Mixed Conducting Molten Salt Electrolyte for Na/$NiCl_2$ Cell: *Tannaz Javadi*[1]; Anthony Petric[1]; [1]McMaster University

Na/$NiCl_2$ battery contains two types of electrolytes, one liquid ($NaAlCl_4$) and one solid (Na-ß"-alumina). During cycling (300°C), NaCl or $NiCl_2$ phases are formed alternately in the cathode. Electrons are distributed within the cathode by a matrix of excess Ni metal powder. SEM micrographs show that during charging, the $NiCl_2$ phase forms on Ni particles. Moreover, during discharge, isolated Ni particles can form, surrounded by liquid electrolyte. In this regard, the electronic conductivity of Ni particles is impeded by both the $NiCl_2$ phase and the liquid electrolyte. Therefore, the capacity of the cell decreases as the number of available active sites for reaction is reduced. Having a mixed conducting electrolyte can facilitate both ionic and electronic transfer inside the cathode. Therefore, different dopants were added to promote electronic conductivity in the ionically conductive $NaAlCl_4$. The conductivity of the electrolyte was measured by using EIS. The dopant type and concentration were optimized.

5:10 PM
Effect of Al-Substitution and Melt-Spining Process on Microstructural and Hydrogen Storage Properties of LaNi5 Intermetallic Compounds: O. Uzun[1]; F. Yilmaz[2]; M.F. Kilicaslan[3]; G.Y. ÖZALP[4]; *Soon-Jik Hong*[5]; [1]Gaziosmanpasa University; [2]Gaziosmanpa University; [3]Kastamonu University; [4]International Centre for Hydrogen Energy Technologies; [5]Kongju National University

Hydrogen storage alloys have been investigated as environmental-friendly materials for hydrogen gas storage as a fuel source and negative electrode of a rechargeable battery. Researchers have shown great interest in intermetallic compound LaNi5 because of its high hydrogen capacity, easy activation and fast reaction kinetics, etc. In order to improve the overall properties of LaNi5, the substitutions of B site element (Ni) with other metals have been studied by many researchers. In this study, LaNi4.7Al0.3 alloy was prepared by arc-melting followed by a melt-spinning treatment, the influence of the either alloy preparation methods or Al addition on the microstructure and hydrogen absorption/desorption properties of the alloys was investigated by means of SEM, XRD and Sieverst's type apparatus. The results showed that substituting Ni with Al led to desirable decrease in absorption/desorption plateau pressure as well as hysteresis; whereas melt-spinning process only reduced absorbtion pressure without reduction in its hydrogen capacity.

5:15 PM
Phase Transitions of Nano-scaffold Confined Ammonia Borane Dependent on Pressure: *Yongzhou Sun*[1]; Jiuhua Chen[1]; Vadym Drozd[1]; Shah Najiba[1]; [1]Florida International University

Nanoconfinement has attracted more and more interests based on its excellent thermal dynamic and kinetic property for decomposing ammonia borane. We have conducted in situ Raman spectroscopy study to investigate phase stability of nano-scaled ammonia borane in SBA-15 (mixed with 1:1 ratio) at high pressures up to 11 GPa (with an interval of 0.35 GPa) using diamond anvil cell (DAC). Similar work has been conducted to neat ammonia borane up at different temperature from 20 ^{o}C to 80 ^{o}C as a comparison. At room temperature, we found the two pressure-induced phase transitions were shifted to ~0.5GPa, ~9.7GPa for nanoscaled ammonia borane from ~0.9 GPa, ~10.2 GPa for neat ammonia borane, respectively.

Annealing Effect and Tensile Interface Fracture Mechanism of Pure Silver Bonding Wires: *Hao-Wen Hsueh*[1]; Fei-Yi Hung[1]; Truan-Sheng Lui[1]; Li-Hui Chen[1]; [1]Department of Materials Science and Engineering, National Cheng Kung University, Tainan, Taiwan
Since Ag wires have similar hardness and bonding properties to Au wires, they can be applied in some pads. In the present study, the annealing effect (at 225°C~275°C for 30min) on the tensile mechanical properties of silver wires with \149; =23μm was investigated. In addition, the microstructural characteristics and the mechanical properties before and after an electric flame-off (EFO) process were also studied. Experimental results indicate that with annealing temperatures of more than 250□, the silver wires possessed a fully annealed structure, the tensile strength and the hardness decreased, and the elongation was raised significantly. Under the thermal effect of EFO, the necks of the Ag balls underwent recrystallization and grain growth was induced, and the annealed Ag wires had a shorter zone of HAZ (220μm). The bonding strength and the neck-strength of the Ag wires were more than 7gf and possessed excellent bonding properties.

