multiple investigations and studies. The current state of the knowledge is fairly well advanced and there is very little discrepancy or controversy with respect to many of the phenomena associated with anode effects. Included in this is the belief they are: 1) AE are the predominate emitter of PFC into the atmosphere 2) AE are triggered by low alumina concentrations near the anode surface 3) Short circuiting of at least part of the anode cathode inter electrode gap is required to terminate an anode effect. This paper will cover some of less discussed aspects of anode effect including the 1) the initiation at a single random anode in the circuit. 2) The propagation to multiple anodes until the whole circuit is on anode effect 3) The reason it is necessary to short circuit the anodes to terminate anode effect.

9:50 AM

**Towards Eliminating Anode Effects:** *Ali Al Zarouni*<sup>1</sup>; Barry Welch<sup>2</sup>; Maryam Al-Jallaf<sup>1</sup>; Arvind Kumar<sup>1</sup>; <sup>1</sup>DUBAL; <sup>2</sup>Welbank Consulting Ltd

It has been established that the atmosphere contains appreciable amount of per fluorocarbon (PFC) gases. These are powerful greenhouse gases and with extremely long lifetime. Although these gases are being used in the semiconductor industry, it has been established that aluminium smelters are the main source. Emissions of PFC Gases from the aluminium industry have therefore become an environmental issue. The PFCs are emitted from an aluminium reduction cell when it is on an 'anode effect'. The exact nature of the onset of an anode effect is still shrouded in mystery. However, an

astounding reduction in number of anode effects has been achieved by understanding, attributing and implementing a strict process control regime to eliminate assignable causes. Dubal's progress in reducing anode effect frequency to less than 0.05 AE/pot-day in a sustained manner in poline 5B has been discussed and presented.

10:10 AM Break

10:20 AM

**Monitoring Air Fluoride (F-) Concentration around ALUAR Smelter in Puerto Madryn (Chubut Province, Argentina):** *Jorge Zavatti*<sup>1</sup>; Claudio Lopez Moreno<sup>1</sup>; Juliana Lifschitz<sup>2</sup>; Gabriela Quiroga<sup>1</sup>; <sup>1</sup>ALUAR Aluminio Argentino SAIC

The emissions of F- is a significant environmental aspects of aluminum industry. Therefore the government have established regulations aimed at controlling the environmental performance of smelters through monitoring of F- emissions. Chubut Province (Argentina), sets emission limits, 1 kg F-/ton Al and following recommendations by the World Health Organization, they set a guideline for inmission at 16.0 µg F-/m<sup>3</sup>. In this paper we present: i)the monitoring network that ALUAR deployed in Puerto Madryn, 14 air sampling stations; ii)sampling procedures and analysis adopted; iii)the results of air fluoride concentration from July 2009 to June 2010; iv)the validation of these results by three scientific institutes of Argentina. The results show that in Puerto Madryn (100000 inhabitants; 2 km from ALUAR's Plant), the median concentration in air was 1.61 µg F-/m<sup>3</sup> (N = 471 - p95 = 5.32). These values met the inmission guideline level determined by the supervisory authority.

10:40 AM

**Correlation between Moisture and HF Formation in the Aluminium Process:** *Camilla Sommerseth*<sup>1</sup>; Karen Osen<sup>2</sup>; Thor Aarhaug<sup>2</sup>; Egil Skybakmoen<sup>2</sup>; Asbjørn Solheim<sup>2</sup>; Christian Rosenkilde<sup>1</sup>; Arne Ratvik<sup>1</sup>; <sup>1</sup>Norwegian University of Science and Technology, NTNU; <sup>2</sup>SINTEF

Hydrogen fluoride (HF) emission to the working atmosphere is still a problem in the aluminium industry. Moisture in secondary alumina fed to the cell and humidity in the ambient air reacts with fluorides in the bath and fluoride vapours to form hydrogen fluoride. The relation between the various sources of water and the resulting HF emission is still not well understood. In this work, industrial measurements have been done to determine where HF escapes from the bath. The quantities of HF and moisture at the specific sites have also been determined. Measurements were done in the duct during normal operation as well as during anode change, above the feeder hole and above an open hole in the crust. A strong correlation between feed cycle and HF levels was measured. Increased HF emissions were also recorded during anode change.

11:00 AM

**Particulate Emissions from Electrolysis Cells:** *Heiko Gaertner*<sup>1</sup>; Arne Ratvik<sup>1</sup>; Thor Aarhaug<sup>2</sup>; <sup>1</sup>NTNU; <sup>2</sup>SINTEF

In the dry cleaning of the exhaust gas from the aluminium cells impurities are accumulated in the finer fractions of secondary alumina from the dry scrubbers. The present work describes new methods for the determination of dust composition, aiming at increasing the understanding of the effect of cell operation on the amount and the composition of dust in the fume. New and advanced analysis methods are used to characterize a broad specter of emissions. An Electrical Low Pressure Impactor is used to sample and analyze the dust from the cells. The equipment enables real-time particle size distribution analysis of 12 particle classes in the range 30 nm - 10 µm. The size classified samples are analyzed by means of SEM/EDS and XRD to determine the characteristic chemical composition of the different fractions. Understanding the evolution, evaporation, and condensation of particulates in the cell emissions under different operational conditions may facilitate new standards for environmental friendly and energy efficient high amperage electrolysis cells.

11:20 AM

**Investigation of Solutions to Reduce Fluoride Emissions from Anode Butts and Crust Cover Material:** *Guillaume Girault*<sup>1</sup>; *Maxime Faure*<sup>1</sup>; *Jean-Marc Bertolo*<sup>1</sup>; *Stéphanie Massambi*<sup>1</sup>; *Georges Bertran*<sup>1</sup>; <sup>1</sup>Rio Tinto Alcan

For many aluminium smelters, reducing fluoride emissions is often a condition to increase production. Since they contribute up to 40% of the overall roof vent emissions, anode change operations are often targeted for improvements and specifically the emissions from the anode butts and crust cover. The Rio Tinto Alcan Research Centre, LRF, has been conducting an R&D programme over the past few years aimed at improving the understanding of the physical phenomena involved and ultimately minimising this specific contribution. On this basis, different conceptual solutions have been developed and their relative performance evaluated. These tests, associated with past experience of enclosed butt boxes and crust bins, concluded that any container receiving a hot butt and bath crust would require almost complete sealing to be effective. The next stage in this programme is engineering design with the aim of developing smelter technology with the lowest environmental footprint.

11:40 AM

**PFC Survey in Some Smelters of China:** *Wangxing Li*<sup>1</sup>; *Xiping Chen*<sup>1</sup>; <sup>1</sup>Zhengzhou Research Institute of Chalco

PFC survey was performed by CHALCO. Results of the first PFC survey from seven different Chinese potlines are discussed in this paper. This survey included normally-operated, newly-started, power-limitation and control-mode changing potlines. The measurement equipment used in the survey is MG2030 FTIR which comes from MKS Instruments. Gas sampling was directly pumped out of main exhaust duct before stack and transmitted into FTIR by Teflon tube. Fugitive PFC emission was not measured. The calculation of PFC amount was based on IPCC Tier 3a method. Total PFC emission was calculated from duct PFC emission divided by collection efficiency. Newly-started, control-mode changing and power-limitation potlines emitted much more PFC than normally-operated ones. PFC emission from power-limitation potline was the highest among seven. Three of seven potlines have PFC emission close to IAI 2010 target. Two potlines have similar PFC emission to Australia 2006 average level. The lowest PFC emission is 0.21 tCO<sub>2</sub>-e/t-Al.

## Approaches for Investigating Phase Transformations at the Atomic Scale: Transformations in Fe, Ni and Al Based Systems II

8:30 AM Invited

**Nuclear Reactor Materials at the Atomic Scale:** *Emmanuelle Marquis*<sup>1</sup>; *Ceri Williams*<sup>2</sup>; *Nadine Baluc*<sup>3</sup>; *Samuel Humphry-Baker*<sup>2</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>University of Oxford; <sup>3</sup>Paul Scherrer Institute

The development of next-generation fission and fusion reactors requires new and improved materials, which will withstand extreme combinations of temperature, stress and irradiation. In order to develop these materials,

fundamental understanding is required of the atomic-scale behaviour of candidate alloys subjected to extreme treatment. We report progress in the combined use of 3-D atom probe analysis and transmission electron microscopy to study the atomic processes occurring in Fe-Cr,oxide-dispersion-strengthened steels and W alloys after thermal and heavy ion irradiation treatments. In each case, the materials exhibit highly complex patterns of behaviour on the nanometre scale, including solute clustering, segregation to dislocations, grain boundaries and interphase interfaces, and the formation of second phase particles. These phenomena have been quantitatively investigated. Similarities and differences in the behaviour of the different materials will be described, and implications for the optimisation of future reactor materials design will be discussed.

8:55 AM Invited

**A Multiple Technique Approach for Understanding Phase Separation in Nanostructured Ferritic Steels:** *Michael Miller*<sup>1</sup>; *C.L. Fu*<sup>1</sup>; *C.M. Parish*<sup>1</sup>; *X.-L. Wang*<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

Nanostructured ferritic steels are under consideration for use in future generations of advanced nuclear systems due to their stability against high temperature creep and, more importantly, their remarkable tolerance to high dose neutron and ion irradiation. A synergistic combination of first principle calculations with atom probe tomography, transmission electron microscopy, and neutron scattering experiments have been used to understand the phase separation and diffusion processes that occur in these mechanically alloyed, nanostructured ferritic steels. From this multiple characterizations approach, the microstructural features responsible for these remarkable properties, including high number densities of nanoclusters and solute segregation to the grain boundaries, have been identified. This research was sponsored by the U.S. Department of Energy, Materials Sciences and Engineering Division. Research at the Oak Ridge National Laboratory SHaRE User Facility is sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

9:20 AM Invited

**Atomic Scale Investigation of Y-Ti-O Nanoclusters in Nanostructured Ferritic Alloys:** *Brian Wirth*<sup>1</sup>; *Hyon-Jee Lee*<sup>2</sup>; *Lauren Marus*<sup>2</sup>; *G. Robert Odette*<sup>3</sup>; <sup>1</sup>University of Tennessee; <sup>2</sup>University of California, Berkeley; <sup>3</sup>University of California, Santa Barbara

Nanostructured ferritic alloys (NFAs) are characterized by very high tensile and creep strength, and resistance to neutron irradiation. These properties result from a very high number density dispersion of nm-scale Y-Ti-O rich features (NFs) that precipitate homogeneously at high consolidation temperatures from mechanically alloyed Fe-Cr-Ti-Y<sub>2</sub>O<sub>3</sub> powders. The NFs have been studied by small angle neutron scattering, atom probe tomography, transmission electron microscopy, positron annihilation spectroscopy, and x-ray absorption spectroscopy. NFs form rapidly at number densities, sizes and characters (compositions and structures) that are dictated by the processing temperature and alloy composition. However, the precise natures of various NFs are not well understood, and appear to range from coherent solute enriched GP-type zones to near stoichiometric complex oxides, such as Y<sub>2</sub>TiO<sub>5</sub> and Y<sub>2</sub>TiO<sub>7</sub>. In this presentation, atomic scale modeling results, developed from ab-initio electronic structure calculations, are presented that provide insight into the structure and composition of the NFs.

9:45 AM

**Characterization of Nanofeatures and Oxides in Nanostructured Ferritic Alloys – Cross Comparison SANS, SAXS, TEM, APT and Other Techniques:** *G. Robert Odette*<sup>1</sup>; *Nicholas Cunningham*<sup>1</sup>; *Takuya Yamamoto*<sup>1</sup>; *Yuan Wu*<sup>1</sup>; *Auriane Etienne*<sup>1</sup>; *Erich Stergar*<sup>1</sup>; <sup>1</sup>UC Santa Barbara

Nano-structured ferritic alloys (NFAs) have high tensile and creep strength permitting service up to 800°C and manifest remarkable resistance to radiation damage. These outstanding properties derive from an ultrahigh density of Ti-Y-O enriched nano-features (NFs) that provide dispersion strengthening, help stabilize dislocation and fine grain structures, reduce excess concentrations of displacement defects by enhancing vacancy-self-interstitial recombination and trap helium in fine, and relatively harmless, bubbles. However, the compositions and structures of the NFs, especially

TUESDAY AM

at the smallest sizes, are not well understood. The results of SANS, SAXS, TEM, APT and other characterization techniques are cross compared. The general trends in structure and composition suggest that the smallest NFs (less than 5 nm) are consistent with cubic Y<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>, while at larger sizes (5 to 25 nm) they are often more consistent with orthorhombic Y<sub>2</sub>TiO<sub>5</sub>. However many features cannot be identified with any known Y-Ti oxide and most often they are non-stoichiometric.

#### 10:00 AM

**Effect of Elastic Strain on Phase Separation in Fe-20% Cr-6% Al-0.5% Ti ODS Alloy:** *Carlos Capdevila-Montes*<sup>1</sup>; Mike Miller<sup>2</sup>; Isaac Toda<sup>1</sup>; Jesus Chao<sup>1</sup>; <sup>1</sup>CENIM-CSIC; <sup>2</sup>ORNL

The effect of elastic deformation on temporal evolution of the microstructure resulting from phase separation of an Fe-20% Cr-6% Al-0.5% Ti oxide dispersion strengthened (ODS) alloy at a temperature of 708 K has been analyzed by atom probe tomography (APT). Microstructures with high (as-cold rolled material) and low (coarse grained recrystallized material) dislocation densities have been tested at both 0.8 and 1 times the yield strength of this material during aging at 708 K. Microstructural analysis by APT revealed simultaneous phase separation kinetics into Fe-rich  $\alpha$ , Cr-rich  $\alpha'$  and Fe-Ti-Al phases. The roles of Al and Ti during the decomposition process have been investigated. Proximity histogram analysis revealed significant partitioning of Al and Ti, which is consistent with theoretical calculations. Research at the Oak Ridge National Laboratory SHaRE User Facility was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

**Nano-Structural Characterizations Using Advanced Methods - A Case Study of Nanosized Cu Precipitates in C Containing Fe-1.2 Wt% Cu Alloys:** *Rajashekhara Shabadi*<sup>1</sup>; Roland Taillard<sup>1</sup>; <sup>1</sup>University of Science and Technology of Lille, France

This study deals with the sole effect of C on Cu precipitation in Fe-1.2 wt% Cu steels. Four C contents up to 750 ppm were studied. Addition of carbon substantially increases both the kinetics and magnitude of precipitation strengthening up to longer aging times. Advanced methods of characterization such as Small Angle X-ray Scattering (SAXS) and Tomographic Atom Probe (TAP) were adopted to precisely determine the composition, size, density and volume fraction of the nanometer sized precipitates after different aging periods. It was observed that C was not co-precipitated with Cu, but C agglomerations were present close to the precipitates. The accelerating effect on the Cu precipitation is discussed with regards to both the driving force of nucleation and the kinetics of Cu diffusion. Combining results of SAXS, TAP and TEM gave complementary results in following Cu precipitation sequence in the presence of the third alloying element.

#### 10:55 AM

**Anharmonic Phonon Behavior in  $\alpha$ -Fe at Temperatures near the Structural Phase Transition:** *Lisa Mauger*<sup>1</sup>; Matthew Lucas<sup>2</sup>; Jorge Munoz<sup>1</sup>; Brent Fultz<sup>1</sup>; <sup>1</sup>California Institute of Technology; <sup>2</sup>Air Force Research Laboratory

The phonon density of states (DOS) of bcc Fe was measured from room temperature up through the 1185K fcc phase transition using Nuclear Resonant Inelastic X-ray Scattering of <sup>57</sup>Fe. At higher temperatures all phonons shift to lower energies (soften) with thermal expansion. Above the 1043K Curie temperature, low energy transverse modes soften more rapidly, suggesting strongly anharmonic behavior before the  $\alpha$ -Fe to  $\gamma$ -Fe structural transition. Interatomic force constants for the bcc phase were obtained by iteratively fitting a Born von-Karman model to the experimental phonon spectra using a global optimizer. Trends in these force constants are used to interpret the thermal softening of the different phonon modes. The unusually large phonon anharmonicity of the transverse modes at elevated temperatures is assessed with the temperature dependences of the first and second-neighbor interatomic force constants.

#### 11:10 AM

**Atomic Scale Investigation of Gamma Prime Precipitation in Nickel Base Alloys Coupling Aberration-Corrected STEM with Atom Probe Tomography:** *Antariksh Singh*<sup>1</sup>; Gopal Viswanathan<sup>2</sup>; Soumya Nag<sup>1</sup>; Junyeon Hwang<sup>1</sup>; Jaimie Tiley<sup>2</sup>; Hamish Fraser<sup>3</sup>; *Rajarshi Banerjee*<sup>1</sup>; <sup>1</sup>University of North Texas; <sup>2</sup>Air Force Research Laboratory; <sup>3</sup>The Ohio State University

The compositional and microstructural evolution of gamma prime precipitates during continuous cooling at different rates, followed by isothermal aging, of a commercial nickel base superalloy, Rene 88DT, have been characterized by coupling multiple atomic scale characterization techniques. The primary focus was on investigating the mechanisms governing gamma prime precipitation as a function of cooling rate. Classical nucleation and growth is the dominant mechanism of precipitation in case of slower cooling rates, especially at lower undercoolings. In contrast, at faster cooling (quench) rates, the gamma prime precipitation appears to take place via a spinodal clustering (phase separation or compositional partitioning) within the disordered gamma matrix followed by chemical ordering. Direct experimental atomic scale evidence for such a mechanism will be presented based on results of aberration-corrected HAADF-STEM at atomic resolution and atom probe tomography.

#### 11:25 AM Invited

**Exploring Initial Stages of Precipitate Formation in Aluminum Alloys through Kinetic Lattice Monte Carlo Simulations:** *Marcel Suijter*<sup>1</sup>; <sup>1</sup>TU Delft

The very first stages of clustering that precede precipitation are still poorly understood. However, those stages can be important for the ultimate mechanical properties as empirical treatments such as spike pre aging prior to natural aging during storage in industrial alloys have shown. In order to augment atom probe experiments and to illuminate the role of vacancy-solute interactions, kinetic lattice Monte Carlo simulations have been employed for multicomponent Al alloys with realistic compositions, such as those based on Al-Mg-Cu and Al-Mg-Li. It is shown that these simulations, at least during the initial stages, can yield cluster distributions as function of time that resemble those from atom probe experiments provided that the solute-vacancy binding and vacancy dynamics are properly accounted for.

#### 11:50 AM

**Primary Crystallization Behavior Change Induced by Minor Element Substitution:** *Feng Yi*<sup>1</sup>; Seth Imhoff<sup>1</sup>; John Perepezko<sup>1</sup>; Paul Voyles<sup>1</sup>; <sup>1</sup>UW-Madison

Structural characterization by fluctuation electron microscopy (FEM), a technique sensitive to nanoscale order in glasses, combined with conventional techniques including BFTEM, XRD, and DSC, and computer simulations was applied to understand the primary crystallization reaction in Al-based metallic glasses. FEM shows that the glass contains nanoscale, Al-like medium range order (MRO) regions; other kinetics data demonstrate that these regions act as nucleation sites. Comparison of the FEM results to computer simulations indicates that the MRO size  $d$  and number density  $\rho_{961}$  are (1.92 $\pm$ 0.34) nm and (1.81 $\pm$ 1.67) $\times 10^{25}/m^3$  in Al<sub>88</sub>Y<sub>7</sub>Fe<sub>5</sub>. Substitution of 1 at.% Cu for Y decreases the crystallization onset,  $T_x$  by 50  $\pm$  176C with a doubling of  $\rho_{961}$  while substitution 1 at.% Cu for Al increases  $T_x$  by 10  $\pm$  176C, and reduces  $\rho_{961}$  by 30%. All the observations are consistent with a classical nucleation theory model including transient kinetics.

##### Role of Substrate Material Properties in Modulating Cell Fate and Function: *Shu Chien*<sup>1</sup>; <sup>1</sup>University of California, San Diego

Variations in physicochemical properties of the substrate can modulate the fate (proliferation and differentiation) of pluripotent stem cells (hPSCs) and the structure and function of adult cells such as vascular endothelial cells (ECs). Using a high-throughput screening approach, we have identified synthetic polymers that can be used as matrix macromolecules to support attachment, proliferation and self-renewal of several types of human hPSCs. Such findings can help to accelerate the translational applications of hPSCs in regenerative medicine. Variations in substrate rigidity under the extracellular matrix (ECM) can also regulate the proliferation and differentiation of hPSCs, with modulations of their mechanical properties. Culture of ECs on ECM seeded on substrates with different rigidity leads to alterations of their intracellular rheology and functional behavior, including signal transduction and gene expression. The material properties of the substrate can exert significant effects on the rheology of cells to modulate cell structure and function.

##### Strategies to Promote Mammalian Cell Functions Pertinent to Tissue Formation at the Tissue-Implant Interface: A Materials Perspective: *Rena Bizios*<sup>1</sup>; <sup>1</sup>UTSA

Cellular and molecular events at tissue/implant interfaces dictate the fate of implants and, thus, have crucial clinical implications. The need (1) for biomaterials with properties similar to those of physiological tissues (characterized by surface grain sizes in the nanometer range) and (2) for identification/characterization of the optimal conditions, which maximize specific cell functions responsible for neotissue formation surrounding implants in the human body, has motivated investigation of chemical and topographical modifications of existing materials as well as design of nanostructured material formulations and of protein-engineered biomaterials. Biomaterials, which reliably and predictably promote specific interactions of biomolecules leading to targeted modulation of select mammalian cells and/or control of subsequent cell functions pertinent to new tissue formation and regeneration, have the potential of novel biotechnology-related and tissue-engineering-related applications as well as of major clinical impact. This presentation will highlight bio-inspired biomaterials-related accomplishments, current challenges and novel developments of great promise.

#### 9:45 AM

##### Protein Adsorption on Bioceramic Nanoparticles and Monoliths: *Kenneth Stanton*<sup>1</sup>; *Éilís McGrath*<sup>1</sup>; *John Gibbons*<sup>2</sup>; *Iseult Lynch*<sup>1</sup>; *Kenneth Dawson*<sup>1</sup>; <sup>1</sup>University College Dublin; <sup>2</sup>Royal College of Surgeons in Ireland

When a biomaterial is placed in-vivo, proteins will immediately adsorb to the surface and mediate the response of other biological entities such as cells. Over a short amount of time, a specific group of proteins will form a

quasi-equilibrium layer which has become known as the hard-corona while other less-tightly bound proteins comprise the soft corona. The nature of the corona will depend not only on the surface-charge distribution on the material but also on the way the material presents to the medium: i.e. as an effective monolithic surface or as a nano-particle and also on the specific proteins present and finally the nature of the suspension medium. Here, we present the results of protein adsorption experiments using human blood plasma and a range of bio-ceramic materials including hydroxyapatite, alumina and zirconia. Hard coronas are characterized using 1-D SDS-PAGE and the results from nano-particles are compared with those of monoliths.

#### 10:05 AM

##### Utilization of Diatoms to Collect Metallic Ions: *Itaru Jimbo*<sup>1</sup>; *Takahiro Sekiguchi*<sup>1</sup>; *Hiroaki Onizawa*<sup>1</sup>; <sup>1</sup>Tokai University

Microalgae have a capability to collect metallic ions from the aqueous solutions for their negatively charged surface. A number of works have already been published where heavy metals could be collected and contaminated water system was cleaned by biological measures. In the present study, diatoms are utilized to collect metallic ions such as silver and lead ions from the aqueous solution. Collecting processes are adsorption of ions on the diatoms surfaces and taking the ions inside the diatoms bodies through the cell membrane. Analyses were accomplished with the observation of the dried specimen with SEM and EPMA. Experimental results revealed that these processes depended both on illumination and temperature. These processes seem to be closely related to photosynthesis. Discussion will also include seasonal variations in the yields of the metals by the diatoms.

##### Aligned TiO<sub>2</sub> Nanotubes for Strong Osseo-Integration in Orthopaedic Implants: *Sungho Jin*<sup>1</sup>; <sup>1</sup>UC San Diego

For improvement of the structural connection between living bone and implant, vertically aligned TiO<sub>2</sub> nanotubes with different dimensions were introduced on Ti implant surface by anodization and used for in vitro and in vivo studies. The presence of surface nanotube structure on titanium orthopaedic implants significantly enhances the kinetics of bone formation and interfacial bond strength as demonstrated by in vitro and in vivo experiments with rabbit and mice. It is also shown that the nanotube geometry has a profound effect on osteoblast and mesenchymal stem cell behavior, with the cell stretching and elongation becoming quite pronounced at a particular nanotube diameter regime, affecting the osseo-integration and bone bonding [1-2]. [1] Karla Brammer, et al, Acta Biomaterialia 5(8), 3215-3223 (2009). [2] Lars M. Bjursten, et al, J. Biomed. Mater. Res. 92A, 1218-24 (2010).

#### 11:05 AM

##### Surface Free Energy Modification of Titania for Bioactive Surfaces: *Kyle Krzywosinski*<sup>1</sup>; *Molly Gentleman*<sup>1</sup>; <sup>1</sup>Texas A&M University

Titanium implants have gained popular use in orthopedic implants, specifically hip implantation. As a result, effort is being made to increase the osseointegration between these load bearing artificial implants and native bone. In previous studies the observed wettability of a surfaces has been shown to be a good indicator of the quality and rate of osseointegration. In this study, the surface energy properties of titanium dioxide, the native oxide on titanium metal implants, is modified by to identify the relationship between surface energy and subsequent osseointegration. It has been demonstrated that thermal exposure increases the wettability of single crystal titania wafers by increasing both the acid and base components of surface free energy. XPS studies have been completed relating changes in surface energy to oxidation and reduction of the titania surface. These surfaces were then examined for cell adhesion to elucidate this relationship.

11:25 AM

**Cellular Response of Grain Boundary Grooved Nanograined/Ultrafine-grained Structures:** Pavan Challa<sup>1</sup>; Devesh Misra<sup>1</sup>; <sup>1</sup>University of Louisiana at Lafayette

We describe here the significance of grain boundary grooved nanograined/ultrafine-grained (NG/UFG) metallic substrates in comparison to planar (non-grooved) NG/UFG substrate in terms of improved surface and biological properties. In this regard, grooving of nano/ultrafine-grains by electrochemical etching is a potential approach to increase the biomechanical interlocking which results in improved cellular response. The differences in the cellular response of planar and grain boundary grooved NG/UFG surface are attributed to favorable surface topography that accelerates the cellular activity. Experiments on the effect of grain boundary grooved NG/UFG substrate indicated that cell attachment, proliferation, viability, morphology, and spread are favorably modulated and significantly different from planar (non-grooved) NG/UFG substrate.

11:45 AM

**Enhanced Bone Cell Response on Zirconium Oxide Nanotube Surface:** Christine Frandsen<sup>1</sup>; Karla Brammer<sup>1</sup>; Kunbae Noh<sup>1</sup>; Sungho Jin<sup>1</sup>; <sup>1</sup>University of California, San Diego

The present work investigates the bio-feasibility of a unique vertically-aligned, laterally-spaced nanotube nanostructure made of ZrO<sub>2</sub> fabricated by anodization. The growth, morphology, and functionality of osteoblasts cultured on ZrO<sub>2</sub> nanotubes have been examined. The initial cell response of adhesion and spreading was considerably improved on the nanotube surface as compared to a Zr surface without nanostructure. The morphology of adhered cells on the nanotube surface elicited a highly organized cytoskeleton with crisscross pattern actin, which was lacking on the flat Zr. Increased alkaline phosphatase levels, indicative of increased bone forming ability, and the formation of concentrated calcified extracellular matrix implied improved osteoblast functionality and mineralization on the nanotube substrate. This in vitro study shows that ZrO<sub>2</sub> nanotubes are highly promising as a biomedical implant surface because of their large surface area and unique nanoscale geometry which enhanced the osteoblast response and apparent role in providing a platform for bone growth.

12:05 PM

**Quantification of Osteoblast Adhesion Strength on Hydroxyapatite-Carbon Nanotube Coated Bioimplant Surface:** Debrupa Lahiri<sup>1</sup>; Ana Paula Benaduce<sup>1</sup>; Lidia Kos<sup>1</sup>; Arvind Agarwal<sup>1</sup>; <sup>1</sup>Florida International University

Adhesion of cells on orthopedic implant surface is important for integration of the implant with the bone. This study proposes the nanoscratch technique as an effective method to quantify the shear strength required to detach a single cell, from the underlying substrate. The method has been evaluated for osteoblast cells grown on plastic slides as well as hydroxyapatite (HA) coatings on Ti-6Al-4V alloy, with and without carbon nanotube (CNT) reinforcement. The cells were grown on the plastic slides and HA coatings for 1, 3 and 5 days. The measurement shows no change in the adhesion strength of osteoblast on plastic slides, with increasing culture-time. On the contrary, the adhesion strength of osteoblast increases with culture time for both HA and HA-CNT coated surfaces. Interaction of osteoblast cells with HA is responsible for such behavior. Addition of CNT to HA further increases the adhesion strength of osteoblast to the coating surface.

## Bulk Metallic Glasses VIII: Structures and Mechanical Properties I

8:30 AM Keynote

**Mechanical Properties of Metallic Glasses: An Atomistic View:** Takeshi Egami<sup>1</sup>; <sup>1</sup>University of Tennessee

Many mysteries surround the mechanical properties of metallic glasses, and make it a fascinating subject of study. For instance people assume that deformation occurs because of some defects, such as free-volume or shear transformation zones, but nobody seems to have seen them in action. I propose a rather different view, that the "potential" defects are abundant, as much as a quarter in volume fraction. But fluctuations, thermal or otherwise, statistically activate only a few of them, making precise prediction difficult. Defects are defined by topological instability of the nearest neighbor shell, and can be detected by simulation of the structure, static or dynamic under stress, or by diffraction measurements carried out with applied stress. In this view mechanical failure is the stress-induced glass transition, that can occur without heating nor volume dilation. This work was supported by the Department of Energy, Basic Science Program.

9:00 AM

**Structural Changes in BMG after Mechanical Fatigue and Pre-Loading:** Wei Guo<sup>1</sup>; Wojciech Dmowski<sup>1</sup>; Andrew Chuang<sup>1</sup>; Gongyao Wang<sup>1</sup>; Yoshihiko Yokoyama<sup>2</sup>; Yang Ren<sup>3</sup>; Peter Liaw<sup>1</sup>; Akihisa Inoue<sup>2</sup>; Takeshi Egami<sup>1</sup>; <sup>1</sup>University of Tennessee; <sup>2</sup>Tohoku University; <sup>3</sup>Advanced Photon Source

We studied changes in the atomic structure of bulk metallic glasses after a mechanical fatigue and elastic pre-loading below the yield stress. The Zr-based BMGs were fatigued for 10<sup>6</sup> cycles with mechanical load amplitude corresponding to 10, 50 and 70% of the elastic limit and 10<sup>5</sup> cycles at 80%. The mechanical preloading was done for 24 hrs at 1.5 GPa. The x-ray diffraction was carried out at APS using high energy x-rays and the structure function and PDF were determined. Measurements were performed at room temperature and at 5 K. In addition to statistical errors several sample cross-sections and spots were examined to assess systematic errors. Both room and low temperature data indicated small changes in the fatigued samples that were consistent with structural disordering. However, at the largest load amplitude we also observed that small volume of the sample was crystallized. Supported by the NSF-DMR-0906744 and U.S. DOE DE-AC05-00OR-22725

**X-Ray Strain Measurements in Metallic Glasses:** Todd Hufnagel<sup>1</sup>; <sup>1</sup>Johns Hopkins University

Several groups have recently used x-ray or neutron scattering to examine the structural effects of nominally elastic loading of metallic glasses. Most of the published data report x-ray elastic moduli that are uniformly larger (by some 5-20%) than the moduli determined by ultrasonic measurements. Furthermore, when strain is measured from shifts in the peak of the pair correlation function  $g(r)$ , a length-scale dependence of strain is observed, with the strain at small atomic separations being smaller than the macroscopic strain, increasing to asymptotically approach the macroscopic strain at large distances. In this talk, we review these results in light of several possible physical mechanisms, including local anelastic deformations and the

proposed presence of elastic heterogeneities in metallic glasses. We also discuss the application of scattering techniques to problems of interest, including x-ray measurements of the strain distribution around crack tips in metallic glasses under load.

**Insights on Thermomechanical Deformation in Bulk Metallic Glasses from In-Situ X-Ray and Neutron Scattering Experiments:** Alexandru Stoica<sup>1</sup>; Dong Ma<sup>1</sup>; John Daniels<sup>2</sup>; Ken Littrell<sup>1</sup>; *Xun-Li Wang*<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory; <sup>2</sup>European Synchrotron Radiation Facility

We have used in-situ neutron diffraction and synchrotron x-ray scattering to investigate the compressive deformation in several bulk metallic glass materials at temperatures below the glass transition temperatures. In situ, time resolved data revealed the structure evolution from atomic to nanometer length scales resulting from the thermomechanical deformation. In the case of a Ca-based metallic glass, after yielding the sample exhibits a transient softening stage that characterizes the homogeneous flow due to the local atomic structure rearrangement, followed by a hardening stage that originates from nano-scale crystallization. Our study provides insights for understanding homogeneous and inhomogeneous flows in metallic glasses from structure changes at multiple length scales.

**Atomic Structure and Dynamics of BMG during Mechanical Deformation:** *Wojciech Dmowski*<sup>1</sup>; Andrew Chuang<sup>1</sup>; Wei Guo<sup>1</sup>; Konstantin Lokshin<sup>1</sup>; Yoshihiko Yokoyama<sup>2</sup>; Tatsuya Iwashita<sup>1</sup>; Yang Ren<sup>3</sup>; Matt Stone<sup>2</sup>; Peter Liaw<sup>1</sup>; Akihisa Inoue<sup>2</sup>; Takeshi Egami<sup>3</sup>; <sup>1</sup>University of Tennessee; <sup>2</sup>Tohoku University; <sup>3</sup>Advanced Photon Source; <sup>4</sup>SNS; <sup>5</sup>ORNL

We studied changes in the atomic structure and dynamics of metallic glasses during mechanical deformation below the yield stress. The x-ray diffraction was carried in-situ in tensile and compressive loading with applied stress up to 1.75 GPa. The inelastic neutron scattering was performed during compression up to 1.5 GPa. We obtained anisotropic components of the x-ray S(Q) and PDF in the nominal elastic mechanical regime as function of the applied load at room temperature and after the high temperature creep. Analysis of the anisotropic PDF showed that "elastic" deformation is not affine. However, the anisotropic PDF could be divided into elastic (affine) and anelastic components. Analysis showed that for any applied stress level about 24% of the apparent strain was anelastic. The inelastic neutron data show anisotropic component. We also observed changes in the inelastic part of the neutron scattering with the applied stress. Supported by the U.S. DOE, DE-AC05-00OR-22725.

**Fracture Toughness of Bulk Metallic Glasses:** *John Lewandowski*<sup>1</sup>; <sup>1</sup>Case Western Reserve Univ

The effects of changes in chemistry and stress state on the fracture toughness has been determined for a number of different metallic glass systems. Both notched and fatigue precracked samples have been tested in order to determine the effects of changes in notch severity on the fracture energy/toughness of a number of systems. In addition, the effects of different loading rates and test temperatures on the fracture energy of a Zr-based bulk metallic glass have been determined. The results will be reviewed in the light of previous and ongoing work documenting the effects of such changes on damage tolerance of bulk metallic glass systems.

#### 10:40 AM

**Using Artificial Microstructures to Understand Microstructure Property Relationship in Metallic Glasses:** *Baran Sarac*<sup>1</sup>; Golden Kumar<sup>1</sup>; Jan Schroers<sup>1</sup>; <sup>1</sup>Yale University

Materials science seeks to correlate microstructure with (mechanical) properties. Various approaches have been employed to understand this correlation including conventional direct approaches where the microstructure is varied through processing parameters and composition and the effects on the mechanical properties determined. Technologically relevant materials have reached a level of complexity that conventional metallurgical strategies

as well as above mentioned model and simulation strategies are at their limit. Therefore, we propose a novel approach to study microstructure-property relationship; artificial microstructures, which allow us to individually and independently vary parameters and thereby determine their individual effects on mechanical properties. The artificial microstructure will be fabricated using our recently developed miniature fabrication method. Examples of this novel approach are toughening mechanism in metallic glasses, size effects, and the transition from plastic deformation to elastic buckling in metallic glass heterostructures.

#### 10:50 AM Invited

**Incipient Plasticity in Bulk Metallic Glasses at Elevated Temperatures and under Cyclic Loading:** *Oliver Franke*<sup>1</sup>; Christopher Schuh<sup>1</sup>; <sup>1</sup>MIT

Nanoindentation is used to study the initial yielding of bulk metallic glasses (BMG). The distribution of the pop-in events in the load displacement curves gives insight into the factors that control deformation. BMGs exhibit a high sensitivity to structural inhomogeneities which is studied at different rates, temperatures and different preconditions. One particular preconditioning of the BMGs is to cyclically load the sample in the elastic regime. At room temperature the passing of a critical threshold load causes significant hardening, while below the threshold several thousand cycles do not have any measurable effect. At elevated temperatures the emergence of thermal relaxation affects the ability of the glass to cyclically harden.

#### 11:10 AM Invited

**Inhomogeneous Deformation and Kinetics of Shear Banding in Metallic Glasses:** *Robert Maass*<sup>1</sup>; David Klaumünzer<sup>1</sup>; Jörg Löffler<sup>1</sup>; <sup>1</sup>Swiss Federal Institute of Technology (ETHZ)

Inhomogeneous flow in bulk metallic glasses is still an elusive topic with respect to the underlying deformation mechanisms which govern localized shear band operations. In this study we investigate the inhomogeneous flow both in the serrated and non-serrated regimes. In particular, we evaluate the characteristic times and velocities of the deformation kinetics during shear banding. Using temperature-dependent measurements we are able to show that the shear band propagation of an individual flow serration is a thermally activated process and not a catastrophic event. Electron microscopy investigations before and after an individual serration reveal that shear banding is not a nucleation-controlled mechanism, but rather that there is a one-to-one correspondence between flow serration and shear-offset formation. We also assess the behaviour of a single shear band operating at sub-ambient temperatures. These results indicate that stable flow at low temperatures is not an intrinsic property of cryogenic temperature plasticity.

#### 11:30 AM Invited

**Elastic, Plastic and Fracture Response of Bulk Metallic Glass Matrix Composites:** *Upadrashta Ramamurty*<sup>1</sup>; R. L. Narayan<sup>1</sup>; P.S. Singh<sup>1</sup>; K. Boopathy<sup>1</sup>; Indrani Sen<sup>1</sup>; D. C. Hofmann<sup>2</sup>; <sup>1</sup>Indian Institute of Science; <sup>2</sup>California Institute of Technology

Bulk metallic glasses (BMGs) exhibit extraordinary strengths but suffer from low ductility and fatigue resistance. A possible way to alleviate these problems is through the composite route. In the recent past, it has been shown that BMG matrix composites with tailored microstructures of crystalline dendrite phase in the amorphous matrix yield a combination of higher ductility, strength and toughness. The role of the constituent phases on the elastic, plastic and fatigue crack growth behaviors of several BMG matrix composites are investigated in this work. For this purpose, a variety of experimental tools such as nanoindentation, in-situ testing are employed. Further, the influences of temperature and strain rate are explored. The results of these experiments will be presented and the micromechanisms of deformation and fracture in BMG composites will be discussed.

#### 11:50 AM

**Mechanical Inhomogeneity in As-Cast Bulk Metallic Glass:** *John Plummer*<sup>1</sup>; Russell Goodall<sup>1</sup>; Ignacio Figueroa<sup>2</sup>; Iain Todd<sup>1</sup>; <sup>1</sup>University of Sheffield; <sup>2</sup>Universidad Nacional Autonoma de Mexico

A surface softening effect induced during copper-mould casting of bulk metallic glass is investigated as a function of rod diameter and kinetic glass

fragility index by nanoindentation. A reduction in hardness and reduced modulus at the rod surface is found to not be present in all rods and is favoured in small diameter castings and in fragile systems. Enhanced propensity for shear transformation zone nucleation in the low moduli surface is explained in terms of reduced atomic connectivity, arising from a reduction in local coordination number and a lowering of the shear modulus. Finally, the structure and mechanical diversity that is possible in a single as-cast bulk metallic glass rod is explored through a relative quantification of shear modulus and plastic zone size.

**12:00 PM Invited**

**Effect of Structure of  $\beta$  Phase on the Mechanical Properties of Ti-Based Bulk Metallic Glass Composites:** Chang Wook Bang<sup>1</sup>; Ka Ram Lim<sup>1</sup>; Jin Man Park<sup>1</sup>; Won Tae Kim<sup>1</sup>; *Do Hyang Kim*<sup>1</sup>; <sup>1</sup>Yonsei University

Ductile-phase-reinforced BMG composites show enhanced global plasticity and more graceful failure since soft crystalline inclusions stabilize the glass against the catastrophic failure associated with unlimited extension of a shear band. In the present study, role of ductile dendritic phase in optimizing the mechanical properties of Ti-rich Ti-Zr-Be-Cu-Ni-Nb BMG composites has been investigated from major two aspects: 1) quasi-stable equilibrium condition for beta phase and glass matrix and 2) effect of structure of beta phase on the mechanical properties of composites. As a result, combination of strength and plasticity is optimized by tailoring relative volume fraction of beta phase and glass matrix. The effect of martensitic transformation in beta phase during cooling and deformation has been investigated. Depending on the composition of beta phase, martensitic transformation occurs in the beta phase affecting the mechanical properties and deformation behavior of the bulk metallic glass matrix composites.

**In-Situ TEM/STEM Investigations on Crack Propagation with Plasticity in Zr-Based Metallic Glass:** Jingwei Deng<sup>1</sup>; *Manling Sui*<sup>2</sup>; <sup>1</sup>Shenyang National Laboratory for Materials Science, Institute of Metal Research, Chinese Academy of Sciences; <sup>2</sup>Beijing University of Technology

By in situ tensile test in a transmission electron microscope (TEM), the crack propagation with plasticity was observed in Zr-based metallic glass without nanocrystals formation. Different from that the dislocations generated at the crack tip and propagated along crystallographic planes in the crystalline materials, the plastic flow zone in front of crack presented in a zigzag trace in the monolithic metallic glass. Shear events were observed dynamically in the plastic flow zone by using a scanning imaging mode in TEM, i.e. STEM. It was found that the shear events were sensitive to the local sample thickness. The zigzag propagation of the crack is associated with every shear event in front of the crack. This work was supported by the Cheung Kong Scholars Programme of China and the Natural Sciences Foundation of China

**12:40 PM**

**In-Situ Studies of Micromechanical Behavior of Porous W/Zr-Based Amorphous Alloy Composite:** *Yunfei Xue*<sup>1</sup>; <sup>1</sup>Beijing Institute of Technology

The in-situ high energy X-ray diffraction (HEXRD) was employed to investigate the micromechanical behavior of the porous W/Zr-based amorphous alloy composite during compressive deformation. The lattice strain was measured by HEXRD along the loading direction for different  $\{h k l\}$  planes of W phase in the yielding stage. When the stress is less than 1250 MPa, the lattice strains responds linearly to the applied stress, indicating that only elastic deformation occurs during this stage in W phase. With the increment of stress, the lattice strains exhibit greater deformation, suggesting that the W phase still subjected to a great stress at this stage of deformation and it is an evidence of work-hardening for the W phase. The non-linearity was mainly due to the redistribution caused by interactions of grain-to-grain within W phase and phase-to-phase between the amorphous matrix and W phase.

## Cast Shop for Aluminum Production: Direct Chill Casting

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee

*Program Organizers:* Geoffrey Brooks, Swinburne University of Technology; John Grandfield, Grandfield Technology Pty Ltd

Tuesday AM  
March 1, 2011

Room: 16A  
Location: San Diego Conv. Ctr

*Session Chairs:* Dmitry Eskin, Delft University of Technology; Arild Hakonsen, Hydro Aluminium

### 8:30 AM Introductory Comments

**8:35 AM**

**Cold Cracking during Direct-Chill Casting:** *Dmitry Eskin*<sup>1</sup>; Mehdi Lalpoor<sup>1</sup>; Laurens Katgerman<sup>2</sup>; <sup>1</sup>Materials innovation institute; <sup>2</sup>Delft University of Technology

Cold cracking phenomenon is the least studied, yet very important defect occurring during direct-chill casting. The spontaneous nature of this defect makes its systematic study almost impossible, and the computer simulation of the thermo-mechanical behavior of the ingot during its cooling after the end of solidification requires constitutive parameters of high-strength aluminum alloys in the as-cast condition, which are not readily available. In this paper we describe constitutive behavior of high-strength 7XXX-series alloys in the as-cast condition based on experimentally measured tensile properties at different strain rates and temperatures, fracture and impact toughness at different temperatures, and thermal contraction. In addition fracture and structure of specimens and real cold-cracked billets are examined. As a result a fracture-mechanics-based criterion of cold cracking is suggested based on the critical crack length, and is validated upon pilot-scale billet casting.

**9:00 AM**

**Surface Defect Structures On Direct Chill Cast 6xxx Aluminum Billets:**

Mikael Erdegren<sup>1</sup>; *Torbjörn Carlberg*<sup>1</sup>; <sup>1</sup>Mid Sweden University

The surface zone in air-slip DC cast aluminum ingots of the alloys 6063, 6005 and 6082 have been analysed by metallographic methods and by chemical analysis. Inverse segregation to the surface was quantitatively analysed. The concentration profiles were coupled to the appearance of the defects and to microstructures from corresponding areas. Surface defects, of the type vertical drags (VD), were investigated and compared to defect free surfaces for the different alloys. It was shown, that for the 6005 VD defects, there was no change, neither for the segregation zone depth nor for the intermetallic phase particles, compared to undamaged surface areas. In the defect zones the grains started to come apart thus creating an increase in porosity. For the 6063 samples the defect zones had different particles compared to the general surface. The segregation in a defect free surface area contained mostly  $\beta$ -particles while at the defects  $\alpha$ -particles dominated.