2:25 PM
Directional Solidification of Zn-Sn Alloys: Marco Zurco[1]; Carlos M. Rodriguez[2]; *Carlos E. Schvezov*[2]; Claudia M. Mendez[1]; Alicia Ares[2]; [1]Faculty of Sciences, University of Misiones; [2]CONICET/FCEQyN-UNaM
Zinc-Tin alloys were directionally solidified in an horizontal device. During solidification the distribution of temperatures were measured by using thermocouples located strategically. From the measured temperatures the following parameters were calculated; the local temperature gradient, the cooling rate and the velocities of the liquidus and solidus fronts. Comparing the structure of the samples and the values of these parameters it was found that the temperature gradient at the instant of the columnar-to-equiaxed transition (CET) reaches minimum values of as low as - 1.5 °C/cm, and the velocities of the fronts were around 0.1 cm/s. In addition, the grain size and secondary dendrite arm spacing were measured along the length of the samples and correlated with thermal parameters and compared with the predictions from available models. The results are presented and discussed in the frame of the available theories and the results obtained before in our group for other alloy systems.

2:50 PM
Dynamic Recovery during Low Temperature Deformation in an Al-0.1Mg Alloy: *Yan Huang*[1]; Philip Prangnell[2]; [1]Brunel University; [2]The University of Manchester
An Al-0.1Mg alloy was firstly deformed at room temperature by ECAE to a true strain of 10, where a steady state deformation was established and further processing had little effect on grain refinement. The ECAE samples, with an average grain size of ~0.55 μm, were then compressed in a channel die at 77K- 473K to various reductions. Microstructures were characterized by electron backscatter imaging and EBSD in a FEGSEM. Grain refinement to the ECAE submicron structure occurred during deformation at cryogenic temperatures of 77 – 213K, whereas coarsening took place during deformation at elevated temperatures of 373-473K. A steady state deformation was observed at all temperatures where a constant grain structure was developed and maintained upon further straining due to dynamic recovery. The analysis of thermal activation behaviour in relation to the dynamic recovery suggested that quantum effect should be considered in order to understand the kinetics of the dynamic recovery.

3:15 PM
Applications of Thermo-Chemical and Thermo-Physical Models in the Copper and Lead Pyrometallurgical Industries: *Pengfu Tan*[1]; [1]Xstrata Copper
The thermodynamic models for copper smelting and converting, lead smelting and refining, the slag chemistry model and the slag viscosity model have been developed. Those models have been applied successfully in several copper and lead smelters in Australia, the Philippines, Zambia, Kazakhstan and Italy. Those models have been applied to optimize the process parameters and to solve the industrial technical issues, such as high copper loss in slag and converter foamover etc. Several examples for the industrial applications have been presented in this paper.

Challenges in Compound Forging of Steel-Aluminum Parts: *Klaus-Georg Kosch*[1]; Bernd-Arno Behrens[1]; [1]Institute of Metal Forming and Metal-Forming Machines, Leibniz Universität Hannover
In times of increasing energy costs automotive lightweight construction is gaining more importance. This paper deals with the production of hybrid steel-aluminum compounds by forging. The compound forging process is a promising method to successfully manufacture functional parts by applying resource-saving process steps. Nevertheless, challenges resulting from the different material properties must be solved. The heating of hybrid material work pieces made of steel and aluminum is a great challenge. Steel is forged at a temperature of at least 900°C, while aluminum should not exceed a temperature of 500°C. For the realization of the required temperature gradient extensive experimental investigations have been carried out. Intermetallic phases form during the manufacturing process and influence the bonding and the global part quality. In addition methods for the characterization of the joining zone between the materials steel and aluminum are analyzed and the factors influencing the formation of intermetallic phases are determined experimentally.

4:20 PM
Study of Supercritical CO2 Emulsion in Ni Electroplating and Application in Fabrication of Defect-Free Micromechanical Component with High Aspect Ratio: *Tso-Fu Mark Chang*[1]; Chiemi Ishiyama[1]; Masato Sone[1]; [1]Tokyo Institute of Technology
Application of supercritical fluid (SCF) in integrated circuit industry and micro-electro-mechanical-systems is believed to be one of the solutions for problems encountered in miniaturization of the devices. Critical point of CO2 is relatively low compared to other solvents, which makes supercritical CO2 (Sc-CO2) as one of the commonly used and studied solvent. However, Sc-CO2 is non-polar, which limits its application in electrochemistry. The limitation is overcame by usage of a surfactant to create an emulsified phase compose of the aqueous electrolyte and Sc-CO2. Film smoothening and grain refinement effects have been reported for Ni film electroplated by Sc-CO2 emulsion (Sc-CO2-E). In this study, effects of Sc-CO2-E, such as pressure, volume fraction of CO2 and the surfactant in electroplating of Ni are studied. Defect is often found in electroplating of micromechanical components using high current density. By application of Sc-CO2-E, defect-free Ni micro-pillars can be fabricated using high current density.