**9:25 AM**

**Effect of Cooling Water Quality on the Dendrite Arm Spacing of DC Cast Billets:** *Satyra Mohapatra*<sup>1</sup>; Suvendra Nanda<sup>1</sup>; Anindya Palchowdhury<sup>1</sup>;

<sup>1</sup>National Aluminium Company

For a given alloy chemistry and casting technology, the quality of a billet produced through DC casting route is largely defined by the DAS (Dendrite arm spacing). DAS in turn is determined by the cooling rate and local solidification time. The cooling rate is influenced by the quality and quantity of water besides casting speed and melt temperature. This paper focuses on the relationship between the quality of cooling water and the resultant DAS during production of billets during DC casting process. An empirical relation is derived to indicate the influence of cooling water characteristics on the DAS, based on a mathematical model supplemented by experimental investigations. The model has been validated in plant scale trials.

9:50 AM

**Mould Wall Heat Flow Mechanism in a DC Casting Mould:** *Arvind Prasad*<sup>1</sup>; Ian Bainbridge<sup>1</sup>; <sup>1</sup>University of Queensland

Experiments have been performed to study the effect of the mode of heat transfer on the heat flow in the wall of a DC casting mould. Billet casting uses graphite as inner lining material within the mould-wall. Graphite being a black-body, provides a possible pathway for radiation to play a role in the mould-wall heat transfer. As such, experiments were performed with a graphite probe on the experimental apparatus presented at TMS 2010. An overview of these results will be presented together with the implications of the results for the DC casting process.

10:25 AM

**Productivity Improvements at Direct Chill Casting Unit at Aluminium Bahrain (ALBA):** Abdulla Ahmed<sup>1</sup>; *Sukanta Chateeriji*<sup>1</sup>; A Rasool Maki<sup>1</sup>; <sup>1</sup>Aluminium Bahrain (Alba)

ALBA has been producing Rolling Ingots utilizing two DC casting units via., DC1 and DC6. Out of total annual production of 140,000 MT of Rolling Ingot, DC6 production was 100,000 MT (1XXX, 3XXX and 8XXX series alloys) while DC1 production was 40,000 MT of 5XXX series alloy. Due to higher cost of production and low productivity at DC1 ALBA management decided to close down DC1 as a part of restructuring exercise and maximizing production at DC6 to meet customers demand. An extensive study was carried out towards improving productivity. Four levers of improvement which has the maximum impact were identified e.g., furnace preparation practices, preparatory activities between casts, increasing casting speed etc. Various action plans were drawn up and were implemented. These actions were closely monitored by DC operators themselves by using trend charts. As a result a 30% improvement in productivity was achieved at DC6 on a consistent basis

10:50 AM

**The Coupling of Macroseggregation With Grain Nucleation, Growth and Motion in DC Cast Aluminum Alloy Ingots:** *Miha Založnik*<sup>1</sup>; Arvind Kumar<sup>1</sup>; Hervé Combeau<sup>1</sup>; Marie Bedel<sup>2</sup>; Philippe Jarry<sup>2</sup>; Emmanuel Waz<sup>2</sup>; <sup>1</sup>Institut Jean Lamour; <sup>2</sup>Alcan CRV

The phenomena responsible for the formation of macroseggregations and grain structures during solidification are closely intertwined. We present a model study of a DC cast extrusion ingot. The modeling of these phenomena in DC casting is a challenging problem due to the size of the products, the variety of the phenomena to be accounted for, and the nonlinearities involved. We used a two-phase multiscale model that describes nucleation on inoculant particles and grain growth, coupled with macroscopic transport: fluid flow driven by natural convection and shrinkage, transport of free equiaxed grains, heat transfer, solute transport. The roles of shrinkage, natural convection and grain motion on the sump shape and macroseggregation are analyzed. The formation and evolution of inoculated grains are discussed. We show that it is important to account for all these phenomena and the coupling of segregation and structure formation to be able to explain macroseggregation patterns observed experimentally.

11:15 AM

**Investment Casting of Surfaces with Microholes and Their Possible Applications:** *Todor Ivanov*<sup>1</sup>; Andreas Buehrig-Polaczek<sup>1</sup>; Uwe Vroomen<sup>1</sup>; Claudia Hartmann<sup>2</sup>; Arnold Gillner<sup>2</sup>; Kirsten Bobzin<sup>1</sup>; Jens Holtkamp<sup>2</sup>; Nazlim Bagcivan<sup>1</sup>; Sebastian Theiss<sup>1</sup>; <sup>1</sup>RWTH Aachen University; <sup>2</sup>Fraunhofer-Institute for Laser Technology

The common way to realize microstructured features on metallic surfaces is to generate the designated pattern on each single part by means of laser ablation, electro discharge machining or micromilling. The disadvantage of these process chains is the limited productivity due to the additional processing of each part. The approach to overcome this bottle neck is to replicate microstructured surfaces together with the parts. Therefore an investment casting process to produce functional 3D-surfaces with geometrical features in micrometer range on near-net-shape-cast parts is

investigated. The main research objective deals with the investigation of the single process steps of the investment casting process with regard to the molding accuracy. To demonstrate the potential of microcasted surfaces, current results of the casting of a microstructured hydrophobic surface are shown.

11:40 AM

**Using SEM and EDX for a Simple Differentiation of  $\alpha$ - and  $\beta$ -AlFeSi-Phases in Wrought Aluminum Billets:** *Marcel Rosefort*<sup>1</sup>; Christiane Matthies<sup>1</sup>; Hinrich Buck<sup>1</sup>; Hubert Koch<sup>1</sup>; <sup>1</sup>TRIMET ALUMINIUM AG

Aluminum 6xxx extrusions have considerable potential to make cars lighter. Thus there is a growing demand for high quality aluminum billets. Additionally there is a requirement to improve the aluminum properties. An important issue to fulfill these increasing requirements is the optimization of the microstructure. While utilizing 6xxx-alloys the formation and optimization of the AlFeSi-phase is important. The determination of  $\alpha$ - and  $\beta$ -AlFeSi-phases is a challenge, because  $\beta$ -AlFeSi-phases affect the mechanical properties negatively. A determination in wrought alloys via microscopy is often complicated and leads to questionable results due to the low amount of the phases. TRIMET has investigated one possibility of determining  $\alpha$ - and  $\beta$ -AlFeSi-phases with the help of scanning electron microscope and energy dispersive X-ray. The paper describes the first tests, the phase simulations and the casting experiments. Finally it presents the tests of such phase determinations in the production of 6xxx-alloys like the new TRIMAL 52.

## Characterization of Minerals, Metals and Materials: Characterization of Steel and Cast Iron

8:30 AM

**Effect of Initial Structure on Grain Refinement of Medium Carbon Steel Processed by ECAP:** *Jozef Zrník*<sup>1</sup>; Sergey Dobatkin<sup>2</sup>; George Raab<sup>3</sup>; Martin Fujda<sup>4</sup>; Libor Kraus<sup>5</sup>; <sup>1</sup>Comtes FHT, Inc.; <sup>2</sup>Russian Academy of Science; <sup>3</sup>Ufa State University; <sup>4</sup>Technical University of Kosice; <sup>5</sup>COMTES FHT Inc.

The work deals with grain refinement of medium carbon steel having different initial microstructure modified by thermal and/or thermomechanical treatment. In case of TM treated steel preliminary structure refinement was achieved due to multistep open die forging. Fine recrystallized ferrite structure and with nest-like pearlite colonies was obtained. The further grain refinement of steel samples was accomplished during warm Equal Channel Angular Pressing (ECAP) at 400°C. Employment of this processing route resulted in extensive deformation of ferrite grains where mixture of subgrains and ultrafine grain was found regardless the preliminary treatment of steel. The dynamic polygonization and recrystallization became active to form mixture of polygonized subgrains and submicrocrystalline grains. The straining and moderate ECAP temperature caused the partial cementite lamellae fragmentation and spheroidization. The tensile behaviour was characterized by strength increase for both structural steel states. The work hardening behaviour was modified in steel where preliminary TM treatment was introduced.

TUESDAY AM

8:45 AM

**Effect of Test Temperature and Prior Straining on the Deformation Mode of Austenitic Stainless Steel during Tensile Testing:** Supratik Roychowdhury<sup>1</sup>; Suman Neogy<sup>1</sup>; Mayank Gupta<sup>2</sup>; Vivekanand Kain<sup>1</sup>; Dinesh Srivastava<sup>1</sup>; G.K. Dey<sup>1</sup>; R.C. Prasad<sup>3</sup>; *Raghvendra Tewari<sup>4</sup>*; <sup>1</sup>Bhabha Atomic Research Centre; <sup>2</sup>PEC; <sup>3</sup>IIT, Bombay; <sup>4</sup>Bhabha Atomic Resrach Centre

Austenitic stainless steels are an important material of construction for Boiling Water Reactors (BWR). These stainless steels are amenable to strengthening by strain hardening. Various deformation modes at different test temperatures and strain become active. In the present investigation type 304LN stainless steel was used in the annealed and strain hardened condition. Thin foils were prepared from gauge section for TEM investigation after tensile testing at room temperature and at 288°C. TEM investigation reveals that twinning is the major mode of deformation for the tests carried out at room temperature while dislocation cross slip is the major mode of deformation at higher temperature. Stacking faults were also observed to a limited extent. The extent of twinning was much higher for the tests carried out using the rolled material. The formation of martensite in the stainless steel due to straining was investigated by the analysis of selected area diffraction patterns.

9:00 AM

**Susceptibility of Low and High Manganese X70 Pipeline Steel to Hydrogen Embrittlement:** Daniel Hejazi<sup>1</sup>; Ayesha Haq<sup>1</sup>; Nima Yazdipour<sup>1</sup>; Druce Dunne<sup>1</sup>; Andrzej Calka<sup>1</sup>; Frank Barbaro<sup>2</sup>; *Elena Pereloma<sup>1</sup>*; <sup>1</sup>University of Wollongong; <sup>2</sup>BlueScope Steel

Hydrogen, even in very low concentrations, can diffuse to regions of high stress concentration resulting in a degradation of mechanical properties. The transport of hydrogen depends on the interaction between hydrogen atoms and the traps which, in turn, is related to microstructure. The influence of composition and microstructure on hydrogen embrittlement susceptibility was investigated by selecting pipeline steels with different Mn and S contents and in different conditions – normalized transfer bar, as-received strip and heat affected zone (HAZ). HAZ simulations were conducted using Gleeble thermo-mechanical machine to simulate a thermal cycle typical of in-service repairs. Notched and fatigue pre-cracked samples were subjected to electrochemical hydrogen charging using a solution of H<sub>2</sub>SO<sub>4</sub> and NaAsO<sub>2</sub> to achieve 2 and 4 ppm hydrogen content. Three point bend tests were conducted on as-received and hydrogen-charged samples. The results obtained are discussed in relation to the microstructure and fractography of the samples

9:15 AM

**Evaluation of Aging Embrittlement of Austenitic Stainless Steels JN1, JJ1 and JK2 by Cryogenic Small-Punch Testing:** Maribel Saucedo-Muñoz<sup>1</sup>; *Victor Lopez-Hirata<sup>1</sup>*; Shin-ichi Komazaki<sup>2</sup>; Toshiyuki Hashida<sup>3</sup>; <sup>1</sup>Instituto Politecnico Nacional (ESIQIE); <sup>2</sup>Muroran Institute of Technology; <sup>3</sup>Tohoku University

Small-punch tests were conducted at 4, and 77 K on three types of austenitic stainless steels JN1, JJ1 and JK2, which were solution treated, and then aged at 923-1073 K for 5 hours. Small-punch test energy was employed for the evaluation of the aging-induced embrittlement behavior in these materials. Fracture surface of small punch test specimen for the solution treated steels exhibited a ductile fracture, showing the highest SP test energy values. The presence of intergranular brittle fracture was observed in aged specimens. Small-punch test energy decreased significantly as the aging process progressed. The highest and lowest decrease in small-punch test energy with aging temperature occurred in JN1 and JK2 steels, respectively. The decrease in small-punch test energy showed to examine appropriately the aging-induced embrittlement in these materials. The difference in aging-induced embrittlement behavior for these steels was explained based on the volume fraction of intergranular precipitates in aged samples.

9:30 AM

**Investigations on the Cyclic Crack Growth Behaviour of Spring Steel Wire Reinforced EN AW-6082:** *Matthias Merzkirch<sup>1</sup>*; Kay Weidenmann<sup>1</sup>; Volker Schulze<sup>1</sup>; <sup>1</sup>Karlsruhe Institute of Technology

Unidirectional reinforced light weight materials such as the aluminium alloy EN AW-6082 are adequate partners for the future use in transportation means like automobiles and airplanes. Due to the occurring cyclic loads knowledge about the crack growth behaviour of these composites is needed. The investigations at a load ratio of R=0.18 show that the crack growth rate of the aluminium matrix is reduced if it is reinforced by spring steel wire with a reinforcing ratio of only about 1 Vol.-%. Further analyses with the help of a self designed capacitive travel measuring gauge show that the reinforcing element causes an increase of the stiffness resulting in a smaller crack opening in comparison to the pure matrix material. Additionally, the acoustic emission analysis allows to detect crack growth within the matrix material, crack propagation along the interface wire/matrix and crack closure. The qualitative results are verified by metallographic and SEM investigations.

9:45 AM Invited

**Effect of Cr Content on Corrosion Resistance of Fe-Based Alloys under SCW Condition:** *Jian Li<sup>1</sup>*; Wenyue Zheng<sup>1</sup>; William Cook<sup>2</sup>; <sup>1</sup>CANMET-MTL; <sup>2</sup>University of New Brunswick

Resistance to high temperature corrosion is one of the key challenges in future nuclear reactor material development. Iron based materials with low Cr content shows superior high temperature mechanical properties. However, due to relative low Cr content, their corrosion resistances under SCW conditions are generally poor. High-Cr alloys although show much improved corrosion resistance, often suffer from embitterment due to the pre-cipitation of sigma phase in the microstructure. In this study, corrosion resistance high Cr alloy (25%Cr) showed much better corrosion resistance compared to that of low Cr alloy (14%Cr). The high-Cr alloy was subsequently used as coating material for commercial P91 alloy.

10:30 AM

**Variations of Elastic Modulus of Automotive Steels after Yielding:** Paolo Matteis<sup>1</sup>; Giorgio Scavino<sup>1</sup>; *Donato Firrao<sup>1</sup>*; <sup>1</sup>Politecnico di Torino

Numerical simulations of both production processes (e.g.: sheet cold forming) and service behavior (e.g.: low-speed car impact), used in the automotive industry to minimize the tests number and shorten the car design and industrialization, can be significantly affected by the variation of the steel elastic modulus due to plastic deformation. However, this phenomenon is not usually modeled, also for lack of specific data. Hence, five steel grades, belonging to different categories, were examined before and after several successive 4% true strain steps, and up to the uniform elongation. After each deformation step, the specimen was unloaded, the cross-section was re-measured, and the modulus was evaluated from a series of loading and unloading ramps in the elastic range. In most cases, the elastic modulus decreases approximately from 205 GPa in the as-received condition to 165 GPa after deformation, with most of this drop often occurring in the first deformation step alone.

10:45 AM

**The Development of a High Strength Microalloy Steel TiC Deposited by Reactive Magnetron Sputtering:** *Narayanna Ferreira<sup>1</sup>*; Edalmy Almeida<sup>1</sup>; Marcio Mendes<sup>1</sup>; Clodomiro Alves Júnior<sup>1</sup>; <sup>1</sup>UFRN

High strength low alloy steels (HSLA) are generally composed of micro-alloying elements Nb, V and Ti. Commonly are microalloyed with niobium and vanadium, however, the development of steels microalloyed with Ti have been objects of constant research. The mechanical properties of microalloyed steels result from the interaction between different hardening mechanisms involving dislocations, solid solution, ferritic grain refinement and precipitation of carbonitrides. The aim of this study was developed from a titanium microalloyed steel using the technique of enrichment by precipitation of TiC powder of iron deposition by reactive magnetron sputtering using different proportions of the mixture CH<sub>4</sub>, H<sub>2</sub>, Ar. This

work was realized on the microstructural characterization by SEM / EDX, XRD, XRF and microhardness. The results showed that the precipitation of titanium carbide by magnetron sputtering is viable and confirmed by the characterization techniques performed in this study.

**11:00 AM**

**Microstructure and Properties of New Wear Resistant Steel with High Strength and High Toughness:** *Li Hongbin*<sup>1</sup>; <sup>1</sup>Baosteel

A multi-element wear-resistant low-alloy steel with high strength and high toughness was developed. Microstructure, hardness, tensile properties and impact properties were carried out in order to establish a correlation amongst the parameters and to optimize the microstructural features and mechanical properties for superior wear performance. The results show that the optimal microstructure and mechanical properties were got when quenching at 880 °C and tempering at 180 °C. Fine martensite can be obtained, and the hardness is above 550HB, the tensile strength is above 1700MPa, the yield strength is above 1350MPa, the elongation is above 10%, and the impact energy is about 50J. The results obtained have been supplemented through the characteristics of the worn surfaces, subsurface regions, debris and fractured surfaces. These analyses also helped to understand the operative mechanisms of material removal and failure.

**11:15 AM**

**Evaluation of Growth Rates of Austenitic Transformation Products in Fe-C-Cr Alloys Using Laser Scanning Confocal Microscopy:** *Peter Kolmskog*<sup>1</sup>; *Peter Hedström*<sup>1</sup>; *Annika Borgenstam*<sup>1</sup>; <sup>1</sup>Royal Institute of Technology, KTH

An evaluation of the growth rates of the transformation products from austenite in three Fe-C-Cr alloys (Fe-1C-1Cr, Fe-1C-4Cr and Fe-0.15C-4Cr) during isothermal heat treatment has been performed in-situ using Laser Scanning Confocal Microscopy (LSCM) equipped with a hot-stage. The LSCM technique enables the clear observation of phase transformation that gives a surface relief e.g. Widmanstätten cementite and ferrite, bainite and inverse bainite. Specimens have been isothermally heat treated at temperatures from 275 to 700 °C and the growth rate of the different austenitic transformation products has been evaluated. The microstructures of the transformed specimens have been analyzed using LOM and SEM in order to verify the obtained results.

**11:30 AM**

**Internal Friction and Three Dimensional Atom Probe Analysis of Bake Hardening Phenomenon in Ultra-Low Carbon Bake Hardening Steel:** *Hua Wang*<sup>1</sup>; *Wen Shi*<sup>1</sup>; *Lin Li*<sup>1</sup>; <sup>1</sup>Shanghai University

Two samples of Ultra-Low Carbon Bake Hardening (ULC-BH) steel with different compositions were prepared by annealing and water quenching. These samples were pre-deformed with various levels from 2% to 10%, and further baked at 170 °C for 20min. The distribution of solute C in the processed samples was characterized by 3DAP, and the BH values of the samples with different pre-deformation were also determined. In addition, the relationship between the distribution of solute C in BH steels and the BH values was analyzed.

**11:45 AM**

**A New Understanding on the Initiation of Pitting Corrosion of Austenitic Stainless Steels in Salt Water:** *Xiu-Liang Ma*<sup>1</sup>; <sup>1</sup>Institute of Metal Research, Chinese Academy of Sciences

The pitting corrosion of stainless steels is generally believed to result from the local dissolution in MnS inclusions which are more or less ubiquitous in stainless steels. Nevertheless, the microstructure information on the local site where MnS dissolution preferentially occurs is lacking, which makes pitting corrosion remain the big headache for numerous engineering materials. We have applied in-situ ex-environment transmission electron microscopy and have identified the initial site, at an atomic scale, of MnS dissolution. We find that fine nano-octahedral precipitates of spinel MnCr<sub>2</sub>O<sub>4</sub> are dispersedly distributed in the MnS inclusions. In-situ TEM studies indicate that the MnS initially dissolves at the MnCr<sub>2</sub>O<sub>4</sub>/MnS interface in the presence of salt water. First-principles calculations indicate that the MnCr<sub>2</sub>O<sub>4</sub> nano-

octahedron with metal terminations is more reactive in catalyzing the MnS dissolution than O-terminated ones. This work sets up a new basis for understanding the initiation of pitting corrosion.

**8:30 AM**

**Evaluation of 2.25Cr-1Mo Alloy for Containment of LiCl/KCl Eutectic during the Treatment of Used Nuclear Fuel:** *Brian Westphal*<sup>1</sup>; *S. Li*<sup>1</sup>; *G. Fredrickson*<sup>1</sup>; *D. Vaden*<sup>1</sup>; *T. Johnson*<sup>1</sup>; *J. Wass*<sup>1</sup>; <sup>1</sup>Idaho National Laboratory

Recovery of uranium from the Mk-IV and Mk-V electrorefiner vessels containing a LiCl/KCl eutectic salt has been on-going during the pyrometallurgical processing of used nuclear fuel for 14 and 12 years, respectively. Although austenitic stainless steels are typically utilized for LiCl/KCl salt systems, the presence of cadmium in the Mk-IV electrorefiner dictates an alternate material. A 2.25Cr-1Mo alloy (ASME SA-387) was chosen due to the absence of nickel in the alloy which has a considerable solubility in cadmium. Using the transition metal impurities (iron, chromium, nickel, molybdenum, and manganese) in the electrorefined uranium products, an algorithm was developed to derive values for the contribution of the transition metals from the various input sources. Weight loss and corrosion rate data for the Mk-V electrorefiner vessel were then generated based on the transition metal impurities in the uranium products. To date, the corrosion rate of the 2.25Cr-1Mo alloy in LiCl/KCl eutectic is "outstanding" assuming uniform (i.e. non-localized) conditions.

**8:50 AM**

**Numerical and Experimental Study of Fluid Flow during Electrolytic Process for Magnesium Production:** *Hyun Na Bae*<sup>1</sup>; *Myung Duk Seo*<sup>1</sup>; *Seon Hyo Kim*<sup>1</sup>; *Go-Gi Lee*<sup>2</sup>; *Jae Young Jung*<sup>2</sup>; <sup>1</sup>POSTECH; <sup>2</sup>RIST

Bubbles form at the anode during the electrowinning of magnesium and cause hydrodynamic acceleration and electrical field disturbance. A three-dimensional computational model was developed to investigate the effect of the geometry of the electrochemical chamber and the size distribution of bubbles on the fluid flow in the cell of a pilot plant. The results were validated by measurements of the surface characteristics of molten salt and of the formed bubbles. Fluid flow at the surface was recorded with a high speed camera, and the distribution of bubble size was determined by inspecting the video images frame by frame. The measured size distribution of the bubbles was entered into the computer simulation for multi-phase flow. A sloped roof was installed above the electrodes and enhanced the flow of the molten salt, resulting in higher current efficiency, lower energy consumption, and higher quality of magnesium metal.

**9:10 AM**

**Magnesium Removal from Secondary Aluminum Melts in Reverberatory and Rotary Furnaces:** *Eulogio Velasco*<sup>1</sup>; *Marcos Cardoso*<sup>2</sup>; *Jose Nino*<sup>2</sup>; <sup>1</sup>Texas State University; <sup>2</sup>NEMAK

Recycling of aluminum scrap for production of secondary alloys used for automotive applications is increasing continuously. Aluminum can be recycled with large energy and emission savings with minimal loss in material properties. Automotive alloys require a strict control to remove

TUESDAY AM

alloy impurities, inclusions and excess of magnesium. The aim of this work is to study the magnesium removal from recycled aluminum by chlorine injection in a reverberatory furnace, and removal by an oxidation process at high temperature in an industrial rotary furnace. The magnesium removal by gas injection is carried out by the reaction between chlorine and magnesium, with its efficiency associated to kinetic factors. In the rotary rapid oxidation of aluminum and magnesium elements at high temperature is characterized by the formation of surface films composed of magnesium oxide. Additionally this work reviews the benefits of an efficient demagging process.

**9:30 AM**

**Rapid Removal of Chlorine in Molten Salt Electrolysis of Magnesium Chloride:** *Gökhan Demirci*<sup>1</sup>; *Ishak Karakaya*<sup>2</sup>; <sup>1</sup>Aselsan Inc.; <sup>2</sup>Middle East Technical University

Energy consumption in electrolytic magnesium cells is well above the theoretical values. However, the mechanism of the back reaction, the main cause of the current losses, has not been fully understood yet. Magnesium dissolution into the melt is generally regarded as the limiting step for the back reaction. Accordingly, present cell designs are made with priority given to fast magnesium removal from the cell. However, experimental data and modeling results in this study indicate that the limiting step for the back reaction between magnesium and chlorine is the chlorine dissolution into the electrolyte when physical contact between electrolysis products was eliminated. Effects of chlorine bubbles on the current efficiency and the cell potential were investigated. Results show that the extent of back reaction is proportional to the chlorine surface area in contact with the electrolyte per unit time, and the cell potential increases with the amount of chlorine bubbles inside the electrolyte.

**9:50 AM**

**Preparation of Al-Ca Alloys by Molten Salt Electrolysis Method:** *Sh Yang*<sup>1</sup>; *Fengli Yang*<sup>1</sup>; *Mingzhou Li*<sup>1</sup>; *Xianwei Hu*<sup>2</sup>; *Zhaowen Wang*<sup>2</sup>; *Zhongning Shi*<sup>2</sup>; *Bingliang Gao*<sup>2</sup>; <sup>1</sup>Jiangxi University of Science and Technology; <sup>2</sup>School of Materials and Metallurgy117#, Northeastern University

Aluminum-calcium alloys were prepared by molten salt electrolysis method. 15w%KCl-80w%CaCl<sub>2</sub>-5w%MgF<sub>2</sub> was taken as electrolysis. Content of calcium in alloys was to be higher than 13w%, and tests were carried out with 0.80-1.20A•cm<sup>-2</sup> of cathode current density at 680-720°. The highest current efficiency was 80%. Aluminum-calcium alloys with different calcium contents could be prepared directly from the cell by molten salt electrolysis method. Compared with traditional method, the method not only could reduce the loss of calcium in the alloy manufacture process, but to reduce Greenhouse Gases and energy consumption. Moreover, component of alloys prepared by molten salt electrolysis method was even, and production could be carried out continuously.

**10:10 AM Break**

**10:25 AM**

**The Dissolution Behavior of TiCxO1-x Solid Solutions in Chloride Melt:** *Xiaohui Ning*<sup>1</sup>; *Chao Du*<sup>1</sup>; *Qiuyu Wang*<sup>1</sup>; *Shuqiang Jiao*<sup>1</sup>; *Hongmin Zhu*<sup>1</sup>; <sup>1</sup>University of Science and Technology Beijing

TiCxO1-x solid solutions were synthesized by sintering a mixture of titanium carbide and titanium monoxide at 1600 °C. The corresponding structures and morphologies of the TiCxO1-x solid solutions were characterized by XRD and SEM. A series of tests has been performed on the electrochemical dissolution behavior of TiCxO1-x solid solutions in NaCl-KCl molten salt. The influences of synthesis time and electrochemical parameters on the anodic dissolution behavior were also investigated in detail. The results showed that TiCxO1-x solid solutions can dissolve as Ti<sup>2+</sup> into alkali chloride melt. The tail gas on the anode was monitored by a mass spectrometer. And it was found the synthesis time significantly affects the components of the anodic gas. Titanium ion species dissolved from TiCxO1-x solid solutions changes between Ti<sup>2+</sup> and Ti<sup>3+</sup> depending on the applied potential.

**10:45 AM**

**Study on Mechanism of Alumina Carbothermic Reduction-Chlorination Process in Vacuum:** *Fulong Zhu*<sup>1</sup>; *Bin Yang*<sup>1</sup>; *Qingchun Yu*<sup>1</sup>; *Baoqiang Xu*<sup>1</sup>; *Yongnian Dai*<sup>1</sup>; <sup>1</sup>National Engineering Laboratory for Vacuum Metallurgy

In this paper, the mechanism of the carbothermic reduction-chlorination process to extract aluminum from alumina in vacuum was investigated. Content of CO in gas, phases of the reduction slag, surface morphology of the reduction slag and the product aluminum were measured by means of gas chromatography (GC), XRD, and SEM. The experimental results indicated that content of CO in gas decreased, but Al<sub>4</sub>C<sub>3</sub> increased with reduction time increasing at 1773K during carbothermic reduction process of alumina. AlCl(g) and C were produced by the reaction between Al<sub>4</sub>C<sub>3</sub> and AlCl<sub>3</sub>(g) at 1773K, then aluminum beads were generated after decomposition of AlCl(g). It implied that mechanism of alumina carbothermic reduction-chlorination process in vacuum should match with the following three steps: the carbothermic reduction process of Al<sub>2</sub>O<sub>3</sub> to produce Al<sub>4</sub>C<sub>3</sub>, the chlorination process of Al<sub>4</sub>C<sub>3</sub> by AlCl<sub>3</sub>(g) to produce AlCl(g), and the decomposition process of AlCl(g) to produce Al(l).

**11:05 AM**

**Investigation on the Corrosion Resistance of Several Steel Materials to LiCl-KCl Melt:** *Bing Li*<sup>1</sup>; <sup>1</sup>East China University of Science and Technology

In this paper the corrosion resistances of three steel materials including 304, 306, Q235A steels to the LiCl-KCl melt were investigated. The electrochemical impedance spectroscopies, Tafel curves and polarization curves of the three steel materials in the LiCl-KCl melt were measured and some dynamic parameters such as corrosion current, corrosion potential, exchange current density, transfer coefficient and electron transfer resistance were obtained. And then the corrosion resistances of the three steel materials were tested by immersing into the LiCl-KCl melt at 600° for 50h and then their surface morphology and composition were characterized by SEM and EDS, and their weight changes before and after immersion into the melt were compared. At the same time, electrolysis experiments were carried out in LiCl-KCl melt at about 450° by selecting the three steel materials as cathodes, respectively, and the corrosion of metal Li produced in-situ on them were analyzed.

**11:25 AM**

**Electrochemical Removal of Impurity Mg from LiCl-KCl Containing MgCl<sub>2</sub> Melt:** *Bing Li*<sup>1</sup>; *Miao Shen*<sup>1</sup>; *Jingwei Lou*<sup>1</sup>; <sup>1</sup>East China University of Science and Technology

As a main impurity in primary lithium metal, magnesium is difficult to remove because of the very close relative volatility of the two metals. Electrochemical refining provides a possibility to completely remove Mg in the LiCl-KCl melt prior to Li reduction. MgCl<sub>2</sub> reduction processes in LiCl-KCl-MgCl<sub>2</sub> melt were investigated by cyclic voltametry (CV) and square wave voltametry (SWV). The results showed that MgCl<sub>2</sub> is reduced in one step with two-electron transfer. The reduction potential was well defined. By constant potential electrolysis at the Mg reduction potential, Mg was reduced on a solid cathode (mild steel) and a liquid cathode (Zinc and Lead). Cyclic voltametry (CV) and square wave voltametry (SWV) were also employed to compare the removal effect after several hours of electrolysis. The dissolution kinetics of the deposited Mg in the above melt was investigated, and the relations between the activity and the dissolution kinetics of deposited Mg were discussed.

**11:45 AM**

**Direct Synthesis of Niobium Aluminides Powders by Sodiothermic Reduction in Molten Salts:** *Na Wang*<sup>1</sup>; *Chao Du*<sup>1</sup>; *Shuqiang Jiao*<sup>1</sup>; *Kai Huang*<sup>1</sup>; *Hongmin Zhu*<sup>1</sup>; <sup>1</sup>University of Science and Technology Beijing

Niobium aluminides were directly synthesized by a sodiothermic reduction process of NbCl<sub>5</sub> - AlCl<sub>3</sub> which was dispersed into LiCl - KCl - NaCl - CaCl<sub>2</sub> melts. The melt supplied a homogenous reaction medium which was substantially beneficial to the co-reduction of Nb and Al to form niobium aluminides in situ. The reduction was performed at 500° for 4 hours. The products were analyzed by X-ray diffraction (XRD) and scanning electron

microscope (SEM). The corresponding results indicated that niobium aluminides powders have been successfully synthesized.

### Computational Thermodynamics and Kinetics: Brent Fultz Honorary Session II

**Iron Alloys through the Lens of Nuclear Resonant Spectroscopy:**  
*Wolfgang Sturhahn*<sup>1</sup>; <sup>1</sup>Jet Propulsion Laboratory

In recent years, nuclear resonant scattering techniques that utilize synchrotron radiation have provided new opportunities for the study of vibrational and magnetic properties of condensed matter under extreme conditions. In particular, the determination of the vibrational density of states with nuclear resonant inelastic x-ray scattering (NRIXS) and the study of valencies and magnetic properties with synchrotron Mössbauer spectroscopy (SMS) provided unique results. In this presentation, the work of Prof. Brent Fultz on the vibrational and magnetic properties of iron and its alloys using these novel nuclear resonant scattering techniques will be highlighted. In particular, we will discuss the effects of particle size and high pressure in iron metal as well as chemical disorder in various iron alloys on atomic vibrations and magnetic properties. This work is supported by grants from the National Aeronautics and Space Administration (NASA).

#### 9:00 AM Invited

**Mixing Properties in Oxide Solid Solutions Relevant to Nuclear Fuels:**  
Ben Hanken<sup>1</sup>; *Mark Asta*<sup>2</sup>; Chris Stanek<sup>3</sup>; Fei Zhou<sup>4</sup>; Vidvuds Ozolins<sup>4</sup>; Niels Gronbech-Jensen<sup>1</sup>; <sup>1</sup>University of California, Davis; <sup>2</sup>University of California, Berkeley; <sup>3</sup>Los Alamos National Laboratory; <sup>4</sup>University of California, Los Angeles

Among Professor Fultz's many accomplishments are his important contributions to the field of alloy theory. His experimental measurements of vibrational entropy inspired an extensive body of theoretical work aimed at incorporating non-configurational contributions to the entropy of mixing and ordering in first-principles calculations of alloy phase diagrams. In this talk we discuss non-configurational contributions to the mixing thermodynamic properties of oxide solid solutions, originating from electronic degrees of freedom. The work focuses on urania-ceria solid solutions, a surrogate system for mixed-oxide nuclear fuels. First-principles calculations, combined with classical interatomic-potential modeling are used to investigate contributions to mixing thermodynamic properties associated with electronic disorder arising from charge transfer between uranium and cerium ions. The results are discussed in light of conflicting experimental measurements in the literature. Overall, our results suggest that charge disorder likely plays an important role in governing the thermochemical and phase stability properties in this system.

#### 9:30 AM Invited

**Time-Resolved Measurements of Transient Behaviors by Asynchronous In-Situ Neutron Diffraction at the Spallation Neutron Source:** *Ke An*<sup>1</sup>; Alexandru Stoica<sup>1</sup>; Harley Skorpenske<sup>3</sup>; Abhijit Pramanick<sup>1</sup>; Rick Riedel<sup>1</sup>; Steve Miller<sup>1</sup>; Hahn Choo<sup>2</sup>; Jabob Jones<sup>3</sup>; James Kohl<sup>1</sup>; Xun-Li Wang<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory; <sup>2</sup>University of Tennessee; <sup>3</sup>University of Florida

Unlike the conventional histogram data collection method, the event-based data acquisition scheme at the Spallation Neutron Source (SNS) records neutrons with an intrinsic timing resolution of 100ns. A novel asynchronous neutron diffraction measurement technique has been demonstrated at VULCAN, the engineering diffractometer at SNS by making use of both neutron scattering and sample environment parameters in time event data acquisition mode. The asynchronous measurement strategy is an entirely new approach to study time-resolved phenomena such as in-situ phase transformation at elevated temperatures, lithiation and delithiation in rechargeable Li-ion batteries, and low cycle fatigue of stainless steel where the relevant time scales are minutes to milliseconds. The ultimate time resolution achievable with this technique is expected to be <10  $\mu$ s, which will enable the investigation of fast transition phenomena by neutron scattering. Details of this measurement methodology as well as its application in various scientific cases will be presented.

#### 10:00 AM Break

#### 10:20 AM

**Phonon Density of States and High Temperature Thermodynamics of MgB<sub>2</sub>:** *Jorge Munoz*<sup>1</sup>; Nikolay Markovskiy<sup>1</sup>; Matthew Lucas<sup>2</sup>; Olivier Delaire<sup>3</sup>; Chen Li<sup>1</sup>; Matthew Stone<sup>3</sup>; Douglas Abernathy<sup>3</sup>; Brent Fultz<sup>1</sup>; <sup>1</sup>California Institute of Technology; <sup>2</sup>Air Force Research Lab; <sup>3</sup>Oak Ridge National Lab

Inelastic neutron scattering spectra were measured from 7 to 750 K on polycrystalline MgB<sub>2</sub> and phonon density-of-states (DOS) curves were obtained. The thermal expansion was measured from 300 to 900 K using x-ray diffraction. First-principles calculations were conducted to study the phonon DOS curves and thermal expansion behavior in the quasi-harmonic approximation. The electronic DOS shows a peak at the Fermi level composed predominantly of in-plane boron hybridized states. These states couple strongly to the E<sub>2g</sub> phonon modes. Quantitative agreement was found between experiment and the quasi-harmonic simulations, suggesting a small role for anharmonicity in most modes. Nevertheless, the modes in the energy range from 60 to 75 meV, which include the E<sub>2g</sub> modes along the  $\Gamma$ -A direction, have different temperature dependence. This anomaly could be caused by the adiabatic electron-phonon interaction, which induces a broadening of sharp features in the electronic DOS and can alter the electronic screening behavior.

#### 10:40 AM Invited

**Phonon Studies with Inelastic Neutron Scattering and First-Principles Simulations:** *Olivier Delaire*<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

Inelastic neutron scattering is the preferred technique to measure phonons in materials, with recent advances allowing to fully map out the four-dimensional scattering function S(Q,E) for microscopic dynamics. First-principles calculations of the electronic structure and phonons have also reached a high level of accuracy, allowing for a powerful comparison with experiments. Studies combining these experimental and computational techniques will be presented. In particular, we have identified that the adiabatic coupling of phonons and electronic structure at high temperature significantly affects the thermodynamics in several classes of materials. This effect was investigated in details with temperature-dependent phonon measurements on powders and single-crystals, and with ab-initio molecular dynamics. We also present results on thermoelectric materials, where phonons are important to understand thermal transport, which directly relates to the thermoelectric efficiency. Work was partially supported by the US DOE, Basic Energy Sciences, as part of an Energy Frontier Research Center, DE-SC0001299.

## 11:10 AM Invited

**Phonon Thermodynamics of Binary Fe Alloys:** *Matthew Lucas*<sup>1</sup>; <sup>1</sup>Air Force Research Laboratory

The phonon density of states gives insight into interatomic forces and provides the vibrational entropy, making it a key thermodynamic function for understanding alloy phase transformations. The significance of phonon thermodynamics is discussed in the context of recent measurements on binary alloys of Fe with Al, Co, Cr, and V. For equiatomic B2 ordered FeAl, the vibrational entropy of vacancy formation counteracts the corresponding change in configurational entropy, destabilizing vacancies at higher temperatures. Changes in the phonon spectrum upon ordering in equiatomic FeCo are accurately captured using the cluster inversion method for measurements on random solid solutions. For FeCr alloys, the positive vibrational entropy of mixing helps to stabilize the random solid solution with respect to the unmixed phase. The change in vibrational entropy upon ordering for equiatomic FeV is found to be positive, which is consistent with recent calculations of the phonon density of states.

## 11:40 AM

**The Temperature Dependence of Phonons in Scandium Fluoride, a Material with Large Negative Thermal Expansion:** *Chen Li*<sup>1</sup>; *Xiaoli Tang*<sup>1</sup>; *Jorge Munoz*<sup>1</sup>; *Brandon Keith*<sup>1</sup>; *Doug Abernathy*<sup>2</sup>; *Sally Tracy*<sup>1</sup>; *Benjamin Greve*<sup>3</sup>; *Angus Wilkinson*<sup>3</sup>; *Brent Fultz*<sup>1</sup>; <sup>1</sup>California Institute of Technology; <sup>2</sup>Oak Ridge National Laboratory; <sup>3</sup>Georgia Institute of Technology

It has recently been discovered that cubic scandium tri-fluoride has a negative thermal expansion as large as  $1 \times 10^{-5}/\text{K}$  over a temperature range of 100 to 700 K. Inelastic neutron scattering experiments were performed to study the temperature-dependent lattice dynamics of  $\text{ScF}_3$  from 7 to 750 K. The measured phonon densities of states (DOS) shows a large non-harmonic behavior in the same range of temperature as the negative thermal expansion. Calculations of phonons with first-principles methods identified the individual modes in the DOS, indicating that the correlated rocking of the structural octahedra reduces the lattice parameter while preserving the cubic structure symmetry. First-principles molecular dynamics simulations showed that large thermal excursions of F atoms cause their neighboring Sc atoms to be drawn together with increasing temperature.

## David Pope Honorary Symposium on Fundamentals of Deformation and Fracture of Advanced Metallic Materials: Intermetallics III, Superalloys, and Gum Metal

## 8:30 AM Invited

**Stability and Structure of Transition Metal C14/C15 Laves Phases:** *Masao Takeyama*<sup>1</sup>; *Shigehiro Ishikawa*<sup>2</sup>; <sup>1</sup>Tokyo Institute of Technology; <sup>2</sup>Former graduate student (Currently Sumitomo Metal Co.)

Phase stability and crystal structure change between hexagonal C14 and cubic C15 Laves phases at elevated temperatures has been examined along the pseudo-binary lines of  $\text{A}_2\text{B}-\text{C}_2\text{B}$  and  $\text{A}_2\text{B}-\text{A}_2\text{C}$  in Fe-Nb-M and Co-Nb-Cr ternary systems (M: transition metals). In C14-C14 combinations, a continuous solid solution is formed between the two Laves phases in any

system. In C14-C15 combinations, the C14 phase region becomes enlarged extensively toward the counterpart, whereas the C15 region is limited to the binary edge. In C15-C15 combinations, however, the Laves phase region is limited to its binary edge and a large C14 region appears in between. These results suggest that C14 structure is thermodynamically more stable than C15 structure. The higher stability of C14 structure is associated with interaction energy among sublattices. The details will be discussed in terms of the site occupation of M and structure change of the tetrahedral unit in their crystal structures.

## 9:00 AM Invited

**Resemblance and Difference in Mechanical Properties between  $\text{L}_{12}$  and  $\text{E}_2$  Type Ordered Crystal Structures:** *Yoshisato Kimura*<sup>1</sup>; <sup>1</sup>Tokyo Institute of Technology

The ordered crystal structure of  $\text{E}_2$  can be regarded as ternary  $\text{L}_{12}$  stabilized by an interstitial carbon at the cell center. Objective of the present work, aiming at the heat resistant alloy design, is to understand mechanical properties of  $\text{E}_2$   $\text{M}_3\text{AlC}_{1-x}$  (M=Fe, Co, Ni) compounds from the viewpoint of resemblance and difference between  $\text{L}_{12}$  and  $\text{E}_2$  type ordered crystal structures. Single crystals of  $\text{M}_3\text{AlC}_{1-x}$  were prepared by directional solidification using optical floating zone melting and their mechanical properties were evaluated by compression tests. The operative slip systems of  $\text{E}_2$   $\text{Ni}_3\text{AlC}_{1-x}$  are the same as  $\text{L}_{12}$   $\text{Ni}_3\text{Al}$ ; octahedral slip at lower temperatures and cube slip at higher temperatures than 1073 K. Only cube slip operates in  $\text{Fe}_3\text{AlC}_{1-x}$  above 1073 K, while octahedral slip operates in a wide temperature range from 77 to 1373 K in  $\text{Co}_3\text{AlC}_{1-x}$  in which the extra ordering of carbon atoms plays quite important role.

## 9:30 AM Invited

**Microstructure Evolution and Solubility Change of Constituent Phases in Mo-Si-B Based Alloys at 1800 Degree C:** *Kyosuke Yoshimi*<sup>1</sup>; *Seong-Ho Ha*<sup>1</sup>; *Kouichi Maruyama*<sup>1</sup>; <sup>1</sup>Tohoku University

Microstructure evolution of as-cast Mo-rich Mo-Si-B alloys at 1800 degree C was experimentally investigated with referring some projection diagrams of the liquidus surfaces and some equilibrium phase diagrams of the alloys. As-cast microstructures of the alloys were drastically changed by heat treatment at 1800 degree C for 24 h, and thermally stable microstructures were developed during the heat treatment. For example, Mo2B crystallized out during solidification as the primary or secondary phase along with their solidification paths even though the alloy composition lied in the triangle of Mo-Mo3Si-Mo5SiB2. However, the unstable Mo2B was completely decomposed during the heat treatment and contributed to develop uniform, fine microstructures. The compositions of constituent phases after the heat treatment were carefully analyzed by EPMA with some Mo-Si-B alloy standards, and an equilibrium phase diagram in the Mo-rich side of the Mo-Si-B ternary system at 1800 degree C was established.

## 10:00 AM Break

**Overview of Creep Deformation of Nickel Base Superalloys and Intermetallics:** *Dilip Shah*<sup>1</sup>; <sup>1</sup>Pratt & Whitney

In comparison to tensile properties determined at high strain rate, diffusion controlled creep deformation is a far more complex process. The primary focus of the development of high temperature materials has been improvement in creep resistance. Creep deformation is not only a measure of temperature capability of the material but also affects other low strain rate deformation such as dwell fatigue and thermal-mechanical fatigue. This presentation provides an overview of creep deformation of nickel base superalloys and intermetallics. It will touch upon a variety of phenomena, such as primary creep, influence of crystal orientation, effects of alloying additions, role of phase instability, ordering, two phase structure and heat treatments. Also, the time has come to pay more attention to artifacts of load controlled creep testing of anisotropic single crystal alloys and to environmental interactions, even for nominal laboratory conditions.

10:45 AM

**Localized Shear Deformation in Gum Metal at Ideal Strength:** *Shigeru Kuramoto*<sup>1</sup>; *Tadahiko Furuta*<sup>1</sup>; *Naoyuki Nagasako*<sup>1</sup>; *John Morris*<sup>2</sup>; <sup>1</sup>Toyota Central R&D Labs., Inc.; <sup>2</sup>University of California, Berkeley

Experimental results on localized shear deformation in a multifunctional Ti-36Nb-2Ta-3Zr-0.3O alloy (mass%), Gum Metal, are summarized and the mechanism for the shear deformation is considered in relation to elastic softening in C11- C12. Very small value of C11- C12 in the alloy means sufficiently low Peierls stress required for dislocation motion. However, actual deformation strength of the alloy is much higher; resolved shear stress in nanopillars of the alloy has been reported to approach its ideal shear strength during compression test. Results of microstructural analyses in various size scales performed so far support that the key basic process of plastic deformation would be localized shear deformation accompanied by inhomogeneous crystal lattice rotation. The actual shear deformation stress at ideal strength along with elastic softening in the alloy implies that the localized shear deformation involves anisotropic shear melting process by local stress increase in specific crystal lattice orientation.

11:00 AM

**Microstructural Characterization and Deformation Behavior of Ideal Strength Metallic Materials:** *Tadahiko Furuta*<sup>1</sup>; *Shigeru Kuramoto*<sup>1</sup>; *Kaveh Edalati*<sup>2</sup>; *Zenji Horita*<sup>2</sup>; <sup>1</sup>Toyota Central R & D Labs., Inc.; <sup>2</sup>Kyushu University

The plastic deformation of metallic material is based on the dislocation theory, which well explains large difference between the ideal shear strength and the practical strength. We recently found that the actual deformation stress is considered to be closer to their ideal strength in Ti-23Nb-0.7%Ta-2%Zr-1.2O (in at%) and Fe-18.1%Ni-34.9%Co-9.3%Ti alloys. They are composed of body-centered cubic crystal with lattice softening along specific orientation and have nano-sized obstacles in their microstructures, which can suppress the dislocation motion up to high strength level, possibly near ideal strength. In this study, effects of phase stability on change in microstructure during severe plastic deformation and deformation behavior in both alloys and their deformation characteristics were compared. From these experimental results, requirements for ideal strength deformation will be discussed.

11:15 AM

**Non-Planar Deformation as a Dominant Deformation Mechanism Following Low Cycle Fatigue of a Ni-Based Superalloy:** *Patrick Phillips*<sup>1</sup>; *Libor Kovarik*<sup>2</sup>; *Raymond Unocic*<sup>3</sup>; *Dan Wei*<sup>4</sup>; *David Mourer*<sup>4</sup>; *Michael Mills*<sup>1</sup>; <sup>1</sup>Ohio State University; <sup>2</sup>PNNL; <sup>3</sup>ORNL; <sup>4</sup>GE Aviation

Many materials demonstrate strictly planar deformation during low cycle fatigue (LCF), which often takes the form of persistent slip bands. In the general case of Ni-based superalloys, these slip bands consist of paired dislocations traveling on {111} planes. However, extensive electron microscopy characterization has revealed non-planar deformation to be a dominant mode in polycrystalline R104, resulting from ample cross-slipping processes between {111} and {100} planes. Somewhat unexpectedly, this mechanism appears at both low and high temperatures, although the macroscopic material response is quite different. In addition to temperature effects, any deformation dependencies on grain orientation or cycle number will be discussed. Preliminary results comparing dwell fatigue deformation mechanisms to those observed during LCF will also be presented.

11:30 AM

**Investigation of Fatigue Crack Growth Mechanisms in a Ni-Based Superalloy:** *Clarissa Yablinsky*<sup>1</sup>; *Katharine Flores*<sup>1</sup>; *Michael Mills*<sup>1</sup>; *James Williams*<sup>1</sup>; <sup>1</sup>The Ohio State University

Historically, the critical design parameter for Ni-based superalloy turbine blades has been creep resistance. With modern airfoil designs and longer service times, fatigue resistance can also be a limiting factor. In this study, compact tension specimens of monocrystalline Ni-based superalloy René N5 were tested under cyclic loading conditions. Test temperature, environment, frequency, and orientation were varied in order to examine the effects of plastic zone size, recovery, and other time dependant processes on crack

growth. Fracture surfaces and microstructures were characterized using a high resolution scanning electron microscope in order to examine crack path selection, fracture topography, and the  $\gamma/\gamma'$  morphology along the crack wake and in the bulk material. Dislocation arrangements were characterized via transmission electron microscopy using site-specific foils prepared by focused ion beam techniques in order to understand the damage mechanisms active during fatigue crack growth.

11:45 AM

**Fatigue Life Modeling of Single Crystal Nickel-Base Superalloys:** *Clinique L. Brundidge*<sup>1</sup>; *Tresa M. Pollock*<sup>2</sup>; <sup>1</sup>University of Michigan; <sup>2</sup>University of California, Santa Barbara

Factors influencing the fatigue life of a single crystal nickel-base superalloy tested at 538/176C have been examined. The role of cooling rates during solidification has been investigated with the use of a liquid metal cooling (LMC) directional solidification process in comparison to a conventional Bridgman technique. Increases in cooling rates during solidification significantly decrease primary and secondary dendrite arm spacings as well as decrease the size of solidification shrinkage pores. Increases in cooling rates improve the fatigue life by as much as a factor of seven. Fatigue cracks originate from casting porosity, where the size of the largest pores in the samples scales with the secondary dendrite arm spacings. The development of a microstructure-based model to quantify the total life of single-crystals will be discussed.

12:00 PM

**The Effect of Temperature on the Microstructure and Mechanical Behavior of Two-Phase Fe<sub>30</sub>Ni<sub>20</sub>Mn<sub>20</sub>Al<sub>30</sub> Alloy:** *Xiaolan Wu*<sup>1</sup>; *Ian Baker*<sup>1</sup>; <sup>1</sup>Thayer School of Engineering, Dartmouth College

This paper describes the microstructures and mechanical properties of Fe<sub>30</sub>Ni<sub>20</sub>Mn<sub>20</sub>Al<sub>30</sub> at elevated temperatures. Both post-mortem and in-situ heating transmission electron microscopy (TEM) accompanied by energy dispersive X-ray spectroscopy were used to characterize the microstructures. At temperatures less than 723 K, the alloy Fe<sub>30</sub>Ni<sub>20</sub>Mn<sub>20</sub>Al<sub>30</sub> consisted of alternating Fe- and Mn-rich B2-ordered, and Ni- and Al-rich L<sub>2</sub><sub>1</sub>-ordered phases aligned along  $\langle 100 \rangle$ , which probably formed by spinodal decomposition. At  $\sim 723$  K, the L<sub>2</sub><sub>1</sub>-ordered Ni- and Al-rich phase started to disorder to a B2 structure. At  $\sim 773$  K only two B2 phases were present. Compression tests performed at temperatures up to 873 K at a strain rate of  $5 \times 10^{-4} \text{ s}^{-1}$  showed a brittle-to-ductile transition and a large drop in yield strength at  $\sim 773$  K, which was coincident with the L<sub>2</sub><sub>1</sub> to B2 temperature. Also, the deformation mechanism both at room temperature and at  $\sim 773$  K will be discussed in the paper.

## Deformation, Damage, and Fracture of Light Metals and Alloys: Session I

*Sponsored by:* The Minerals, Metals and Materials Society, MS&T Organization, TMS Light Metals Division, TMS: Chemistry and Physics of Materials Committee, TMS/ASM: Mechanical Behavior of Materials Committee

*Program Organizers:* Qizhen Li, University of Nevada, Reno; Xun-Li Wang, Oak Ridge National Laboratory; Yanyao Jiang, University of Nevada, Reno

8:30 AM Invited

**Modeling Dislocation Slip Transmission across Alpha-Beta Interface in Ti-Alloy:** *Chen Shen*<sup>1</sup>; *Ju Li*<sup>2</sup>; *Yunzhi Wang*<sup>3</sup>; <sup>1</sup>GE; <sup>2</sup>University of Pennsylvania; <sup>3</sup>Ohio State University

We apply 3D microscopic phase field model to study dislocation transmission across alpha-beta interfaces with residual interfacial dislocations in Ti-alloys. The model employs complex alloy energetics directly from ab

TUESDAY AM

initio calculations, circumventing the need for fitting atomistic potential. We first compute the generalized stacking fault (GSF) energy surface of HCP (alpha) and BCC (beta) Ti. After matching the two GSFs at the alpha-beta interface with Burgers orientation relationship, we perform microscopic phase field simulations. These simulations have been previously checked against the Peierls model calculations and have been shown to agree with the Peierls model results completely. The new calculations in alpha-beta-alpha sandwich configurations reveal intricate dislocation pileup, transmission, storage and reaction mechanisms similar to what have been seen in atomistic simulations and experimental characterizations. A coarse-grained dislocation density based description coupled to continuum elasticity could be developed to predict the overall interface-strengthening behavior of the alloys.

#### 9:00 AM Invited

##### **Deformation and Fracture of Nanostructured fcc Materials under Monotonic and Cyclic Loading:** *Diana Farkas*<sup>1</sup>; <sup>1</sup>Virginia Tech

We present simulations using embedded atom method (EAM) potentials that investigate the deformation, fracture and fatigue behavior in nanocrystalline fcc materials. The simulations include deformation studies where strain localization and sustained emission of dislocations from the grain boundaries are shown to lead to crack initiation. Cracks nucleate preferentially in weak grain boundaries that are perpendicular to the loading direction. The simulation results also revealed a particular nanoscale mechanism of crack propagation as the main crack links with nano-voids nucleated ahead of the crack tip. Depending on the particular orientation relationships, cracks can also be stopped by grain boundaries. Under applied cyclic loading and show particular mechanisms of crack advance related to damage accumulation.

#### 9:30 AM

##### **Using Ab Initio Calculations in Designing BCC MgLi-X Alloys for Ultra-Lightweight Applications:** *Martin Friak*<sup>1</sup>; William Counts<sup>2</sup>; Dierk Raabe<sup>1</sup>; Joerg Neugebauer<sup>1</sup>; <sup>1</sup>Max Planck Institute for Iron Research

Body-center-cubic Mg-Li-based alloys are a promising light-weight structural material. In order to tailor the Mg-Li composition with respect to specific industrial requirements, systematic materials-design concepts need to be developed and applied. We have therefore performed a quantum-mechanical study of fundamental physical properties of bcc MgLi-X substitutional ternaries with solutes from the 3rd row (Na, Al, Si, P, S, Cl) and 4th row transition metal (Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn) elements. The computed properties are used to determine engineering parameters such as (i) specific Young's modulus or (ii) bulk over shear modulus ratio (B/G) differentiating between brittle and ductile behavior. Analyzing these extensive and systematic ab initio data sets we derive chemical trends and explain why none is able to simultaneously improve both specific Young's modulus and ductility (see Counts et al., *Acta Materialia*, vol. 57, 69 (2009)).

#### 9:45 AM

##### **The Effect of Crystallographic Orientation on Void Growth: A Molecular Dynamics Study:** *Mehul Bhatia*<sup>1</sup>; *Kiran Solanki*<sup>1</sup>; *Amitava Moitra*<sup>1</sup>; *Mark Tschopp*<sup>1</sup>; <sup>1</sup>Mississippi State University

In ductile materials, fracture involves void nucleation, growth and coalescence. The objective of this research is to understand how crystallographic orientation influences void growth in Al for uniaxial tensile deformation. Molecular Dynamics simulation with Cubical specimens having periodic boundary condition were provided with one embedded spherical void and were subjected to remote uniaxial tension of different crystal orientation. The simulation results show how crystallographic orientation affects the yield stress and void growth corresponding to dislocation nucleation from surface of the void resulting in shear loops in perfect FCC lattice. The effect of crystallographic orientation was evident as very different dislocation patterns/shear loops occurred in the specimen with different orientations. The significance of this research is that atomistic simulations of this type can help to inform continuum void growth models for multiscale models.

#### 10:15 AM Invited

##### **Creep Deformation of Al-Sc-X Alloys:** *Matthew Krug*<sup>1</sup>; *David Seidman*<sup>1</sup>; *David Dunand*<sup>1</sup>; <sup>1</sup>Northwestern University

Three alloys (Al-0.12Sc, Al-2.9Li-0.11Sc, and Al-5.53Li-0.048Sc-0.0092Yb, at.%) were aged at 325°C to produce coherent, misfitting L12 Al<sub>3</sub>[Sc(Li,Yb)] nano-precipitates that are coarsening resistant. Compared to Al-0.12Sc, Al-2.9Li-0.11Sc has higher peak-strength, and the time to onset of over-aging is delayed from 24 to 96 h. The aged alloys were crept at 300°C in compression, over minimum steady-state strain rates between 10<sup>-9</sup> and 10<sup>-4</sup> s<sup>-1</sup>. The alloys exhibit high apparent stress exponents (n=14–33), indicative of threshold stress behavior. Calculated threshold stresses range between 8 and 20 MPa. The threshold stress normalized by the Orowan stress increases with precipitate size and lattice parameter mismatch due to elastic strains induced in the matrix, and their interactions with dislocations. Comparisons are made with past work on similar Al-Sc-RE alloys, helping to draw conclusions about the benefits of ternary additions to creep- and coarsening-resistant Al-Sc alloys.

#### 10:45 AM Invited

##### **Impression Creep – A Localized Technique for Characterizing Creep Deformation of Materials:** *Fuqian Yang*<sup>1</sup>; <sup>1</sup>University of Kentucky

The impression test using a flat-ended indenter has been developed to study the time-dependent plastic deformation of materials. In contrast to the sharp-instrumented indentation, the contact area remains constant during the impression allowing a constant average contact stress when subjected to constant loads. Steady-state creep of various materials has been observed. The impression creep tests of a precipitation hardenable Mg-8Zn-4Al-0.5Ca (wt.%) casting alloy were performed in the temperature range of 403–623 K and under the punching stress range of 1.68–60.4 MPa. Using a hyperbolic sine stress law between the steady-state impression velocity and the punching stress, a single activation energy was found to be 77.5 kJ/mol, which is about half of the activation energy for lattice diffusion in Mg. A single mechanism of grain boundary fluid flow was proposed to be the controlling mechanism for the creep behavior of the Mg-8Zn-4Al-0.5Ca alloy under the testing conditions.

#### 11:15 AM

##### **Creep Fatigue Behavior of 319 Aluminum Casting Alloys under Hot Compressive Dwell Conditions:** *Xiang Chen*<sup>1</sup>; *Diana Lados*<sup>1</sup>; *Richard Pettit*<sup>2</sup>; <sup>1</sup>Worcester Polytechnic Institute; <sup>2</sup>FractureLab

Fatigue crack growth under Hot Compressive Dwell (HCD) conditions is an important failure mode for many high temperature applications, such as cylinder heads for internal combustion engines. A new testing methodology was developed to study the creep mechanism that accelerates the growth of cracks loaded with a compressive dwell cycle. Tensile residual stress build up at the crack root is considered a key factor contributing to crack growth under HCD conditions. To evaluate this effect quantitatively, stress relaxation and crack growth tests were performed to determine the creep and crack growth responses of the material. A Blunt Compact Tension (BCT) specimen was then analyzed using FRANC2D to determine the stress distribution, and obtain a 2D weight function K-solution. The residual stress distribution is then applied via the weight function to determine residual K that builds up during the operating life of the part. These results will be presented and discussed.

#### 11:30 AM

##### **Room Temperature Creep and Substructure Formation in Pure Aluminum at Ultra-Low Strain Rates:** *Junjie Shen*<sup>1</sup>; *Iketa Ken-ichi*<sup>1</sup>; *Hata Satoshi*<sup>1</sup>; *Nakashima Hideharu*<sup>1</sup>; <sup>1</sup>Kyushu University

The creep behavior in highly pure aluminum (5N) and industrial pure aluminum (1070) with different grain sizes has been investigated by helicoid spring creep tests at ultra-low strain rates lower than 10<sup>-9</sup>s<sup>-1</sup> and room temperature. Obtained results show that different types of deformation mechanisms are closely related with grain sizes and impurity concentrations: when the average grain size was 24 μm, the stress exponent, n ~ 1. The

dominant deformation mechanism was considered to be grain boundary sliding; on the other hand when the average grain size was 1.6 mm, the stress exponent,  $n \sim 5$ , which was interpreted as dislocation creep. Microstructural observation shows dislocation tangle, cell formation; in an industrial pure aluminum with grain size of 25  $\mu\text{m}$ , the stress exponent,  $n = 2$ . Microstructure observations revealed dislocation emission from grain boundary acts as main deformation mechanism and intergranular dislocations tangle, cell formation as coordination mechanism.

**11:45 AM**

**Quantifying the Relationship Between Deformation-Induced Surface Roughness, Grain Orientation, and Strain Localization in Polycrystalline Aluminum:** *Mark Stouder*<sup>1</sup>; Joseph Hubbard<sup>1</sup>; Adam Creuziger<sup>1</sup>; Lyle Levine<sup>1</sup>; <sup>1</sup>National Institute of Standards and Technology

Since bulk plastic deformation in polycrystalline materials is strongly dependent on the character of the individual grains, careful examinations of surface morphology and grain orientations with strain can reveal considerable information about the active deformation mechanisms and directly quantify the morphological conditions that promote strain localization. High-resolution topographical analyses, performed *in-situ* on aluminum sheet that was incrementally strained in uniaxial tension, were used to construct maps of the localization potential as a function of strain. These maps were integrated with EBSD measurements of the initial grain orientations to yield a grain-by-grain assessment of the microstructural conditions required to produce the critical surface morphology. The results suggest the relationship between grain orientation and strain localization depends on multiple factors such as grain misorientation and Taylor factors. The methodologies used, and details regarding the nature of the relationships between strain, microstructure, and surface morphology shall be presented and discussed.

**Dynamic Necking of Structures Submitted to High Strain Rate Loadings:** *Alain Molinari*<sup>1</sup>; Sébastien Mercier<sup>1</sup>; <sup>1</sup>Université Paul Verlaine-Metz

The fragmentation of structures has received a large attention during the last decades. A large effort was recently made to understand the behavior of structures subjected to an intense blast. To ensure integrity of structures, the conditions for the onset of fragmentation as well as for delaying the occurrence of such phenomenon have to be understood. Experiments conducted on rings and cylinders under rapid expansion have shown that the ductility of materials and the fragmentation process are significantly affected by the loading rate. Our scope is to describe by theoretical means the process of multiple necking that leads to the failure of structural elements under dynamic loading (bars, plates, cylinders, rings and hemispherical shells). The effects of material parameters, material inertia, loading conditions and sample geometry are analysed by means of a linearized stability analysis. Results are compared to experimental data.

**9:00 AM**

**3-D Modelling of Local and Global Spall Damage in Shocked FCC Multicrystals:** *Kapil Krishnan*<sup>1</sup>; Leda Wayne<sup>1</sup>; Andrew Brown<sup>1</sup>; Pedro Peralta<sup>1</sup>; Shengnian Luo<sup>2</sup>; Darrin Byler<sup>2</sup>; Aaron Koskelo<sup>2</sup>; <sup>1</sup>Arizona State University; <sup>2</sup>Los Alamos National Laboratory

3-D finite element (FE) simulations were used to study effects of microstructure, e.g., grain boundaries (GBs), on spall damage in copper multicrystals. Laser-driven plate impact experiments were conducted at low pressures (2-6 GPa) to capture spall damage at the nucleation stage. The 3-D FE model was developed from serial sectioning of the tested samples. Analysis was performed with ABAQUS/EXPLICIT using anisotropic elasticity and the Steinberg-Guinan (SG) model, where plastic anisotropy was modeled using Hill's anisotropic yield criterion. A damage model based on a cut-off tensile pressure was incorporated for element removal to study interactions between release waves and existing voids. The global damage appeared at the expected spall plane and the difference between target and flyer diameters led to release waves from the corner of the flyer that localized damage zone towards this region. Locally, damage localized near GBs. The FE results were compared with the experimental observations.

**9:20 AM**

**Examination of the Damage and Failure Response of Tantalum and Copper under Varied Shock Loading Conditions:** Ellen Cerrata<sup>1</sup>; Darcie Dennis-Koller<sup>1</sup>; Neil Bourne<sup>1</sup>; George Gray<sup>1</sup>; *Curt Bronkhorst*<sup>1</sup>; Davis Tonks<sup>1</sup>; Irene Beyerlein<sup>1</sup>; Benjamin Hansen<sup>1</sup>; Ricardo Lebensohn<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

A number of plate impact experiments have been conducted on high purity polycrystalline tantalum and copper samples using graded flyer plate configurations to alter the loading profile. These experiments are designed in a way so that a broad range of damage regimes are probed. The results show that the nucleation of damage primarily occurs at the grain boundaries of the materials. This affords us the opportunity to propose a porosity damage nucleation criterion which begins to account for the length scales of the microstructure (grain size distribution) and the mechanical response of the grain boundary regions (failure stress distribution). This is done in the context of a G-T-N type model for the ductile damage and failure response of both the materials examined. The role of micro-inertial effects on the porosity growth process is also considered.

**9:40 AM**

**Geometric and Microstructural 3-D Characteristics of Incipient Spall Damage in Shock Loaded Cu Multicrystals and Polycrystals:** *Andrew Brown*<sup>1</sup>; Leda Wayne<sup>1</sup>; Kapil Krishnan<sup>1</sup>; Pedro Peralta<sup>1</sup>; Shengnian Luo<sup>2</sup>; Scott Greenfield<sup>2</sup>; Darrin Byler<sup>2</sup>; Kenneth McClellan<sup>2</sup>; Aaron Koskelo<sup>2</sup>; <sup>1</sup>Arizona State University; <sup>2</sup>Los Alamos National Laboratory

Spall-induced void structures were analyzed in shock loaded copper samples to determine void size, shape, and spacing distributions. Copper samples (1000  $\mu\text{m}$  thick) were impacted by laser-driven flyer plates (500  $\mu\text{m}$  thick) at low pressures (2-6 GPa) to encourage incipient spall damage. Serial sectioning and Electron Backscattering Diffraction (EBSD), along with in-plane and through-thickness optical microscopy, were used to create 3-D renditions of the voids and their surrounding microstructure to characterize and compare their local and global geometrical and crystallographic characteristics. Analysis of regions of localized damage indicates that grain boundaries with misorientations between 30° and 50° are preferred sites for intergranular voids, which were typically shaped as sheets following the boundaries. Damage on the spall plane contained a spatial distribution of pores that was statistically uniform, indicating 1-D conditions. Effects of pre-existing plastic deformation on damage sites were also studied using half-hard and annealed samples with similar grain size.

TUESDAY AM

## 10:00 AM

**Instrumented Ring Expansion for the Measurement of High Strain Rate Constitutive and Fracture Behavior:** *Jason Johnson*<sup>1</sup>; Geoff Taber<sup>1</sup>; Gregg Fenton<sup>2</sup>; Glenn Daehn<sup>1</sup>; <sup>1</sup>Ohio State University; <sup>2</sup>Applied Research Associates

The study and development of high strain rate constitutive models is pertinent to several fields, yet the test methods utilized to probe this high strain-rate realm are limited in both number and standardization. New technologies have been leveraged to revive an old, under-utilized test method – the axisymmetric expanding ring. The combination of Photon Doppler Velocimetry (PDV) and one of several ring launch techniques allows the successful testing and instrumentation of samples loaded in tension without wave effects at strain rates in excess of 104 s<sup>-1</sup>. Design and construction of the embodiment of this test at OSU. Examples of expanding low ductility, modest conductivity metal (hardened steel) and a high conductivity, high ductility material will be discussed in depth. In the former case concurrent numerically modeling of the problem is necessary for accurate constitutive modeling, while simpler methods are acceptable in the latter case.

## 10:20 AM Break

## 10:30 AM Invited

**The Dependence of Dynamic Spall Strength on Flow Stress and Temperature:** *Roger Minich*<sup>1</sup>; <sup>1</sup>LLNL

A statistical void nucleation and growth model is presented that relates the dependence of dynamic spall strength on flow stress and temperature. The model is incorporated in a finite element code and compared to a wide range of plate impact experiments. The model successfully predicts the pressure dependence of the spall strength and emphasizes the role of stress fluctuations in determining the size distribution of nucleated voids. It also predicts the observation that the spall strength for two different microstructures are comparable when the corresponding flow stresses are comparable. Also, the temperature dependence of the dynamic spall strength is shown to be consistent with data for temperatures even approaching melt.

## 11:00 AM

**Laser-Shock Induced Spalling and Fragmentation in Vanadium:** *Marc Meyers*<sup>1</sup>; H. Jarmakani<sup>1</sup>; B. Maddox<sup>2</sup>; C. T. Wei<sup>1</sup>; D. Kalantar<sup>2</sup>; <sup>1</sup>University of California, San Diego; <sup>2</sup>Lawrence Livermore National Laboratory

Polycrystalline and monocrystalline vanadium was subjected to shock compression followed by tensile wave release to study spall and fragmentation behavior. The shock pulse was generated by a direct laser drive at energy levels ranging from 11 and 440 J/mm<sup>2</sup> and initial pulse durations of 3 and 8 ns (approximate initial pressures between 10 and 250 GPa). The effects of target thickness, laser energy, polycrystallinity, and pulse duration were studied. Calculations show melting at a pressure threshold of ~150 GPa. Consistent with the analytical predictions, the recovered specimens and fragments show evidence of melting at the higher energy levels. Spalling in the polycrystals occurred by a ductile tearing mechanism that favored grain boundaries. In the monocrystals, it occurred by a mixture of cleavage fracture along {010} planes and ductile dimple fracture. This lower spall strength in polycrystals contradicts predictions from the Hall-Petch equation. Experimentally obtained fragment sizes were compared with predictions from the Grady-Kipp model. The spall strength of vanadium under laser loading conditions was calculated from both VISAR pullback signals and using the spall thickness and found to be considerably higher than predictions from gas-gun experiments. This higher spall strength is suggestive of a strong time dependence of the phenomenon, consistent with the nucleation and growth kinetics of voids and the strain-rate sensitivity embedded in the Grady theory.

## 11:20 AM

**Micro-CT for the Quantification of 3D Voids within Damaged Structures:** *Brian Patterson*<sup>1</sup>; Christopher Hamilton<sup>1</sup>; Ellen Cerreta<sup>1</sup>; Darcie Dennis-Koller<sup>1</sup>; Curt Bronkhorst<sup>1</sup>; Benjamin Hansen<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

Micro X-ray Computed Tomography (MXCT) is widely used in the materials community to examine the internal structure of materials for voids and cracks due to damage or casting, or other defects. Most research in this area focuses on the qualitative aspect of the image, simply answering: Are there voids present? Here we present an ongoing study of the quantified incipient spall voids in Cu with different grain sizes, using a gas gun with various velocities. Data analysis packages for MXCT are just now becoming able to dimensionally measure and produce statistics on the voids present. In order to make the size of the features in the 3D image quantifiable, the question, how many radiographs are required to render the object dimensionally accurate in 3D, must be answered. A series of data sets has been collected, varying the number of radiographs collected in order to determine the appropriate number required.

## 11:40 AM

**Shock-Induced Spallation Phenomena in Copper-Niobium Nanolayered Composites:** *Niraj Gupta*<sup>1</sup>; Alexander Stukowski<sup>2</sup>; Michael Baskes<sup>3</sup>; Srinivasan Srivilliputhur<sup>1</sup>; <sup>1</sup>University of North Texas; <sup>2</sup>Darmstadt University of Technology; <sup>3</sup>Los Alamos National Laboratory

Shock-induced spallation phenomena in Copper-Niobium nanolayered composites conforming to a Kurdjumov-Sach's orientation relation were simulated using molecular dynamics to determine both spallation strength and the nature of void formation. The copper and niobium system is of interest due to its immiscible nature and the orientational relation of the two lattices which creates an interface acting as an effective sink for dislocations and vacancies. The target structures consisted of varying numbers of alternating copper and niobium layers with thicknesses varying from 1 nm to 22 nm. Flyer velocities ranged from 3.5 to 11.5 Å/ps, corresponding to an approximate strain rate of 10<sup>9</sup> /s. Spallation occurs in the vicinity of the Cu-Nb interface, and always in the copper layer. The proposed factors contributing to spallation will be discussed, as well as what effect the layer morphology has on the strength of the target.

## 12:00 PM

**Materials Characterization of Railgun Erosion Phenomena:** *Brenda Machado*<sup>1</sup>; Lawrence Murr<sup>1</sup>; Edwin Martinez<sup>1</sup>; Sara Gaytan<sup>1</sup>; Sikhanda Satapathy<sup>2</sup>; <sup>1</sup>University of Texas at El Paso; <sup>2</sup>The University of Texas at Austin

Railguns, consisting of a Cu rail-stator system with a moving Al projectile armature, are able to launch large, light-weight (usually Al) projectiles hundreds of miles using a high current pulse creating a comparably large magnetic field. Rail erosion has been a limiting feature. In this research, we have examined the Cu rail surface erosion and mixing of rail and Al projectile debris using optical metallography and scanning electron microscopy. The observations illustrate a unique, elongated starting Cu rail grain structure with a high dislocation density observed by transmission electron microscopy (TEM). The rail surface debris coating exhibits a propensity of porous Al (or gas bubble structure) created by temperatures above the Al melting temperature. TEM representative of the Al/Cu interface illustrates little, if any, alloying. The Al projectile and Cu rail form a dynamically recrystallized zone where small Al and Cu grains (~20 nm diameter) allow for solid-state flow.

#### 8:35 AM

**Property Profile of Lab- Scale Anodes Produced with 180°C Mettler Coal Tar Pitch:** Winfried Boenigk<sup>1</sup>; Claudia Boltersdorf<sup>1</sup>; Falk Lindner<sup>1</sup>; Jens Stiegert<sup>1</sup>; <sup>1</sup>RÜTGERS Germany GmbH

The PAH- induced toxicity of coal tar pitch decreases with increasing softening temperature. The use of high- melting pitches is however restricted due to operational challenges. One critical limitation is high-temperature mixing. Temperatures up to 300°C were now realised using a novel developed EIRICH mixer. A 180°C Mettler binder pitch resulted in anodes having a higher baked density (+ 0.03 g/cm<sup>3</sup>). Electrical resistivity and air permeability are reduced whereas compressive strength and Young's modulus are increased. The significantly lower baking loss allows a faster carbonisation process in the low temperature range potentially increasing the throughput of baking furnaces.

#### 9:00 AM

**Quality and Process Performance of Rotary Kilns and Shaft Calciners:** Les Edwards<sup>1</sup>; <sup>1</sup>Rain CII Carbon

Rotary kilns have been used successfully for many years to produce calcined coke for the aluminium industry and they offer a high level of automation, performance and flexibility. Shaft calciners make a high bulk density, coarse particle size product and several papers have been published recently highlighting these benefits. This paper presents a detailed comparison of the merits of these two different calcining technologies from a process and product quality perspective. It addresses several misconceptions about the technologies related to operability, product quality and their ability to handle a wide range of green coke qualities. Both technologies will continue to be used in a complimentary manner in the future.

#### 9:25 AM

**Sub-Surface Carbon Dioxide Reaction in Anodes:** Donald Ziegler<sup>1</sup>; <sup>1</sup>Alcoa Primary Metals

Formation of carbon dust in electrolysis is linked to reaction of the anodes with carbon dioxide. The general understanding is that the reaction takes place inside the anodes, below the bath surface and rather more toward the sides of the anodes than the bottom. Given this, a relevant question is the relative importance of transport through the anode compared to its intrinsic reactivity. To provide quantitative answers, a transport-reaction model has been developed. The key finding is that the extent of reaction is insensitive to the permeability. This is because the reaction produces two moles of CO for every mole of CO<sub>2</sub> consumed, so that there is a net flow away from the reaction locale. Consequently, fresh reactant must be supplied by diffusion rather than convection. Since these two processes are governed by different material properties, this finding opens the possibility of new approaches to optimization of anode structure.

#### 9:50 AM

**Paste Quality Improvements at Alcoa Poços de Caldas Plant:** Beatriz Vry<sup>1</sup>; Ciro Kato<sup>1</sup>; Jeronimo Araujo<sup>1</sup>; Fabiano José Ribeiro<sup>1</sup>; André Luís Abreu<sup>1</sup>; <sup>1</sup>Alcoa

Alcoa Poços de Caldas Soderberg Carbon Plant began its operation in 1965 and after a series of upgrades including the mixer heating system upgrade in

1989, fines control in 2000, mixing temperature optimization in 2004 and installation of coke pre heaters in 2009, the plant now has twice the original production capacity with near world-class paste quality. The benchmark paste quality characteristic is 1.55 g/cc of baked apparent density (BAD), while Poços results are about 1.45 g/cc. The Paste Plant is now challenged to meet Potroom requirements for anode performance (higher loads and dry anode top technology). This paper describes the enablers chosen to improve the baked properties, which includes the optimization of fines production, mixing process and recipe. The quality management system which includes a carbon laboratory with Soderberg baking furnace, sample preparation and baked analysis (BAD, Air Permeability, CO<sub>2</sub> Reactivity and Electrical Resistivity) is also described.

**The Vertical Ball Mill for the Grinding of Calcined Petroleum Coke to Improve the Quality of the Anodes in the Aluminium Industry:** Stefan Gosau<sup>1</sup>; Andreas Wolf<sup>1</sup>; <sup>1</sup>Claudius Peters Projects GmbH

The carbon fines used in anode production have traditionally been generated using the "horizontal" ball mill concept. For carbon fines, the correct particle size distribution with low variation, and low impurity levels are required to produce high quality anodes. A new vertical ball ring mill concept has been developed based on the results of research on the grinding of calcined petroleum coke. Industrial vertical mills are now in operation in seven anode plants around the world. The benefits seen from the mill include lower capital expenditure, reduced variation in sizing and reduced wear of the mill. Results from the plants, showing reduced pitch level variation, improved anode quality and reduced operating costs will be presented in the paper.

#### 10:50 AM

**Prebaked Anode from Coal Extract (2) - Effects of the Properties of Hypercoal-Coke on the Performance of Prebaked Anodes:** Maki Hamaguchi<sup>1</sup>; Noriyuki Okuyama<sup>1</sup>; Nobuyuki Komatsu<sup>1</sup>; Jiro Koide<sup>2</sup>; Keisuke Kano<sup>2</sup>; <sup>1</sup>Kobe Steel, Ltd.; <sup>2</sup>Sumitomo Corporation

Preparation of prebaked anodes utilizing coal solvent extraction technology will be reported. We previously reported that the coal extract prepared from non-hydrogenative extraction of thermal coals using two-ring-aromatic solvent (Hyper-coal) is suitable for feedstock for anode coke. It contains very low levels of the impurities such as sulfur, sodium, nickel, and vanadium that are present in the coke normally used in anodes. In this paper, we will describe the results of detailed analyses of the Hyper-coal coke (HPCC), the effects of calcinating conditions of the Hypercoal, and the performance of prebaked anodes prepared from the HPCC.

#### 11:15 AM

**The New Generation of Vertical Shaft Calciner Technology:** Jingli Zhao<sup>1</sup>; <sup>1</sup>Jinan Aohai Carbon Products Co.,Ltd.

The vertical shaft calciner is widely applied in China for CPC calcination. Its application, however, is restricted by its lower capacity, less automation and no waste heat recuperation. A new generation of energy saving shaft calciner technology with higher capacity and power generation system has been developed recently and is illustrated in this paper. 75 kt of CPC annual production can be achieved by only one new shaft calciner, the waste heat from which can be recuperated to generate electricity of 28 million kWh. The major invention is calciner structure optimization by computer simulation for better volatile combustion and calciner heat balance, which brings about better CPC quality, higher capacity and provides more energy for power generation. The new shaft calciner technology is flexible to the size distribution and volatile content in the green coke and applicable for the pulverous coke and the coke with high volatile content.

TUESDAY AM

## Fatigue and Corrosion Damage in Metallic Materials: Fundamentals, Modeling and Prevention: Fatigue of Nanocrystalline Materials and Fatigue Property Enhancement

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Structural Materials Division

*Program Organizers:* Tongguang Zhai, University of Kentucky; Zhengdong Long, Kaiser Aluminum; Peter Liaw, University of Tennessee

Tuesday AM                      Room: 31C  
March 1, 2011                      Location: San Diego Conv. Ctr

*Session Chairs:* Peter Liaw, University of Tennessee; E-Wen Huang, National Central University

**8:30 AM**  
**Monitoring and Characterization of the Fatigue Response of Nano-Crystalline Mg Composites Reinforced with Ti2AlC:** *Antonios Kotsos<sup>1</sup>; Kavan Hazeli<sup>1</sup>; Babak Anasori<sup>1</sup>; Theodoros Loutas<sup>2</sup>; Michel Barsoum<sup>1</sup>; <sup>1</sup>Drexel University; <sup>2</sup>University of Patras*

Herein we report on the mechanical and fatigue properties of nano-crystalline Mg-matrix composites reinforced with a Ti2AlC powder, fabricated by pressureless spontaneous melt infiltration of porous Ti2AlC preforms. Careful monotonic and cyclic tensile and compression experiments, combined with continuous acoustic emission (AE) monitoring are used to obtain vital information pertinent to the initiation and evolution of deformation and damage mechanisms related to this composite. The fatigue response is shown to be excellent over an extended period of time during which the recorded and extracted AE features are noticeably different from the initial and final stages of fatigue life. These results combined with the observed high damping are consistent with, and can be explained by invoking the formation and annihilation of incipient kink bands. The latter are fully reversible dislocation-based defects consisted of parallel coaxial dislocations formed on easy slip planes of kinking non-linear elastic solids such as Ti2AlC and Mg.

**8:50 AM**  
**Effects of Ultrasonic Nanocrystal Surface Modification on Fatigue Behavior of SUS316 Austenitic Stainless Steel Tube for Stents:** *Auezhan Amanov<sup>1</sup>; Young Sik Pyun<sup>1</sup>; Jun Hyong Kim<sup>1</sup>; Hak Du Kim<sup>1</sup>; Sang Ho Kim<sup>2</sup>; Chae Jong Park<sup>2</sup>; <sup>1</sup>Sun Moon University; <sup>2</sup>M.I. Tech Co., Ltd.*

The present paper describes the effect of Ultrasonic Nanocrystal Surface Modification (UNSM) treatment on fatigue behavior of SUS316 austenitic stainless steel tube for stents which is inserted into clogged heart, superficial femoral, carotid, and renal arteries. The surface hardness, surface integrity and compressive residual stress were compared before and after UNSM treatment. The fatigue test under room temperature is under carrying out and their results will be compared before and after UNSM treatment also. In addition, the possibility of replacement the expensive Co-Cr alloy tube by the UNSM treated SUS316 tube will be analyzed.

**9:10 AM**  
**Increasing the Fatigue Life of SAE52100 Steel by Ultrasonic Nanocrystal Surface Modification:** *Jong Soon Im<sup>1</sup>; Young Sik Pyun<sup>2</sup>; Auezhan Amanov<sup>2</sup>; Sung Jae Lee<sup>1</sup>; Jun Hyong Kim<sup>2</sup>; Chang Min Suh<sup>3</sup>; <sup>1</sup>ILJIN GLOBAL; <sup>2</sup>Sun Moon University; <sup>3</sup>Kyungpook National University*

To increase the fatigue strength of slim bearing rings, the Ultrasonic Nanocrystal Surface Modification (UNSM) treatment was applied to rotary bending fatigue test specimens which are made of bearing steel SAE52100. XRD analysis shows that the structure of subsurface layer has become a nano-grain structure till 100  $\mu\text{m}$  depth from the top surface. Surface structure and nano grain refinement were analyzed and compared before and after UNSM treatment by EBSD analyses as well as fatigue crack growth behavior of UNSM-treated specimens was compared with that of original specimens

which had not been UNSM-treated. It was also revealed from the surface analyses that surface hardness was increased by 20% and compressive residual stress was also induced up to 900 MPa of the UNSM-treated surface which are the main phenomena in prolonging fatigue life of bearings. RCF and friction characteristics after UNSM treatment were also explained.

**9:30 AM**  
**Research on HCF Tests and Damage Model of TC11 Alloy Welded Joints:** *Xiaogang Liu<sup>1</sup>; Guo Hai-ding<sup>1</sup>; <sup>1</sup>Nuaa*

In the paper, the loading controlled fatigue tests of TC11 alloy welded joints have been done; the micro characteristics of fatigue fracture surface have been studied by SEM (scan electron microscope) as well. According to the test results, two types of fatigue source on fracture surface of the welds are found, say, edge fatigue source and internal fatigue source. Then S-N curve of the two types are obtained respectively. The fatigue life of the edge fatigue source is 35-65% longer than that of the internal fatigue source. Moreover, based on the gray distribution of the fracture surface's SEM images, the fractal dimension of fatigue source rejoin on fracture surface has been calculated by box counting method, the relationship between fractal dimension and fatigue life is analyzed. Finally, a fractal damage model which concern macro and micro damage is established based on the combination of damage mechanics theory and fractal theory.

**9:50 AM**  
**Residual Stresses in Alloy CF8C Plus Coated with Iron Aluminide:** *Deepak Kumar<sup>1</sup>; Sebastien Dryepondt<sup>1</sup>; Philip Maziasz<sup>1</sup>; Bruce Pint<sup>1</sup>; Beth Armstrong<sup>1</sup>; Edgar Curzio<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory*

CF8C plus is an economic, cast austenitic stainless steel that has creep resistance comparable to state-of-the-art wrought stainless steel and Ni-base alloy, such as alloy 617, but does not require any post processing heat treatments. In this paper we discuss the evolution of residual stresses when this alloy is coated with aluminide coatings applied by slurry-coating and pack cementation processes with the objective of improving its oxidation resistance. The near surface and bulk residual stresses during heating/cooling of the coated samples were determined by x-ray and neutron diffraction techniques for temperatures up to 900°C. Conventional tension-compression strain-controlled fatigue experiments were conducted on the bare and coated samples to assess the effect of residual stresses on the fatigue strength.

**10:20 AM**  
**Fatigue Behavior of Al 6082-T4 and Al 7075-T73 after Ball Burnishing:** *Yasser Ahmed<sup>1</sup>; Mansour Mhaede<sup>2</sup>; Lothar Wagner<sup>2</sup>; <sup>1</sup>German University in Cairo; <sup>2</sup>Institute of Materials Science and Engineering (IWW), TU of Clausthal*

The effect of ball burnishing on the rotating beam fatigue strength of age-hardened 6082-T4 and 7075-T73 aluminum has been investigated. Deep rolled specimens were cyclically deformed at room temperature using push-pull stress controlled fatigue and compared to the electrically polished condition as a reference. Also Shot peened condition give better results compared to electrically polish. Optimization curve was produced for both SP and BB conditions, due to this optimization shot peened with Almen intensity of 0.2 mmA for both alloys was used. For ball burnishing (deep rolling) 40 bars was used for 6082-T4 and 75 bars for 7075-T73 by deep rolling tool HG13. The observed improvements were from about 45% for Al 6082-T4 while it was the double for Al 7075-T73 compared to electrically polish, while the improvement of fatigue for BB condition compared to SP was 5% for Al 6082-T4 and 28 % for Al 7075-T73. Data analysis shows that the fatigue behavior in these alloys affected by surface treatment. It was found that deep rolling can dramatically enhance the fatigue behavior of aluminum alloys as compared to the shot peening and polished condition due to near surface compressive residual stresses as well as work hardening states and increased hardness induced by mechanical surface treatment (deep rolling).

10:40 AM

**High Temperature Fatigue Behavior of Laser Shock Peened IN718Plus Superalloy:** *Vibhor Chaswal*<sup>1</sup>; S Mannava<sup>1</sup>; Dong Qian<sup>1</sup>; Vijay Vasudevan<sup>1</sup>; Kristina Langer<sup>2</sup>; <sup>1</sup>University of Cincinnati; <sup>2</sup>Wright Patterson Air Force Base

Service temperature fatigue testing is conducted on 2.5 and 5mm thick IN718Plus aeroengine superalloy after laser shock peening(LSP) with a double side patch overlay of 2.5mm spots at 5 to 8 GW/sq.cm using pulsed Nd:glass laser. Initially thermal relaxation of through thickness compressive residual stresses is established using conventional and Synchrotron X-Ray Diffraction. High temperature(HT) fatigue tests are then conducted at R=0.1 and monitored with an HT clip-on strain gauge and AC potential drop(ACPD). Subsequent fatigue induced residual stress relaxation is determined using a dedicated XRD system and correlated with nano and micro-indentation. While conditions for crack initiation and branching are investigated using scanning electron microscopy, ACPD is used to study final fracture. Microstructural evolution of Untreated, LSP treated, LSP + Fatigued samples is characterized using optical and Transmission electron microscopy. Based on dislocation substructures and precipitate morphologies that offer highest strengthening and fatigue resistance, optimum LSP parameters are recommended.

11:00 AM

**Mechanical Properties and Four-Point-Bending Fatigue Behaviors of Non-Heat Treated and Carburized Low-Carbon Steels for Load-Chain Materials:** *Wei Wu*<sup>1</sup>; Gongyao Wang<sup>1</sup>; David Huber<sup>2</sup>; Peter Hogan<sup>2</sup>; Rodney Reynolds<sup>2</sup>; Chris Hale<sup>2</sup>; Lee Whitted<sup>2</sup>; Joe Eudy<sup>2</sup>; John Stewart<sup>2</sup>; Jules Raphael<sup>3</sup>; Doug Fielden<sup>1</sup>; Peter Liaw<sup>1</sup>; <sup>1</sup>The University of Tennessee; <sup>2</sup>Columbus McKinnon Corporation; <sup>3</sup>J R Technical Services

The low-carbon steels, 10B22, 4615, and 4720, are used in electric hoists as load-chain materials. The mechanical properties of non-heat treated and carburized low-carbon steels were investigated. Four-point-bending-fatigue tests were conducted on cylindrical specimens to examine the fatigue behaviors of non-heat treated and carburized low-carbon steels at different stress levels. The four-point-bending-fatigue tests were performed at a stress ratio of 0.1 and a frequency of 10 Hz with a sinusoidal waveform. The fatigue results showed that the fatigue-strength of the carburized 10B22 steel was the highest at the reference cycles, 10<sup>7</sup>. Scanning-electron microscopy (SEM) fractography of tensile samples demonstrates the typical ductile fracture of the non-heat treated steels at room temperature. However, the mixture of the fracture mechanisms can be seen in the carburized steels; the ductile fracture at the core and the intergranular fracture in the hard layer were observed.

11:20 AM

**Sustained Peak Low Cycle Fatigue: The Role of Coatings:** *Britta Laux*<sup>1</sup>; Tresa Pollock<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara

Turbine airfoil durability is often limited by low cycle fatigue, particularly when the cycle contains a compressive hold at elevated temperature. The initiation and growth of cracks in a single crystal superalloy have been studied during strain controlled fatigue at 1093\176C with a cycle that contained a 120s compressive hold. Samples which were fabricated from the SX nickel base superalloy Rene N5 were cycled in the uncoated condition and with aluminate coatings. All cracks initiated at sample surfaces and grew in a plane normal to the applied stress in the early stages of fatigue. Crack tips contained a layer of oxide. The growth process continued by a combined process of oxidation and creep. The role of the coating in this failure process is considered in the context of a model developed for crack growth during sustained peak low cycle fatigue.