4:45 PM
Investigation of the Mechanical Properties and Microstructure of Friction Stir Welded Aluminum Alloy 6061 Sheets: Daniel Colby[1]; *Benjamin Goodman*[1]; Travis Spealman[1]; Shabbir Choudhuri[1]; Prince Anyalebechi[1]; [1]Grand Valley State University

The evolution of microstructure and associated tensile properties along the length of friction stir butt welded 4.6 mm thick AA 6061-T6511 sheets have been investigated. The Friction Stir Welding (FSW) was performed on a vertical milling machine with a profiled cylindrical H-13 tool steel probe. A 2 x 2 factorial design was used to select the FSW process parameters. Consistent with published results, preliminary hardness profiles suggest that softening of the alloy occurred in the stir, thermo-mechanically affected, and heat affected zones. The extent of the softening appeared to be different along the length of the welded sheets, being greatest towards the end of the weld. This is tentatively attributed to the expected increase in friction-induced heat ahead of the welded joint and the attendant dissolution of the precipitates in the age hardened alloy. These results are compared to those observed on gas tungsten-arc welded sheets of the same alloy.

Materials Research in Microgravity: Session IV

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS Extraction and Processing Division, TMS: Process Technology and Modeling Committee, TMS: Solidification Committee

2:00 PM Invited
ISS-Experiments and Modeling of Columnar-to-Equiaxed Transition in Solidification Processing: *Laszlo Sturz*[1]; Gerhard Zimmermann[1]; Charles-Andre Gandin[2]; Bernard Billia[3]; Nathalie Mangelinck[3]; Henry Nguyen-Thi[3]; David John Browne[4]; Wajira U. Mirihanage[4]; Daniela Voss[5]; Christoph Beckermann[6]; Alain Karma[7]; [1]Access e.V.; [2]MINES ParisTech CEMEF; [3]Université P. Cézanne, Marseille; [4]University College Dublin; [5]European Space Agency - ESA/ESTEC; [6]University of Iowa, USA; [7]Northeastern University, USA

The main topic of the research project CETSOL in the framework of the Microgravity Application Promotion (MAP) programme of the European Space Agency (ESA) is the investigation of the transition from columnar to equiaxed grain growth during solidification. Microgravity environment allows for suppression of buoyancy-driven melt flow and for growth of equiaxed grains free of sedimentation and buoyancy effects. This contribution will present first experimental results obtained in microgravity using hypo-eutectic AlSi alloys in the Materials Science Laboratory (MSL) on-board the International Space Station (ISS). The analysis of the experiments confirms the existence of a columnar to equiaxed transition, especially in the refined alloy. Temperature evolution and grain structure analysis provide critical values for the position, the temperature gradient and the solidification velocity at the columnar to equiaxed transition. These data will be used to improve modeling of solidification microstructures and grain structure on different lengths scales.

2:35 PM Invited
Dendrite Growth into Undercooled Melts: Investigated on Earth and in Reduced Gravity: *Dieter Herlach*[1]; [1]Deutsches Zentrum für Luft- und Raumfahrt

Methods of containerless undercooling and solidification are applied to study the dendrite growth velocity as a function of undercooling. On Earth electromagnetic and electrostatic levitation are used. For equivalent experiments in reduced gravity the German facility TEMPUS (German acronym for Containerless Electro-Magnetic Processing Under Weightlessness) is utilized in reduced gravity during parabolic flight and TEXUS sounding rocket missions offered by DLR and ESA. A high-speed camera allows to measure the rapid advancement of the solidification front with a picture frame rate of 50000 pictures per second. Al-Ni and Cu-Zr alloys are investigated. Al-rich Al-Ni alloys show an anomalous dendrite growth dynamics in such that the dendrite growth velocity decreases with increasing undercooling under terrestrial conditions. These measurements are compared with results obtained in reduced gravity. Measurements on Cu-Zr alloys show a maximum in the growth velocity-undercooling relation. The results will be discussed within the frame of models of dendrite growth