11:40 AM

**S-N Fatigue and Fatigue Crack Propagation Behaviors of High Mn Steels:** *HyunJung Lee*<sup>1</sup>; Jackie Kwon<sup>2</sup>; Youngju Kim<sup>2</sup>; Sangshik Kim<sup>1</sup>; <sup>1</sup>Gyeong Sang National Univ.; <sup>2</sup>Korea Institute of Geoscience and Mineral Resources

The increasing concern on safety and economical issues in shipbuilding industry requires new steels with better fatigue behaviors. The efforts to increase yield strength of steel would increase S-N fatigue life, but may

decrease the resistance to fatigue crack propagation (FCP). In the present study, both S-N fatigue and FCP behaviors of high manganese steels were examined and compared to those of pearlite-ferrite and bainite steels. The S-N fatigue and FCP tests were conducted on high manganese steels, the microstructures of which were dominantly either martensitic or austenitic, at an R ratio of 0.1 and along L-T and T-L. It was found that the microstructure and yield strength affected both of fatigue behaviors of high Mn steels. Fatigue crack paths and fracture surfaces demonstrated that the crack tortuosity varied with different microstructure. The present study showed that yield strength alone could not explain the S-N fatigue behavior of steel specimens.

12:00 PM

**High Cycle Fatigue Behavior of Shot-Peened Steels:** *Alan Plumtree*<sup>1</sup>; Mehdi Mirzazadeh<sup>1</sup>; <sup>1</sup>University of Waterloo

The uniaxial fatigue behavior of four shot-peened engineering steels heat treated to the same hardness was investigated. Following long life (10<sup>7</sup>) cycling under fully reversed (R=-1) uniaxial loading conditions, cyclic softening of the surface was accompanied by a decrease in the depth of surface hardness. Neither cyclic softening nor hardening occurred in non shot-peened steels cycled under the same conditions. The greatest amount of cyclic softening occurred in the two(0.4C and 0.7C)shot-peened hot rolled steels, whereas the fatigue limit of a 0.5C powder metallurgical steel increased 14.0%. However, the fatigue limit of a shot-peened heat treated and tempered steel(0.5C) decreased 12.0% due to the relaxation of internal stresses. In general, the beneficial effects of shot-peening, such as those due to compressive residual stresses and work hardening balanced the effects of surface roughness. Crack initiation occurred below the surface.

8:30 AM

**Microstructure and Mechanical Properties of Friction Stir Welded (FSW) AA5454-Joints:** *Xavier Lang*<sup>1</sup>; Dietmar Eifler<sup>1</sup>; *Guntram Wagner*<sup>1</sup>; <sup>1</sup>University of Kaiserslautern

The industrial application of friction stir welding as a high quality joining process requires the understanding of the influence of the FSW process on the developing microstructure and the resulting mechanical properties. The present work provides a comparison of FSW butt welds of the aluminum alloy AA5454 in the states O and H22. The influence of the friction stir welding process on the microhardness profile in the joining areas and the changes of the grain size in the different welding zones in relation to the base material will be described in detail. Furthermore it will be shown that the ultimate tensile strength, the yield strength and the total elongation after friction stir welding are nearly identical independent of the initial state of the investigated Al-alloys. Finally the fatigue behavior of welded AA5454 in the states O and H22 will be discussed.

TUESDAY AM

8:50 AM

**The Effect of Friction Stir Welding on the Dispersoid Particles of Aluminium Alloy 2195:** Roy Crooks<sup>1</sup>; Jorge dos Santos<sup>2</sup>; Kati Savolainen<sup>3</sup>; Hannu Hänninen<sup>3</sup>; <sup>1</sup>Black Laboratories, L.L.C.; <sup>2</sup>GKSS-Research Centre GmbH; <sup>3</sup>Aalto University

Grain coarsening is observed in friction stir welded nuggets of AA2195 after post-weld anneals. One factor which may contribute to this behaviour is the modification of dispersoid particle distributions by friction stir welding (FSW). High volume fractions of small particles are desirable for impeding grain boundary motion, recrystallization and grain growth. The most effective dispersoid in this alloy is the coherent precipitate, Al<sub>3</sub>Zr, which is subject to loss of coherency during dynamic recrystallization and a consequent reduction in Zener drag. Loss of coherency implies an increase in the critical particle size and dissolution of particles below that size. The dispersoid distributions of the base plate were compared to those of the advancing side of the as-welded plate. The effect of FSW on the particle size distributions in FSW AA2195 was studied using small angle x-ray scattering (SAXS). Morphology and coherency changes of Al<sub>3</sub>Zr particles were studied by transmission electron microscopy.

9:10 AM

**Microstructural Characteristics of Sc-Modified Al-Zn-Mg-Cu Alloy Extrusions Joined by Friction Stir Welding:** Carter Hamilton<sup>1</sup>; Stanislaw Dymek<sup>2</sup>; Oleg Senkov<sup>3</sup>; <sup>1</sup>Miami University; <sup>2</sup>AGH University of Science and Technology; <sup>3</sup>UES, Inc

Extruded and T6 tempered plates of a Sc-modified Al-Zn-Mg-Cu alloy were joined by friction stir welding (FSW) at a constant weld velocity and various pin rotation speeds (PRS). At low PRS, hardness decreased from each edge of the weld to a local minimum at the weld center; however, at high PRS, the hardness initially decreased from each edge of the weld, but then rose toward the weld center. The transition in the hardness profile was related to different heating and cooling conditions during FSW. In particular, the peak temperature during FSW increased from ~250°C to 450°C as the PRS increased from 175 to 400 rpm. Differential scanning calorimetry of baseline and welded samples revealed that the volume fraction of GP zones and  $\eta'$  particles within the weld regions strongly depended on the weld conditions. For FSW heating rates, secondary phase dissolution/precipitation temperatures are in proximity to the welding temperatures.

9:30 AM

**AGG Suppression in Friction-Stir-Welded, Spun-Formed Al-Li 2195 Materials:** Stephen Hales<sup>1</sup>; Wesley Tayon<sup>1</sup>; <sup>1</sup>NASA

Currently, the Al 2219 dome caps for cryogenic propellant tanks are welded assemblies, where multiple panels are contoured to shape, heat treated, and joined. A new, single-piece fabrication approach being explored involves spin forming to final shape of Al-Li 2195 flat plates, which have been friction stir welded (FSW'd) together. The approach requires post-forming heat treatment to the T8 temper for service properties. Processing for the T8 condition involves solution heat treatment (SHT), cold water quenching, cold stretching and aging. The occurrence of abnormal grain growth (AGG) during SHT of 2195 FSW'd material has been problematic from the perspective of service properties. The objective of this work was to suppress AGG during SHT by post-forming thermal processing alone. Constraints on the experimental design included applicability to large, complex-shaped, thin-walled domes and the capabilities of commercial heat treatment facilities. In this presentation, the experiments conducted are outlined and research results discussed.

9:50 AM

**Analysis of Temperature and Residual Stress Evolution during Friction Stir Welding of Aluminum 7075-T6:** Yunfeng Cao<sup>1</sup>; Tyler Davis<sup>1</sup>; Yung Shin<sup>1</sup>; <sup>1</sup>Purdue University

In friction stir welding (FSW), it is well understood that the temperature can have a significant effect on the resultant weld quality. It is therefore necessary to examine the temperature evolution during FSW. In this work, a three dimensional model based on finite element analysis is used to investigate the temperature history and thermo-mechanical process in the welding of

aluminum alloy 7075-T6. The temperature history of the workpiece and the residual stress of the welded plate are measured by an infrared camera and the X-ray diffraction technique, respectively. The measured results are compared with the model predictions and a correlation between temperature and residual stresses is established. To achieve desirable residual stresses of the welded plate, a laser shock peening (LSP) process is subsequently applied on the workpiece. A complete LSP model is employed to predict the residual stresses after LSP and predictions are compared with experimental results.

10:10 AM

**Measurement of Residual Stress in Friction Stir Weld Joints:** Adrian DeWald<sup>1</sup>; Michael Hill<sup>2</sup>; Murray Mahoney<sup>3</sup>; <sup>1</sup>Hill Engineering, LLC; <sup>2</sup>University of California, Davis; <sup>3</sup>Consultant

Friction stir welding (FSW) is currently being used to join materials from plastics to high-strength steels in industries including automotive, aircraft, and shipbuilding. FSW employs a non-consumable pin that rotates at moderate speeds, which is plunged into the butting edges of the work pieces to be joined. Although the temperatures attained during FSW are relatively low compared with conventional fusion welding techniques, residual stresses still develop during FSW. The magnitude and distribution of these residual stresses can be detrimental to performance. This paper investigates the residual stresses generated by friction stir welding in a variety of materials including HSLA-65 steel, AA 2195, and AA 7075. Residual stress measurement data were obtained using the contour method and the slitting method. Using the contour method, residual stresses are obtained through the plate thickness for both the longitudinal and transverse orientations.

10:30 AM

**Development of Tatumaki Friction Stir Welding:** Seung Hwan C. Park<sup>1</sup>; Satoshi Hirano<sup>1</sup>; Shinichi Kaga<sup>2</sup>; Mitsuru Onose<sup>2</sup>; Noriaki Tominaga<sup>2</sup>; Yasutsugu Yoshimura<sup>3</sup>; <sup>1</sup>Hitachi Ltd.; <sup>2</sup>Mitsubishi-Hitachi Metals Machinery, Inc.

The authors have developed a double-sided friction stir welding (FSW) technology that consists of a dual-tool rotating mechanism arranged in face-to-face relation on the front and back surfaces of the joint. One rotating tool has a probe that protrudes from the shoulder, while the other rotating tool has a recess formed in the shoulder. The probe is inserted into the recess for receiving the probe during the FSW. With the shoulders pressed against both surfaces of the joint, the rotating tools move along the joint line. The main advantage of this process is the application of a wide range of weld thicknesses and high speed welding by controlling the motor power consumption. In this study, the effect of tool geometry on weld thickness, and its' possible application to continuous rolling system is described.

10:50 AM Break

11:00 AM

**The Role of Plastic Deformation in Suppressing Abnormal Grain Growth in Friction Stir Welded Al-Li 2195:** Eric Hoffman<sup>1</sup>; Robert Hafley<sup>1</sup>; Marcia Domack<sup>1</sup>; Ravi Shenoy<sup>2</sup>; Wesley Tayon<sup>1</sup>; Jessica Robinson<sup>1</sup>; <sup>1</sup>NASA Langley Research Center; <sup>2</sup>Lockheed Martin Space Systems

Traditional methods for producing large scale dome end caps for cryogenic propellant tanks utilize a multi-piece welded gore construction. To reduce the mass and fabrication costs and increase the reliability for these domes, a novel near-net manufacturing process is being explored in which a single-piece dome is spin formed from an Al-Li 2195-OM temper blank. The blank is friction stir welded (FSW) together from two commercial Al-Li 2195-OM temper plates to overcome plate size limitations. This manufacturing approach requires post-forming heat treatments to develop the required T8 temper properties. Abnormal grain growth (AGG) was observed in the FSW after solution heat treatment (SHT) and resulted in degraded mechanical properties. In this study, samples of FSW Al-Li 2195 were subjected to plastic deformation introduced by cold working and laser peening. The minimum level of cold work and laser peening intensity required to suppress AGG during SHT was determined.

11:20 AM

**The Effect of Dispersoid Modification on Abnormal Grain Growth in Friction Stir Welded Al-Li 2195:** Roy Crooks<sup>1</sup>; Ravi Shenoy<sup>2</sup>; Wesley Tayon<sup>3</sup>; Marcia Domack<sup>3</sup>; <sup>1</sup>National Institute of Aerospace; <sup>2</sup>Lockheed Martin Space Systems; <sup>3</sup>NASA Langley Research Center

Friction stir welded (FSW) AA2195 plates have been spun formed into large domes used as end caps for cryogenic tanks for space launch vehicles. After FSW, the plates are annealed, spun, solution treated and aged to peak strength. Solution heat treatment of the FSW and spun formed plates may result in excessive growth of nugget grains, particularly near the advancing side interface. Several factors are related to this growth, including stored strain energy, grain size and dispersoid particle size distributions. Samples of FSW AA2195 were studied after FSW and annealing to quantify the microstructural factors contributing to grain growth during the solution heat treatment. Electron backscattered diffraction (EBSD) systems in a scanning electron microscope (SEM) and in a transmission electron microscope were used. Heat treatments developed to modify these factors were assessed.

11:40 AM

**Friction Stir Welding of 25 mm Thick Al 6061-T651 Plates:** Guru Dinda<sup>1</sup>; Douglas Grant<sup>1</sup>; Matthew Scheid<sup>1</sup>; Ashish Dasgupta<sup>1</sup>; Sudip Bhattacharya<sup>2</sup>; Jyoti Mazumder<sup>2</sup>; <sup>1</sup>Focus: HOPE; <sup>2</sup>University of Michigan

Friction stir welding (FSW) was invented in 1991 by The Welding Institute as a solid-state joining method for a variety of metals and alloys, in particular aluminum alloys. Since the early discovery, FSW of aluminum alloys have been extensively investigated. However, very little work is reported on FSW of thick Al plates in the open literature. The objective of this work is to optimize the process parameters such as travel speed, forge force, rotational speed and tilt angle for butt welding of 25 mm thick Al 6061-T651 plates with a view to produce welds without any defects. A comprehensive design of experiments was conducted to establish a process parameter window for welding 25 mm thick Al 6061-T651 plates of various sizes. The weld quality was assessed via optical microscopy, SEM, XRD, microhardness and tensile testing. The effect of process parameters on the resulting weld properties was analyzed using statistical techniques.

12:00 PM

**Effects of Forge Axis Force and Backing Plate Boundary Condition on FSW of AA6056:** Piyush Upadhyay<sup>1</sup>; Anthony Reynolds<sup>1</sup>; <sup>1</sup>University of South Carolina

For a given set of welding parameters forge axis force can also have a significant effect on stir zone temperature, torque, and in-plane forces. Typically, for a given set of welding parameters, an FSW user chooses an appropriate but arbitrary forge axis force a posteriori based on weld surface quality. This qualitative adjustment of forge axis force can be affected by thermal boundary conditions that are applied to the work-piece. We seek to understand the effects of forge axis force coupled with the thermal boundary condition at the bottom of the work-piece on AA 6056 (4.2mm thick) plate. Forge axis force and backing plate conductivity are varied while holding other parameters constant. Resulting temperature, torque and in-plane forces are analyzed and correlated with the varied parameters. The result demonstrates that for the given gage thickness, metallurgically significant temperature variation can be achieved without changing the rotation/translation speed.

12:20 PM

**Friction Stir Welded "A" Frame For Dual Function Test Fixture:** Alan Handyside<sup>1</sup>; Farzad Baratzadeh<sup>1</sup>; Jeff Buller<sup>1</sup>; Hamid Lankarani<sup>2</sup>; Blair Carlson<sup>3</sup>; Dwight Burford<sup>1</sup>; <sup>1</sup>National Institute for Aviation Research; <sup>2</sup>Wichita State University; <sup>3</sup>General Motors Corporation

Advancements in friction stir welding (FSW) pin tool and joint design have been used to develop an automotive and aerospace test fixture. The fixture was designed and built for a case study analyzing functionality of an advanced bumper / crash box fabricated by FSW. The fixture "A" frame is fabricated using FSW of AA6063-T6 and AA6061-T6. The fixture is used as drop tower for constant acceleration tests and with crash sled for constant velocity tests. Butt welds, similar to those developed and tested for the crash box / bumper, were incorporated into the fixture. FEA simulations

on the "A" frame, including FSW joints, were used for analysis. Tensile test coupons made by FSW were prepared to determine weld parameters, parent and weld material properties. Summary of FSW process development is presented along with weld coupon test results. An overview of fixture function and preliminary fixture test results is presented.

12:40 PM

**Investigation of Lazy S Feature in Self Reacting Tool Welds in 2024-T4 Aluminum:** Karl Warsinski<sup>1</sup>; Michael West<sup>2</sup>; Jim Freeman<sup>3</sup>; Todd Curtis<sup>2</sup>; <sup>1</sup>Michigan Technological University; <sup>2</sup>South Dakota School of Mines and Technology; <sup>3</sup>MTS Systems Corporation

The current research is an examination of the "Lazy S" feature found in self-reacting tool (SRT) friction stir welds. The research objectives are to characterize the feature using scanning electron and optical microscopy and determine its effect on the mechanical properties of the welded material. Welds were conducted in 2024-T4 aluminum. Welding parameters were varied in an attempt to influence the size and location of the feature. Tensile tests were performed on each weld and were correlated with the total length of the feature. Preliminary results indicate that there is a correlation between decreasing feature length and decreasing tensile strength.

## Frontiers in Solidification Science: Experimental Studies

8:30 AM Invited

**Simulation of Dendritic Growth Observed in Synchrotron X-ray Video Experiments:** Christoph Beckermann<sup>1</sup>; Pierre Delaleau<sup>1</sup>; Ragnvald Mathiesen<sup>2</sup>; Lars Arnberg<sup>2</sup>; <sup>1</sup>University of Iowa; <sup>2</sup>NTNU

A mesoscopic model is developed to simulate microstructures observed in situ by X-ray video microscopy during directional solidification of Al-Cu alloys in a Hele-Shaw cell. In the model, a volume-averaged species conservation equation is solved to obtain the solute concentration and solid fraction fields, and an analytical stagnant film model is used to predict the motion of the dendrite envelopes. Good agreement is found between the measured and predicted dendrite envelope shapes, solid fractions, and solute concentration fields. The predicted size of the mushy zone and the extent of the undercooled melt region ahead of the columnar front agree well with the in situ experimental observations. The simulation results show quantitative agreement with internal solid fraction variations measured from the radiographs. The model is also able to realistically simulate a primary dendrite trunk spacing adjustment that was observed in one of the experiments.

9:00 AM Invited

**Solidification of Metallic Alloys under Magnetic Fields:** Yves Fautrelle<sup>1</sup>; Xi Li<sup>1</sup>; Olga Budenkova<sup>1</sup>; Bachir Saadi<sup>1</sup>; Zhongming Ren<sup>1</sup>; <sup>1</sup>Grenoble Institute of Technology

Polyphase AC magnetic fields are used usually to generate either liquid metal stirring or electromagnetic vibrations. The electromagnetically-driven flows promote segregations and influence their distribution. The flow may also promote the CET thanks its effects on both the temperature and solute fields as well as the possible fragmentation mechanism. As far as DC magnetic fields are concerned, it was known that they usually exert a damping of the bulk fluid flows. Nevertheless, due to crystal anisotropy magnetic effects

TUESDAY AM

such that alignment or texturation appear during solidification under high magnetic fields. Furthermore, high-intensity magnetic field interacts with thermo-electric currents to create electromagnetic forces. Those forces are responsible for strong liquid metal flows both in the bulk and in the mushy zone. The forces act both on the liquid and the solid phase. Direct fragmentation of the dendrites are sometimes encountered, leading to equiaxed structures.

**Two-Phased Spiral Dendrites:** *Silvere Akamatsu*<sup>1</sup>; Mikael Perrut<sup>2</sup>; Sabine Bottin-Rousseau<sup>1</sup>; Gabriel Faivre<sup>1</sup>; <sup>1</sup>CNRS - UPMC; <sup>2</sup>ONERA

We report for the first time experimental observations of a steady crystal growth shape called two-phased spiral dendrite in real-time directional solidification of a transparent SCN-DC base nonfaceted ternary alloy in glass-wall samples. Spiral dendrites arise from a ternary-component driven eutectic-cell instability of a two-phased solid. They exhibit an overall parabolic shape, and a lateral branching. Coupled growth occurs continuously from a spiral pattern on the tip, and delivers two intricate helices. The spiral step and the tip radius of curvature vary approximately as the reciprocal of the square root of the solidification rate, and fall close to the minimum-undercooling spacing of binary SCN-DC. The spiral geometry is compatible with a growth of the lamellae perpendicular to the solidification front envelope. In contrast to the one-phased dendrite, the growth direction of spiral dendrites is not determined by any surface tension anisotropy, and is initial-condition dependent.

**Universality and the Pinch-off of Rods by Capillarity:** L. Aagesen<sup>1</sup>; A. Johnson<sup>1</sup>; J. Fife<sup>1</sup>; *Peter Voorhees*<sup>1</sup>; M. Miksis<sup>1</sup>; S. Poulsen<sup>2</sup>; E. Lauridsen<sup>2</sup>; F. Marone<sup>3</sup>; M. Stampanoni<sup>3</sup>; <sup>1</sup>Northwestern University; <sup>2</sup>Riso Laboratory for Sustainable Energy; <sup>3</sup>Swiss Light Source

The detachment of secondary dendrite arms during solidification processing has a significant influence on the resulting microstructure. To understand the fragmentation process when it is driven by capillarity, we examine the evolution of the interfacial morphology of liquid and solid rods in an Al<sub>15</sub> wt.% Cu alloy. Interfacial energy induces a rod develop undulations by the well-known Rayleigh instability. These undulations increase in amplitude and lead to pinching. We show theoretically that sufficiently close to the pinching event the interfacial morphology becomes universal; the interface shape is independent of the initial morphology of the rod-like phase and material system, and its evolution is described by a power law in time. We test this prediction using insitu x-ray tomography and find an excellent agreement between theory and experiment in both the morphology and the kinetics of the pinching process. The implications of this result to various solidification processes will be discussed.

#### 10:45 AM Invited

**Directional Growth Structures in Univariant Eutectics:** *Ralph Napolitano*<sup>1</sup>; <sup>1</sup>Iowa State University

Directional solidification and serial milling are employed here to investigate the three-dimensional features of multiphase microstructures in Al-Cu and Al-Cu-Ag alloys, focusing on univariant two-phase structures in the ternary. The relationships between local eutectic phase topology, crystallographic orientation/misorientation, eutectic fault configuration, faulted domain structure, and grain structure, relative to the constraints of specimen geometry and applied thermal field, are examined.

#### 11:15 AM

**Nucleation Catalysis Potency of Ceramic Nanoparticles in Aluminum Matrix Nanocomposites:** *Michael De Cicco*<sup>1</sup>; John Perepezko<sup>1</sup>; Lih-Sheng Turng<sup>1</sup>; Xiaochun Li<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison

The nanoparticles in metal matrix nanocomposites (MMNCs) were shown to catalyze nucleation of solidification. Nanoparticles of SiC, TiC, and  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> were dispersed in an aluminum alloy A356 matrix using an ultrasonic processing technique. The droplet emulsion technique was used to examine the undercooling in each matrix-nanoparticle system. Despite

their small sizes, the nanoparticles demonstrated the ability to significantly reduce the necessary undercooling for nucleation. In general, the degree of undercooling in the MMNCs containing SiC, TiC and  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> was in agreement with the free growth undercooling. The nucleation catalysis by the nanoparticles resulted in significantly refined microstructures. The grain refining effectiveness of nanoparticles was also examined in pure Al and Al-10Mg using TiC<sub>0.7</sub>N<sub>0.3</sub> nanoparticles. In both pure Al and Al-10Mg the nanoparticle addition significantly reduced the average grain size of the matrix. Comparison was made to the commonly used Al-5Ti-B grain refiner. At the addition levels used, the nanoparticles were more effective than the Al-5Ti-B grain refiner.

### Hume-Rothery Symposium Thermodynamics and Diffusion Coupling in Alloys - Application Driven Science: Diffusion Coefficients and Thermodynamics

**Influence of Thermodynamic Forces on Diffusion in Melts:** *Axel Griesche*<sup>1</sup>; Juergen Horbach<sup>2</sup>; Andreas Meyer<sup>2</sup>; <sup>1</sup>Federal Institute for Materials Research and Testing (BAM); <sup>2</sup>German Aerospace Center (DLR)

We report about diffusion measurements and molecular dynamic simulations in Al-Ni and Al-Cu melts. Capillary methods were used to measure Ni and Cu self diffusion and to measure interdiffusion. The combination of the capillary set-up with X-ray radiography allowed in-situ detecting of convective contributions to the interdiffusion transport by tracking the time dependence of diffusion. Thus, the determination of the interdiffusion coefficient can be restricted to convection-free experiment times resulting in an increased accuracy of the measured interdiffusion coefficient. Additionally, quasi-elastic neutron scattering was used to measure convection-free Ni and Cu self diffusion. Molecular dynamics simulations were used to determine all diffusion coefficients and the thermodynamic factor. The comparison between experiment and simulation shows an excellent agreement of the interdiffusion coefficients as a function of temperature. It was found that interdiffusion is enhanced by thermodynamic forces with a maximum around the stoichiometric composition.

**Atomic Bond Defects; Thermodynamics and Diffusion in Metallic Glasses:** *Gary Shiflet*<sup>1</sup>; Aiwu Zhu<sup>1</sup>; S. Joseph Poon<sup>1</sup>; <sup>1</sup>University of Virginia

Diffusion in metallic glasses and deeply undercooled liquids will be atomistically developed and analyzed using the concept of 'atomic bond deficiency', i.e., cooperative movements of multiple adjacent atoms. Diffusion in metallic glasses and supercooled liquids is a fundamental process that controls the glass formability, thermal stability and viscosity and, to some extent, affects their ductility. Experimental measurements indicate that diffusion in amorphous metals is a thermal activation process with many similarities to crystalline solids, including: simple Arrhenius temperature-dependence of coefficient D; atomic size effect of diffusing species; and the annealing effect of quenched states. However, amorphous metal diffusion is significantly different from crystals, quantitatively in particular, as indicated in: a much larger slope of the Q versus the logarithm of D<sub>0</sub>, and more pronounced positive size effects of diffusing atoms on Q. Comparisons

with previous experimental data and rationalization with seemingly confusing disparate results will be presented and explained.

#### 9:30 AM Invited

**Application of Thermodynamic and Kinetic Modeling to Diffusion Simulations in Nickel-Base Superalloy Systems:** Anders Engström<sup>1</sup>; Henrik Larsson<sup>1</sup>; Johan Bratberg<sup>1</sup>; Lars Höglund<sup>1</sup>; Paul Mason<sup>2</sup>; <sup>1</sup>Thermo-Calc Software AB; <sup>2</sup>Thermo-Calc Software Inc

This paper presents a brief review, followed by some new results from recent diffusion simulations in Ni-base superalloy systems, performed by means of a thermodynamic and kinetic modelling approach as taken in the commercial finite-difference code DICTRA. The DICTRA code solves the multi-component diffusion equations, combining assessed thermodynamic and kinetic data in order to determine the full composition dependent interdiffusion matrix. The link between fundamental physics based models and critically assessed data allows simulations to be performed with realistic conditions and data on alloys of practical importance. Emphasis in this paper is on modelling and simulation of interdiffusion occurring between NiAl coatings and different Ni-base superalloy substrates. For this purpose we have used the so-called homogenization approach to diffusion in multi-phase systems, recently implemented into the DICTRA software. The simulation results obtained are validated against experimental data, and the agreement is very satisfactory given the complexity of the problem.

**Selected Observations from Interdiffusion Study in U-Mo-Al System:** Yongho Sohn<sup>1</sup>; Emmanuel Perez<sup>1</sup>; Bo Yao<sup>1</sup>; Ashley Ewh<sup>1</sup>; Dennis Keiser, Jr.<sup>2</sup>; <sup>1</sup>University of Central Florida; <sup>2</sup>Idaho National Laboratory

Interdiffusion and microstructural development in the U-Mo-Al system with several additional alloying additions was examined using solid-to-solid diffusion couples in the temperature range of 500 to 600°C. In ternary U-Mo (7-12 wt.%) vs. Al diffusion couples annealed at 600°C for 24 hours, interdiffusion microstructure varied of finely dispersed UAl<sub>3</sub>, UAl<sub>4</sub>, U<sub>6</sub>Mo<sub>4</sub>Al<sub>14</sub>, and UMo<sub>2</sub>Al<sub>20</sub> phases while the average composition throughout the interdiffusion zone remained constant at approximately 80 at.% Al. The addition of Si (up to 5 wt.%) in Al significantly reduced the thickness of the intermetallic layer by changing the constituent phases within the interdiffusion zone. The formation of (U,Mo)(Al,Si)<sub>3</sub> with relatively large solubility for Mo and Si was observed. Concurrently, the UAl<sub>4</sub> and U<sub>6</sub>Mo<sub>4</sub>Al<sub>14</sub> phases with poor irradiation behavior were absent. Additional efforts to reduce the growth kinetics of the complex intermetallic layer including alloying additions to the U-Mo alloy and diffusion barriers such as Zr and Nb are presented and discussed.

#### 10:50 AM Invited

**Analysis of the Influence of Vacancy-Solute Interaction on Diffusion of Atomic Monomers and Clusters:** Piotr Warczak<sup>1</sup>; Jaroslav Zenisek<sup>2</sup>; Ernst Kozeschnik<sup>1</sup>; <sup>1</sup>Vienna University of Technology; <sup>2</sup>Materials Center Leoben Forschung GmbH

In the present paper, we investigate the dependence of the diffusional mobility of single solute atoms as well as clusters of atoms on the vacancy-solute binding characteristics with the Monte Carlo (MC) method. Existing work, mainly based on first-principles calculations and atomistic simulations, is reviewed first. Then, we compare these results to our simulations performed with MC and explore these effects in the light of macroscopic diffusive fluxes and atomic clusters movement in the sense of Brownian motion. Finally, we propose a numerical method for incorporation of the movement and potential collisions of clusters in a precipitation kinetics framework.

#### 11:20 AM

**Characterization of Phase Formation and Diffusion Behavior of the Cu-Zn Binary System:** Christopher Eastman<sup>1</sup>; John Kuper<sup>1</sup>; Ji-Cheng (J.-C.) Zhao<sup>1</sup>; <sup>1</sup>The Ohio State University

Diffusivity data are limited for the Cu-Zn binary system and it is still questionable whether β' undergoes a eutectoid decomposition at low temperatures. Zinc is a widely used element in copper alloys; therefore

the diffusion coefficient of Zn in Cu will be useful for simulating phase precipitation in Cu alloys. This paper characterizes phase formation and diffusion behavior in the Cu-Zn binary system through the use of infinite diffusion couples, transient liquid phase diffusion couples, solid-liquid conical diffusion couples by immersion of a Cu cone into molten Zn, and U.S. pennies which consist of a Zn core and an electroplated Cu outer layer. Heat treatments for different durations and at several temperatures were used to characterize the diffusion behavior of the Cu-Zn binary system. Optical microscopy, electron dispersive spectroscopy (EDS) and electron probe microanalysis were used to obtain composition profiles in order to extract the diffusivity values.

#### 11:50 AM

**Interdiffusion Investigation of Mo and Zr in Fe, Fe-Cr and Fe-Ni-Cr Alloys at 650, 750, and 850°C:** Ashley Ewh<sup>1</sup>; Judith Dickson<sup>1</sup>; Bulent Sencer<sup>2</sup>; John Kennedy<sup>2</sup>; Yongho Sohn<sup>1</sup>; <sup>1</sup>University of Central Florida; <sup>2</sup>Idaho National Laboratory

Interdiffusion between molybdenum or zirconium and iron alloys was studied using various solid-to-solid diffusion couples. The couples were assembled with disks of Mo, Zr, Fe, Fe-15Cr, and Fe-15Cr-15Ni, in wt.%, and were isothermally annealed at 650, 750, and 850°C for 45, 30, and 15 days, respectively. Following the diffusion anneal, the couples were water quenched to maintain the high temperature microstructure and were cross-sectioned for analysis. Microstructural observations of the interdiffusion zone were made via optical and scanning electron microscopy. Intermetallic layer phase constituents were identified using a combination of energy dispersive spectroscopy and transmission electron microscopy. Concentration profiles were also determined via electron probe microanalysis and were used to determine relevant interdiffusion coefficients of the individual components. The development and growth kinetics of the intermetallic phases developed in these couples are discussed with regard to the phase diagrams and compared with previous literature.

#### 8:30 AM

**Modeling and Simulation of Mechanical Properties of Magnesium Alloy Wheel Casting for Automobile:** Liang Huo<sup>1</sup>; Zhiqiang Han<sup>1</sup>; Xunming Zhu<sup>2</sup>; Junpeng Duan<sup>2</sup>; Aimin Wang<sup>2</sup>; Baicheng Liu<sup>3</sup>; <sup>1</sup>Key Laboratory for Advanced Materials Processing Technology (Ministry of Education), Department of Mechanical Engineering, Tsinghua University; <sup>2</sup>WANFENG Magnesium Co. Ltd., WANFENG Auto Holding Group; <sup>3</sup>State Key Laboratory of Automotive Safety and Energy, Department of Automotive Engineering, Tsinghua University

Modeling and simulation have become a powerful tool in optimizing casting process and predicting component microstructure. However, a further step is desirable for engineers to predict the mechanical properties based on the casting process and microstructure simulation, so as to optimize the structure of casting component and reduce the developing time. In

the present paper, the mechanical properties of a magnesium alloy wheel casting for automobile were predicted by integrating the model of as-cast microstructure with the model of tensile strength, as well as the simulation of mold filling process and temperature field during solidification. Considering the grain size variation due to different cooling rate, tensile strength was predicted based on Hall-Petch equation. The distribution of grain size and the variation of the tensile strength of the magnesium alloy wheel were predicted by the present model. Metallographic examination and mechanical property test were performed for validation.

#### 8:50 AM Invited

**Engineering Grain Boundary Populations and Connectivity in Polycrystalline Structures:** *Gregory Rohrer*<sup>1</sup>; Herbert Miller<sup>1</sup>; <sup>1</sup>Carnegie Mellon University

Efforts to control the populations of grain boundaries in polycrystals, and the structure sensitive properties that are linked to the grain boundary network structure, are usually referred to as grain boundary engineering. In this paper, I will review progress in understanding the mechanisms by which grain boundary populations and connectivity change during processing. Both the relative populations of different grain boundaries, and their connectivity, have been measured in Ni before and after repeated thermomechanical processing. When the observations are compared to recently measured grain boundary energies, it is observed that higher energy boundaries in the network are replaced by lower energy boundaries. A model for the evolution of the grain boundary populations will be presented. Finally, homology metrics are used to evaluate changes in the connectivity of grain boundaries as a function of processing.

#### 9:15 AM

**The Development of Tools for the Prediction of the Tensile and Fracture Toughness Properties in a/B Titanium alloys:** *Santhosh Koduri*<sup>1</sup>; Peter Collins<sup>2</sup>; Hamish Fraser<sup>1</sup>; <sup>1</sup>The Ohio State University; <sup>2</sup>University of North Texas

The development of tools to predict the mechanical properties based upon compositional and microstructural inputs in multi-component, multi-phase Ti-based alloys represents a significant challenge and a key element of Integrated Computational Materials Engineering. One such solution is the development of high-fidelity databases and the subsequent application of non-linear modeling tools such as neural networks based upon a Bayesian framework to extract the underlying composition-microstructure-property relationships. This talk will highlight the development of such rules-based models for the prediction of the tensile and fracture toughness properties of Ti6Al4V at room temperature. These models have been successfully used to isolate the influence of the individual microstructural features on the mechanical properties, potentially providing the basis for the development of more robust phenomenological models.

#### 9:35 AM

**Quantifying Interface Energetics and Kinetics using Atomic-scale Simulations:** *Moneesh Upmanyu*<sup>1</sup>; <sup>1</sup>Northeastern University

Predictive capabilities of microstructural evolution models are extremely sensitive to their properties, in particular their energetics and kinetics. In polycrystalline microstructures, the interfacial properties are set at the atomic-scale, necessitating the need for i) techniques that extract these properties for individual interfaces with well-known degrees of freedom, and ii) multiphysics integrated efforts that transfer of these properties to larger-scale evolution models. In this talk, I will present progress in computational frameworks that allow efficient extraction of interface free energies, stiffness and mobilities as relevant for fundamental annealing phenomena. A focus will be on techniques that allow us to quantify the effect of solutes for homophase interfaces such as grain boundaries. The relevance for ICME-based efforts will be discussed.

#### 9:55 AM Invited

**Integrated Computational Materials Design and Qualification: Making CyberSteel Fly:** *Greg Olson*<sup>1</sup>; <sup>1</sup>Northwestern University

The numerical implementation of established materials science principles in the form of purposeful engineering tools has brought a new level of integration of the science and engineering of materials. Parametric materials design integrating materials science, applied mechanics and quantum physics within a systems engineering framework has brought a first generation of designer "cyberalloys" that have now entered successful commercial applications, and a new enterprise of commercial materials design services led by QuesTek Innovations LLC has steadily grown over the past decade. The success of materials design established a basis for the DARPA-AIM initiative which broadened computational materials engineering to address acceleration of the full materials development and qualification cycle. The recent flight qualification of the Ferrium S53 CyberSteel for aircraft landing gear demonstrates the power of the integrated computational design + AIM methodology.

#### 10:20 AM Break

#### 10:35 AM Invited

**3-D Modeling of Machining Distortions of Aerospace Components:** *Shesh Srivatsa*<sup>1</sup>; <sup>1</sup>GE Aviation

Aircraft engine and airframe structural components that are machined from forgings represent a significant cost of both military and commercial aircraft. Typical component applications are rotating disks in aircraft engines and structural components in airframes. The buy-to-fly weight ratio, which is the ratio of the forged material weight to the finished part weight, is typically between 4 and 10 for such components. The excess material is removed by various machining operations, which are a major contributor to the cost of forged components. Machining distortions are a problem with most forged components which are quenched rapidly in order to generate the required mechanical properties. Distortion can be caused by material bulk stresses resulting from heat-treating operations, or from local near-surface machining-induced stresses. Typically additional machining operations and setups are added in a time-consuming and costly trial-and-error approach to minimize the effects of part distortion. Manufacturing residual stresses can adversely impact the behavior of the components during service. There is a need to understand the effects of heat treating and machining on distortion and to predict, minimize, and control these distortion-related processes. The objective of this program is to establish a modeling method that accurately predicts distortion during machining of 3-D shaped forgings used in aircraft engines and airframe structures. Prediction and validation of machining distortions due to bulk and surface residual stresses will be presented. This program is funded by the USAF Metals Affordability Initiative (MAI).

#### 11:00 AM Invited

**A Case for ICME - Ti Alloy Design Tool Development at Boeing:** *Donald Shih*<sup>1</sup>; <sup>1</sup>The Boeing Company

Titanium structures are critically important to Boeing. Advanced Ti alloys, e.g. lighter alloys and tougher/ stronger alloys are needed. But it commonly takes too long to develop such an alloy. New design concept and methodology that sharply reduce this cycle duration are a must. Atomic modeling, multiscale simulation and data-mining are proven useful to achieve such goals in other materials. However, they have not been applied in Ti alloys, mainly due to many key challenges. Boeing, with our academic partners, has been developing the concept and methodology to overcome these challenges using the ICME approaches. As a key part of multiscale modeling and simulation in the lighter Ti alloys and tougher/ stronger alloys design effort, DFT based first-principles and phase diagram calculations have been conducted. This presentation will give a case study of using of multiscale modeling and simulation and validation for Ti alloy design tool development will be presented.

11:25 AM Invited

**Application of Computational Modeling during Processing of Stainless Steels:** *Ashish Patel*<sup>1</sup>; <sup>1</sup>Carpenter Technology Corporation

These days process and alloy modeling is gaining prominence, largely due to the urgency in developing new alloys and optimizing the processes that are used in manufacturing these alloys. Currently, there are numerous efforts in both academia and in within the industry to model the effect of alloying elements on microstructure and to get an insight on the effect of processing parameters on properties of high performance alloys. This talk will provide a brief overview of the commonly used processing techniques used during manufacturing of high performance alloys followed by illustrations of typical outcomes from models used to simulate the entire processing sequence for manufacturing high nitrogen austenitic steels. The nitrogen solubility is determined from a CALPHAD based model, a CFD based model is used to simulate the melting and casting, an analytical model for simulating the heat treatment followed by a FEM based simulation for the thermo-mechanical processing.

11:50 AM Invited

**Fast Acting Models for Materials-Centric Engineering Design:** *Triplicane Parthasarathy*<sup>1</sup>; Y.S. Choi<sup>1</sup>; R. Goetz<sup>2</sup>; D. Furrer<sup>2</sup>; R. John<sup>3</sup>; R. Dutton<sup>3</sup>; <sup>1</sup>UES, Inc.; <sup>2</sup>Rolls Royce Engines; <sup>3</sup>Air Force Research Laboratory

Engineering design of turbine disks with complex heat treatment or heat treatment gradients are of interest in pushing the envelope of turbine disks in future aircraft design. The use of such complex process designs make it essential to incorporate material-centric models within the design space. UES has been working in collaboration with Rolls Royce, under Air Force funding, to develop fast acting models that are based on mechanism based higher order models towards property predictions from either microstructural inputs or heat treatment inputs. Results on these efforts are presented and implications discussed.

**Magnesium Technology 2011: Alloy Design/ Development; Grain Refinement and Severe Plastic Deformation**

8:30 AM

**Effect of Zn/Gd Ratio on Phase Constitutions in Mg-Zn-Gd Alloys:** Song Zhang<sup>1</sup>; *Guangyin Yuan*<sup>1</sup>; Chen Lu<sup>1</sup>; Wenjiang Ding<sup>1</sup>; <sup>1</sup>Shanghai Jiao Tong University

The phase constitutions of Mg-Gd-Zn alloys in the Mg-rich corner were investigated using XRD, SEM and TEM. The effect of Gd/Zn ratio and contents of Gd, Zn element on the phase constitutions of Mg-Zn-Gd alloys were studied. Critical contents of Gd and Zn for the formation of long period stacking ordered (LPSO) structure and X phase in the Mg-Gd-Zn system in the Mg-rich corner have been confirmed using conventional cast process. When Zn%-Gd% = 0, LPSO structure and W phase were formed in Mg-Gd-Zn alloys. When Zn%-Gd% = 0.5%, only W phase was found in the alloys. When Zn%-Gd% = 1%, I phase and W phase were observed in the alloys.

8:50 AM

**Optimization of Magnesium-Aluminum-Tin Alloys for As-Cast Microstructure and Mechanical Properties:** Xiaoyu Kang<sup>1</sup>; *Alan Luo*<sup>2</sup>; Penghuai Fu<sup>1</sup>; Zhenzhen Li<sup>1</sup>; Tianyu Zhu<sup>1</sup>; Liming Peng<sup>1</sup>; Wenjiang Ding<sup>1</sup>; <sup>1</sup>National Engineering Research Center of Light Alloys Net Forming and State Key Laboratory of Metal Matrix Composite, Shanghai Jiaotong University; <sup>2</sup>General Motors Research & Development Center

The microstructure and mechanical properties of as-cast Mg-Al-Sn alloys have been investigated using computational alloy design and experimental approaches. The as-cast microstructure of Mg-Al-Sn alloys consists of a-Mg, Mg<sub>17</sub>Al<sub>12</sub> and Mg<sub>2</sub>Sn phases. The volume fractions of Mg<sub>17</sub>Al<sub>12</sub> and Mg<sub>2</sub>Sn phases increase with increasing Al/Sn contents, and show good agreement between computational thermodynamics modeling and the experimental results. Generally, the yield strength of as-cast alloys increases with Al/Sn alloying contents, while the ductility decreases. This study has confirmed an earlier development of Mg-7Al-2Sn alloy and led to a promising new Mg-7Al-5Sn alloy with significantly improved strength and ductility compared to commercial alloy AZ91 (Mg-9Al-1Zn).

9:10 AM

**Thermodynamic Analysis of As-Cast and Heat Treated Microstructures of Mg-Ce-Nd Alloys:** Mark Easton<sup>1</sup>; Suming Zhu<sup>1</sup>; Mark Gibson<sup>2</sup>; Jian-Feng Nie<sup>1</sup>; Joachim Groebner<sup>3</sup>; Artem Kozlov<sup>3</sup>; *Rainer Schmid-Fetzer*<sup>3</sup>; <sup>1</sup>CAST CRC, Monash University; <sup>2</sup>CAST CRC, CSIRO, Clayton; <sup>3</sup>Clausthal University of Technology

The phase relationships in the Mg-rich corner of the Mg-Ce-Nd system have been investigated through the evaluation of selected compositions in the as-cast and heat treated condition. Consistent thermodynamic CALPHAD-type assessments have also been generated for the Mg-Ce-Nd system. It is shown that this system reveals a significant degree of metastability under technologically relevant solidification conditions (i.e. permanent-mould or high pressure die casting). This is simulated in thermodynamic calculations by suppression of the RE<sub>5</sub>Mg<sub>41</sub> phase and reasonable agreement is found with the as-cast microstructures. After heat treatment these microstructures transform, depending on alloy composition, into phase assemblies consistent with the calculated stable equilibrium phase diagram. It is the elucidation of such metastable phase formation and the subsequent transformation from the as-cast to the heat treated state that is a particular strength of the thermodynamic approach and which makes it a powerful tool for alloy development.

9:30 AM

**Compressive Strength and Hot Deformation Behavior of TX32 Magnesium Alloy with 0.4% Al and 0.4% Si Additions:** *Pitchewara Kamineni*<sup>1</sup>; YVRK Prasad<sup>2</sup>; Suresh Kalidass<sup>1</sup>; Chalasani Dharmendra<sup>1</sup>; Norbert Hort<sup>3</sup>; Karl Kainer<sup>3</sup>; <sup>1</sup>City University of Hong Kong; <sup>2</sup>processingmaps.com; <sup>3</sup>GKSS Research Centre

Mg-3Sn-2Ca (TX32) alloy has good corrosion and creep resistance. In this paper, the influence of additions of 0.4%Al and 0.4%Si on its compressive strength and hot working characteristics is reported. It is observed that the compressive strength at higher-temperature dropped significantly. By comparing with the alloy having only 0.4% Al, it is clear that the Si addition is responsible for this deterioration. The hot working behavior as characterized by processing maps revealed that TX32 exhibits two domains of dynamic recrystallization occurring at (1) 300–350 °C and 0.003–0.001 s<sup>-1</sup>, and (2) 400–500 °C and 0.003–0.3 s<sup>-1</sup>. In Al and Si containing TX32, both the domains moved to higher temperatures and the flow instability is reduced. In both the domains, the apparent activation energy is higher than that for self-diffusion in magnesium implying that there is a significant contribution from the back stress generated by the hard particles.

9:50 AM

**An Analysis of the Grain Refinement of Magnesium By Zirconium:** Partha Saha<sup>1</sup>; *Srinath Viswanathan*<sup>1</sup>; <sup>1</sup>University of Alabama

A Design of Experiments approach was used to conduct a systematic study of the grain refinement of magnesium by zirconium: variables included the amount of zirconium, the pouring temperature, and the settling time prior to

TUESDAY AM

casting. Optical microscopy was used to measure the grain size. TEM was used to identify particles that are likely nucleation sites. The TEM results show that a range of particle sizes are likely substrates and that particles which are likely nucleation sites are faceted. Sample dissolution followed by SEM was used to characterize particle size and morphology while an AccuSizer 770 was used to measure particle size distributions, both in the master alloy and grain refined samples. While only 1 to 3% of the total particles serve as nucleation sites, a comparison of the grain density vs. faceted particle density shows close agreement, suggesting that only faceted particles are likely nucleation sites.

#### 10:10 AM

**Study on the Grain Refinement Behavior of Mg-Zr Master Alloy and Zr Containing Compounds in Mg-10Gd-3Y Magnesium Alloy:** *Guohua Wu<sup>1</sup>; Ming Sun<sup>1</sup>; Jichun Dai<sup>1</sup>; Wenjiang Ding<sup>1</sup>; <sup>1</sup>Shanghai Jiao Tong University*

The effects of Mg-Zr master alloy and potassium fluozirconate ( $K_2ZrF_6$ ) salts mixture (KSM) on the grain refinement behavior are studied. The results show that the Mg-10Gd-3Y alloy is well refined by Mg-Zr or KSM. The characteristic microstructure feature of the alloy refined by Mg-Zr master alloy is the Zr-rich cores that exist in most grains, while the Zr-rich cores are not observed in the alloy refined by KSM. It is suggested that the grain refinement mechanisms of zirconium in the two cases are different: the Zr released from Mg-Zr master alloy works by generating heterogeneous nucleation, while the Zr reduced from the in-situ reaction between Mg melt and  $K_2ZrF_6$  works by restricting grain growth. Compared with the Mg-30. wt%Zr master alloy, the KSM refiner shows much longer fading time during smelting.

**The Effect of Rare Earth Elements on the Texture and Formability of Asymmetrically Rolled Magnesium Sheet:** *David Randman<sup>1</sup>; Bruce Davis<sup>1</sup>; Martyn Alderman<sup>2</sup>; Govindarajan Muralidharan<sup>3</sup>; Tom Muth<sup>3</sup>; William Peter<sup>3</sup>; Tom Watkins<sup>3</sup>; Odis Cavin<sup>3</sup>; Edward Kenik<sup>3</sup>; <sup>1</sup>Magnesium Elektron North America; <sup>2</sup>Magnesium Elektron; <sup>3</sup>Oak Ridge National Laboratory*

The lack of formability is a serious issue when considering magnesium alloys for various applications. Standard symmetric rolling introduces a strong basal texture that decreases the formability; however, asymmetric rolling has been put forward as a possible route to produce sheet with weaker texture and greater ductility. It has also been shown in recent work that weaker textures can be produced through the addition of rare earth elements to magnesium alloys. Therefore, this study has been carried out to investigate the effect of rare earth additions on the texture changes during asymmetric rolling. Two alloys have been used (AZ31B and ZEK100). The effect that the rare earth additions have on the texture of asymmetrically rolled sheet and the subsequent changes in formability will be discussed.

#### 11:10 AM

**Improvement of Strength and Ductility of Mg-Zn-Ca-Mn Alloy by Equal Channel Angular Pressing:** *Mingyi Zheng<sup>1</sup>; <sup>1</sup>Harbin Institute of Technology*

Mg-Zn-CaMn alloys are low cost and have good creep resistance, high strength and excellent biocompatibility. In this research, equal channel angular pressing (ECAP) was performed on the as-extruded Mg-5.25wt%Zn - 0.6wt%Ca - 0.3wt%Mn magnesium alloy at 250°C and 300°C for 4 passes, respectively. With the decreasing of ECAP temperature, the grain size was reduced. After ECAP at 250°C for 4 passes, extremely fine grains with the average grain size of about 0.8 micrometer are formed. High UTS of 323 MPa and elongation to failure of 23% were achieved in the specimen ECAPed at 300°C, which was resulted from the fine grains, fine dispersed precipitates and the textures in which the basal plane is oriented parallel to the extrusion direction. While the specimens processed at 250°C have textures with the basal planes inclined at about 45° to the extrusion direction, leading to the lower yield strength.

#### 11:30 AM

**Deformation Behavior of a Friction Stir Processed Mg Alloy:** *Qi Yang<sup>1</sup>; Sergey Mironov<sup>2</sup>; Yutaka Sato<sup>3</sup>; Kazutaka Okamoto<sup>4</sup>; <sup>1</sup>Hitachi America, Ltd.; <sup>2</sup>Department of Materials Processing, Graduate School of Engineering, Tohoku University ; <sup>3</sup>Department of Materials Processing, Graduate School of Engineering, Tohoku University; <sup>4</sup>Hitachi Research Laboratory, Hitachi Ltd.*

Friction stir processing, as a derivative of friction stir welding, in which a non-consumable tool imparts severe plastic deformation to metallic materials, has been used for grain refinement and therefore ductility improvement. In this talk, deformation behavior of a friction stir processed Mg alloy is addressed. Analyses of grain size and crystallographic texture are made to interpret the characteristics of strength and ductility of friction stir processed Mg. Meanwhile, mechanical properties of a friction stir processed Mg alloy are compared with those of a friction stir processed 5083 Al alloy.

#### 11:50 AM

**Effect of Heat Index on Microstructure and Mechanical Behavior of Friction Stir Processed AZ31:** *Wei Yuan<sup>1</sup>; Rajiv Mishra<sup>1</sup>; <sup>1</sup>Missouri University of Science and Technology*

Friction stir processing modifies the microstructure and properties of metals through intense plastic deformation. The frictional heat input affects the microstructure evolution and resulting mechanical properties. 2 mm thick commercial AZ31B-H24 Mg alloy was friction stir processed under various process parameter combinations to investigate the effect of heat index on microstructure and properties. Recrystallized grain structure in the nugget region was observed for all processing conditions with decrease in hardness. Results indicate a reduced tensile yield strength and ultimate tensile strength compared to the as-received material in H-temper, but with an improved hardening capacity. The strain hardening behavior of friction stir processed material is discussed.

#### 12:10 PM

**Strengthening Mg-Al-Zn Alloy by Repetitive Oblique Shear Strain:** *Toshiji Mukai<sup>1</sup>; Hidetoshi Somekawa<sup>1</sup>; Alok Singh<sup>1</sup>; Tadanobu Inoue<sup>1</sup>; <sup>1</sup>National Institute for Materials Science*

Enhancing fracture toughness and/or ductility is requirement for reliability in structural application. It has been reported that the grain refinement is one of the possible ways to enhance the strength without losing the ductility. In this study, severe plastic working by caliber rolling has been demonstrated to refine the grain structure of a commercial AZ31 Mg-Al-Zn alloy effectively at a commercial processing speed with the formation of fine sub-grains in a sub-micro-meter scale and resulted in a high yield stress of more than 400 MPa. A simultaneous operation of oblique shear strain weakened the basal texture compared to that of the initial as-extruded alloy, and resulted in tensile ductility comparable to that of the commercially extruded alloy, and showed a higher asymmetry ratio of yield stress in compression/tension (0.82) than that of the as-extruded alloy (0.57).

## Magnetic Materials for Energy Applications: Nd-Fe-B Sintered Magnets

**Materials for Motors of Hybrid Automobiles:** *Shigeru Konda*<sup>1</sup>; <sup>1</sup>Toyota Motor Corp., Inc.

It has passed over one hundred year after vehicle with gasoline engine had been released. Currently, environmental issues, such as global warming, greenhouse gas and so on, has been discussing. To realize the sustainable mobility society, Hybrid vehicle could be one of the good candidates as eco-friendly car. In this speech, the benefit of Hybrid vehicle could be described. Simultaneously, the needs and expectation for materials would be explained.

### 8:55 AM Invited

**Application of Nd-Fe-B Magnets to the Megawatt Scale Generator for the Wind Turbine:** *Takehisa Minowa*<sup>1</sup>; <sup>1</sup>Shin-Etsu Chemical Co. Ltd.

Wind power generation is cost effective compared to solar energy generation. Although energy efficiency increases with the size of generators, this makes the generator too heavy for installment. One solution is to use Nd-Fe-B based permanent magnets to make the generator smaller and lighter. Various technologies for wind power generators such as interior permanent magnet (IPM) motors and surface permanent magnet (SPM) motors have been proposed, but the best system has not been determined yet. In this talk, I will overview the technological trend and the required properties of permanent magnets for wind power generation.

### 9:20 AM Invited

**Enhancement of Coercivity of Nd-Fe-B Sintered Magnets by Grain Boundary Modifications:** *Kazuhiro Hono*<sup>1</sup>; <sup>1</sup>Tadakatsu Ohkubo<sup>1</sup>; <sup>1</sup>National Institute for Materials Science

Interest in the coercivity mechanism of Nd-Fe-B based permanent magnets has recently been revived in Japan due to the increasing demand for Dy-free Nd-Fe-B magnets for traction motors of (hybrid) electric vehicles, (H)EV. In the current Nd-Fe-B sintered magnets for the traction motors, 30% of Nd is substituted with Dy to use the increased anisotropy field of the (Nd,Dy)<sub>2</sub>Fe<sub>14</sub>B phase, but the natural abundance of Dy is only 10% of Nd. Thus, we are looking for a way to increase the coercivity of the Nd-Fe-B magnets with lower amount of Dy. For this purpose, we investigate the microstructure-coercivity relationships of Nd-Fe-B magnets by investigating the microstructures of commercial and experimental sintered magnets and hydrogen disproportionation desorption recombination (HDDR) powder by HRSEM, TEM and atom probe tomography (APT). In this talk, we will overview our recent work on the enhancement of coercivity of Nd-Fe-B based magnets by grain boundary modifications.

### 9:45 AM Invited

**Novel Approaches to Microstructural Characterisation in NdFeB Materials:** *Thomas Woodcock*<sup>1</sup>; *Nora Dempsey*<sup>2</sup>; *Dominique Givord*<sup>2</sup>; *Stefan Zaeferrer*<sup>3</sup>; *Oliver Gutfleisch*<sup>1</sup>; <sup>1</sup>IFW Dresden; <sup>2</sup>Institute Néel, CNRS-UJF; <sup>3</sup>Max Planck Institute for Iron Research

NdFeB sintered magnets have recently found important new applications in electric motors for hybrid electric vehicles and generators for wind

turbines. Magnet grades with Dy additions are typically used for such applications and this incurs a significant cost penalty. Much research effort has therefore recently been put into reducing the Dy content or eliminating Dy in NdFeB sintered magnets for high temperature applications. In addition to various experimental routes toward this, novel approaches yielding detailed microstructural characterisation are required in order to bring greater understanding of coercivity mechanisms. Recent developments include the use of aberration-corrected TEM to obtain highest spatial resolution images and the application of electron backscatter diffraction (EBSD) to obtain crystallographic orientation data on a local scale from all the phases present in the microstructure. The combination of EBSD and EDX with high resolution serial sectioning yields 3D orientation and chemical data which will also be discussed.

### 10:10 AM Invited

**Modeling of Magnetization Reversal in Nd-Fe-B Based Sintered Magnets:** *Thomas Schrefl*<sup>1</sup>; *Simon Bance*<sup>1</sup>; *Harald Oezelt*<sup>1</sup>; *Gino Hrkac*<sup>2</sup>; <sup>1</sup>St. Poelten University of Applied Sciences; <sup>2</sup>University of Sheffield

High remanent, sintered Nd-Fe-B magnets are a key material for energy saving technology. We study the magnetization reversal mechanism using a multi-scale approach. Atomistic simulations give the local distortion of the Nd<sub>2</sub>Fe<sub>14</sub>B crystal structure near grain boundaries and triple junctions. This translates into a change of the magneto-crystalline anisotropy. The thickness of the distorted region which shows a magnet-crystalline anisotropy that is considerably smaller than in the bulk depends on the composition of the intergranular phase and ranges from 0.6 nm to 1.8 nm. Taking into account these local defects, we apply finite element micromagnetics. The simulations show how reversed domains are nucleated near triple junctions. Domains expand over several grains. Domain walls are equally located at grain boundaries or go through the grains. The simulations show cascade type demagnetization in well-aligned sintered magnets.

### 10:35 AM

**Theoretical Investigation on Formation Mechanism of fcc-NdOx in Nd/Nd-Fe-B Interface:** *Ying Chen*<sup>1</sup>; *Satoshi Hirotsawa*<sup>2</sup>; *Shuichi Iwata*<sup>3</sup>; <sup>1</sup>Tohoku University; <sup>2</sup>NEOMAX Co., Hitachi Metals, Ltd.; <sup>3</sup>The University of Tokyo

The disordered fcc-NdOx phase formed at the interface of Nd/Nd-Fe-B is believed to take an important role in coercivity generation, and its appearance directly influenced by the oxygen concentration. To understand the formation mechanism and properties of this particular Nd oxides phase, the ground state stability analysis for a whole oxygen concentration in Nd-O has been performed based on LSDA + U calculations. It is revealed that at low oxygen concentration, the system tends to separate into dhcp-Nd and NdO-NaCl or NdO-ZnS, whereas at oxygen concentration over 50%, the Nd<sub>2</sub>O<sub>3</sub> becomes most stable. Further investigation is focused on the relation among Fluorite-NdO<sub>2</sub>, C-type(c180)-Nd<sub>2</sub>O<sub>3</sub> and ZnS-NdO which have same fcc-frame of cations and vary in configurations of oxygen anions due to introducing oxygen vacancies. Formation energies, electronic structures for various oxygen vacancies configurations are calculated along this line.

### 10:50 AM

**NdFeB Thick Films for Micro-System Applications:** *Nora Dempsey*<sup>1</sup>; *Mikhail Kustov*<sup>1</sup>; *Daniel O'Brien*<sup>1</sup>; *Yuepeng Zhang*<sup>1</sup>; *Luiz Zanini*<sup>1</sup>; *Georgeta Ciuta*<sup>1</sup>; *Frederic Dumas-Bouchiat*<sup>1</sup>; *Dominique Givord*<sup>1</sup>; <sup>1</sup>Institut Néel CNRS/UJF

For the same reasons (high magnetisation and high coercivity) that NdFeB based magnets are widely used in bulk applications such as hybrid and all electric vehicles and wind turbines, they have much potential for use in magnetic micro-systems. In addition, since the force exerted by a magnet depends of the field gradient it produces, a reduction in its size leads to an increase in the volume forces it exerts. Consequently, much effort has been put into the fabrication of NdFeB in film form. In this work we will present different aspects concerning their eventual use in micro-systems, namely their patterning at the micron-scale, the local characterisation of the magnetic fields they produce and the characterisation and control of strain in the films. Such films may be used in the generation of energy at the micron scale

(micro-generators) and to improve the efficiency of energy consumption at the macro-scale (micro-sensors, micro-actuators).

11:20 AM

**Magnetostrictive Behavior of Fe-W Alloy Single Crystals:** *Gavin Garside<sup>1</sup>; Chai Ren<sup>1</sup>; Biswadeep Saha<sup>1</sup>; Meenakshisundaram Ramanathan<sup>1</sup>; Sivaraman Guruswamy<sup>1</sup>; <sup>1</sup>University of Utah*

A systematic examination of change in magnetostriction as a function of W content in the range of 0 to 10 at.% is presented in this paper. Fe-W alloy single crystals were prepared using vertical Bridgman growth technique. Single crystal samples with [001]-orientation were prepared with faces within 0.5 degrees from [001] orientation. The samples were annealed in the alpha-phase region and quenched. Longer annealing times and higher annealing temperatures increase the magnetostriction values obtained. Rapid increase in magnetostriction is observed with W additions of up to 4.4 at.% W. This is followed by a much slower increase with W content. This behavior is associated with the propensity for second phase formation at higher W contents in these alloys. \*Support of this work by NSF-DMR under the award DMR-0854166 is gratefully acknowledged.

11:35 AM

**Investigation of DO<sub>3</sub> and B2 Type Ordering in Quenched Magnetostrictive Fe-27.5 at.%Ga Alloy Single Crystals:** *Chai Ren<sup>1</sup>; Gavin Garside<sup>1</sup>; Biswadeep Saha<sup>1</sup>; Meenakshisundaram Ramanathan<sup>1</sup>; Sivaraman Guruswamy<sup>1</sup>; <sup>1</sup>University of Utah*

FeGa alloys with large low-field magnetostriction are attractive candidates in energy conversion and harvesting applications. The structural ordering in magnetostrictive Fe-27.5 at.% Ga alloy single crystals that were annealed in the alpha region and quenched was investigated using x-ray diffraction. The annealing temperatures used were 1100 and 1150 degree C. XRD examination as a function of depth in [100] or [111] oriented Fe-Ga samples show dominant existence of DO<sub>3</sub> type ordering arrangement on the top surface to B2 type ordering arrangement in the interior regions of the sample. The detailed examinations of scattering peaks in the XRD patterns suggest that the nature of short-range and long-range ordering present is influenced by sample size and thermal history. Thus sample size and shape will influence magnetostriction measurements. The observations are of importance in magnetostrictive device design. \*Support of this work by NSF through the award DMR-0854166 is gratefully acknowledged.

11:50 AM

**Influence of Plastic Deformation on the Magnetostrictive Behavior of [001]-oriented Fe-Ga Alloy Single Crystals:** *Biswadeep Saha<sup>1</sup>; Gavin Garside<sup>1</sup>; Meenakshisundaram Ramanathan<sup>1</sup>; Chai Ren<sup>1</sup>; Sivaraman Guruswamy<sup>1</sup>; <sup>1</sup>University of Utah*

Structural ordering, defects and second phases can influence the magnetostrictive behavior in Fe-Ga and other Fe-based magnetostrictive

alloys. In this study, the influence of dislocations on the magnetostrictive behavior of [001]-oriented Fe-20 at.% Ga single crystal is examined. Dislocation arrays were introduced through controlled deformation of rectangular parallelepiped single crystal samples with the faces oriented to within 0.25 degrees off the <100> orientation. Alloy single crystals were obtained through vertical Bridgman growth process. The crystals were plastically deformed to predetermined strain level. Magnetostriction measurements as well as TEM and x-ray examinations were performed prior to and after deformation. Results obtained show that deformation decreases magnetostriction values appreciably.\*Support of this work by NSF-DMR through the award DMR-0854166 is gratefully acknowledged.

12:05 PM

**Enhanced Magnetoimpedance Effect in Co89Zr7B4 Ribbon/Fe80Ni20 Bilayer Structures:** *N. Laurita<sup>1</sup>; A. Chaturvedi<sup>1</sup>; A. Leary<sup>2</sup>; P. Jayatilaka<sup>1</sup>; C. Bauer<sup>1</sup>; Casey W. Miller<sup>1</sup>; M.H. Phan<sup>1</sup>; M.E. McHenry<sup>2</sup>; H. Srikanth<sup>1</sup>; <sup>1</sup>University of South Florida; <sup>2</sup>Carnegie Mellon University*

We report the large enhancement of the magnetoimpedance (MI) effect in CoFe89Zr7B4 amorphous ribbon/Fe80Ni20 bilayers. The amorphous ribbons were prepared by rapid quenching. Atomic force microscopy indicate roughnesses for the free and wheel-side ribbon surfaces of 3-6 nm and 150-200 nm, respectively. 100 nm Fe80Ni20 layers were sputtered onto the ribbons; one sample was coated in zero field, another in 200 Oe applied transverse to the length. Magnetoimpedance measurements were carried out along the ribbon axis in applied dc magnetic fields up to 120 Oe over a frequency range of 0.1 ~ 13 MHz. We find that the MI effect is largely enhanced in the Fe80Ni20-coated ribbons. The 200 Oe-deposited sample shows the largest effect (19%), which is about twice that of the bare ribbon (11%). Our studies provide strong evidence for enhancing the MI effect in layered structures for sensor applications. Support: NSF-DMMI (HS). NSF-ECCS (CWM).

**Ultra-Large Scale Simulations of Deformation and Failure of Biological Protein Materials:** *Markus Buehler<sup>1</sup>; <sup>1</sup>Massachusetts Institute of Technology*

Deformation and failure of biological protein materials are critical to our understanding of injuries, disease state, and to reverse-engineer the functional design of biological materials. I will present a survey of recent materiomics studies in our laboratory based on ultra-large scale simulations using LAMMPS. The talk will include a discussion of investigations of intermediate filament fibrils and networks, beta-sheet structures as found in spider silk and amyloids, as well as collagenous tissues that form the structure of tendon and bone. Case studies will be presented that illustrate size effects in protein materials, flaw-tolerance mechanisms, and applications of materials science to genetic diseases, showing how structural defects at the molecular level can have profound effects at the material behavior at larger scales. A detailed analysis will be presented to explain how biological materials overcome the limitations of their building blocks, often functionally inferior, and yet display remarkable functional properties.

### 8:55 AM Invited

**Multilevel Atomistic Modeling of Grain Boundaries and Nanocrystals:** Garritt Tucker<sup>1</sup>; Shreevart Tiwari<sup>1</sup>; David McDowell<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology

Deformation in nanocrystalline metals involves interface-mediated processes that depend on grain boundary network and structure, with atom shuffling/GB sliding/migration and dislocation nucleation as competing modes. As a step towards informing statistical descriptions of initial yield and plastic flow, and setting the stage to quantify percolation and scaling relations, we apply recently developed volume-averaged metrics of continuum kinematic quantities as post-processing “filters” to results of atomistic simulations of deformation using the LAMMPS MD code, computing vorticity, Green strain, dilatation, and lattice microrotation fields within nanocrystalline copper at a temperature of 10K. The results provide a new, alternative perspective into the role of competing deformation mechanisms as a function of boundary type in bicrystals and mean grain size in nanocrystals. Our results indicate potential utility of these continuum metrics in interpreting the wealth of information arising from atomistic simulations of nanocrystalline ensembles.

### 9:20 AM Invited

**Quantitative Studies of Nanoindentation: Coupled Experiments and Modeling:** Lyle Levine<sup>1</sup>; Richard Wagner<sup>1</sup>; Li Ma<sup>1</sup>; Francesca Tavazza<sup>1</sup>; Chandler Becker<sup>1</sup>; Douglas Smith<sup>1</sup>; Dylan Morris<sup>1</sup>; David Bahr<sup>2</sup>; Stefhanni Jennerjohn<sup>2</sup>; <sup>1</sup>National Institute of Standards and Technology; <sup>2</sup>Washington State University

Nanoindentation's ability to probe the local plastic mechanical properties at the surface of almost any specimen has made it the most widely used experimental technique for making such measurements at the nanoscale. However, standard test methods are limited and full traceability to primary reference standards is lacking. At low indentation loads, numerous potential experimental problems exist, including non-traceable force calibration at the nN level, uncharacterized irregular indenter tip shapes, and structural heterogeneities both on and below the sample surface. Similarly, attempts to back out quantitative mechanical properties often suffer from over-reliance on the Hertzian approximation and inaccurate boundary conditions for simulations. Example measurements and simulations (using FEA and LAMMPS-MD) for both new and heavily used indenters will be used to illustrate these problems for metal specimens. Finally NIST's recent efforts to provide quantitative experimental and modeling support for this valuable experimental technique will be described.

### 9:45 AM Invited

**Nanostructurally Small Cracks (NSC): Atomistic Modeling of Fatigue:** Mark Horstemeyer<sup>1</sup>; G. Potirniche<sup>2</sup>; S. Kim<sup>1</sup>; T. Tang<sup>1</sup>; Diana Farkas<sup>3</sup>; <sup>1</sup>Mississippi State University; <sup>2</sup>Univ. Idaho; <sup>3</sup>Virginia Tech

Molecular Dynamics simulations using EAM and MEAM potentials were conducted to study nanoscale fatigue cracks in nickel and copper crystals. Simulation results revealed that the cyclic plastic deformation at the crack tip was the main influencing factor for fatigue crack growth. Two main nanoscale mechanisms of crack propagation were observed: (1) the main cracks linked with the voids nucleated in front of crack tip due to high dislocation density generated by the cyclic loading; and (2) the main cracks broke the atomic bonds in the crack plane without much plasticity. For the bicrystals and polycrystals, the grain boundaries exerted resistance to the crack propagation. Fatigue crack growth rates for nanocracks were computed and compared with growth rates published in the literature. The atomistic simulations indicated that reversible plastic slip along the active crystallographic directions at the crack tip was responsible for advancing the crack during applied cycling.

### 10:10 AM Break

### 10:25 AM

**Atomistic Predictions of Age Hardening in Al-Cu Alloys:** Chandra Veer Singh<sup>1</sup>; Derek Warner<sup>1</sup>; <sup>1</sup>Cornell University

A large class of commercial alloys derive their strength from precipitation hardening. In many alloys, such as Al-Cu, hardening is a complex function of time and temperature as the precipitation process involves several types of competing metastable precipitates. Here we combine analytic models for microstructural kinetics with large-scale atomistic simulations (LAMMPS) of dislocation-precipitate and dislocation-solute interactions to examine the precipitation hardening process in an Al-Cu alloy. We compute the critical stresses for dislocations to overcome both GP zones and theta'' precipitates directly from atomistic simulations and use an improved Labusch model with atomistically computed interaction energies to calculate solute hardening. Combining strengthening effects, age hardening curves are then formulated and compared with experiments. By comprehensively examining the entire age hardening process, insight can be gained into the strengths and weaknesses of both common kinetics models and potential based atomistic simulations for broad application.

### 10:45 AM

**Massively Parallel Molecular Statics Simulations of the Percolation of Dislocations through a Random Array of Forest Dislocation Obstacles in FCC Nickel:** Satish Rao<sup>1</sup>; Dennis Dimiduk<sup>2</sup>; Jaafar El-Awady<sup>3</sup>; Triplicane Parthasarathy<sup>1</sup>; Michael Uchic<sup>2</sup>; Christopher Woodward<sup>2</sup>; <sup>1</sup>UES Inc.; <sup>2</sup>Air Force Research Laboratory; <sup>3</sup>Johns Hopkins University

This talk presents results from massively parallel molecular statics simulations, using LAAMPS with ~ 10,000 processors, of the percolation of dislocations through a random array of forest dislocation obstacles in face-centered cubic Nickel. A single gliding dislocation and 540 forest dislocations are inserted into a 0.6µm by 0.3µm by 0.3µm rectangular parallelepiped cell aligned along the [1-10], [11-2] and [111] directions, containing ~ 1 - 2 billion atoms. The behavior of the percolating dislocation under pure shear stresses applied on the (111) plane are simulated. Details of the percolating wave front and the critical stress required for percolation are obtained from the simulation results. These atomistic results representing the critical percolation stress for dislocations are compared with previous dislocation dynamics and point-obstacle pinning simulation results.

### 11:05 AM

**Atomic Scale Deformation Mechanisms of Amorphous Polyethylene under Tensile Loading:** Mark Tschoop<sup>1</sup>; Jean-Luc Bouvard<sup>1</sup>; Don Ward<sup>2</sup>; Mark Horstemeyer<sup>1</sup>; <sup>1</sup>Mississippi State University; <sup>2</sup>Sandia National Laboratory

Thermoplastic polymers, such as polyethylene and polypropylene, play an important role in components. However, to date, the molecular deformation behavior at an atomistic level involves coarse-graining potentials, such as the Dreiding potential. The objective of this research is to study the deformation mechanisms in full-atom amorphous polymer systems at the atomic scale under various loading conditions. We generated the amorphous structures and then used molecular dynamics simulations to equilibrate/deform the 3D periodic simulation cell. Various parameters like chain length, number of chain, strain rate were taken into consideration to study their influence on both the stress-strain behavior and the deformation mechanisms. Additionally, we analyzed how the energy associated with bond length, bond angle, dihedral angle, and non-bonding interactions evolved as a function of strain. The significance of this research is that understanding the deformation behavior at the atomic scale is vital to predicting bulk mechanical behavior via higher scale models.

### 11:25 AM

**Energy of Slip Nucleation and Transmission at Grain Boundaries:** Michael Sangid<sup>1</sup>; Huseyin Sehitoglu<sup>1</sup>; <sup>1</sup>University of Illinois, Urbana-Champaign

Grain boundaries (GBs) provide a strengthening mechanism in engineering materials by impeding dislocation motion. In a polycrystalline material,

there is a wide distribution of GB types with characteristic slip transmission and dislocation nucleation behaviors. There is a strong need to quantify the energy barriers of the individual GBs. We introduce a methodology to calculate the energy barriers during slip-GB interaction, in concurrence with the general stacking fault energy curve for slip in a perfect FCC material. By doing so, we calculate the energy barriers for slip transmission and nucleation from various classifications of GBs. The character and structure of the GB plays an important role in impeding slip within the material. From this analysis, we show that there is a strong correlation between the energy barrier and static interfacial boundary energy. The results have profound implications in understanding mechanical response influenced by the underlying grain boundary characters.

**11:45 AM**

**Molecular Dynamics Investigations of Polyurethane-Chrome Oxide Interfaces:** *Susanne Opalka*<sup>1</sup>; Kenneth Smith<sup>1</sup>; <sup>1</sup>United Technologies Research Center

Polyurethane-chrome oxide atomic-scale interfacial interactions were simulated with the LAMMPS molecular dynamics code to generate fundamental understanding of adhesion phenomena for component design and optimization. This modeling capability was implemented sequentially at several levels, creating models based upon experimentally-known material properties and validating modeling results with experimental tests. First, polymer models were refined by tuning both polymer characteristics and atomic force field parameters to achieve agreement with measured polymer thermal and mechanical properties. Then, hybrid force field parameters for the interactions of key polyurethane functional groups with the passivated chrome surface layer were customized to match interfacial surface tension measurements. Finally, virtual adhesion tests were conducted on conditioned polyurethane-chrome oxide interface models for comparison with nanoscale pull-test experimentation. The validated models will be used for molecular dynamics investigations of viscoelastic phenomena in a moving polyurethane-chrome oxide contact leading to material friction, wear, and transfer.

**12:05 PM**

**Tendency of Cooperative Grain Boundary Sliding in Nanocrystalline Materials:** *Shreevant Tiwari*<sup>1</sup>; David McDowell<sup>1</sup>; <sup>1</sup>Georgia Institute of Technology

The objective of this research is to identify the tendency of cooperative grain boundary (GB) sliding, leading to grain rotation in nanocrystalline metals. We use molecular dynamics (MD) simulations to uniaxially deform 3D nanocrystalline Cu ensembles in the elastic regime and visualize, for each grain, the rotational component of the atomic displacement vector field relative to the grain center. Our results suggest that the rotational component of the relative displacement is more pronounced in regions near certain preferred GBs and triple junctions, and that the extent of rotation in these favored boundary regions increases with temperature, thereby hinting at a thermally activated, cooperative GB sliding mechanism. Additionally, the rotational displacement field used as a part of this work can potentially help resolve GB sliding from a background of several other competing deformation mechanisms, and augment existing metrics of atomistic deformation kinematics.

**On the Prospects for Developing Advanced Alloys that Are Immune to Irradiation: Challenges and Opportunities:** *G. Robert Odette*<sup>1</sup>; Takuya Yamamoto<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara

The approaches to developing alloys that are highly resistant to irradiation damage at high displacement damage (dpa) and helium levels are discussed. Nanostructured ferritic alloy class (NFAs) is the leading candidate for such irradiation tolerance. NFAs are Fe-Cr based ferritic stainless steels that contain an ultrahigh density of Y-Ti-O nanofeatures (NFs). The NFs are remarkably thermally stable and provide outstanding high temperature properties and remarkable tolerance to displacement damage as well as the degrading effects of transmutation product helium. The results of recent in situ injection experiments show that the NFs trap helium in ultrafine scale interface bubbles. The helium bubbles are effective sinks for point defects as well as additional helium, and at high densities can suppress almost all manifestation of radiation damage. It is argued that NFAs can be tailored to effectively transform helium from a liability to an asset, possibly leading to near immunity to irradiation damage.

**8:55 AM**

**A Multi-Layer Approach to a Stable Alpha Alumina Barrier Layer on Alloy 617:** *Elizabeth Clark*<sup>1</sup>; James Yang<sup>1</sup>; Gokce Gulsoy<sup>2</sup>; Deepak Kumar<sup>2</sup>; Gary Was<sup>2</sup>; Carlos Levi<sup>1</sup>; <sup>1</sup>University of California, Santa Barbara; <sup>2</sup>University of Michigan

Alloy 617 is a candidate material for heat exchangers in the GenIV very high temperature nuclear reactor concept. However, impurities in the He may lead to degradation by oxidation, carburization or decarburization of the alloy with deleterious effects on its structural integrity. Alpha-alumina is attractive as a protective barrier layer, but to assure that this phase forms (rather than transient aluminas) in the low pO<sub>2</sub> environment at the use temperature (T≤1000°C), surface modification is required. Lifetime requirements also demand stability of the modified surface layers against interdiffusion with the substrate, and the ability of the oxide to re-form in the event of cracking or spallation due to thermo-mechanical stresses in the prospective applications. This presentation will discuss concepts involving alloy 617 with combinations of aluminization and/or cladding, their oxidation and interdiffusion behavior, and preliminary results on their response to exposure to He with CO/CO<sub>2</sub> ratios conducive to carburization or oxidation/decarburization.

**9:15 AM**

**Order-Disorder Transformation in a Ni-Cr-Mo Alloy:** *Amit Verma*<sup>1</sup>; *Jung Singh*<sup>1</sup>; Mahadevan Sundararaman<sup>1</sup>; Nelia Wanderka<sup>2</sup>; <sup>1</sup>Bhabha Atomic Research Centre; <sup>2</sup>Helmholtz-Zentrum Berlin für Materialien und Energie GmbH

Ni-Cr-Mo alloys are potential candidates for structural materials application for high temperature reactors. These alloys form a long-range order (LRO) precipitates, Ni<sub>2</sub>(Cr,Mo) (Pt<sub>2</sub>Mo type structure), in the intermediate temperature range. The evolution of ordered precipitates has

been investigated in a Ni-Cr-Mo alloy using resistivity and transmission electron microscopy (TEM). The relative change in resistance as a function of temperature could be divided into 5 regimes, which could be attributed to different microstructural states. TEM investigations revealed the presence of two types of short-range order (SRO) in solution treated and quenched state: a  $\{1\ 1/2\ 0\}$  type SRO and a  $1/3\{110\}$  type SRO of Pt<sub>2</sub>Mo type. The formation of the LRO could be identified to initiate at  $\{1\ 1/2\ 0\}$  SRO which transformed first to  $1/3\{110\}$  type SRO followed by LRO transition. The SRO state also had an important influence on the kinetics of the transformation.

#### 9:35 AM

**Creep Characteristics of a Grade 91 Steel:** *Tirratna Shrestha*<sup>1</sup>; Mehdi Basirat<sup>1</sup>; Zachary Wuthrich<sup>1</sup>; Indrajit Charit<sup>1</sup>; Gabriel Potirniche<sup>1</sup>; Karl Rink<sup>1</sup>; <sup>1</sup>University of Idaho

Modified 9Cr-1Mo (Grade 91) steels are being considered as a potential candidate material for reactor pressure vessel applications for the Very High Temperature Reactor (VHTR). This research has been focused on studying the tensile creep behavior of as received and welded Grade 91 steel as a function of temperature (500–700 °C) and stress levels (50–200 MPa). The creep testing on the monolithic materials revealed a deformation regime with a stress exponent of ~10 at the higher stress levels. Microstructural analysis using transmission electron microscopy (TEM) is being carried out on the specimens before and after the creep deformation. TEM results will be correlated with the creep parametric dependencies to elucidate the underlying creep mechanisms.

#### 9:55 AM

**Microstructural Characterization of Nuclear Grade Graphites:** *Joshua Kane*<sup>1</sup>; Karthik Chinnathambi<sup>1</sup>; Rick Ubic<sup>1</sup>; Darryl Butt<sup>1</sup>; <sup>1</sup>Boise State University

Nuclear graphite is a prime candidate material for application in Generation IV Very High Temperature Reactor (VHTR) cores because of its high temperature thermo-mechanical properties, resilience to neutron absorption, and chemical resistance. Irradiation induced damage and creep are considered two primary degradation mechanisms for graphite and therefore major life-limiting issues for the VHTR core. This work reports preliminary transmission electron microscopy results of the microstructure characterization of Generation IV VHTR candidate virgin graphite grades PCEA and NBG-18 as well as historical grades IG-110 and PGX. Various microstructural features such as filler, binder, and quinoline insoluble particles have been identified for each grade and compared. Studies are currently underway to identify and analyze dislocations and pinning sites considered, in many theories, essential to irradiation creep in graphite.

#### 10:25 AM

**Evaluation of Nanofeature Evolution in the Sequence of Atomization to Consolidation Steps in Processing a Fe<sub>14</sub>Cr<sub>3</sub>W<sub>0.4</sub>Ti<sub>0.2</sub>Y Alloy:** *Nicholas Cunningham*<sup>1</sup>; Erich Stergar<sup>1</sup>; Auriane Etienne<sup>2</sup>; G. Robert Odette<sup>1</sup>; Yuan Wu<sup>1</sup>; Brian Wirth<sup>2</sup>; Stuart Maloy<sup>3</sup>; <sup>1</sup>UC Santa Barbara; <sup>2</sup>UC Berkeley; <sup>3</sup>Los Alamos National Laboratory

Nanostructured ferritic alloys (NFAs) contain an ultrahigh density of Y-Ti-O nanofeatures (NFs) that provide outstanding high temperature properties and remarkable tolerance to irradiation damage. NFA powders were produced by gas atomization from a melt containing Fe-14%Cr-3%W-0.4%Ti-0.2%Y. Electron probe microanalysis (EPMA), atom probe tomography (APT), small angle neutron scattering (SANS), transmission electron microscopy (TEM) and microhardness measurements were used to characterize the NFA in the as-atomized, ball milled, ball milled and annealed and hot isostatic pressed (HIP) consolidated conditions. Y is phase separated in the as atomized powders. However, attritor milling for 20 to 40 h mixes the Y and introduces O. Subsequent powder annealing and consolidation treatments, typically at 1150°C, result in the precipitation of a high density of NFs. All the annealed powder variants and consolidated alloys show a bimodal grain size distribution, but APT shows the presence of NFs in both large and small grains.

#### 10:45 AM

**Spatially-Dependent Cluster Dynamics Modeling of Vacancy and Interstitial Cluster Evolution in Ferritic/Martensitic Fe-Cr Alloys:** *Thibault Faney*<sup>1</sup>; Aaron Kohnert<sup>1</sup>; Brian Wirth<sup>1</sup>; Djamel Kaoumi<sup>2</sup>; Arthur Motta<sup>3</sup>; <sup>1</sup>UC Berkeley; <sup>2</sup>USC; <sup>3</sup>Penn State University

Computational materials modeling will investigate the mechanisms controlling microstructural evolution in ferritic/martensitic alloys following high dose, high temperature radiation exposure. The aim of this study is to understand and predict primary defects production and defects diffusion, clustering and interaction in a thin foil heavy ion irradiation of ferritic/martensitic steels. The model involves spatially dependent rate theory, or cluster dynamics, equations that describe the evolution of self-interstitial (mainly interstitial loops) and vacancy clusters (voids) in ferritic-martensitic steels under irradiation. The key parameters that are input to the model are determined from a combination of atomistic materials modeling and available experimental data. A new cascade dynamics model from molecular dynamics has been implemented which improves the accuracy of the results, as well as adaptive time stepping methods which allow to simulate up to higher doses. The Modeling predictions are compared with experimental results obtained at the IVEM facility in Argonne National Laboratory.

#### 11:05 AM

**Experimental and Modeling Studies on the Effects of a Wide Range of Flux on the Microstructures and Mechanical Properties of RPV Steels – Predicting Low Flux High Fluence Embrittlement:** *Takuya Yamamoto*<sup>1</sup>; G. Robert Odette<sup>1</sup>; Nicholas Cunningham<sup>1</sup>; Douglas Klingensmith<sup>1</sup>; Randy Nanstad<sup>2</sup>; <sup>1</sup>Univ. California Santa Barbara; <sup>2</sup>Oak Ridge National Laboratory

Transition temperature shifts (TTS) of reactor pressure vessels (RPV) steels must be predicted at extended life fluences that are far beyond the existing surveillance database. High fluences can be achieved only in test reactors at fluxes that are much higher than under vessel service. TTS are primarily caused by nm-scale hardening features including: a) thermally stable defect solute matrix features; b) thermally unstable matrix defects; c) and Cu-Mn-Ni rich precipitates. Flux affects both the concentrations and balance of these features, thus, the TTS for a given alloy and irradiation condition. We present a database and analysis of irradiation hardening and the evolution of the nm-scale features for a large set of alloys for a very wide range of fluxes and fluences in both the as-irradiated and annealed conditions. The database and analysis is used to develop a physically based model for predicting TTS at high fluence and low flux.

#### 11:25 AM

**Material Constraints on Accelerator Driven Sub-Critical Molten Salt Thorium Reactors:** *John Wallace*<sup>1</sup>; Ganapati Myneni<sup>2</sup>; <sup>1</sup>Casting Analysis Corp; <sup>2</sup>Thomas Jefferson Nat. Accelerator Facility

The development of linear superconducting accelerators has progressed so efficient and reliable machines can be used for neutron spallation sources. Future materials advances in these machines can be expected to improve their operating efficiencies. These hinge on understanding hydrogen and coatings in the niobium superconducting resonant cavities which provide the accelerating fields. Other than basic research these machines open the possibility of controlling thorium fission reactors as a heat sources for power generation and PWR nuclear waste digestion. This compact reactor is examined for long term materials stability both in the interface region of the spallation source, the long term integrity of the internal graphite structures and nickel based containers and piping. Historically there is limited data on materials degradation in the molten salt environment for periods of 40 years. Accelerated testing and monitoring of material degradation in a range of environments will be discussed along with preliminary experiments.

#### 11:45 AM

**Stress Corrosion Cracking Behavior of Ferritic and Austenitic Stainless Steels in High Temperature Water:** *Raul Rebak*<sup>1</sup>; Peter Andresen<sup>1</sup>; <sup>1</sup>GE Global Research

Austenitic stainless steels such as type 304 and 316 are used widely as core internals components in light water reactors. Under certain operation conditions these materials may be susceptible to stress corrosion cracking

and irradiation assisted stress corrosion cracking. Irradiation may produce hardening and alter the local chemistry of the alloys, which may increase their susceptibility to environmentally assisted cracking. Ferritic stainless steels are less susceptible to irradiation damage such as void swelling than the austenitic cousins. Ferritic stainless steels also offer higher thermal conductivity and lower expansion coefficients. Little is known however about the stress corrosion cracking behavior of ferritic steels in high temperature water. Crack propagation rate studies were conducted using four types of ferritic steels in high purity water at 288°C containing dissolved oxygen or dissolved hydrogen. The cracking susceptibility results obtained with the ferritic steels are compared with literature data for austenitic stainless steels.

12:05 PM

**Mechanical Properties of Advanced NF616 Steel:** *Mikhail Sokolov*<sup>1</sup>; *Lizhen Tan*<sup>1</sup>; <sup>1</sup>ORNL

Fracture toughness, Charpy impact and tensile properties of advanced ferritic-martensitic 9Cr-1.8WNbV steel NF616 were characterized in the wide temperature range from room temperature to 650C. This steel is one of the candidates of high-temperature structural materials in the next generation nuclear systems. Tensile properties are similar in transverse and longitudinal orientations. Strength was decreasing with increase of test temperature. This alloy exhibited considerable fracture toughness properties up to 650C. In addition, thermomechanical treatment is being developed on the as-received NF616. Preliminary results of Vickers microhardness and tensile tests showed enhancement in microhardness and both strength and ductility compared to the as-received NF616. Microstructural characterization is being performed to explain the properties enhancement induced by the thermomechanical treatment. The effects of thermomechanical treatment on fracture toughness will be discussed as well.

## Materials in Clean Power Systems VI: Clean Coal-, Hydrogen Based-Technologies, and Fuel Cells: Materials for Gasification and Turbines II

**Gas Turbines of the Future: Hydrogen and Oxy-Combustion Environments:** *Jeffrey Hawk*<sup>1</sup>; *Gordon Holcomb*<sup>1</sup>; <sup>1</sup>U.S. Department of Energy

Materials issues related to higher efficiency power plants, like hydrogen or oxy-fuel fired gas turbines, require materials with higher temperature capability than the current generation of turbines. Research to extend the usable critical temperature of nickel superalloys has focused on maintaining the strength and integrity of grain boundaries and the interface between the grain boundary phases (carbide and/or TCP) and the matrix, as well as improving the long-term stability of fine strengthening precipitates at the use temperature. Concurrent with achieving these goals is to understand how temperature, stress, and environment affect grain boundary, matrix and surface/coating interface stability as a consequence of exposure to the gas turbine environment. This presentation will focus on specific features of the microstructure and how these features are affected due to exposure to an

oxy-combustion type environment. The affect on low cycle fatigue will be discussed as well as the fracture morphology.

8:55 AM

**Tempered Martensitic Ferritic Steel Alloy Development for Ultrasupercritical Steam Applications:** *Christopher Cowen*<sup>1</sup>; *Jeffrey Hawk*<sup>1</sup>; *Paul Jablonski*<sup>1</sup>; <sup>1</sup>United States Department of Energy

Advanced 9-12% Cr tempered martensitic ferritic steels form the majority tonnage of components used in coal fired power plants that operate in the temperature range of 570-620°C. Computational and experimental alloy development efforts at NETL are focused on increasing the temperature capability of this class of alloy to 650°C in order to increase power plant efficiency while simultaneously decreasing the cost of construction and carbon footprint. This presentation focuses on microstructural stability issues and preservation of strengthening mechanisms that are keys to the successful development of advanced 9-12% Cr steels that meet minimum creep life requirements at 650°C for 100,000 hours and 100 MPa. Compositional, thermo-mechanical, weldability, and inspectability requirements for advanced 9-12% Cr steels are also discussed. Microstructural development and creep behavior determined in tandem for the newly developed NETL alloys as well as for COST E, B2, and FB2 alloys is presented.

9:15 AM Invited

**Accelerating High-Performance Materials Design: An Integrated Computational and Experimental Approach:** *Michael Gao*<sup>1</sup>; *De Nyago Tafen*<sup>1</sup>; *Kaisheng Wu*<sup>1</sup>; *Rongxiang Hu*<sup>1</sup>; *Vijay Jain*<sup>1</sup>; *Omer Dogan*<sup>1</sup>; *Jeff Hawk*<sup>1</sup>; *Chris Cowen*<sup>1</sup>; *Paul Jablonski*<sup>1</sup>; *Michael Widom*<sup>2</sup>; <sup>1</sup>NETL; <sup>2</sup>Carnegie Mellon University

In order to reduce harmful environmental emission from coal-fired power plants, National Energy Technology Lab has developed various high-performance materials. For example, high-temperature structural alloys based on Cr and Nb for components to be used in oxy-fuel or hydrogen combustion turbines; crystalline and non-Pd amorphous membrane alloys for hydrogen separation; ferritic Fe-based alloys capable of use at 650°C in advanced combustion systems to reduce the amount of CO<sub>2</sub> emission. We have adopted an approach that integrates computer simulations with critical experiments to accelerate new materials design. Balancing structure-property relationship require delicate tradeoffs and compromises by manipulating alloy system and composition, microstructure, coatings, and materials processing. During this talk, we will present ongoing research effort implementing this approach to design high-performance materials, using combination of computer simulation techniques such as first principles calculations, Molecular Dynamics simulations, CALPHAD modeling, microstructure simulations using phase field, and mechanical property simulations using discrete FFT.

9:40 AM Invited

**Effect of Oxy-Firing on Fireside Corrosion Rates:** *Michael Bestor*<sup>1</sup>; *Bruce Pint*<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

Oxy-firing has been suggested as a method to reduce NO<sub>x</sub> emissions and capture CO<sub>2</sub> from coal-fired power plants. This process involves recirculating the flue gas and will increase the CO<sub>2</sub>, and likely the H<sub>2</sub>O and SO<sub>2</sub> concentrations, in the boiler. In order to understand the role of substrate chemistry on corrosion behavior, commercial and model alloys are being exposed in standard fireside corrosion tests with and without synthetic ash. The gas composition is varied to reflect air-firing and various oxy-firing scenarios. The current testing was performed at 600°C with ferritic steels the primary focus; however, austenitic steels and Ni-base alloys also were exposed with the former showing the lowest corrosion attack. Research sponsored by the Office of Fossil Energy, Advanced Research Materials Program, U. S. Department of Energy.

**Oxidation Kinetics Modeling Applying Phase Field Approach:** *Youhai Wen*<sup>1</sup>; Long-Qing Chen<sup>2</sup>; Jeff Hawk<sup>1</sup>; <sup>1</sup>National Energy Technology Laboratory; <sup>2</sup>Penn State University

Components in high temperature fossil energy applications are usually exposed to an aggressive environment containing H<sub>2</sub>O, CO, CO<sub>2</sub>, CH<sub>4</sub>, and O<sub>2</sub>. As service temperature of advanced fossil energy systems increase, chemical reaction rates will increase exponentially and environmental attack will become much more of a concern to designers and in life prediction models. In this work, a general phase-field model is formulated to model the oxidation kinetics. This model can be used to simulate the temporal evolution of oxide thickness and oxygen profile under various conditions such as microstructure dependent diffusivities and simultaneous scale formation and exfoliation. The long term goal of this project is to develop a quantitative tool to predict oxidation kinetics under realistic environmental conditions for certain materials. Pathway of achieving this goal will be discussed.

**10:40 AM**

**Cyclic Oxidation Behavior of HVOF MCrAlY Coatings Deposited on La- and Y-Doped Superalloys:** Michael Bestor<sup>1</sup>; Allen Haynes<sup>1</sup>; Bruce Pint<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

One suggested strategy for improving the performance of thermal barrier coating (TBC) systems used to protect hot section components in gas turbines is the addition of low levels of dopants to the Ni-base superalloy substrate. For the more aggressive environment expected for coal-derived, synthesis gas-fired turbines, this strategy may be effective in retaining TBC durability. To quantify the benefit of these dopants, coupons of three commercial alloys with different Y and La contents were coated with the same commercial NiCoCrAlYHfSi bond coating by high velocity oxygen flame spraying. Coupons were oxidized in cyclic tests at 1050°, 1100° and 1150°C and the oxidation rate and alumina scale adhesion were compared in an effort to better understand the benefit of superalloy dopants. This research was sponsored by the U.S. Department of Energy, Office of Coal and Power R&D, Office of Fossil Energy, (R. Dennis program manager).

**11:00 AM**

**An Investigation on Hot Corrosion Resistance of Plasma Sprayed YSZ-Ceria TBC in Na<sub>2</sub>SO<sub>4</sub>+V<sub>2</sub>O<sub>5</sub> at 1050 °C:** Mohsen Saremi<sup>1</sup>; M.H. Habibi<sup>1</sup>; <sup>1</sup>University of Tehran

Thermal Barrier Coatings are subjected to spallation and destabilization due to oxidation and hot corrosion. In this research, the hot corrosion behaviors of three types of composite coatings were investigated: (1) Conventional YSZ, (2) YSZ+CeO<sub>2</sub> (the composite layer of Ceria and YSZ), (3) CeO<sub>2</sub>/YSZ (The over layer of Ceria on YSZ). The treated samples were characterized using XRD and SEM equipped with EDS. Based on the microscopic observations, the formation of YVO<sub>4</sub> crystals and YSZ spallation, and the amount of phase transformations of tetragonal ZrO<sub>2</sub> to monoclinic, were the criteria for evaluating the resistance of composite coatings. It was observed that CeO<sub>2</sub>/YSZ the best resistant coating against hot corrosion test while conventional YSZ was the least among the three coatings. It was shown that the interaction of V<sub>2</sub>O<sub>5</sub> with yttria resulted in formation of YVO<sub>4</sub> which is detrimental to YSZ because of its accelerated destabilization.

**11:20 AM**

**An Investigation of the Electrochemical Properties of 3 Types PVD Coated on STS304:** *Min-Seok Moon*<sup>1</sup>; Woo KeeDo<sup>2</sup>; Chan-Won Kwak<sup>3</sup>; Sang-Hyuk Kim<sup>2</sup>; Joon-Hyuk Song<sup>1</sup>; Je-Ha Oh<sup>1</sup>; <sup>1</sup>Chonbuk National University, Jeonju Institute of Machinery Carbon Composites; <sup>2</sup>Chonbuk National University; <sup>3</sup>Se-Won Hard Facing Co., Ltd.

In the PEM fuel cell need to reduced weight and total fabrication cost of a fuel cell stack, and increased durability during the operating condition. Typically bipolar plates are a key component of PEMFC and other Fuel cells. In order to reduce both the weight and cost of the bipolar plates, nowadays consider attention is being paid to developing metallic bipolar plates to replace dense graphite. In this study, try to 3 types Nitride coating

process on an austenitic stainless steel (STS304) using a PVD technology (plasma enhanced reactive evaporation) to increase the corrosion resistance of the STS304. Contact angle, SEM, and potentiodynamic tests were used to characterize the 3 types Nitride coating process on the STS304. This study is focus on the best PVD nitride coating process for the corrosion resistance in the PEMFC operating conditions, and could potentially be used in PEMFCs as a bipolar plate material requirement.

**11:40 AM**

**Gaseous Hydrogen Embrittlement of Pipeline Steels:** *Nicholas Nanninga*<sup>1</sup>; Yaakov Levy<sup>2</sup>; Andrew Slifka<sup>1</sup>; <sup>1</sup>NIST; <sup>2</sup>NRCN

The tensile properties of x52, x65, x80 and x100 pipeline steels have been measured in a high pressure (13.6 MPa), high purity, hydrogen gas environment. Significant losses in elongation to failure and reduction in area were measured when testing in hydrogen compared to air (NTP), and these changes were accompanied by major changes in fracture morphology. For hydrogen charged specimens, surface crack initiation and growth was the primary failure mechanism, compared to a typical cup-and-cone failure for specimens tested in air. In addition to baseline characterization of the effects of strength and microstructure, several tests were conducted on the x100 alloy to determine the effects of strain rate and hydrogen gas pressure. Losses in ductility were observed with increases in pressure (up to 68 MPa) and decreases in strain rate, though a plateau in the effects of these variables was evident for the x100 alloy.

**8:30 AM**

**Exploratory Research in Reactive Spark Plasma Extrusion:** *P Mehra*<sup>1</sup>; K. Morsi<sup>1</sup>; <sup>1</sup>San Diego State University

Spark plasma sintering has gained a considerable amount of attention over the past decade, due to its rapid sintering rates, and low temperature requirements, but has so far been usually limited to the production of simple geometries. The present paper examines the current-activated production of extended geometries through the process of spark plasma "extrusion". Of interest in the present study is exploratory research into the effect of electrical current activation on the reactive consolidation of powder systems to form intermetallic materials.

**8:45 AM**

**Preliminary Investigations of the Effect of Particle Size and Tip Size in the Current Activated Tip-Based Sintering (CATS) of Nickel Powder Compacts:** *A. El-Desouky*<sup>1</sup>; K. Morsi<sup>1</sup>; K.S. Moon<sup>1</sup>; S.K. Kassegne<sup>1</sup>; <sup>1</sup>San Diego State University

Current Activated Tip-based Sintering (CATS) is a new process for the powder-based fabrication of macro, micro and possibly nano-scale features and shapes. This new and unique process enables selective sintering of powders by localizing electrically activated sintering conditions through a stationary or moving electrically conducting tip. We present preliminary experimental results on the effect of tip size in the CATS process as well as the effect of initial powder particle size on the sintering behavior of nickel powder.

TUESDAY AM

9:00 AM

**Determination of the Spark Plasma Sintering Fundamental Densification Mechanisms by Novel Cyclic Loading Approach:** *Wei Li*<sup>1</sup>; William Bradbury<sup>1</sup>; Joanna McKittrick<sup>1</sup>; Randall German<sup>2</sup>; Eugene Olevsky<sup>2</sup>; <sup>1</sup>University of California San Diego; <sup>2</sup>San Diego State University

Determination of fundamental densification mechanisms during spark plasma sintering (SPS) of particulate materials is critical in analyzing defect formation and density evolution. A new cyclic loading approach is applied to determine the dominant mechanism of material transport during SPS. The advantage of the cyclic loading technique is that only one experimental run is needed to determine the constitutive properties of a powder material for any given heating schedule, and no interrupted tests taking into account the grain growth kinetics are necessary. This methodology is employed for sintering compacts pressed from metal (pure spherical copper) and ceramic (alumina) powders. SPS experiments with different heating rates are conducted with the application of different load levels. The step-wise pressure cyclogram is utilized during processing. The determined material constitutive parameters serve as a basis for a full-scale modeling of spark-plasma sintering process.

9:15 AM

**Exploratory Investigations in Reactive Current Activated Tip-based Sintering (CATS):** *A Numala*<sup>1</sup>; K. Morsi<sup>1</sup>; K.S. Moon<sup>1</sup>; S.K. Kassegne<sup>1</sup>; <sup>1</sup>San Diego State University

Current Activated Tip-based Sintering (CATS) is a new process for the powder-based manufacturing of macro, micro and possibly nano-scale features and shapes. CATS enables the selective sintering of powders by localizing current activation conditions through an electrically conducting small tip (either in the stationary or moving mode). This paper presents preliminary experimental results on the CATS of reactive mixtures of Ni/Al powder to form nickel aluminide intermetallics. Preliminary investigations on the effect of current on the reaction characteristics is discussed.

9:30 AM

**Microstructural Evolution of Cu, Ni and Al Powder Particles Processed by Cold Spray:** *Yu Zou*<sup>1</sup>; Eric Irissou<sup>2</sup>; Jean-Gabriel Legoux<sup>2</sup>; Stephen Yue<sup>1</sup>; <sup>1</sup>McGill University; <sup>2</sup>Industrial Materials Institute (IMI), National Research Council Canada (NRC)

Cold spray is a relatively new coating technology by which coatings can be produced using high-velocity impact of powder particles without significant heating introduced. Micron-sized pure Cu, Ni and Al powder particles were processed by the cold spray, respectively. Microstructural evolutions of these particles were investigated using electron backscatter diffraction and transmission electron microscopy. The results show that non-uniform microstructures with elongated grains/subgrains in the size of microns, equiaxed grains in sub-microns and nanocrystalline grains appear in as-sprayed materials. Moreover, deformation twins in nano-scale are observed in the cold sprayed Cu. Formation of these structures is explained by high strain-rate deformation with the dynamic recovery/recrystallization in the complex thermo-mechanical process during cold spray.

9:45 AM

**Elucidating Microstructure Formations in Ta(x)C(1-x) at Various Carbon Contents:** Robert Morris<sup>1</sup>; *Gregory Thompson*<sup>1</sup>; <sup>1</sup>University of Alabama

TaC has a melting temperature near 4000°C and can precipitate out Ta-rich carbide precipitates with similar high melting temperatures. This offers the ability to engineer the microstructure for thermomechanical loading. A series of tantalum carbides have been hot isostatically pressed (HIP) from constituent TaC and Ta powders. Depending on carbon content various microstructures could be processed. These include equiaxed single phase TaC or Ta<sub>2</sub>C grains, equiaxed TaC grains which encased a hatch-pattern of Ta<sub>4</sub>C<sub>3</sub> laths, or acicular grains with very fine laths of TaC/Ta<sub>4</sub>C<sub>3</sub>/Ta<sub>2</sub>C running parallel to the major axis of the grain. To elucidate the microstructure formation mechanisms, a HIP diffusion couple of TaC – Ta metal powders was prepared. The HIP couple revealed the entire span of microstructures. The location of specific microstructures in relationship to the initial powder states provided insights

into the precipitation and reactions from which specific phases and grain morphologies formed.

10:00 AM Break

10:15 AM

**Fabrication, Characterization and Comparison of Spinel ZnFe<sub>2</sub>O<sub>4</sub> Obtained by Sonochemistry Way and Ceramic Way:** *Oscar Restrepo*<sup>1</sup>; Edgar Chavarriaga<sup>1</sup>; Juan Montoya<sup>1</sup>; Leidy Jaramillo<sup>1</sup>; Miguel Hernández<sup>1</sup>; <sup>1</sup>National University of Colombia

This paper provides an analysis of ZnFe<sub>2</sub>O<sub>4</sub> spinel type ceramic pigment obtained by the alternative manufacturing method sonochemistry and the ceramic way. The method sonochemistry appears as an attractive method with enormous advantages in ceramic chemistry, that is why in the synthesis of compounds of industrial interest is emerging as a possible route. The objective is to evaluate the influence that can produce the particle size with optical properties, which are of interest in ceramic pigments industry, also make a comparison with the ceramic way from colorimetric and physical properties. The methods used to characterize the ceramic pigments were x-ray diffraction (XRD), scanning electron microscopy (SEM) and UV-VIS spectrophotometry.

10:30 AM

**Properties and Performance of Composites Based on Superrefractories Cements:** *Ilyoukha Nickolai*<sup>1</sup>; Timofeeva Valentina<sup>1</sup>; Schabanov Alexander<sup>1</sup>; <sup>1</sup>Academic Ceramic Center

Superrefractories cements (1800-2700°C) is a new refractory insulating material and objective of this work is to enlarge our knowledge about this new product and to search solutions for problems the industry is facing. Based on this target, we realized several test to find answers to important questions about the application of this product in severe industrial conditions and to analyze how this material performs in high temperatures. High temperature composites and coatings based on superrefractories cements are meant to protect units from influence of temperature more than 2000°C and used for manufacturing monolithic lining, crucibles used in the melting of pure metals, including alloys on rare-earth elements, for closing one of ceramic modules of fire wall, in refractory lining of quartzglas tanks, petrochemistry reactors, in burial of radiation fuel by extreme environments in nuclear reactors.

10:45 AM

**Predicting the Mechanical Properties of Aluminium-SiC Functionally Graded Materials Processed by Centrifugal Rotation Method:** *Veerarajkumar Aparna*<sup>1</sup>; Savita Kaliya Perumal Veerapandian<sup>1</sup>; <sup>1</sup>College of Engineering, Guindy, Anna University

Materials characterized by variation in composition and structure gradually over volume, resulting in corresponding changes in properties are defined as functionally graded materials (FGM). Al-SiC FGM's were obtained by centrifugal rotation of die in a muffle furnace. The paper develops a reliable model to predict the functional gradient to the analyzed systems. The wear properties were studied using the pin-on tester. A fem code is employed to estimate the effective elastic properties along the gradient distribution. The obtained values were compared with the theoretical calculation acquired by the rule of mixtures. The results revealed that the properties were significantly influenced by the graded distribution of SiC in the matrix. The resultant FGM's were carefully characterized, a great attention devoted to micro structural investigation.

11:00 AM

**Improvement on the Tribological Characteristics of Particulate Copper Silicon Carbide Composites:** *David Esezobor*<sup>1</sup>; Atinuke Oladoye<sup>1</sup>; <sup>1</sup>University of Lagos

Particulate Cu-SiC composites find applications as wear and heat resistant materials in electrical sliding contacts such as in homopolar machines, railway overhead current collector systems where high electrical/thermal conductivity combined with good wear properties is required. However, challenges occur during machining due to the presence of hard reinforcement in the matrix this may lead to high turnover of tool wear and

poor surface finish. The adoption of near-net shape technology to produce such hard-to-machine metal matrix composites and subsequent finish machining with its attendant cost has reported limited success. This paper critically appraises the challenges and opportunities in the improvement of tribological characteristics of particulate Cu-SiC composites and identifies low cost reinforcement material that could be used to improve its tribological characteristics.

**11:15 AM**  
**Study on Preparation of High-Purity Magnesium Carbonate Whisker from Low-Grade Magnesite:** Caiyun Lu<sup>1</sup>; Min Chen<sup>1</sup>; Jingkun Yu<sup>1</sup>; <sup>1</sup>Northeastern University

Mg(HCO<sub>3</sub>)<sub>2</sub> solution was prepared through light burning, hydrous carbonation by using low-grade magnesite as the raw materials, and then the impurities were removed by using activated carbon as adsorbent. In this paper, the effect of different additives on the morphology of Mg(HCO<sub>3</sub>)<sub>2</sub> pyrolytic products and the effect of the heating rate on the morphology of the obtained magnesia were studied. The XRD result showed that the main components of Mg(HCO<sub>3</sub>)<sub>2</sub> pyrolytic products were 3MgCO<sub>3</sub>·Mg(OH)<sub>2</sub>·3H<sub>2</sub>O and MgCO<sub>3</sub>·3H<sub>2</sub>O, which contained less impurities such as CaO<0.04% and TFe<0.02% after adsorbing the impurities by activated carbon. SEM results showed that the morphology of magnesium carbonate was highly dependent to the preparation conditions, namely, without any additive, the flake-like pyrolytic product was obtained, petal shaped pyrolytic product was prepared with potassium dihydrogen phosphate additive, spherical pyrolytic product was obtained with ammonium carbonate additive, and whisker pyrolytic product was obtained while soluble magnesium salts was added, because the additives hindered the growth of crystals in one direction, while promoting the directions of crystal growth to without obstruction. The calcining system had a direct impact on the morphology of magnesia converted from the whisker precursor, while the calcining temperature was elevated at 5 °C·min<sup>-1</sup>, magnesia powder was obtained, while the calcining temperature was elevated at 2 °C·min<sup>-1</sup>, most magnesia maintained whisker morphology, because the decomposition of magnesium carbonate was divided into three stages, the calcination product could keep whisker morphology as precursor through control the decomposing speed.

**11:30 AM**  
**Preparation of Metal Cobalt Powder by Coprecipitation and Heat Decomposition Method:** Xue Ping<sup>1</sup>; Guo Xueyi<sup>2</sup>; Tian Qinghua<sup>2</sup>; Liang Sha<sup>2</sup>; <sup>1</sup>Jiangnan University; <sup>2</sup>central south university

This research provides a novel method to prepare the metal cobalt powder. This method prepared the precursor powder of Co(OH)<sub>x</sub>(CO<sub>3</sub>)<sub>y</sub> by the conventional chemical precipitation, the phase analysis made by X-ray and the infrared spectrum proved that component of the precursor powder was Co(OH)<sub>x</sub>(CO<sub>3</sub>)<sub>y</sub> adsorbing NH<sub>4</sub><sup>+</sup> and Cl<sup>-</sup> and the organic functional group. The precursor powder was prepared for metal cobalt powder through heat decomposition. Based on DSC-TGA analysis, influence of additive reagent and temperature factor to prepare for the cobalt powder were observed in heat decomposition. The results show when the amount of the additive reagent is 63.64%, calcination temperature is 500 °C, all the product is metal cobalt, and the properties are fine.

**Simulations of Voids and Gas Bubbles in Irradiated Materials:** Marius Stan<sup>1</sup>; Shenyang Hu<sup>2</sup>; <sup>1</sup>Argonne National Laboratory; <sup>2</sup>Pacific Northwest National Laboratory

The irradiation of nuclear reactor structural materials leads to the formation of voids that cause swelling while in nuclear fuels the accumulation and transport of fission products leads to the formation of gas bubbles that decrease the thermal transport. We review computer simulation techniques for predicting the evolution of voids and gas bubbles. To illustrate the challenges, we discuss phase-field simulations of the nucleation and growth of voids and gas bubbles, focusing on the role of the self-interstitial atoms and vacancies. The simulations show that a high rate of generating interstitials during displacement cascades delays the formation of void lattices. Phase field simulations of UO<sub>2</sub> show that gas bubble nucleation is favored at grain boundaries due to the trapping of fission products and the high mobility of vacancies and gas atoms. The effective thermal conductivity strongly depends on the bubble volume fraction but weakly on the morphology of the bubbles.

### 9:10 AM

**Modeling the Helium Transport, Fate in Tempered Martensitic Steels and Nanostructured Ferritic Alloys – Consequences to Void Swelling:** Takuya Yamamoto<sup>1</sup>; G. Robert Odette<sup>1</sup>; <sup>1</sup>Univ. California Santa Barbara

A rate theory cluster dynamics model that tracks helium transport and partitioning to, and recycling between, matrix sites, precipitates, dislocations and grain boundaries is applied to treat precipitation of helium bubbles in a tempered martensitic steel, F82H, and a nanostructured ferritic alloy, MA957. The model uses kinetic and thermodynamic parameters derived from atomistic simulations. The predictions are shown to be in good agreement with data from in-situ He implantation experiments. Recently, the model has been extended to treat void nucleation and growth. The model predicts significant swelling in F82H, even with conservative parameters: following an incubation dose of ~ 20 dpa at 40 appm He/dpa and 500°C swelling reaches 3.2 % at 100 dpa and 16.6 % at 200 dpa. The predictions of a more detailed and improved model will be compared to the in-situ He-implanter experiment up to 25 dpa and 1250 appm He.

### 9:30 AM

**Modeling He Behavior in Tungsten: Relevance of the Implantation Model:** Marc Hou<sup>1</sup>; Charlotte Becquart<sup>2</sup>; Andree De-backer<sup>2</sup>; Christophe Domain<sup>3</sup>; Christophe Ortiz<sup>4</sup>; <sup>1</sup>Physique des Solides Irradiés et des Nanostructures CP234; <sup>2</sup>UMET, UMR 8207, EM2VM; <sup>3</sup>EdF, R&D, EM2VM; <sup>4</sup>Laboratorio Nacional de Fusión por Confinamiento Magnético, CIEMAT

The binary collision approximation code Marlowe, and object kinetic Monte-Carlo simulations parameterized on Density Functional Theory (DFT) data have been used to investigate the fate of He atoms implanted in tungsten. The He atoms and the associated damage have been introduced either at random in the tungsten matrix or according to distributions provided by Marlowe, taking into account the crystalline nature of the matrix or considering it as an amorphous structure. The results indicate that

in order to reproduce the experimental results, one has to model properly the implantation sequence. They furthermore underline the significant contribution of the crystalline nature of the matrix.

**9:50 AM**

**Stability and Evolution of He Clusters and Complex Defect Clusters Investigated by Ab Initio Calculations and OKMC Simulations in Tungsten:** *Charlotte Becquart*<sup>1</sup>; *Andree De Backer*<sup>1</sup>; *Christophe Domain*<sup>2</sup>; <sup>1</sup>UMET, UMR 8207, EM2VM; <sup>2</sup>EdF, R&D, EM2VM

Understanding and predicting the behavior of helium in metals is an important issue in particular in the context of materials used in fusion reactors nowadays. Indeed in these conditions, two sources of He are present: transmutation and implantation from the plasma. In tungsten, which is a candidate for the divertor in fusion reactors, theoretical and experimental results indicate that helium is very mobile already below room temperature and can form He clusters very easily. We have used state of the art ab initio calculations to investigate the stability of He clusters associated or not with point defects in tungsten as well as impurities. Small He clusters are mobile and one notable result is that the smallest ones exhibit a 1D motion at low temperatures. The consequences on the evolution of the microstructure under irradiation conditions will be discussed in the framework of an object kinetic Monte Carlo model.

**10:10 AM**

**Mesoscale Simulation of Irradiation-Induced Gas Bubbles: Evolution and Impact on Macroscale Properties:** *Paul Millett*<sup>1</sup>; *Anter El-Azab*<sup>2</sup>; *Michael Tonks*<sup>1</sup>; <sup>1</sup>Idaho National Laboratory; <sup>2</sup>Florida State University

Nuclear materials used in fission and fusion applications can be subjected to simultaneously high displacement rates as well as gas production rates. The characteristics of the resultant gas bubble structure, i.e. internal gas density, bubble number density, and bubble distribution, are strongly dependent on the relative defect production rates as well as microstructure (e.g. grain size). Here, we implement a phase-field model capable of capturing multi-component defect (vacancies, self-interstitials, and gas atoms) diffusion, bubble nucleation and growth, and bubble/grain boundary interactions to investigate these processes throughout time and for varying irradiation conditions. Furthermore, we have utilized this simulation capability to develop models of bubble percolation and the effective thermal transport across heterogeneous microstructures. Interestingly, thermal conductivity is found to be strongly dependent on the relative distribution of intergranular versus intragranular bubbles. This research was supported by the Nuclear Energy Advanced Modeling and Simulation (NEAMS) program within DOE-NE.

**10:30 AM Break**

**10:50 AM**

**Simple Concentration-Dependent Pair Interaction Model for FeCr Alloys with Vacancy Supersaturation:** *Enrique Martinez Saez*<sup>1</sup>; *Maximilien Levesque*<sup>2</sup>; *Frederic Soisson*<sup>2</sup>; *Maylise Nastar*<sup>2</sup>; *Chu Chun Fu*<sup>2</sup>; <sup>1</sup>LANL; <sup>2</sup>CEA-Saclay

FeCr alloys are foreseen as strong candidates for fission and fusion applications as matrix for structural materials. A lattice pair interaction model based on the RedLich-Kister polynomial is presented. The interaction coefficients have been fitted to ab-initio data. The model captures the complex thermodynamics of the system, including the short-range order found experimentally for low Cr concentrations. The broken-bond model has been implemented into the synchronous parallel kinetic Monte Carlo algorithm [J. Comp. Phys. 227 (2008) 3804-3823] so to be able to extend the size of the system and therefore the statistics of the calculation as well as the total time studied. Correlation length and precipitate number density of voids and a' precipitates have been studied as well as their shape and size distributions and the results compared to the experimental results available in the literature. We have found a very good agreement between the kinetic model and the experiments.

**11:10 AM**

**Atomistic Study of Interstitial Migration in the Proximity of a Helium Bubble in the Fe-Cr System:** *Jeffery Hetherly*<sup>1</sup>; *Alfredo Caro*<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

We investigate the effect that helium bubbles have on the diffusion of self interstitials in Fe-Cr alloys using atomistic techniques. Different bubble pressures and bubble locations (bulk versus grain boundaries) are explored. The results are interpreted in terms of the sink capture efficiency of a bubble for interstitials and the anisotropy of interstitial diffusion in the presence of a stress field. Coated bubbles, either depleted or enriched in solute, are also of interest and are expected to give a different behavior than plain voids.

**11:30 AM**

**Microstructure Evolution of Two Model Ferritic/Martensitic Steels Irradiated with Ions In-Situ in a TEM:** *Djamel Kaoumi*<sup>1</sup>; *Jimmy Adamson*<sup>1</sup>; *Athur Motta*<sup>2</sup>; *Mark Kirk*<sup>3</sup>; <sup>1</sup>The University of South Carolina; <sup>2</sup>The Pennsylvania State University; <sup>3</sup>Argonne National Laboratory

Two model steels (one ferritic/martensitic(Fe12Cr0.1C) and one fully martensitic(Fe9Cr0.1C)) were custom-made with the intent of reproducing the type of starting microstructure of F/M steels, but without the complications of additional alloying elements. The alloys were irradiated with 1-MeV Kr ions at 25°C, 200°C, 300°C to doses up to 10 dpa in-situ in a TEM. The microstructure evolution was followed and characterized at successive doses in terms of defect formation, black dot density, number density of defect clusters, and stability of as-fabricated microstructure using weak-beam dark-field imaging and g.b analysis. The effect of the irradiation temperature on the damage density and on the stability of the initial microstructure is assessed. The overall goal is to determine directly the spatial correlation of the time evolution of the irradiation-induced defect structures with the pre-existing alloy microstructure and to compare with calculations based on rate-theory modelling. The results are summarized in this paper.

**11:50 AM**

**Atomic-Scale Features of Strengthening Due to Impenetrable Obstacles in Iron:** *Yury Osetskiy*<sup>1</sup>; *Roger Stoller*<sup>1</sup>; <sup>1</sup>ORNL

Oxide dispersion strengthened (ODS) alloys are considered as promising structural materials and therefore are under study by different experimental, theoretical and modeling techniques. In this presentation we report the first results of an extensive atomic-scale study of mechanical properties of materials containing impenetrable obstacles simulating ODS particles. We have considered rigid spherical coherent precipitates embedded into bcc-iron matrix. At the first stage we simulated a  $\frac{1}{2}\langle 111 \rangle$  edge dislocation gliding in the plane intersecting precipitates of diameter from 1 to 6nm at different distances to their equator. Different interaction mechanisms were observed depending on the dislocation glide plane position and temperature. The conditions of maximum strength were investigated and the results were discussed in the view of existing experimental data.

**12:10 PM**

**Mobility of Low Energy Boundaries in FCC Copper during Irradiation:** *James Belak*<sup>1</sup>; *Bryan Reed*<sup>1</sup>; *Ming Tang*<sup>1</sup>; *Joel Bernier*<sup>1</sup>; *Vasily Bulatov*<sup>1</sup>; *Thomas LaGrange*<sup>1</sup>; *Mukul Kumar*<sup>1</sup>; <sup>1</sup>Lawrence Livermore National Laboratory

The mobility of ideal low energy boundaries (e.g. Sigma 3) in FCC copper has proven difficult to study using molecular dynamics due to the long time-scales involved. However, by introducing a small vicinal step or shear along the boundary (to nucleate a stepped region), these low energy boundaries readily move. Here we quantify the mobility of Sigma 3 boundaries in FCC copper as a function of vicinal angle and local boundary shear stress. These simulations are used to drive the boundary through regions of irradiation damage (vacancies, interstitials and defect clusters). The defect field initially enhances the step density and mobility, which saturates as the boundary roughens. The simulation results are used to parameterize a simplified model of boundary mobility during irradiation. \*Work performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344 and supported by the U.S. Department of Energy, Office of Basic Energy Sciences.

#### From Structure to Nano-Structure: Materials Research with X-Rays and Neutrons: *Gernot Kostorz*<sup>1</sup>; <sup>1</sup>ETH Zurich

X-rays and neutrons have served as probes for the study of structural and dynamic properties of materials for a long time. Improvements in X-ray and neutron sources and user-oriented research facilities continue to enhance possibilities for increasingly sophisticated experimentation. Some applications of neutron and X-ray scattering – diffraction, diffuse and small-angle scattering – will be presented, with emphasis on recent developments and combination with other methods.

### 8:55 AM Invited

#### Diffuse Scattering as an Aid to the Understanding of Polymorphism in Pharmaceuticals: *Richard Welberry*<sup>1</sup>; Darren Goossens<sup>1</sup>; Eric Chan<sup>1</sup>; Aidan Heerdegen<sup>1</sup>; <sup>1</sup>Australian National University

Polymorphism occurs when the same molecular compound can crystallise in more than one distinct crystal structure. Its study is a field of great interest and activity. This is largely driven by its importance in the pharmaceutical industry but polymorphism is also an issue in the pigments, dyes and explosives industries. The polymorph formed by a compound generally exerts a strong influence on its solid-state properties. The polymorphic form of a drug molecule may affect ease of manufacture and processing, shelf-life and most significantly, the rate of uptake of the molecule by the human body. They can even vary in toxicity; one polymorph may be safe, a second may be toxic. In this paper we show how diffuse scattering experiments coupled with Monte Carlo computer modeling can aid in the understanding of polymorphism. Examples of the two common pharmaceuticals benzocaine and aspirin, both of which are bimorphic, will be discussed.

#### Modeling Diffraction from Thin Film Structures: *I Noyan*<sup>1</sup>; Andrew Ying<sup>1</sup>; Braxton Osting<sup>1</sup>; Conal Murray<sup>1</sup>; <sup>1</sup>Columbia University

We present a rigorous model of kinematic diffraction of a coherent, monochromatic, X-ray beam, focused by a Fresnel zone plate onto a thin, perfect, single-crystal layer. In this model, we first calculate the coherent wave emanating from an ideal zone plate equipped with a direct-beam stop and order sorting aperture. Then, we compute the diffraction of the focused wavefront by a thin silicon film positioned at the primary focal spot. Finally, we propagate the diffracted wavefront to the position of an area detector, and map the intensity distribution in the detector plane. Our model showed that the data analysis of kinematic diffraction patterns obtained from area detectors have some differences from traditional radial scans. These differences were verified through experiments.

### 9:35 AM Invited

#### Multiple Diffraction in Quasicrystals: *Walter Steurer*<sup>1</sup>; Changzeng Fan<sup>1</sup>; <sup>1</sup>ETH Zurich

Multiple diffraction takes place when a crystal is oriented in a way that more than one set of atomic planes is in a position to diffract the incoming monochromatic radiation simultaneously. Because of the interaction between the excited reflections, the total amount of intensity will be redistributed among them. Multiple diffraction is omnipresent during a diffraction measurement on a quasicrystal as a result of its dense set of Bragg reflections. It can bias weak Bragg intensities, which are the key to the solution of the structure of quasicrystals. A complete understanding of multiple diffraction in quasicrystals will help us to get more accurate data sets. Therewith, quasicrystal structure refinement can be substantially improved. Here we report the first results of our study on multiple diffraction in quasicrystals and its influence on quasicrystal structure analysis.

#### Development of Ultrasmall-Angle X-Ray Scattering / X-Ray Photon Correlation Spectroscopy (USAXS/XPCS) for In Situ Studies of Equilibrium and Non-Equilibrium Dynamics over Extended Length and Time Scales: *Jan Ilavsky*<sup>1</sup>; Andrew Allen<sup>2</sup>; Fan Zhang<sup>2</sup>; Lyle Levine<sup>2</sup>; Alec Sandy<sup>1</sup>; Gabrielle Long<sup>1</sup>; <sup>1</sup>APS, Argonne National Laboratory; <sup>2</sup>National Institute of Standards and technology

Scattering and imaging techniques are applicable in static microstructural studies over the full nanometers-to-micrometers feature size range. The dynamics of materials, especially their response to abrupt changes in the sample environment, is on the other hand the domain of the X-ray photon correlation spectroscopy (XPCS). However, existing XPCS facilities are limited to microstructure length scales smaller than about 50 nanometers, thus eliminating large classes of materials that are of major technological importance. We have developed combined ultrasmall-angle X-ray scattering / X-ray photon correlation spectroscopy (USAXS/XPCS) technique to probe the slow equilibrium and non-equilibrium dynamics of optically opaque materials with prominent scattering features in the range 100 nm to several micrometers, i.e., between the ranges of dynamical light scattering and conventional XPCS. Presented example of USAXS-XPCS capabilities will be study of equilibrium dynamics of colloidal dispersions at various volume concentrations as a function of temperature.

### 10:15 AM Invited

#### X-ray Studies of the Lattice Dynamics of Cr across Its Antiferromagnetic Transition: *Tai Chiang*<sup>1</sup>; Ruqing Xu<sup>1</sup>; Mary Upton<sup>2</sup>; Hawoong Hong<sup>2</sup>; <sup>1</sup>University of Illinois; <sup>2</sup>Argonne National Laboratory

Spin-lattice coupling is a classic topic in solid state physics. While generally weak, it is relevant to the basic physics of how elementary excitations interact. A striking case is the Neel transition at  $T_c = 311$  K in chromium. Ultrasonic measurements revealed a substantial, anomalous softening in the elastic constants near  $T_c$ . However, this anomaly has not been detected by neutron scattering. To clarify this issue we have carried out both inelastic x-ray scattering (IXS) and x-ray thermal diffuse scattering (TDS) measurements of this system. IXS scans at several selected regions in reciprocal space did not find significant changes in phonon frequencies, in agreement with prior neutron scattering results. However, TDS measurements near a Brillouin zone center, where IXS measurements had difficulties, revealed an anomalous behavior of the phonons. Our findings suggest that the spin-lattice coupling in chromium is dominated by long-wavelength interactions.

### 10:35 AM Invited

#### Diffuse X-Ray Scattering of Bulk Au-50 at.% Pd and a Ni-23 at.% Pt(100) Surface: *Bernd Schoenfeld*<sup>1</sup>; <sup>1</sup>ETH Zurich

Experimentally no ground state structure is known for bulk Au-Pd, but a series of structures were suggested by electronic structure calculations. In search of plausible superstructures, diffuse x-ray scattering from single crystalline Au-50 at.% Pd was taken for a quenched state of thermal equilibrium. Maxima in short-range order scattering are seen at  $2k_F$  positions, repeatedly found with Au or Cu based alloys. Using the effective

pair interaction parameters, the existence of the suggested structures close to 1:1 stoichiometry is addressed, based on the values of the respective ordering energies. In the course of the ongoing research to characterize the near-surface microstructure of Ni-Pt by grazing incidence diffraction, Ni-23 at.% Pt(100) was measured at 970 K. In contrast to the (110) surface previously investigated, the (100) near-surface regime is connected with strong order leading to strong crystal truncation rods through 100 positions. A tetragonal model is applied to analyze diffuse scattering.

**Diffraction from Nanocrystalline Materials: Reciprocal Space versus Direct Space Methods:** *Paolo Scardi*<sup>1</sup>; Matteo Leoni<sup>1</sup>; Luca Gelisio<sup>1</sup>; Alberto Leonardi<sup>1</sup>; <sup>1</sup>University of Trento

Diffraction Line Profile Analysis (LPA) is commonly employed in the characterization of nanocrystalline materials, to gather information on nanocrystal size and shape, lattice defects and atomic-scale distortions. Despite the popularity of LPA in most nanomaterial studies, the applicability of traditional methods based on the reciprocal space approach down to the characteristic dimensions of a few nanometers is not so straightforward, and should be questioned when non-crystallographic structures are involved. The intrinsically discrete nature of the matter on the nanoscale is better described by direct space methods, like those based on the Debye equation. However, the change of paradigm - from reciprocal to direct space - opens new challenges in LPA, to develop computationally effective methods and to obtain a better understanding and representation of the real structure of nanocrystals.

#### 11:30 AM Invited

**Doing Neutron Scattering Science with the Multi-Axis Crystal Spectrometer at the NCNR:** *Jose Rodriguez-Rivera*<sup>1</sup>; <sup>1</sup>University of Maryland/NIST Center for Neutron Research

The Multi-Axis Crystal Spectrometer at the NIST Center for Neutron Research began commissioning operation on 2009 and is in the user program since January 2010. With a Energy range up to 20meV, the high neutron flux, up to  $5 \times 10^8$  neutrons/cm<sup>2</sup>/s will open new areas of condensed matter physics to exploration through inelastic neutron Scattering. The high neutron flux is obtained by using a doubly focusing monochromator subtending a solid angle of up to 0.005 Sr to the cold neutron source. The detector system consist of an array of 20 channels. Each detector channel is built around a vertically focusing double crystal analyzer. The MACS instrument is particularly powerful for probing the wave vector dependence of inelastic neutron scattering in select ranges of energy transfer to access the dynamic structure of fluctuating systems. The first experiment shows the instrument capabilities and opens a new horizon for neutron scattering science.

#### 11:50 AM

**Diffraction Measurements to Identify Structural Changes In Li[Li<sub>1/3-2x/3</sub>NixMn<sub>2/3-X/3</sub>]O<sub>2</sub> (x=1/5) Cathode Materials for Lithium Ion Batteries:** *Christopher Fell*<sup>1</sup>; Shirley Meng<sup>2</sup>; Jacob Jones<sup>1</sup>; <sup>1</sup>University of Florida; <sup>2</sup>Unveristy of California San Diego

The lithium-excess layered oxide compounds Li[NixLi<sub>1/3-2x/3</sub>Mn<sub>2/3-x/3</sub>]O<sub>2</sub> ( $0 < x < 1/2$ ) are of great interest as a new generation of positive electrode materials for high energy density lithium-ion batteries. Following lithium deintercalation and the associated oxidation of Ni<sup>2+</sup> to Ni<sup>4+</sup>, lithium may continue to be extracted from this material despite the fact that all the manganese and nickel ions are in their fully charged (+4) oxidation state. In order to understand the electrochemical processes in Li[Li<sub>0.2</sub>Ni<sub>0.2</sub>Mn<sub>0.6</sub>]O<sub>2</sub>, we investigated the structural changes in the bulk material quantitatively using synchrotron x-ray and neutron diffraction. Synchrotron X-ray diffraction data of electrochemically cycled electrode materials show an expanded c/a lattice ratio, peculiar cation migration and growth of a second phase. Neutron diffraction data following chemical delithiation confirms that not only the Li ions but the transition metal ions (i.e. Ni) are dynamically migrating during the delithiation process.

#### 12:00 PM Invited

**Site Occupation of Atoms in Crystal Lattice Determined by High-Pressure X-Ray Diffraction Technique:** *Zhihua Nie*<sup>1</sup>; Yandong Wang<sup>1</sup>; Zhenwei Huang<sup>2</sup>; Dongmei Liu<sup>2</sup>; Qiaoshi Zeng<sup>3</sup>; Wenge Yang<sup>3</sup>; Yang Ren<sup>4</sup>; <sup>1</sup>Beijing Institute of Technology; <sup>2</sup>Northeastern University; <sup>3</sup>Carnegie Institution of Washington; <sup>4</sup>Argonne National Laboratory

Both mechanical and functional behaviors of alloys rely greatly on their crystal lattice structure and lattice-site occupation (LSO) of atoms. The detailed LSO of added alloying elements in a crystalline phase can only be determined through the Rietveld refinement by fitting a theoretical line profile to experimental X-ray or neutron diffraction data or constructing the atomic pair distribution function in the real space. However, so far it is impossible to obtain the accurate information on the LSO of specified atoms with less difference in scattering factor between the alloying element and fundamental constitutive elements. Here we present a new method for determining the LSO through the change in lattice parameters and phase transition behavior under hydrostatic pressure by in-situ XRD, in comparison with that obtained by the first-principles calculations considering different LSOs of atoms. This method is successfully demonstrated through the high pressure XRD experiments of a NiCoMnIn magnetic-field-driven alloy.

#### 12:20 PM Invited

**In situ Neutron Diffraction Studies of Phase Transformations in Shape Memory Alloys:** *Raj Vaidyanathan*<sup>1</sup>; <sup>1</sup>UCF

We report on in situ neutron diffraction measurements performed on NiTi-based shape memory alloys during selected combinations of heating, cooling and mechanical loading at Los Alamos National Laboratory. The choice of alloy systems is motivated by the temperature range at which they exhibit phase transformations that result in the shape memory effect - from below room temperature for NiTiFe alloys and near room temperature for NiTi alloys to above room temperature for NiTiPd alloys. Micromechanical and microstructural changes, i.e., texture, strain and phase volume fraction evolution were quantified for the cubic B2 to trigonal R to monoclinic B19' phase transformations in NiTiFe, the cubic B2 to monoclinic B19' phase transformation in NiTi and the cubic B2 to orthorhombic B19 phase transformation in NiTiPd. The implications of these results for engineering shape memory alloys with useful ternary and quaternary elemental additions for aerospace applications is presented.

#### 12:40 PM Invited

**Temperature Dependence of Diffuse Scattering in PZN:** *Darren Goossens*<sup>1</sup>; Ross Whitfield<sup>1</sup>; T. Welberry<sup>1</sup>; <sup>1</sup>Australian National University

Structural disorder appears to relate to the useful physical properties of ferroelectrics and relaxors. One such material is PZN, PbZn<sub>1/3</sub>Nb<sub>2/3</sub>O<sub>3</sub>. To explore what aspects of the disorder are specific to the polarised state, the temperature dependence of diffuse scattering in PZN has been investigated. Data were collected using both neutron and X-ray single crystal experiments in a range of temperatures from 100K to 500K. It has been found that some features, like the diffuse scattering from the B-site ordering, remain unchanged with change of temperature in terms of both intensity and peak shape. However, other diffuse scattering features evolve with T, for example the size-effect scattering around the Bragg peaks. The size-effect becomes less pronounced with increasing temperature, with the diffuse scattering becoming more symmetric around the Bragg peaks. The diffuse rods caused by the planer domains change only slightly with temperature.

## **Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Alloy and Microstructure Development**

**Structure and Transformation in Sn-Rich Sn-In Solders:** *John Morris*<sup>1</sup>; Kyu-Oh Lee<sup>2</sup>; Fay Hua<sup>2</sup>; <sup>1</sup>University of California Berkeley; <sup>2</sup>Intel Corporation

Of the Pb-free solders, Sn-rich InSn is unusually interesting in its structural and mechanical properties. The phases found for Sn-rich compositions include the  $\alpha$  (diamond) and  $\beta$  (tetragonal) structures of pure Sn, and the  $\square$  (hexagonal) structure of InSn. The  $\beta$ -Sn structure is notable for its complexity, which complicates the properties of all Sn-rich solders. The  $\square$ -InSn structure is notable for its simplicity; in ambient it is a solid solution rather than an ordered compound, and is one of few materials that crystallize in a simple hexagonal structure. Surprisingly, the  $\beta$ - and  $\square$ -structures of InSn have simple crystallographic connections, which not only facilitate transformation between them, but also permit martensitic transformation on cooling or under load. Here we describe the crystallographic relations and explore their influence on the microstructure and properties of Sn(7-13) In solders. Interestingly, transformation-induced plasticity (TRIP) occurs under appropriate conditions, including the first documented example of TRIP-mediated creep.

### **8:55 AM Invited**

**Optimization of Pb-Free Solder Joint Reliability from Metallurgical Perspective:** *Kejun Zeng*<sup>1</sup>; <sup>1</sup>Texas Instruments Inc.

Electronic packages with NEMI recommended Sn3.9Ag0.6Cu solder joints have shown poor performance in BLR tests. To improve package performance in board level drop test, a low Ag content of SnAgCu solder is preferred. On the other hand, the resistance of SnAgCu solder to thermal fatigue is dependant on the Ag content. Packages with low Ag content of SnAgCu solder have poor performance in thermal cycling test. In order for SnAgCu solder joints to perform well in both drop and thermal cycling tests, the key is to have better interfacial reliability. We will discuss how to optimize the Pb-free solder joint reliability by considering the effects of both solder alloys and surface materials on the metal pads. We will demonstrate that it is possible to keep a high content of Ag in the solder to get high resistance to thermal fatigue while the drop performance of the joints is not compromised.

### **9:20 AM Invited**

**On the Driving Force for Massive Spalling in Solder Systems:** W. M. Chen<sup>1</sup>; C. Robert Kao<sup>1</sup>; <sup>1</sup>National Taiwan University

To identify the driving force for the massive spalling phenomenon, well-designed experiments were carried out in this study. Copper-doped solder was reacted with Ni to form the Sn-0.6Cu/(Cu,Ni)6Sn5/Ni structure first. The original Sn-0.6Cu solder was then removed and replaced with Sn-0.3Cu, or with fresh Sn-0.6Cu. The swapping of solder to Sn-0.3Cu caused the massive spalling of (Cu,Ni)6Sn5. Without this swapping or in the case of swapping to fresh Sn-0.6Cu, the massive spalling did not occur. The results of this study unequivocally proved that the massive spalling reported in literature was caused by a driving force of pure thermodynamics in nature.

### **9:45 AM Invited**

**A Study of the Factors Affecting the  $\beta$  to  $\alpha$  Transition in Solder Alloys:** *Christopher Hunt*<sup>1</sup>; Davide Di Maio<sup>1</sup>; <sup>1</sup>National Physical Laboratory

With introduction of lead-free alloys into harsh conditions, there is some concern that these alloys will undergo the catastrophic solid state  $\beta$  to  $\alpha$  transformation. In this transformation, with an equilibrium temperature of 13°C, tin becomes a semiconductor and there is a 27% increase in volume. In this paper techniques that have been developed to monitor the transformation rate based on a time lapse technique and the application of electrical continuity measurements in the bulk tin. A technique for initiating the transformation based on the use of a seed is described. In this paper, various factors affecting the transformation rate were investigated: stress, alloy composition, and nucleating seed. Of very significant interest is the effect of flux and its residues, and that of oxides in influencing the transformation rates. Experiments are reported that show how these factors can affect the transformation rate.

### **10:10 AM**

**Effect of Solidification Temperature on the Microstructure of SnAgCu Solder Joints:** *Babak Arfaei*<sup>1</sup>; Eric Cotts<sup>1</sup>; <sup>1</sup>Binghamton University

Variations in the microstructure of SnAgCu solder joints resulting from changes in solidification temperatures are examined. Sample and pad size, thermal history and substrate finish all may affect the solidification temperature. Solder joint Sn grain morphology, and intermetallic precipitate size and number, are directly affected by solidification temperature; thus solder joint mechanical properties are strongly influenced by this parameter. The Sn grain morphologies and precipitate microstructures were examined in near eutectic SnAgCu solder joints solidified at undercoolings between ten and eighty degrees. Larger solder joints (e.g. ball grid array, 500 micron diameter) generally solidify at higher temperatures and show a beach ball twinning structure, however through the control of thermal history, the solidification temperature of such large solder joints was reduced thirty degrees. An interlaced twinning morphology was then observed. Corresponding changes in precipitate morphology are reported. Effects on creep and cyclic failure times of SnAgCu solder joints are discussed.

### **10:40 AM**

**Effect of the Ternary Quasiperitectic Reaction on the Formation of Microstructure during Freezing of Ternary Pb-Free Solder Alloys:** *Doug Perovic*<sup>1</sup>; Leonid Snugovsky<sup>1</sup>; Polina Snugovsky<sup>2</sup>; John Rutter<sup>1</sup>; <sup>1</sup>University of Toronto; <sup>2</sup>Celestica Inc.

The banning of Pb as a toxic material has led to the introduction of ternary solder alloys, such as the SAC series, to replace the traditional Pb-Sn eutectic solder. The addition of a third element to the solder alloy brings with it the possibility of the introduction of ternary solidification reactions, in addition to the usual binary reactions, during freezing of the solder. Such a ternary reaction, known as a quasiperitectic reaction, has been observed in the phase diagrams of certain Pb-free systems. In particular, these are alloy systems in which the phenomenon of "spalling" occurs in joints made with the associated solder alloys. It is the purpose of this paper to show the effect of the ternary quasiperitectic reaction on the formation of microstructure during freezing of such Pb-free solder alloys. Solder joint formation of Sn-Ag-Cu alloys and Sn-Zn-Cu Alloy on Cu/Ni substrate will be presented.

### **11:00 AM**

**Development of SAC3595 Solders Alloyed with Al, Mn, or Zn for High Reliability:** *Adam Boesenberg*<sup>1</sup>; Iver Anderson<sup>2</sup>; Joel Harringa<sup>2</sup>; <sup>1</sup>Iowa State University; <sup>2</sup>Ames Laboratory

As a robust replacement for leaded solders that can become environmental toxins, a family of near-eutectic Pb-free solder alloys based on Sn-Ag-Cu (SAC) compositions have shown promise worldwide for electronic assembly. However, reliability issues in divergent assembly methods and aggressive operating environments have arisen. Micro-alloying of Sn-3.5Ag-0.95Cu (wt.%) solder with Al, Mn, Zn was developed for reliable heterogeneous nucleation control in solder joint solidification to address drop impact and

thermal cycling issues. Cu substrate solderability of these SAC3595+X alloys was investigated at concentrations between 0.01-0.25wt% using globule wetting balance tests to quantify any increased oxidation during reflow. Composition dependence of these X additions also was explored in simplified Cu joints by differential scanning calorimetry, microstructure analysis, and X-ray diffraction to determine coupling between undercooling and joint microstructure development on single and multiple reflow cycles. Supported by Iowa State University Research Foundation and Nihon-Superior, Inc., through Ames Lab contract DE-AC02-07CH11358.

**11:20 AM**

**Effect of Gold Content on the Microstructural Evolution of SAC305 Solder Joints under Isothermal Aging:** *Mike Powers*<sup>1</sup>; Jianbiao Pan<sup>2</sup>; Julie Silk<sup>1</sup>; Patrick Hyland<sup>2</sup>; <sup>1</sup>Agilent Technologies; <sup>2</sup>California Polytechnic State University

Au over Ni on Cu is a widely used printed circuit board (PCB) surface finish, under bump metallization and component lead metallization. It is generally accepted that less than 2-3 weight percent Au in Sn-Pb solder joints will preclude reliability issues associated with the formation of Au based intermetallic compounds. However, the critical limit for Au content in Pb-free solder joints is not well established. This paper investigates the microstructural evolution of SAC305 solder joints with varying Au content under isothermal aging. Three surface mount package platforms with different Au thicknesses on their component leads were soldered to PCB with two different Au thicknesses, in a realistic manufacturing setting. The assembled boards were divided into three groups: one without thermal treatment, one isothermally aged at 125\176 C for 30 days and the third aged at 125\176 C for 56 days. The resulting microstructure of the test groups is compared.

**11:40 AM**

**Rare Earths Addition Effect on Microstructure and Intermetallic Layer Growth Kinetics on Lead-Free Solder Sn-Ag-Bi:** *Miguel Neri*<sup>1</sup>; Alberto Martinez-Villafañe<sup>1</sup>; Caleb Carreño<sup>1</sup>; <sup>1</sup>CIMAV, S.C.

Rare earths were added to Sn-Ag-Bi alloy in order to determine its effect on microstructure and Tin-Copper intermetallic layer growth kinetics. There were 3 different sample alloys prepared: Sn-Ag-Bi, Sn-Ag-Bi + Nd, and Sn-Ag-Bi + Pr. These alloys were applied to an electrolytic copper substrate and were given ageing heat treatments at temperatures between 50 to 150 °C at different times of permanence (0, 50, 150, 250 and 500 hours), in order to determine the Tin-Copper intermetallic layer growth kinetics and microstructure evolution on the soldered joints. These samples were prepared by metallographic techniques in order to measure the intermetallic layer thickness, and observe the microstructure thickening depending on temperature and time of ageing heat treatment, using optical microscopy, scanning electron microscopy, and EDS. The intermetallic layer thickness grew by increasing temperature and ageing treatment time, while microstructure was thickening with increasing temperature and ageing treatment time.

**12:00 PM**

**Magnetically-Driven Three-Dimensional Manipulation and Inductive Heating of Magnetic-Dispersion Containing Lead-Free Solders:** *Aimissa Ramirez*<sup>1</sup>; Xu Huang<sup>1</sup>; Joshua Calabro<sup>1</sup>; Brian Lewis<sup>1</sup>; <sup>1</sup>Yale University

Fundamental to the development of three-dimensional microfabrication is a material that enables vertical geometries. Here we show lead-free solders containing iron dispersions that can be remotely manipulated by magnetic fields to create vertical geometries and thus enable three-dimensional fabrication. These iron dispersions enhance the mechanical properties needed for strong, reliable interconnects, without significantly altering the electrical properties. Additionally, these iron dispersions act as susceptors during electromagnetic induction heating conditions, allowing the rapid melting of these novel materials at lower temperatures than those usually reported for conventional solder. Such capabilities have potential applications in the assembly of temperature-sensitive devices by localizing high temperatures and by reducing the temperature excursions associated with other lead-free solders.

## Physical and Mechanical Metallurgy of Shape Memory Alloys for Actuator Applications: Characterization of Shape Memory Alloys: Microstructural Transformation

*Sponsored by:* The Minerals, Metals and Materials Society

#### 8:35 AM Plenary

**Hysteresis, Reversibility, and Shape Memory:** *Richard James*<sup>1</sup>; Vijay Srivastava<sup>1</sup>; Yintao Song<sup>1</sup>; <sup>1</sup>University of Minnesota

We present some recent measurements of hysteresis, in materials undergoing first order phase transformations, that resulted from a systematic program of tuning of the lattice parameters by changing composition. The lattice parameters were tuned so that a certain non generic condition of compatibility between phases was satisfied. The tuned alloys exhibit thermal hysteresis as low as 2 C by careful bulk measurements, and in all cases less than 6 C. The procedures are effective for broad classes of hard materials undergoing diffusionless transformations, including metals and oxides. Studies of reversibility show improved stability of the transformation, measured by the migration of the hysteresis loop under repeated cycling. Some examples of this tuning in Heusler systems show fascinating convergence of shape memory and magnetism. Using these tuned Heuslers, we demonstrate new devices that 1) convert heat directly into electricity, 2) convert heat directly into kinetic energy.

**Effects of Surface Modifications on Twinning Stress and the Stability of Twin Microstructures of Magnetic Shape-Memory Alloys:** *Peter Müllner*<sup>1</sup>; Markus Chmielus<sup>2</sup>; Cassie Witherspoon<sup>1</sup>; Rainer Schneider<sup>3</sup>; Kari Ullakko<sup>1</sup>; <sup>1</sup>Boise State University; <sup>2</sup>Boise State University and Helmholtz Centre Berlin for Materials and Energy; <sup>3</sup>Beuth Hochschule für Technik und VDI/VDE Innovation and Technik GmbH

Twinning is the primary deformation mechanism in magnetic shape-memory alloys (MSMA). Inclusions, precipitates and defects hinder or even prevent twin boundary motion in the bulk of MSMA single crystals. We study the effect of surface damage on the mechanical properties and twin structure of Ni-Mn-Ga single crystals. Surface damage was produced with spark erosion, ion implantation, shot blasting and abrasive wearing. The degree of surface modification was characterized with x-ray diffraction where the broadening of Bragg reflections and of rocking curves was taken as a measure of localized elastic and plastic strains. Surface deformation stabilizes a dense twin-microstructure and prevents twins from coarsening. The density of twins increases with increasing degree of deformation. With increasing surface deformation and twin density, twinning stress and hardening rate increase. The stabilization of a dense twin microstructure prevents damage accumulation in high-cycle magneto-mechanical actuation and is critical for technological applications of MSMA.

**In-Situ Neutron Scattering Studies of Shape Memory Alloy Actuator Materials:** *Donald Brown*<sup>1</sup>; Bjorn Clausen<sup>1</sup>; Thomas Sisneros<sup>1</sup>; <sup>1</sup>Los Alamos National Lab

Neutrons are uniquely suited to probe the crystallographic response of materials to external stimuli because of their high penetration, which allows

them to sample the bulk of the material.. This is important for shape memory alloys (SMA's) as surface grains might be expected to behave differently from those in the bulk due to the different constraints. The SMARTS neutron diffractometer at the Lujan Center was built on the philosophy of studying materials under their operating conditions, and this philosophy has been aggressively applied to SMA's. The design of SMARTS allows for determination of the phase fraction, internal stress, and, to a degree, the texture evolution of SMA's under various conditions including tensile, compressive, or cyclic loading while simultaneously controlling temperature and/or magnetic field. This talk will highlight these capabilities, which are available to general users, by describing several examples of recent research on SMA's under multiple environmental conditions.

**Nanocrystalline Shape Memory Alloys:** *Thomas Waitz*<sup>1</sup>; Wolfgang Pranger<sup>2</sup>; Clemens Mangler<sup>1</sup>; Martin Peterlechner<sup>1</sup>; Gerd Steiner<sup>1</sup>; Thomas Antretter<sup>3</sup>; Franz Dieter Fischer<sup>3</sup>; Peter Müllner<sup>4</sup>; <sup>1</sup>University of Vienna; <sup>2</sup>Materials Center Leoben Forschung GmbH; <sup>3</sup>Montanuniversität Leoben; <sup>4</sup>Boise State University

Martensitic phase transformations can be significantly affected by a grain size and specimen size on the micro- and nanoscale. Bulk nanocrystalline shape memory alloys for actuator applications can show large recovery stresses. Thin films and small pillars are promising candidates for actuators for micro- and nanoelectromechanical systems. In the present work, the effect of a grain size at the nanoscale on the martensitic phase transformation is studied using bulk materials processed by severe plastic deformation that include NiTi and high temperature NiTiHf shape memory alloys as well as NiMnGa and high temperature NiFeGaCo ferromagnetic shape memory alloys. Grain refinement causes a suppression of the martensitic phase transformation that can occur in burst like events. Considering a size dependent energy barrier opposing the transformation, the phase stability and unique martensitic morphology of the nanograins is explained.

**New Microscopic Tools Applied for the Study of SMA:** *Dominique Schryvers*<sup>1</sup>; <sup>1</sup>University of Antwerp

In recent years several new electron microscopic tools have become available for the study of the crystallography and microstructure of functional materials. Atomic crystal structures can be refined with new optimization procedures including dynamic diffraction allowing focusing on nanoscale structures such as metastable Ni<sub>4</sub>Ti<sub>3</sub> precipitates in Ni-Ti SMA. Quantitative analysis of atomic resolution images and spectroscopic data yields three-dimensional views of concentration gradients and strain fields in the matrix surrounding such precipitates while tomographic slice-and-view techniques result in three-dimensional shape and distribution functions for the precipitates. More conventional techniques provide insight in the role of lattice parameter relations between parent and product for the lowering of the hysteresis and energy dissipation and the corresponding twin configurations. Site-specific sample preparation with FIB provides new ways for the study of surface and interior of micro-wires treated by a variety of processes. Examples of these and other applications will be presented.

**Modulated Martensite: Why it Forms and Why it Deforms Easily:** *Sebastian Fähler*<sup>1</sup>; <sup>1</sup>IFW Dresden

The high strain up to 10% in magnetic shape memory alloys is only observed in martensitic phases exhibiting modulations. In order to understand the origin of modulated martensites and consequences for the twin boundary mobility we analyze epitaxial Ni-Mn-Ga films as a model system. In agreement with the concept of adaptive martensite modulations are induced by the geometrical constraints at the habit plane. Hence modulated martensite is build from nanotwinned tetragonal martensite. We observe coarsening of these twin variants by doubling of periodicity in discrete steps from the atomic to the micrometer scale. When the activation energy for this process is too high, a second hierarchy of mesoscopic twin boundaries forms.

In contrast to the common, atomically sharp twin boundaries, the complex unit cell of an adaptive phase results in diffuse, mesoscopic twin boundaries. The extraordinarily high mobility of mesoscopic twin boundaries can be attributed to their broad pinning potential

**Transformation Characteristics of Ni-Mn-Ga High Temperature Shape Memory Alloys:** Ruben Santamarta<sup>1</sup>; *Jaume Pons*<sup>1</sup>; Catalina Picornell<sup>1</sup>; Eduard Cesari<sup>1</sup>; Joan Font<sup>2</sup>; Joaquim Muntasell<sup>2</sup>; Ibrahim Karaman<sup>3</sup>; Dimitris Lagoudas<sup>3</sup>; <sup>1</sup>University of the Balearic Islands; <sup>2</sup>Polytechnical University of Catalonia; <sup>3</sup>Texas A&M University

The martensitic transformation (MT) characteristics of several Ni-Mn-Ga alloys with high transformation temperatures (TTs) will be presented. The studied alloys with the highest TTs, ~750K, are unstable; the MT is degraded after a few cycles by intense precipitation of \947' phase or lath-shaped particles similar to the Ni<sub>5</sub>Al<sub>3</sub> phase. Alloys with Ni content close to stoichiometry show an excellent thermal stability upon ageing. For instance, the alloys Ni<sub>51.2</sub>Mn<sub>33.1</sub>Ga<sub>17.7</sub> (TT~485K) and Ni<sub>51.2</sub>Mn<sub>33.1</sub>Ga<sub>15.7</sub> (TT~575K) aged at 770 K for years do not experience any significant change in the TTs. In other alloys, like Ni<sub>55.2</sub>Mn<sub>29.1</sub>Ga<sub>15.7</sub> (TT~665K) and Ni<sub>58.3</sub>Mn<sub>15.5</sub>Ga<sub>25.8</sub> (TT~525K), precipitation of lath-shaped or \947' phases take place after several days at 670K or 770K, respectively. The superelasticity and shape memory characteristics will also be presented both in single phase alloys and in alloys with controlled precipitation of second phases introduced to improve the ductility. Finally, the effects of Cu additions will be discussed.

#### 11:15 AM

**Microstructural Instability in NiTi Based Shape Memory Alloy Actuators:** *Nicholas Jones*<sup>1</sup>; David Dye<sup>1</sup>; <sup>1</sup>Imperial College London

NiTi based shape memory alloy (SMA) actuators offer the potential for simple dynamic components that can reduce aerospace emissions. For these components to be structurally useful, they require a significant bias load. However, despite fabrication of successful demonstrator components, the cyclic instability of the martensitic transformation continues to prevent this technology from transferring into full scale production. The addition of copper can alter the transformation sequence including an orthorhombic martensite, which seems to decrease the rate of cyclic destabilisation. Using synchrotron X-ray diffraction we have studied the behaviour of both a near equiatomic and a copper containing NiTi SMA over several thermal cycles under different uniaxial loads. The martensitic microstructure is found to evolve during cycling and an accumulation of strain is observed, which appears to be driven by accommodation of the applied load. The observed effects are discussed, relating the transformation fundamentals to the instability of the material.

#### 11:30 AM

**The R Phase Transformation in Rapidly Solidified Ti-47.3Ni(at%) Alloy Ribbons:** *Tae-hyun Nam*<sup>1</sup>; Hyo-jung Mun<sup>1</sup>; Yinong Liu<sup>2</sup>; Hong Yang<sup>2</sup>; Yeon-wook Kim<sup>3</sup>; <sup>1</sup>Gyeongsang National University; <sup>2</sup>University of Western Australia; <sup>3</sup>Keimyung University

In the present study, Ti-47.3Ni(at%) alloy ribbons with a thickness of 32±1µm were prepared by melt spinning and then microstructures and transformation behavior were investigated by means of transmission electron microscopy(TEM), X-ray diffraction(XRD), electrical resistivity(ER) measurement and differential scanning calorimetry(DSC). Nano-sized Ti<sub>2</sub>Ni particles with a specific orientation relationship with matrix were observed in as-spun ribbons. The B<sub>2</sub>-R-B<sub>19'</sub> transformation occurred in as-spun ribbons and moreover the B<sub>2</sub>-R transformation was separated clearly from the R-B<sub>19'</sub> transformation. The two-stage B<sub>2</sub>-R-B<sub>19'</sub> transformation behavior was still preserved after annealing the as-spun ribbons at the temperature range from 673 K to 1223 K for 3.6 ks. When the annealing temperature was higher than 973 K, the B<sub>2</sub>-R and the R-B<sub>19'</sub> transformations were not separated clearly, which was ascribed to the fact that nano-sized Ti<sub>2</sub>Ni particles grew and lost the specific orientation relationship with matrix by high temperature annealing.

11:45 AM

**Characterization of Nanoscale Precipitates in a Ni-Rich Ni-29.7Ti-20Hf (at.%) High Temperature Shape Memory Alloy:** Taisuke Sasaki<sup>1</sup>; B. C. Hornbuckle<sup>1</sup>; Glen Bigelow<sup>2</sup>; Ronald Noebe<sup>2</sup>; Mark Weaver<sup>1</sup>; *Gregory Thompson*<sup>1</sup>; <sup>1</sup>University of Alabama; <sup>2</sup>NASA Glenn Research Center

Though Ni-rich Ni-Ti alloys have superior dimensional stability compared to Ti-rich compositions, after several thermomechanical cycles, retained strain can occur. The ternary addition of Hf has been observed to reduce this effect and has the added benefit of raising the transformation temperatures. The Hf addition has been shown to form nanoscale precipitates; however, little is understood with respect to the microstructure of this fine phase. In this work, we investigated the effect of aging on the transformation temperature and microstructure of an extruded Ni-29.7Ti-20Hf (at.%) alloy. The samples were solution treated at 1050°C for 0.5 hr followed by aging at 550°C for various times. Unlike the recent P-phase reported in NiTiPt, the NiTiHf alloys exhibit a different crystal structure. Transmission electron microscopy and atom probe tomography have been performed to quantify the structure.

12:00 PM End of Session

## Polycrystal Modelling with Experimental Integration: A Symposium Honoring Carlos Tome: Hexagonal Materials and Twinning

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Materials Processing and Manufacturing Division, ASM-MSCTS: Texture and Anisotropy Committee, TMS/ASM: Mechanical Behavior of Materials Committee, TMS/ASM: Computational Materials Science and Engineering Committee

**Role of Stress Fluctuations in the Nucleation of Deformation Twinning in Hcp Metals:** *Irene Beyerlein*<sup>1</sup>; Anand Kanjarla<sup>1</sup>; Carlos Tome<sup>1</sup>; Ricardo Lebensohn<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

We present an experimental and theoretical approach for understanding the statistical nature of deformation twinning in hexagonal close packed (hcp) polycrystals. We first describe statistical studies of {1012} twinning in high-purity Zr and Mg that correlate deformation twinning with certain microstructural features, such as grain size, grain orientation, and grain boundary misorientation angle. To determine the impact of twinning on aggregate deformation behavior, these metallographic results are combined with a multi-scale constitutive model for hcp metals. The predictions indicate that the amplitude and variation in the stress fluctuations between the grain interior and grain boundary play a crucial role. In light of this, we consider two models, the second-order (SO) VPSC approach (Lebensohn et al., 2007) and Fast Fourier Transform method (FFT) (Lebensohn et al., 2004), both of which account for grain orientation in the calculation of stress states. We report on how the modeling results compare for various cases.

8:55 AM Invited

**Orthotropic Strain Rate Potential for Hexagonal Metals:** *Oana Cazacu*<sup>1</sup>; Ioan Ionescu<sup>2</sup>; <sup>1</sup>University of Florida; <sup>2</sup>LPMTM, University Paris 13

Existing strain rate potentials are applicable only to materials with cubic crystal structure. In this paper, an anisotropic strain rate potential for hexagonal metals is developed. First, an exact dual to the isotropic form of Cazacu et al. (2006) stress potential is derived. Next, this isotropic strain

rate potential is extended such as to account for orthotropic symmetry. The ability of the developed anisotropic strain rate potential to describe the complex behavior of hexagonal metals is demonstrated by comparison with experimental data on titanium.

9:20 AM

**Modeling Deformation Twinning with a Binary-Tree Based Polycrystal Model:** *Sivasambu Mahesh*<sup>1</sup>; <sup>1</sup>IIT Kanpur

A novel polycrystal model that explicitly accounts for intergranular interactions is described. In this model, the polycrystal is regarded as a binary tree. Leaf nodes of the binary tree represent the grains and successively higher nodes represent increasingly larger sub-aggregates of grains culminating with the root of the tree, which represents the entire polycrystalline aggregate. Traction and velocity continuity conditions are imposed across the interface between the children of each non-leaf node in the binary tree. The present model is employed to model deformation twinning of hcp magnesium and zirconium. Texture predictions from the present model are compared with those obtained using the VPSC model by Dr. Tome' and co-workers, and with experimental observations.

**Effect of Texture on Anisotropic Creep of Zr-2.5Nb Tubes:** *Rick Holt*<sup>1</sup>; W. Li<sup>1</sup>; S. Tracy<sup>1</sup>; Ricardo Lebensohn<sup>2</sup>; <sup>1</sup>Queen's University; <sup>2</sup>Los Alamos National Laboratory

We have investigated the anisotropy of thermal creep of cold-worked Zr-2.5Nb tubes for a range of textures and stress states. The tests were performed on internally pressurized thin-wall standard capsules at a stress of 300MPa at 350C. The stress state was modified by applying a load to the ends of the capsules to give a stress ratio of  $0.25 < \sigma_{hoop} / \sigma_{axial} < 0.75$ . The tests showed an obvious correlation of creep anisotropy with the texture. A self-consistent visco-plastic polycrystalline model (SELPOLY) based solely upon crystallographic texture showed a poor correlation with the experimental results. A modified self-consistent model is introduced to take into account different pre-existing anisotropic dislocation distributions from cold-work. The anisotropic dislocation structures are calculated using an elasto-plastic self consistent model (EPSC). Much better agreement with the experimental creep anisotropy is found, indicating that individual dislocation distributions in grains with different orientations are important in controlling the creep anisotropy.

10:20 AM Invited

**Atomistic Modeling of Deformation Twinning Mechanisms in Hcp Metals:** *Jian Wang*<sup>1</sup>; Irene Beyerlein<sup>1</sup>; Carlos Tome<sup>1</sup>; <sup>1</sup>LANL

Twin propagation and growth are responsible for the hardening and texture evolution characteristic of Mg alloys subjected to plastic deformation. Propagation, however, does not take place unless it is preceded by twin nucleation. As a consequence, understanding nucleation and accounting for it in material models is a prerequisite for understanding the constitutive response of Mg alloys. Experimental observations indicate that twin formation tends to form in suitably oriented grains, and some studies report a positive grain size effect, wherein twinning appears to form more easily in larger grains. In this talk, some fundamental issues, such as grain boundary structures, twinning dislocations, and nucleation and propagation mechanisms of twins, are discussed. Finally, we propose a comprehensive approach for understanding deformation twinning from atomic-scale to micro-scale. Such approach relies on, and relates, molecular dynamics (MD) simulations, EBSD, and a nucleation model.

10:45 AM

**Grain Size and Neighbor Grain Effects on Deformation Twinning:** *Rodney McCabe*<sup>1</sup>; Irene Beyerlein<sup>1</sup>; Carlos Tome<sup>1</sup>; <sup>1</sup>Los Alamos National Laboratory

Whether or not twins nucleate and grow in a grain depends on several microstructural characteristics of the grain and its neighbors. Grain orientation is a good predictor of the probability of twinning. However, not all grains of similar orientation exhibit twins, and a considerable fraction of

observed twins are not of the twin variant with the highest resolved shear stress based on the orientation of the grain and the bulk stress state of the material. Here we examine the role that grain size and neighbor grain attributes (neighbor orientation, grain boundary misorientation) play in this statistical nature of twinning. We examine these effects using large numbers of twin statistics developed using electron backscatter diffraction (EBSD) for {1012} twinning in magnesium, {1012} and {1122} twinning in zirconium, and {130} twinning in uranium.

**11:05 AM**

**Texture Evolution during Thermo-mechanical Processing of Zircaloy-4:** *Christabel Evans*<sup>1</sup>; *David Dye*<sup>1</sup>; *Trevor Lindley*<sup>1</sup>; *David Rugg*<sup>2</sup>; *Nicholas Jones*<sup>1</sup>; <sup>1</sup>Imperial College London; <sup>2</sup>Rolls-Royce plc.

Zirconium alloys are widely used for nuclear reactor core internals due to their low neutron absorption cross section and good corrosion resistance. Zircaloy-4 is an alpha-Zr alloy which deforms at room temperature by both slip and twinning. The textures used are engineered so as to optimize service performance. In order to understand how texture can evolve in Zr under a variety of conditions, in situ synchrotron X-ray diffraction compression and tension tests have been performed on rolled Zry-4 under varying strain rates and temperatures up to 550 °C, along with post-hoc EBSD, to understand how the deformation mechanisms change from the texture evolution. The results are interpreted with the aid of Tome's now-famous VPSC model.

**11:25 AM**

**Crystal Plasticity Based Finite Element Simulations of Deformation in AM30 Magnesium Alloy Under Complex Strain Paths:** *Adel Izadbakhsh*<sup>1</sup>; *Kaan Inal*<sup>1</sup>; *Raja Mishra*<sup>2</sup>; <sup>1</sup>University of Waterloo; <sup>2</sup>General Motors R&D Center

Deformation of AM30 magnesium alloy subjected to complex strain paths has been simulated using a Crystal Plasticity based Finite Element Method (CPFEM). A new crystal plasticity framework that satisfies equilibrium and compatibility requirements throughout the polycrystal aggregate and incorporates the interaction between twinning and slip through the kinematics of deformation has been developed. The model includes contraction and double twinning mechanisms in addition to basal and non-basal slip and extension twinning. A rate-dependent crystal plasticity constitutive law calibrated with uniaxial tension and compression data at room temperature and at 2000C is implemented in a User defined MATerial subroutine (UMAT) in LS-DYNA. The deformation pattern of AM30 tubes, especially the initiation and propagation of localization during the "Ring Hoop Tension Test", simple shear and pure bending has been simulated. Simulations show that neglecting contraction and double twinning can significantly delay/defer the initiation of localized deformation and its propagation.

**11:45 AM**

**Experimental and Simulation Studies on the Evolution of Rolling Texture in a Two Phase Titanium Alloy:** *Nilesh Gurao*<sup>1</sup>; *Satyam Suwas*<sup>1</sup>; <sup>1</sup>Indian Institute of Science, Bangalore

The evolution of deformation texture and microstructure during rolling of a two phase (α+β) titanium alloy with a nominal composition Ti-13Nb-13Zr has been studied. Two different morphologies, namely, colony and equiaxed, were generated by suitable heat treatments prior to rolling. Microstructural evolution was examined using Electron Back Scatter Diffraction (EBSD) and textures were measured by X-ray diffraction. A characteristic texture evolution was noted in both the HCP α and the BCC β phase irrespective of the different initial morphology. The evolution of higher intragranular misorientations in the β phase indicates that the softer β phase carries most of the strain. Texture evolution was simulated using viscoplastic self-consistent (VPSC) model. The experimental textures were successfully reproduced using VPSC simulations that incorporated the different initial morphologies of both the phases.

**12:05 PM**

**Hardening Mechanisms upon Profuse Twinning in Pure Magnesium:** *Andrew Oppedal*<sup>1</sup>; *Haitham El Kadiri*<sup>1</sup>; *Carlos Tomé*<sup>2</sup>; *James Baird*<sup>1</sup>; *Sven Vogel*<sup>2</sup>; *George Kaschner*<sup>2</sup>; *Mark Horstemeyer*<sup>1</sup>; <sup>1</sup>Mississippi State University; <sup>2</sup>Los Alamos National Laboratory

Textured hexagonal close packed double-lattice structures show stronger anisotropy than textured single-lattice structures. The reason lies behind the necessity to activate glide twinning and hard slip dislocation modes. Although the mechanisms behind activation of dislocations with non-basal Burgers vectors are still not fundamentally understood, the effect of twinning on hardening presents the most substantial challenge to polycrystal plasticity modelers. The origin of the increasing strain hardening rate regime (Regime II) upon profuse twinning is still not fundamentally clear. Previous successful attempts to fit stress-strain behavior based on a Hall-Petch effect by twin segmentation led to discrepancies in predicting intermediate textures and/or twin volume fraction evolution. A recent dislocation-based hardening rule incorporated into the Visco-Plastic Self-Consistent (VPSC) model allows slip and twinning to be physically coupled in the simulations. In this paper, we investigate hardening mechanisms in pure magnesium and apply a dislocation based formalism to model anisotropy.

**Micromechanical Model of Metals and Alloys of Low Symmetry Deforming by Slip and Twinning:** *Katarzyna Kowalczyk-Gajewska*<sup>1</sup>; <sup>1</sup>Institute of Fundamental Technological Research, Warsaw

The micromechanical model of finite plastic deformations of polycrystalline materials of low symmetry, characterized by high specific strength, is presented. As concerns texture evolution the model accounts for appearance of new twin related orientations using a new reorientation scheme called Probabilistic Twin Volume Consistent scheme. It takes into account the history of the deformation process and maintains the volume fraction of reoriented grains at a level consistent with the shear activity of twins contributing to the deformation. Within the proposed framework the hardening rule describing slip-twin interactions is developed. Evolution of critical shear stress for slip due to twin activity is described by the rule accounting for geometrical effects of twin boundaries in reducing main free path distance for dislocations. It also takes into account the lamellar substructure of single grain which evolves during twinning. Model predictions are verified for titanium alluminide intermetallic of near gamma microstructure and magnesium.

**8:35 AM Keynote**

**Coarsening Models Applicable to Sintering:** *Randall German*<sup>1</sup>; <sup>1</sup>San Diego State University

Treatments of sintering are analyzed to show grain size is determined by the microstructure contiguity during densification. Grain size determines the sintering rate. Thus, not only do properties pivot around grain size, but the rate of sintering traces to control of the interfaces during sintering. With nanoscale powders there is more demand for controlled coarsening during

TUESDAY AM

sintering. This treatment shows a simple model that links grain growth to interfacial features - pores, liquids, dispersoids, or other second phases. Since sintering converges toward a self-similar grain shape and grain size distribution, most of the relations are fairly simple. Then grain growth rates are predicted based on the fraction of each interface and the transport events associated with the evolving solid-liquid-vapor microstructure. Reviews of data from classic experiments to recent nanoscale SPS experiments are used to illustrate the model. Means to densify without extensive coarsening are extracted from the model.

### 9:05 AM

**Challenges in the Scalability of Field Assisted Sintering:** *Chris Haines*<sup>1</sup>; Darold Martin<sup>1</sup>; Deepak Kapoor<sup>1</sup>; William Bradbury<sup>2</sup>; Eugene Olevsky<sup>2</sup>; <sup>1</sup>US Army ARDEC; <sup>2</sup>San Diego State University

Field-Assisted Sintering Technology (FAST) aka Spark Plasma Sintering (SPS) is a revolutionary, game-changing technology which provides the ability to consolidate materials to full density in minutes, as opposed to hours with conventional sintering techniques. To date, most research has reported on sample sizes in the range of a few centimeters to a few inches. In order for the technology to mature as a viable manufacturing technology in the industrial base, significant scale-up is required. Scaling of such a highly energetic sintering technology is not trivial and presents many challenges. We have observed, both experimentally and in our modeling, a significant dependence on factors such as sample dimensions, geometry, and die design on the temperature and current distribution during sintering. These effects can subsequently be seen in the resulting microstructure of the sintered specimens. Proposed solutions to these challenges will be discussed.

### 9:25 AM

**Cryomilled Commercially Pure Ti Consolidated via Spark Plasma Sintering:** *Osman Ertoer*<sup>1</sup>; Troy Topping<sup>1</sup>; Ying Li<sup>1</sup>; Wes Moss<sup>2</sup>; Enrique Lavernia<sup>1</sup>; <sup>1</sup>University of California - Davis; <sup>2</sup>TRD

Cryomilled nanocrystalline CP-Ti powders were spark plasma sintered (SPS) using varied process parameters (i.e., heating rate, temperature, pressure, and dwell time) in order to study densification, microstructure, and mechanical behavior. Results were rationalized on the basis of the relevant literature and experimental results, and they reveal a strong dependence on SPS parameters. An interesting finding was that the measured high ductility was accompanied by a moderate strength (YS > 700 MPa, UTS > 840 MPa with elongation to failure values larger than 20%). The strain rate sensitivity of produced samples was also studied. The combinations of microstructure and mechanical response were attributed to the multi-step processing using various SPS parameters as well as to the presence of interstitial solutes introduced during cryomilling.

### 9:45 AM

**Microstructural Characterization of Mechanically Alloyed Lanthana-Bearing Oxide Dispersion Strengthened Steels:** *Somayeh Pasebani*<sup>1</sup>; Indrajit Charit<sup>1</sup>; Kerry Allahaar<sup>2</sup>; Brian Jaques<sup>2</sup>; Darryl Butt<sup>2</sup>; James Cole<sup>3</sup>; <sup>1</sup>University of Idaho; <sup>2</sup>Boise State University; <sup>3</sup>Idaho National Laboratory

Oxide dispersion strengthened (ODS) alloys are being considered for advanced reactor applications due to their excellent creep and radiation damage resistance imparted primarily due to the presence of fine oxide particles. The objective of this study is to develop a new ODS alloy by mechanical alloying (MA) followed by spark plasma sintering (SPS). Different amounts (0-1 wt.%) of lanthanum oxide were mixed with a base alloy composition of Fe-14Cr-0.9Ti-0.3Mo (in wt.%) and processed via MA for different durations using the stainless steel milling media. Differential scanning calorimetry (DSC) was performed on the MA powders to study the kinetics of any phase transformation occurring. Further, detailed phase analysis was carried out using X-ray diffraction (XRD). Scanning electron microscopy (SEM) was also used to determine the particle size, shape and distribution. SPS will be used to produce the bulk ODS samples and characterized for microstructure and mechanical properties.

### 10:05 AM

**Spark Plasma Sintering of Ultra-Fine Grained and Nanocrystalline WC Based Hard Metals:** *Milan Dopita*<sup>1</sup>; David Chmelik<sup>1</sup>; Anton Salomon<sup>1</sup>; C. Sriram<sup>2</sup>; Hans Seifert<sup>1</sup>; <sup>1</sup>Technical University of Freiberg; <sup>2</sup>National Institute of Technology Tiruchirappalli

Modern trends in the materials research emphasizing the increase of the materials serving life-time tend to the preparation of the materials with nanocrystalline microstructure as it has been shown that nanocrystalline hard metals have better mechanical properties in comparison to their coarse-grained counterparts. In our work we focused on sintering of the nanocrystalline WC based hard metals using the spark plasma sintering method. Two types of materials i) WC-Co composites and ii) binderless WC were studied. The main accent was focused on the study of individual sintering parameters (temperature, time and pressure) and their correlations with sintered specimens microstructure and mechanical properties. Sintered specimens were investigated using XRD, SEM/EBSD, TEM/HRTEM, hardness and fracture toughness measurements. We derived favourable conditions for sintering of fully dense nanocrystalline hard metals and proved that the specimens sintered using these conditions have significantly improved mechanical properties in comparison to classical coarse grained hard metals.

### 10:25 AM Break

### 10:35 AM

**Preliminary Investigations in Current-Activated Tip-Based Sintering (CATS): Modeling and Experiments:** *A. El-Desouky*<sup>1</sup>; S.K. Kassegne<sup>1</sup>; K.S. Moon<sup>1</sup>; K. Morsi<sup>1</sup>; <sup>1</sup>San Diego State University

Spark Plasma Sintering (SPS) has emerged as a process with unique advantages such as lower sintering temperatures and shorter holding times than conventional sintering, in addition to the production of materials with unique microstructures and properties. However, the process has been largely limited to the production of bulk materials with simple geometries on a relatively moderate size scale. In this presentation preliminary experimental and modeling results on novel current-activated tip-based sintering (CATS) powder compacts are presented. CATS enables the selective sintering of micro-scale (and potentially nano-scale) features using a moving or stationary (electrically conductive) tip configuration. Preliminary finite element modeling results on current and temperature distributions under typical CATS conditions is also presented, in addition to a discussion on the versatility and extended applications of this new process.

### 10:55 AM

**The Role of Sintering Methods (HP & SPS) on Substructure and Its Correspondence on Creep Properties in Alumina Based Ceramic Materials:** *Ebrahim Karamian*<sup>1</sup>; Alain Bataille<sup>2</sup>; Ahmad Monshi<sup>3</sup>; Ehsan Mohamadi Zahrani<sup>4</sup>; <sup>1</sup>Isfahan University of Technology; <sup>2</sup>UMET, Unité Matériaux et Transformations, UMR CNRS 8207, University of Lille Science and Technology; <sup>3</sup>Department of Materials Engineering, Isfahan University of Technology; <sup>4</sup>Department of Materials Engineering, University of British Columbia

Spark plasma sintering method (SPS) is more than a decade to be an interesting alternative to classical densification processes for ceramic materials. Owing to the advantage of rapid heating, the alumina ceramics obtained by SPS have a grain size and density comparable to those of HPed ones. This paper describes the effect of HP & SPS on substructure and its correspondence on creep properties in alumina based ceramic materials. Pure alumina (SM8, Baikowski) was densified SPS at 65 MPa (1200°C) and 45 MPa (1450 °C) by HP (hot pressing). The grain size of the HP alumina was more twice coarser than the grain size of SPS sample. The grain growth is more active during creep of SPS alumina (1300 °C,  $\sigma = 30$  MPa) than of HP alumina. Generally, the fineness of SPS materials microstructure shall speed up all processes related to diffusion. So, creep resistance shall be decreased.

11:15 AM

### Spark Plasma Sintering of Ferritic Oxide Dispersion Strengthened

**Alloys:** Kerry Allahar<sup>1</sup>; Jatuporn Burns<sup>1</sup>; Brian Jaques<sup>1</sup>; Indrajit Charit<sup>2</sup>; Darryl Butt<sup>1</sup>; James Cole<sup>3</sup>; <sup>1</sup>Boise State University; <sup>2</sup>University of Idaho; <sup>3</sup>Idaho National Laboratory

Oxide Dispersion Strengthened (ODS) alloys are candidate cladding materials due to their resistance to radiation, thermally induced creep, and swelling. Conventional powder metallurgy consolidation techniques have been primarily used in the development of ferritic ODS alloys with limited application of spark plasma sintering (SPS). Sintering by SPS is achieved by Joule heating using a pulsed DC coupled with uni-axial pressure. Advantages of SPS include faster heating rates, uniform heating condition, lower sintering temperature and shorter dwell time. The influences of SPS processing parameters on the microstructural evolution are presented for two pre-alloyed Fe/Cr/Al and Fe/Cr/Mo powders where the composition of Y<sub>2</sub>O<sub>3</sub> was varied (0 to 0.5%). Parameters included temperature (600 to 1100 oC), dwell time (5 to 30 minutes) and heating rate (50 to 200 oC/min). Characterization of the grain sizes and boundaries was performed using EBSD and SEM and the fate of the ceramic dispersions was studied using TEM.

11:35 AM

**Characteristics of Tin/Fe Cermet Fabricated by Mechanical Milling and Pulse Current Sintering:** Hiroyuki Nakayama<sup>1</sup>; Keizo Kobayashi<sup>1</sup>; Kotaro Kikuchi<sup>2</sup>; <sup>1</sup>National Institute of Advanced Industrial Science and Technology; <sup>2</sup>SS Alloy Co., Ltd.,

Titanium nitride (TiN) shows poor wettability with various liquid metals, thus the fabrication of TiN based cermets is difficult using conventional sintering. Therefore, in this study, we examined the fabrication of TiN based cermet by mechanical milling and subsequent pulse current sintering. The Fe as a binder phase was selected, because it is one of the most economical elements. The TiN powder (70 mass%) and Fe powder (30 mass%) were mechanically milled for 28.8 ks using planetary ball milling under Ar atmosphere. Subsequently, the milled powder was successfully consolidated using pulse current sintering method at 1473 K for 300 s under 60 MPa. The sintered compact was composed of TiN and Fe defined by X-ray diffraction, and the hardness achieved to HRA 91.5.

## Recent Developments in the Processing, Characterization, Properties and Performance of Metal Matrix Composites: Processing, Microstructure and Mechanical Properties I

**Sponsored by:** The Minerals, Metals and Materials Society  
**Program Organizers:** Martin Pech-Canul, Centro de Investigacion y de Estudios Avanzados del Instituto Politecnico Nacional; Zariff Chaudhry, Arkansas State University; Golam Newaz, Wayne State University

Tuesday AM  
March 1, 2011

Room: 6A  
Location: San Diego Conv. Ctr

**Session Chair:** Martin Pech-Canul, Cinvestav Saltillo

8:30 AM

**Effects of Zr on the Microstructure and Tensile Properties of Al-15wt%Mg2Si Metal Matrix Composite:** Ahmad Razaghian<sup>1</sup>; Amin Bahrami<sup>1</sup>; Masoud Emamy<sup>2</sup>; Nargues Nemati<sup>3</sup>; Hamid Reza Jafari Nodoshan<sup>4</sup>; <sup>1</sup>Imam Khomeini International University; <sup>2</sup>Center of Excellence for High Performance Materials, School of Metallurgy and Materials, University of Tehran; <sup>3</sup>Sahand University of Technology; <sup>4</sup>Islamic Azad University

The effects of Zr modification on the microstructure and tensile properties of an in situ prepared Al-15wt%Mg<sub>2</sub>Si composite have been investigated. Microstructural examinations were conducted by optical and scanning electron microscopy equipped with energy dispersive spectrometry. The optimum amount of Zr was selected as 1 wt. %. It was found that the addition

of Zr reduces the average size of Mg<sub>2</sub>Si primary particles. Adding Zr also raised both tensile strength (from 240MPa to 300MPa) and elongation values (from 2.4 to 6%). Fractographic examination of the unmodified composite also showed that large Mg<sub>2</sub>Si particles are responsible for fracture behavior.

8:50 AM

**Investigation of Wear Properties of Hot Extruded Al-15wt%Mg2Si In-Situ Metal Matrix Composite:** Hamid Reza Jafari Nodoshan<sup>1</sup>; Masoud Emamy<sup>2</sup>; Amin Bahrami<sup>3</sup>; Ashkan Zolriasatein<sup>4</sup>; <sup>1</sup>Islamic Azad University; <sup>2</sup>University of Tehran; <sup>3</sup>Imam Khomeini International University; <sup>4</sup>K. N. Toosi University of Technology

In recent years, lightweight metal matrix composites (MMC) have received wider attention for their technological application, such as automotive parts etc. For structural application, the wear properties are considered to be one of the major factors controlling the performance. In this study wear behavior of Al based composites reinforced with in-situ Mg<sub>2</sub>Si particles have been investigated. The composite was prepared by casting followed by extrusion at various temperatures with different ratio. The wear behavior of sample was investigated using a pin-on-disk technique under an applied load of 10N. In the extruded samples, the composite exhibited superior wear resistance than as cast in-situ composite.

9:10 AM

**Microstructural Development of Al-15wt.%Mg2Si in Situ Composite with Be Addition:** Mortaza Azarbarmas<sup>1</sup>; Masoud Emamy<sup>1</sup>; Jafar Rassizadehghani<sup>1</sup>; Mohammad Alipour<sup>1</sup>; Mostafa Karamouz<sup>1</sup>; <sup>1</sup>University of Tehran

In this study, the effects of Be additions on the microstructural development of an in situ Al-15wt.%Mg<sub>2</sub>Si composite were investigated. A study of the specimen's surfaces via scanning electron microscope (SEM) and optical microscope revealed that with increasing Be additions in the composites, the average size of primary Mg<sub>2</sub>Si particles was reduced, and that the amount of alpha phase surrounding the Mg<sub>2</sub>Si particles was increased, with a little change in morphology of this particles. Meanwhile the morphology of pseudo-eutectic phase was changed.

9:30 AM

**Microstructural Properties and Wear Behaviour of AlSi9Mg Matrix B4Cp Reinforced Composites:** Fatih Toptan<sup>1</sup>; Isil Kerti<sup>1</sup>; Ahmet Sagin<sup>1</sup>; Mustafa Cigdem<sup>1</sup>; Sibel Daglilar<sup>1</sup>; Fatih Yuksel<sup>1</sup>; <sup>1</sup>Yildiz Technical University

In the present work, AlSi<sub>9</sub>Mg alloy matrix composites reinforced with 10, 15 and 20% (wt.) B<sub>4</sub>Cp were produced by casting route at 850 °C. Titanium-containing flux (K<sub>2</sub>TiF<sub>6</sub>) was used to overcome the wetting problem between B<sub>4</sub>C and liquid aluminium metal. The microstructure of matrix/reinforcement interfaces were investigated with SEM studies. The reaction layer was also characterized with EDS analysis and X-ray mapping. It was found from the microstructural observations by high resolution field emission gun SEM (FEG-SEM) that the wetting improved by the formation of very thin (80-180 nm in thickness) TiC and TiB<sub>2</sub> reaction layers. The samples were subjected to pin-on-disc wear tests against AISI 4140 pin under dry sliding conditions. The worn surface was studied through SEM and EDS analysis. It has seen that, wear resistance increased as particle volume fraction increased.

9:50 AM

**Modification of Al-Mg2Si In Situ Composite by Boron:** Mortaza Azarbarmas<sup>1</sup>; Masoud Emamy<sup>1</sup>; Jafar Rassizadehghani<sup>1</sup>; Mostafa Karamouz<sup>1</sup>; Mohammad Alipour<sup>1</sup>; <sup>1</sup>University of Tehran

In this work, the effects of B additions on the microstructural development of an in situ Al-15wt.%Mg<sub>2</sub>Si composite were investigated. It was found from scanning electron microscope (SEM) and optical microscope images that with increasing B additions in the composites, the average size of primary Mg<sub>2</sub>Si particles was reduced, and that the amount of alpha phase surrounding the Mg<sub>2</sub>Si particles was increased. Meanwhile with the addition of B the pseudo-eutectic Al-Mg<sub>2</sub>Si was formed in a regular morphology

TUESDAY AM

in cells separated with the alpha phase. Moreover, a small amount of B-containing compounds were formed as a result of B additions .

#### 10:10 AM Break

#### 10:30 AM

**The Influence of Li on the Microstructure and Mechanical Properties of Hot Extruded Al-Mg<sub>2</sub>Si Metal Matrix Composite:** Amin Bahrami<sup>1</sup>; Masoud Emamy<sup>2</sup>; Ahmad Razaghian<sup>1</sup>; Hamid Reza Jafari Nodooshan<sup>3</sup>; Ashkan Zolriasatein<sup>4</sup>; <sup>1</sup>Imam Khomeini International University; <sup>2</sup>University of Tehran; <sup>3</sup>Islamic Azad University; <sup>4</sup>K. N. Toosi University of Technology

This article investigates the effect of Li as modifier on microstructure and mechanical properties of hot extruded the In-situ Al-15wt%Mg<sub>2</sub>Si composite. This composite have already been introduced as a new class of light materials but the brittle structure of the primary Mg<sub>2</sub>Si which is formed during solidification of these composites limits its application. Modified composite was directly extruded as rod by using three different dies with diameters 20, 10 and 5 mm and various temperature. Microstructures after this type of extrusion was studied by optical microscopy. Mechanical properties of the composite after various extrusions were tested by hardness and tensile tests. The results showed that Li addition were highly effective in reducing Mg<sub>2</sub>Si particle size from 30µm to about7µm and affects to the flow of material during the extrusion process and mechanical properties of extruded samples.

#### 10:50 AM

**Characterization of Composite Materials Interface Aimed to Suppress Vibration in Cast Parts:** M. David Hanna<sup>1</sup>; Shung Sung<sup>1</sup>; <sup>1</sup>General Motors

Damping performance of inserted castings is critically dependent on the nature of the interface between the insert and the casting. This investigation involved an attempt to analyze sound data over a wide frequency range and assess the damping performance with different insert coating properties for a grey cast iron component. Based on the measured frequency response function, characteristic damping behavior of different coatings has been identified. The graphite base coating material showed enhanced sound damping properties compared to another refractory type material when applied to a steel insert. The parts with the graphite-based coated inserts have shown significant improvements in: (a) modal frequency reduction, (b) sound pressure level (SPL) reduction at the most dominant circumferential modes, (c) 1/3 octave band SPL reduction over wide frequency bands and finally (d) a modal damping ratio increase.

#### 11:10 AM

**In-Situ Synthesis of AlN/Mg Matrix Composites:** Xiao Ma<sup>1</sup>; Salin Kuplin<sup>1</sup>; David Johnson<sup>1</sup>; Kevin Trumble<sup>1</sup>; <sup>1</sup>Purdue University

Magnesium matrix composites with AlN reinforcements are potential engineering materials for automobile and aerospace applications. Attractive properties of AlN include high thermal conductivity and hardness. AlN-reinforced Mg composites have been synthesized by in-situ reaction using pure Al and AZ31B and Si<sub>3</sub>N<sub>4</sub> powder as raw materials. Microstructures containing 15 vol.% AlN were obtained by heating the raw materials at 770°C for one hour under argon atmosphere. Composite microstructures were characterized by X-ray diffraction, optical microscopy, scanning electron microscopy. Final microstructures consisted of AlN particles 1-5 µm in size distributed within the Mg alloy matrix.

#### 11:30 AM

**Performance Evaluation of Particulate Reinforced Al-SiC Bolted Joints:** Gergis William<sup>1</sup>; Samir Shoukry<sup>1</sup>; Jacky Prucz<sup>1</sup>; <sup>1</sup>West Virginia University

The increasing requirements of weight savings and extended durability motivated the potential application of metal matrix composite technology into the heavy vehicle market. However, significant technical barriers such as joining are likely to hinder the broad applications of MMC materials in heavy vehicles. This paper examines the feasibility of manufacturing and the behavior of bolted joint connections made from aluminum reinforced with silicon carbide particles. Initially, the study concentrates on experimental evaluation of bolted joints of 20% and 45% MMC material. The behavior of joints is studied as a function of various design parameters. Then, a finite

element model is generated to predict the behavior of a double-lap joint of the same material. It is seen that experimental and numerical results agree well with each other. The results indicate that MMC joints are likely to fail early in the bearing mode, because of the brittle behavior of MMC materials.

#### 11:50 AM

**Synthesis and Mechanical Behavior of Ultrafine-Grained Al-B4C Composites:** Zhihui Zhang<sup>1</sup>; Ying Li<sup>1</sup>; Troy Topping<sup>1</sup>; Rustin Vogt<sup>1</sup>; Yizhang Zhou<sup>1</sup>; Julie Schoenung<sup>1</sup>; Enrique Lavernia<sup>1</sup>; <sup>1</sup>University of California Davis

The study of Al based ultrafine-grained (UFG) composites is prompted by the objective to develop ultrahigh strength (>1000 MPa), low density materials that also possess attractive high strain rate behavior. In this study, UFG Al/B<sub>4</sub>C composites with a B<sub>4</sub>C reinforcement size of ~1 µm and ~50 nm, respectively, were produced via cryomilling followed by consolidating via HIP and extrusion. The results showed that the mechanical milling process led to a homogeneous distribution of the micro- and nano-particles in the matrix and the matrix had an average grain size of ~300 nm after consolidation. HRTEM revealed a clean Al/B<sub>4</sub>C interface and no detrimental interfacial phase or defects such as voids were observed. The mechanical behavior of the UFG composites were studied and the strengthening mechanisms were discussed in the frame work of load transfer, Hall-Petch strengthening, geometry necessary dislocation strengthening and dispersion strengthening.

### Shape Casting IV: Light Metals Division Symposium in Honor of Prof. John T. Berry: Modeling

*Sponsored by:* The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Processing Committee, TMS: Solidification Committee

#### 8:40 AM

**The History of Casting Process Simulation:** Christof Heisser<sup>1</sup>; <sup>1</sup>MAGMA Foundry Technologies, Inc.

An overview of significant steps in the development of casting process simulation will depict its development from simple "solidification-only" tools to comprehensive casting process simulation tools, which are irreplaceably integrated in the current product development process. The presentation will include topics like autonomous optimization and transfer of simulation results to FEA and lifetime prediction tools.

#### 9:05 AM

**State of the Art Review of Modelling Entrainment Defects in the Shape Casting Process:** Carl Reilly<sup>1</sup>; Nick Green<sup>2</sup>; Mark Jolly<sup>2</sup>; <sup>1</sup>University of British Columbia; <sup>2</sup>University of Birmingham

Entrainment of oxide films into liquid metals has been shown to be detrimental to casting integrity. A number of mechanisms have been shown to initiate the entrainment of oxide films including returning waves, plunging jets, bubble trails and fountains. Computational fluid dynamics (CFD) software packages allow foundry staff to improve casting systems using qualitative parameters. Optimization software is now a viable option for foundries. It does, however, require a measurable parameter which allows the quantification of defects. This is becoming an important research area to allow the optimization software manufacturers to meet the needs of industry. The current methods of modeling surface film and bubble generated casting

defects have been described and critically reviewed shedding light on the qualities and issues currently associated with the present available methods. However, it is clear that further investigations and developments are still required to allow the accurate and efficient modeling of casting defects.

**9:30 AM**

**Physical and Computational Models of Free Surface Related Defects in Low-Pressure Die-Cast Aluminum Alloy Wheels:** *Jianglan Duan*<sup>1</sup>; *Daan Maijer*<sup>1</sup>; *Steve Cockcroft*<sup>1</sup>; *Carl Reilly*<sup>1</sup>; *Ken Nguyen*<sup>2</sup>; *Dominic Au*<sup>2</sup>; <sup>1</sup>University of British Columbia; <sup>2</sup>Canadian Autoparts Toyota, Inc.

A water analogue model has been used to simulate the free surface behavior during mould filling of a low-pressure die-cast (LPDC) wheel. The water analogue has been used to validate a mathematical model of the filling process. A transparent die was manufactured with a 2D profile extracted from a typical production die, and the experimental parameters used were based upon the production process. The flow occurring in the model was recorded with camera. A mathematical model of the filling process was developed to reproduce the behavior observed in the water model. Both the experimental and modeled results have shown a relative tranquil fill of the sprue and the rim, while persistent returning waves were developed in the spoke. The results highlight the significant effects of venting, both in the water model and computational model. Future work is required to improve the accuracy of venting modeling of the mould cavity.

**9:55 AM**

**Solidification Model Coupling Lattice Boltzmann Method with Cellular Automaton Technique:** *Hebi Yin*<sup>1</sup>; *Liang Wang*<sup>2</sup>; *Sergio Felicelli*<sup>1</sup>; <sup>1</sup>Mississippi State University; <sup>2</sup>Mississippi State University

A two dimensional model combining the lattice Boltzmann method (LB) and the cellular automaton technique (CA) was developed to simulate dendrite growth during solidification. The LB method was used for the coupled-calculation of temperature, composition, and velocity fields while the liquid/solid interface was tracked by the CA method. The LB-CA model was validated by comparing tip velocity and equilibrium composition with analytical solutions. Single and multi- dendrite growth was simulated with energy and solute transport not only by diffusion but also by convection. In addition, the simulation morphology and computational time obtained with the LB-CA model was compared to that of a finite element – CA model.

**10:40 AM**

**Physical Characterization of the Permeability of Equiaxed Eutectic Structures in Hypoeutectic Aluminum Alloys:** *Ehsan Khajeh*<sup>1</sup>; *Daan Maijer*<sup>1</sup>; <sup>1</sup>University of British Columbia

The permeability of hypoeutectic aluminum alloys during equiaxed eutectic solidification has been determined through physical modeling. The 3D geometries of primary phase obtained from X-ray microtomography (XMT) scans of solidified aluminum alloys have been used to generate computational domains for use in simulating the eutectic transformation. By applying the Cellular Automaton technique to simulate the growth of eutectic colonies, the evolution of the liquid channels has been modeled. Large-scale analogues of the simulated structures were produced by rapid prototyping for use as physical models. A glycerin-based solution was passed through the physical models and the permeability was calculated from measurements of the discharge flow rate and pressure drop. This work presents an alternative technique to determine permeability compared to conventional permeameters and shows a deviation from the conventional Carman-Kozeny expression at high eutectic grain density.

**11:05 AM**

**Foam Filters Used in Gravity Casting:** *Fu-Yuan Hsu*<sup>1</sup>; *Huey-Juan Lin*<sup>1</sup>; <sup>1</sup>National United University

Ceramic foam filters are normally used for reducing the velocity of liquid metal in the design of runner system. In this study four designs of runner systems with various orientations of foam filters were explored and their apparent velocities were estimated by casting experiment and computational modeling. In the casting experiment, trajectory and metal weighing methods

were employed for measuring apparent velocity and flow rate, respectively. Using Forchheimer's equation, a porous material such as a foam filter could be simulated in the modeling. The modeling result was validated by the casting experiment. For high efficient usage of a foam filter, through which liquid metal with high flow rate and low velocity was transformed, the optimized design is recommended in all of runner systems.

**11:30 AM**

**Simulation of Macrosegregation during Directional Solidification Using Mesh Adaptation:** *Udaya Sajja*<sup>1</sup>; *Sergio Felicelli*<sup>1</sup>; <sup>1</sup>Mississippi State University

Modeling of the formation of macroscopic segregation channels during directional solidification processes has important applications in the casting industry. Computations that consider thermosolutal convection involve different length scales ranging from the small solute boundary layer at the dendrite tips to the characteristic size of the casting. In general, numerical models of solidification in the presence of a developing mushy zone are computationally inefficient due to nonlinear transport in an anisotropic porous medium. In the present work, mesh adaptation with triangular finite elements is used in conjunction with an efficient fractional-step solver of the momentum equations to predict the occurrence of channel-type segregation defects or freckles. The triangulations are created dynamically using an unstructured grid generator and a refinement criterion that tracks the position of the channel segregates. The efficiency of mesh adaptation is illustrated with simulations showing channel formation and macrosegregation in directional solidification of a Pb-Sn alloy.

**11:55 AM**

**A Mathematical Model for Simulating the Microporosity of Squeeze Casting of Aluminum Alloy:** *Zhiqiang Han*<sup>1</sup>; *Jinxi Li*<sup>1</sup>; *Wen Yang*<sup>1</sup>; *Baicheng Liu*<sup>1</sup>; <sup>1</sup>Tsinghua University

A mathematical model for simulating the microporosity of squeeze casting of aluminum alloy has been developed, in which the heat transfer, solidification shrinkage, feeding flow, pressure transfer, and hydrogen conservation were taken into account. The shrinkage induced flow and the pressure drop in the mushy zone were calculated by solving continuity and momentum equations. A mechanical model was solved for obtaining the pressure transferred into the liquid core of the casting. By coupling the pressure drop and the pressure transferred into the liquid core, the pressure in the mushy zone was calculated. Based on the hydrogen conservation equation, the microporosity volume fraction was estimated by referring to the pressure in the mushy zone. The squeeze casting processes of aluminum alloy under different process conditions were simulated and the simulation results were compared with experimental results for assessment of the developed model.

**Quantitative In-situ TEM to Investigate Defect – Strength Relations:** *Daniel Kiener*<sup>1</sup>; <sup>1</sup>Austrian Academy of Science & University of Leoben

While reports consistently find that 'smaller is stronger', the governing mechanisms remain elusive due to lack of direct observations. *In-situ*

TUESDAY AM

TEM testing is ideally suited to provide this missing information, as the governing dislocation processes can be directly monitored. Experiments on FIB prepared samples depict that deformation is source controlled for compression samples, leading to single-slip deformation of small specimens oriented for multi-slip. With a novel tensile approach, we exclude effects from specimen taper and other compression boundary conditions and observe defect exhaustion with ongoing straining, resulting in strengths reported for whiskers. Significant changes in the 'mechanical annealing' behavior were observed for pre-deformed or proton irradiated samples. The proton irradiated material changes from a source controlled size-dependent strength at small dimensions to a size-independent strength governed by dislocation-defect interactions. Using *in situ* annealing, we achieved defect-free samples, which deformed at stresses near the theoretical strength of the material.

#### 9:00 AM

**Insights into Mg Plasticity From In Situ Nanomechanical Testing in the TEM:** *Qian Yu*<sup>1</sup>; Raj Mishra<sup>2</sup>; Andrew Minor<sup>3</sup>; <sup>1</sup>University of California Berkeley; <sup>2</sup>General Motors Corporation; <sup>3</sup>University of California Berkeley & Lawrence Berkeley National Laboratory

Magnesium is a lightweight metal that would be much more useful for structural applications than it currently is if not for its complicated and anisotropic plastic deformation behavior. The HCP structure of Mg has limited dislocation slip systems and, thus, twinning generally accompanies dislocation plasticity. Recently, we have run a series of *in situ* mechanical tests in a TEM on pure Mg where we have quantitatively measured and characterized the deformation behavior in both compression and in tension, and in both basal slip and non-basal slip orientations. By comparing the quantitative deformation behavior in these experiments we are able to provide significant insights into the twinning mechanisms and the origins of the compression-tension asymmetry in Mg.

#### 9:20 AM Invited

**In Situ TEM Studies of Plastic Deformation in Small-Volume Samples near Room Temperature:** *Evan Ma*<sup>1</sup>; <sup>1</sup>Johns Hopkins University

This talk reports on *in situ* TEM investigations of size effects in mechanical behavior carried out at our new research center, Center for Advancing Materials Performance from the Nanoscale (CAMP-Nano), founded in 2009 at XJTU. Recent projects at CAMP-Nano, led by Prof. Z. W. Shan, Prof. Ju Li and the speaker, have yielded interesting results. In this short talk, we will briefly describe two representative ongoing studies. For crystalline materials, an example will be given regarding the strong sample size effect on deformation twinning in a Ti alloy (Q. Yu et al., Nature 2010), illustrating a Hall-Petch type of dependence of deformation twinning on crystal size. For glassy materials, amorphous silica will be discussed as an example, demonstrating superplastic flow of nano-sized silica glass wires and particles near room temperature inside a TEM (in collaboration with K. Zheng, X.D. Han, Z. Zhang et al. at BJUT, Nature Communications, 2010).

#### 9:50 AM

**Dislocation Nucleation in Confined Crystalline Volumes: In-Situ TEM Observations and Micro-Mechanical Tests on Submicron Al Fibers:** *Frederic Mompiou*<sup>1</sup>; Marc Legros<sup>1</sup>; Daniel Caillard<sup>1</sup>; Daniel Gianola<sup>2</sup>; Andreas Sedlmayr<sup>3</sup>; Oliver Kraft<sup>3</sup>; <sup>1</sup>CEMES-CNRS; <sup>2</sup>University of Pennsylvania; <sup>3</sup>Karlsruher Institut für Technologie

Small crystals have an initial resistance to deformation much larger than their bulk counterpart, but the physical explanations for this multiplied yield stress are still highly debated. One critical step seems to be the nucleation of fresh dislocations and the nature of the sources. In the present work we present an extensive *in situ* TEM study of dislocation multiplication and shearing processes in sub-micrometer Al fibers that were kept free of FIB preparation. The size of operating sources and their production mode has been systematically analyzed and compared to the crystal dimensions and initial microstructure. In addition to the source operating regime, a very low ductility plastic regime has been observed in fibers containing no preexisting dislocations. These plastic behaviors have been correlated to stress and strain measurements obtained by micro-mechanical testing. Possible strengthening mechanisms and size effect on the mechanical properties will be discussed.

#### 10:10 AM Break

**Mechanical Annealing in Submicro-sized Molybdenum Crystals:** Ling Huang<sup>1</sup>; *Zhiwei Shan*<sup>1</sup>; Ju Li<sup>2</sup>; Jun Sun<sup>1</sup>; Evan Ma<sup>3</sup>; <sup>1</sup>Xi'an Jiaotong University; <sup>2</sup>University of Pennsylvania; <sup>3</sup>Johns Hopkins University

*In situ* TEM compression tests were carried out to investigate the mechanical behavior of single crystal molybdenum pillars with diameters ranging from 75 nm to 300 nm. Despite the high density initial defects, the flow stress of those focused ion beam (FIB) fabricated pillars increased monotonously as the size decreased, with the maximum value up to 8.5 GPa for pillars with a diameter of 75 nm. The power-law exponent of strength vs. pillar diameter is -0.92, about 2 times higher than that reported in previous works for larger pillars. More surprisingly, contrary to that predicated by computer simulation, significant mechanical annealing phenomena, followed by catastrophic failure, is observed during the compression test of these body centered cubic (BCC) metal pillars when their size is less than 200 nm. These striking findings shed new light on revealing the underlying physical mechanisms that are responsible for the plasticity of small scaled BCC crystals.

#### 11:00 AM

**A Length Scale Dependent Phase Transformation in Si:** *Aaron Beaber*<sup>1</sup>; Steven Girshick<sup>1</sup>; William Gerberich<sup>1</sup>; <sup>1</sup>University of Minnesota

The phase transformation of silicon during indentation has been widely studied over the past thirty years. The use of *in situ* indentation, particularly Raman microscopy and electrical characterization, has greatly clarified the transformation process. In the current work, TEM *in situ* indentation of Si nanospheres and *ex situ* indentation of confined nanotowers are used to propose a length scale dependent phase transformation. Below a critical dimension of approximately 100 nm, deformation of Si is dominated by dislocation plasticity rather than a phase transformation. This is shown to be consistent with multiple geometries, including spheres, towers, and wedges. Furthermore, the reverse transformation upon unloading is shown to occur at decreasing stresses for smaller geometries. These findings reinforce the importance of shear stresses during anisotropic loading and confirm the notion of enhanced ductility in Si at small scales.

#### 11:20 AM Invited

**Probing Size Dependent Mechanical Properties of Metallic Nanowires in Tension:** Yang Lu<sup>1</sup>; Cheng Peng<sup>1</sup>; Yogi Ganesan<sup>1</sup>; Hao Lu<sup>1</sup>; Jianyu Huang<sup>2</sup>; Jun Lou<sup>1</sup>; <sup>1</sup>Rice University; <sup>2</sup>Sandia National Laboratories

This talk presents some of our recent efforts to study the size dependent mechanical behaviors of metallic nanowires. We have developed a simple micro-device that allows *in situ* quantitative mechanical characterization of metallic nanowires, in SEM or TEM chamber equipped with a quantitative nanoindenter. The unique design of this device makes it possible to convert compression from nanoindentation to uni-axial tension at the sample stages. By utilizing this device, *in situ* results on deformation and fracture behavior of Ni and Au nanowires will be discussed. Also in this work, we performed *in situ* quantitative tensile tests on individual <111> single crystalline ultrathin gold nanowires (diameter ~7-15 nanometers) inside TEM. Significant load drop observed in stress-strain curve suggests the occurrences of dislocation nucleation. Corresponding high resolution TEM (HRTEM) imaging demonstrated that plastic deformation was indeed initiated and dominated by surface dislocation nucleation, mediating ultrahigh yield and fracture strength in gold nanowires.

#### 11:50 AM

**Micro-Cantilever Testing of Ti Alloys:** Jicheng Gong<sup>1</sup>; *Angus Wilkinson*<sup>1</sup>; <sup>1</sup>University of Oxford

Micro-cantilevers were machined using a focused ion beam from pure Ti(945), Ti-6Al (945) and Ti-6Al-4V (945+946) and tested in bending using a nano-indenter. The cantilevers had triangular cross-sections with widths varied across the range 10  $\mu$ m to 1  $\mu$ m. EBSD mapping of large areas allowed suitably oriented grains to be identified and the cantilevers cut so as to select specific slip systems. Strain-bursts and/or load-drops are much less

severe for the load-displacement curves for the cantilevers than for similarly sized compression pillars. Critical resolved shear stresses were extracted from the bend tests by fitting load-displacement data with crystal plasticity finite element simulations. All three systems exhibit a size effect consistent with a back stress from pile-up of dislocations against the low stress region at the neutral axis.

**Thermal Annealing of ZnO Films Using High-Density Plasma Arc Lamps:** *Adrian Sabau*<sup>1</sup>; *Ralph Dinwiddie*<sup>1</sup>; *Jun Xu*<sup>1</sup>; *Joseph Angelini*<sup>1</sup>; *David Harper*<sup>1</sup>; <sup>1</sup>Oak Ridge National Laboratory

Nanostructured materials are rarely synthesized with appropriate phase and/or morphology. In this study, critical additional of as-synthesized nanostructured materials, such as annealing and/or activation of dopants, are addressed using infrared plasma arc lamps (PAL) over areas as large as 1,000 cm<sup>2</sup>. The broad spectral range of the PAL and the spectral variation of light absorption in nanostructured materials make the selection of processing parameters extremely difficult, posing a major technological barrier. In this study, the measurement of the surface temperature using various techniques for ZnO films on crystalline silicon wafers is discussed. An energy transport model for the simulation of rapid thermal processing using PAL is presented. The experimental and computational results show that the surface temperature cannot be measured directly and that computer simulation results are an effective tool for obtaining accurate data on processing temperatures.

### 9:00 AM

**Glass Transition at a Polymer Surface Monitored by Localized Surface Plasmon Resonance:** *Kaan Kalkan*<sup>1</sup>; *Ratan Putla*<sup>1</sup>; <sup>1</sup>Oklahoma State University

We investigate glass transition on a polymer surface by embedding gold nanoparticles (AuNP). The impregnation of AuNP into the polymer causes a spectral shift in the LSPR due to the changing dielectric environment. AuNP, at an average size of 8 nm, were synthesized on poly isobutyl methacrylate (PiBMA) films on glass by thermal evaporation. Subsequently, time series LSPR spectra of AuNP on PiBMA were acquired in a temperature controlled optical cell. The effective dielectric constant surrounding the AuNP was calculated from LSPR optical extinction peak. Depth and velocity of penetration were derived from the measured dielectric constant on the basis of dielectric mixing. The onset of AuNP penetration was found to be at 45 C, which is 10 C below the reported glass transition of "bulk" PiBMA. The penetration velocity was found to be fairly constant in time until complete embedding while temperature activated at 0.05 eV.

### 9:20 AM

**Oxidation and Interfacial Structure of Ti<sub>3</sub>Al:** *Muralidharan Ramachandran*<sup>1</sup>; *Ramana Reddy*<sup>1</sup>; <sup>1</sup>The University of Alabama

The isothermal oxidation of binary Ti<sub>3</sub>Al was studied as function of temperature in pure oxygen atmosphere. Weight gain data were acquired using thermo-gravimetric analyzer (TGA). The phase analysis of the base metal and the oxide layer were performed using x-ray diffraction, while the morphology and elemental composition were determined using scanning electron microscopy (SEM) and Transmission Electron Microscopy (TEM). The rate constant of the oxidation process increases from 9.75 X 10<sup>-4</sup> mg<sup>2</sup>/cm<sup>4</sup>/min at 1023K to 5.05 X 10<sup>-2</sup> mg<sup>2</sup>/cm<sup>4</sup>/min at 1223K. The activation energy for the oxidation process was determined to be 240.5 kJ/mol. The particle size in the oxide scale increased with the increase in temperature. At higher temperatures formation of layered structures was observed. The composition and structure of the metal/oxide interface was analyzed.

### 9:35 AM Break

**Fabrication and Characterization of MWCNT Reinforced Aluminum Using Spark Plasma Sintering**

: *Vineet Yadav*<sup>1</sup>; *Sandip Harimkar*<sup>1</sup>; <sup>1</sup>Oklahoma State University

Spark plasma sintering (SPS) technique was used to fabricate aluminum-based metal matrix composites reinforced with MWCNT. The developments of composites properties such as hardness, strength, wear resistance, and corrosion resistance with reinforcement content and composite microstructure was investigated. In this presentation, the influence of CNT dispersing agents and SPS processing parameters on microstructure and properties of the Al-MWCNT composite will also be discussed.

### 10:00 AM

**Microstructure and Wear Behavior of Pulse Electrodeposited Nickel-Carbon Nanotube (Ni-CNT) Composite Coatings:** *Tushar Borkar*<sup>1</sup>; *Sandip Harimkar*<sup>1</sup>; <sup>1</sup>Oklahoma State University

Due to excellent mechanical properties such as high strength, high elastic modulus and large elastic, as well as fracture strain, carbon nanotubes (CNTs) are attracting significant interest as reinforcements in metallic coatings. In the present investigation, carbon nanotube (CNT) reinforced nickel composite coatings were deposited on a stainless steel substrate using pulse electrodeposition process employing a nickel Watts bath. The presence of CNTs in the composite coating prohibited the columnar growth of the nickel grains resulting in random/weak texture and smaller thickness of the composite coatings. The Ni-CNT composite coatings exhibited significantly improved microhardness (580±15 HV) compared to pure nickel coatings (320±15 HV). The pin-on-disc wear testing data indicated that the reinforcement of CNTs significantly improved wear resistance of the composite coatings compared to pure nickel coatings.

### 10:15 AM

**Synthesis and Characterization of Graphene after Ion Implantation:** *Tomoka Colon*<sup>1</sup>; *Cydale Smith*<sup>1</sup>; *Mohamed Seif*<sup>1</sup>; *Satilmis Budak*<sup>1</sup>; *Claudiu Muntele*<sup>1</sup>; *Lawrence Holland*<sup>1</sup>; *Robert Zimmerman*<sup>1</sup>; *Daryush Ila*<sup>1</sup>; <sup>1</sup>Alabama A&M University

Graphene is a flat monolayer of carbon atoms tightly packed into a two-dimensional (2D) honeycomb lattice and is a basic building block for graphitic materials of all other dimensionalities. It can be wrapped up into 0D fullerenes, rolled into 1D nanotubes, or stacked into 3D graphite. Graphene nanoribbons (GNRs) are essentially single layers of graphene that are cut in a particular pattern to give it certain electrical properties. Graphene's high electrical conductivity and high optical transparency make it a candidate for transparent conducting electrodes, required for such applications as touchscreens, liquid crystal displays, organic photovoltaic cells, and organic light-emitting diodes. In this study, we have synthesized graphene on silicon dioxide, used accelerated ion beams to induce defects, and then studied the effects those defects have on the properties of epitaxial graphene.

TUESDAY AM

10:30 AM

**A Facile Route to Synthesis and Characterisation of Hydrophobic Titania Nanofibres:** *T. Sundararajan*<sup>1</sup>; S. Abirami<sup>1</sup>; P. Manohar<sup>1</sup>; <sup>1</sup>Anna University

Polymer based hydrophobic titania nano fibers were fabricated using a simple Low Volume Medium Pressure (LVMP) spray gun. The FE-SEM studies showed that it resembled the nanofibers produced by electro spinning method. Spraying parallel to the length of the glass slide gave better contact angle values and the fibers were more entangled. The hydrophobicity was developed in the coating immediately after spraying. The contact angle measurements were done using Goniometer. Curing the fibers in hot air oven at 80°C reduced the contact angles. Three different sources of titania were experimented. Powder characterization was done by XRD, Raman spectroscopy. A set of nine experiments based on Taguchi's Method were also conducted for contact angle optimization. Even a small amount (0.03g) of hydrothermal titania with 0.7g of polystyrene gave a contact angle as high as 149.77°, which is close to super hydrophobic range.

10:45 AM

**Application of the Strong Contrast Technique to Thermoelastic Characterization of Nanocomposites:** *Majid Baniassadi*<sup>1</sup>; Akbar Ghazavizadeh<sup>1</sup>; David Ruch<sup>1</sup>; Yves Rémond<sup>1</sup>; Said Ahzi<sup>1</sup>; Hamid Garmestani<sup>1</sup>; <sup>1</sup>CRP Henri Tudor

The effective thermoelastic properties of composites filled with cylindrical nanofillers are evaluated using the statistical continuum theory of strong contrast. In terms of aspect ratio, the inclusions vary across a wide range from nanoplatelets to nanowires. As nanostructure descriptors, the statistical two-point correlation functions are calculated using the Monte Carlo method. Then the three-point correlation functions are estimated via an innovative technique. The resulting quadruple and sextuple integrals are calculated using the Monte Carlo integration. The final complex tensorial equations of the elastic part are solved by trial and error. Finally, to verify our proposed approach, it is implemented on a computer generated nanocomposite and the thermoelastic properties are compared with other results..

**Multifunctional Plasmonic-Ferromagnetic Surface Nanocomposites Synthesized by Bilayer Liquid Self-Organization:** Hare Krishna<sup>1</sup>; Ritesh Sachan<sup>2</sup>; Nozomi Shirato<sup>2</sup>; Jeremy Strader<sup>2</sup>; Hernando Garcia<sup>3</sup>; Anup Gangopadhyay<sup>1</sup>; *Ramki Kalyanaraman*<sup>2</sup>; <sup>1</sup>Washington University in St. Louis; <sup>2</sup>University of Tennessee; <sup>3</sup>Southern Illinois University

Tunable ferromagnetic and resonant plasmon optical behavior in nanostructures provides opportunity to realize multifunctional materials. Here we will review the robust synthesis of such multifunctional surface nanostructures by self-organization via dewetting of bilayer films. Experimentally, such nanomaterials can be synthesized by nanosecond pulsed laser melting of ultrathin metallic films. We found that nanoscale bilayer films of immiscible metallic liquids show different self-organized patterning characteristics based on their arrangement on a substrate. The different bilayer arrangements change the signs of intermolecular interactions, which changes the mode of coupled deformations and the patterning characteristics. We will also discuss the physical properties of the Ag-Co nanocomposite particles created by this process which show tunable concentration dependent ferromagnetism and localized surface plasmon resonances. \* This work has been supported by NSF grants CAREER DMI-0449258, CMMI-0757589, and DMR-0805258 and by grants from CMI at Washington University and SEERC at the University of Tennessee.

11:45 AM **Invited**

**Nanocomposite Magnetic Materials: Improved Performance by Nanostructuring:** *Matthew Willard*<sup>1</sup>; Maria Daniil<sup>1</sup>; Keith Knipling<sup>1</sup>; Ramasis Goswami<sup>1</sup>; Ashish Baraskar<sup>2</sup>; Soack Yoon<sup>2</sup>; Vincent Harris<sup>2</sup>; <sup>1</sup>Naval Research Laboratory; <sup>2</sup>Northeastern University

Development of new magnetic materials, capable of providing higher energy products for permanent magnets and lower core losses for soft magnets, enables smaller, lighter, and more efficient devices. Over the past two decades, a major focus of research has been microstructure refinement to the nanoscale, which has advantages for each class of magnetic material, allowing permanent magnets to store more energy and soft magnets to dissipate less energy than alternative materials. These advantages originate in the exchange correlation length, a fundamental magnetic length scale determined by the strength of coupling between magnetic moments causing them to align, which has typical values with nanoscale dimensions. This presentation will highlight recent work on nanocomposite soft and hard magnetic materials produced by pulsed laser deposition and rapid solidification processing. The effect of nanostructure on the magnetic material performance will be shown experimentally and discussed from a theoretical perspective.

**Thermally Activated Processes in Plastic Deformation: Dislocation Ensemble Evolution**

8:30 AM **Invited**

**On the Cross Slip of Dislocations in the Face-Centered Cubic Metals:** *Joël Bonneville*<sup>1</sup>; <sup>1</sup>University of Poitiers

Cross slip is the mechanism by which a screw dislocation changes from its primary glide plane to move on a locally more favourable stressed glide plane. Cross slip has been recognised to significantly contribute to plastic deformation by creating dislocation microstructure and causing dislocation annihilation, dynamic recovery, obstacle bypass, strain softening as well as strain hardening, etc. There has been in the recent years a renewed interest for studying the cross-slip of screw dislocations in the face-centered cubic structure. The main reasons originate from the development in computational power and algorithms allowing for realistic atomistic simulations and the need in integrated computational materials engineering for precise quantitative and predictive models. Our purpose is to present relevant models used for describing cross-slip processes from historical approaches up to the more recent theoretical developments. A particular emphasis will be placed to extract the significant characteristics deduced by the different approaches.

9:00 AM

**Measurement of Cross-Slip Activation Parameters in Pure Ni via Bonneville-Escaig Experiments:** *Jaafar El-Awady*<sup>1</sup>; Michael Uchic<sup>2</sup>; Sang-Lan Kim<sup>3</sup>; Paul Shade<sup>4</sup>; Satish Rao<sup>3</sup>; Dennis Dimiduk<sup>2</sup>; Christopher Woodward<sup>2</sup>; <sup>1</sup>Johns Hopkins University; <sup>2</sup>Air Force Research Laboratory; <sup>3</sup>UES, Inc.; <sup>4</sup>Universal Technology Corporation

To accurately incorporate the thermally-activated process of dislocation cross-slip into mobility laws of dislocation dynamics simulations, it is necessary to experimentally determine the activation volume and energy barrier for dislocation cross-slip. To achieve this we revisit the Bonneville-Escaig experiments to characterize cross-slip activation in pure-nickel single crystals. In this study, large Ni-single crystals were pre-strained in

compression to strains that correspond to the transition between stage-II and stage-III deformation. Meso-scale (5-80 micrometer diameter) and macro-scale (mm size) crystals were prepared from the pre-strained crystals, to explore whether modern microtesting methods can eliminate the need for 'large' single crystals in these experiments. The orientation of the compression axis of the children crystals is such that an avalanche of cross-slip events is produced at the yield stress. The results are interpreted in terms of the Escaig cross-slip model, and the recent molecular-statics simulations of cross-slip nucleation at screw-dislocation intersections with forest dislocations.

#### 9:20 AM Invited

**Atomistic Simulations of Cross-Slip Nucleation at Screw Dislocation Intersections in Face-Centered Cubic Nickel and Copper and L12 Ni3Al:** *Satish Rao*<sup>1</sup>; Dennis Dimiduk<sup>2</sup>; Jaafar El-Awady<sup>3</sup>; Triplicane Parthasarathy<sup>1</sup>; Michael Uchic<sup>2</sup>; Christopher Woodward<sup>2</sup>; <sup>1</sup>UES Inc.; <sup>2</sup>Air Force Research Laboratory; <sup>3</sup>Johns Hopkins University

We describe molecular-statics simulations of screw character dislocation intersections with forest dislocations, in FCC Ni and Cu and L12 Ni3Al, to illustrate a mechanism for cross-slip nucleation. The simulations show how such intersections readily produce cross-slip nuclei. There exists a finite activation barrier for the screw dislocation to transfer from the fully glide plane or the fully cross-slip plane state to the partially cross-slipped state at these intersections, which is a factor of 2 - 5 lower than without the presence of an intersection. The activation barrier for cross-slip at these intersections is shown to be linearly proportional to  $(d/b)\ln(1.732d/b)0.5$ , as with the case of no intersections, where 'd' is the Shockley partial spacing of the partial dislocations and 'b' is the Burger's vector of the screw dislocation. These results suggest that cross-slip should be preferentially observed at selected screw dislocation intersections in FCC materials as well as L12 Ni3Al.

#### 9:50 AM

**Dislocation Kinetics in Fe and Fe Alloys Investigated by In Situ TEM Straining Experiments:** *Daniel Caillard*<sup>1</sup>; <sup>1</sup>CNRS

Microsamples of pure Fe have been strained in a JEOL 2010HC transmission microscope, between 100K and 473K. At room temperature, dislocation loops exhibit straight screw portions moving slowly and steadily, and curved non-screw ones with a much higher mobility. The velocity of screw parts is proportional to their length, in agreement with the kink-pair model. The velocity-stress dependence of a single dislocation has been deduced from an in situ relaxation experiment. At low temperatures, the motion of screw dislocations becomes jerky. This change of kinetics has been interpreted by a change in the mechanism of motion of screw dislocations across the Peierls potential, and correlated to the change in the corresponding macroscopic activation parameters. The softening effect of carbon, and the hardening effect of silicon and chromium, are shown to result from the shift of the transition between the two mechanisms to respectively lower and higher temperatures.

#### 10:30 AM Invited

**Discrete Dislocation Dynamics: Principle and Recent Applications:** *Marc Fivel*<sup>1</sup>; <sup>1</sup>SIMaP-GPM2

The concept of three-dimensional discrete dislocation (DD) simulations has been imagined by L. Kubin, Y. Bréchet and G. Canova in the early 1990s. The first code MICROMÉGAS was a simple model for which dislocation lines of a f.c.c. single crystal are discretized in sets of edge and screw dislocation segments embedded in a continuum media. Typical output of DD simulations are obviously the dislocation microstructure but also many statistical data such as the dislocation densities, the cumulated shear strain, the stored energy, the local stresses and also the actual shape of any part of the crystal deformed by the dislocations. From some points of view, DD simulations can be seen as an ideal tool to fill the gap between atomic simulations (MD) and continuum modelling (FEM). This talk presents recent simulations performed at Grenoble using the edge-screw code Tridis derived from Canova's initial model.

#### 11:00 AM

**Forest Hardening in Materials with High Lattice Friction:** *Benoit Devincere*<sup>1</sup>; Ghiath Monnet<sup>2</sup>; Jonathan Amodeo<sup>3</sup>; <sup>1</sup>CNRS; <sup>2</sup>EDF; <sup>3</sup>Lille 1 University

In materials with high lattice friction like body centred cubic (bcc) crystals at low temperatures, the thermally activated motion of screw dislocations by the kink-pair mechanism governs the yield properties and also affects strain hardening. In this work, the problem of forest hardening at low temperature is revisited with DD simulations. Results are presented in the case of two illustrative materials, i.e. Iron and MgO. Unlike the classical picture of forest hardening in fcc crystal, calculations show that the strength of forest interaction is temperature and strain rate dependant. Hence, simplistic models based on the Taylor equation do not apply and alternative approaches must be considered. The results of massive simulations are compared with existing models. Finally, a new model accounting in a quantitative manner for the effects of temperature and dislocation density is proposed.

#### 11:20 AM

**Simulating the Evolution of the Dislocation Network under Irradiation:** *Dan Mordehai*<sup>1</sup>; Georges Martin<sup>2</sup>; <sup>1</sup>Technion; <sup>2</sup>CEA-Siège

The dislocation network evolution in metals under irradiation is a complex process, which is still a matter of controversy. While crystalline plasticity involves conservative motion of dislocations, the large concentration of point defects produced under irradiation contributes to plastic deformation either by eliminating at sinks (like climb of the existing dislocation network) or agglomerate into new defects. In this work, we propose a method to include dislocation climb in Dislocation Dynamics simulations, based upon the diffusion theory of point defects. In particular, we present an analytical model to calculate the climb rate of dislocations due to interstitial flux, in coordination with the dislocation network. We employ this model to demonstrate that when accounting for the dislocation network, the annihilation of dislocation pairs with opposite signs and the annihilation of low-angle tilt grain boundaries is accelerated under irradiation.

#### 11:40 AM

**Mobility of Dislocation Populations as a Thermally Activated Process:** *Craig Hartley*<sup>1</sup>; <sup>1</sup>El Arroyo Enterprises LLC

Dislocation Dynamics (DD) simulations offer an attractive means of providing basic input to Crystal Plasticity (CP) calculations by permitting micro-scale virtual experiments using models for dislocation behavior based on the physics of individual dislocations. While some of this information can be supplied by atomic models of lattice defects, modifications that employ the principles of stress-assisted, thermally activated motion of dislocations can expand the predictive power of such simulations. Deformation of an element is expressed as an appropriate average of unit processes over the volume of a representative element. To inform CP models, results of these virtual experiments must be expressed in terms of constitutive equations having parameters demonstrably related to the properties and behavior of the dislocation ensemble. This work describes a simple mathematical model for a constitutive relationship in terms of the motion of an ensemble of dislocations where individual dislocation behavior occurs by a thermally activated unit process.

#### 2:05 PM

**Deformation Twinning in Nanocrystalline HCP Mg Alloys:** *Yuntian Zhu*<sup>1</sup>; X.L. Wu<sup>2</sup>; K.M. Youssef<sup>1</sup>; C.C. Koch<sup>1</sup>; S.N. Mathaudhu<sup>3</sup>; L.J. Kecskes<sup>3</sup>; <sup>1</sup>North Carolina State Univ; <sup>2</sup>Institute of Mechanics; <sup>3</sup>U.S. Army Research Laboratory

Nanocrystalline (nc) hexagonal close-packed (hcp) metals are rarely observed to deform by twinning, although twinning is a major deformation mechanism in their coarse-grained counterparts. This behavior is contrary to what is observed in face-centered cubic metals. Here we report that by alloying Mg with other elements, deformation twins are observed in the nc Mg alloy processed by severe plastic deformation. The formation of deformation twins is attributed to the alloying effect, which may change the energy path for twinning. These results point to a promising approach to design nc hcp alloys for superior mechanical properties.