3:10 PM
Coupled Growth in Ternary Systems under Directional Solidification Conditions: *Ralph Napolitano*[1]; Irmak Sargin[1]; [1]Iowa State Univ

Exhibiting multiphase composite structures as well as nonplanar growth modes associated with solutal instability, eutectic solidification in ternary and higher-order systems may give rise to a broad scope of solidification morphologies, where microstructural evolution depends on the interplay between local eutectic phase topology, crystallographic orientation/misorientation, eutectic fault configuration, faulted domain and grain structure, and segregation phenomena, all relative to geometric constraints and applied thermal fields. In the study reported here, directional solidification methods are used to investigate the mechanisms of grain boundary migration and grain selection, the origin and configuration of eutectic faults, interface destabilization, and both two- and three-phase couple growth structures in Al-Cu-Ag alloys. Specific attention is given to three-dimensional morphology, transient evolution of solidification structures, and implications for microgravity research. This work is sponsored by the National Aeronautics and Space Administration, under contract NASA-CGA NNX10AT61G, in collaboration with the European Space Agency SETA Project.

Influence of Convection on Dendrite Growth and Microstructure Evolution by Using AC + DC Electromagnetic Levitator: *Hideyuki Yasuda*[1]; Yuki Kanzawa[1]; Takashi Fukuda[1]; Tomoya Nagira[1]; Masato Yoshiya[1]; [1]Osaka University

Electromagnetic levitator has been widely used for examining solidification in undercooled melt and for measuring physical properties. The electromagnetic force causes not only the lift force but also the stirring force. As a result, oscillation and convection are induced in a levitated droplet. Simultaneous imposition of static magnetic field with a sufficient intensity can suppress oscillation and convection and a droplet rotates like a hard sphere. Thus, the levitator using alternating and static magnetic fields allows to study solidification in a undercooled droplet without convection. This paper presents dynamics of a levitated droplet and effect of magnetic field on dendrite growth and microstructure evolution. Based on the results, effect of convection on solidification will be also discussed.

4:30 PM

Liquid Droplet Dynamics in Gravity Compensating High Magnetic Field: *Valdis Bojarevics*[1]; Stuart Easter[1]; Koulis Pericleous[1]; [1]University of Greenwich

Numerical models are used to investigate behaviour of liquid droplets suspended in magnetic fields of various configurations providing microgravity-like conditions. Using a combination of DC and AC fields it is possible to create conditions with laminar viscosity and heat transfer to measure viscosity, surface tension, electrical and thermal conductivities, and heat capacity of a liquid sample. Even a purely DC magnetic levitation can be used for advanced material research. The oscillations in a high DC magnetic field are quite different for an electrically conducting droplet, like liquid metal. The transition of the droplet behaviour from the low to high magnetic field is the subject of investigation in this paper. At the high values of magnetic field some oscillation modes are damped quickly, while others are modified with a considerable shift of the oscillating droplet frequencies and the damping constants from the non-magnetic case.

Measurements of Dendritic Growth Velocities in Undercooled Melts of Pure Nickel Under Static Magnetic Fields: *Jianrong Gao*[1]; Zongning Zhang[1]; Yingjie Zhang[1]; [1]Northeastern University

Dendritic growth velocities in undercooled melts of pure Ni have been intensively studied over the past fifty years. However, the experimental data are at marked variance with the prediction of the LKT model both at low and at large undercoolings. In the present work, bulk melts of pure Ni samples of different impurities were undercooled by glass fluxing treatment under a static magnetic field. The recalescence processes of the samples at different undercoolings were recorded using a high-speed camera, and were modeled using a software to determine the dendritic growth velocities. The present data confirmed the effect of melt flow on dendritic growth velocities at undercoolings below 100 K. On the other hand, the present data suggested the effect of impurities on dendritic growth velocities at undercoolings larger than 200 K.

5:30 PM

Diamagnetic Levitation by a Superconducting Magnet: A Method for Non-Contact Measurement of the Surface Tension of Aqueous, and other, Diamagnetic Liquids: *Richard Hill*[1]; Laurence Eaves[1]; [1]University of Nottingham

We use diamagnetic levitation by a superconducting magnet to study the shapes and dynamics of aqueous droplets in a pseudo-weightless environment. The diamagnetic force balances the force of gravity at the molecular level throughout the body of the liquid, and may be compared with the centrifugal force on an orbiting body. Precise measurements of a liquid's surface tension can be obtained from the oscillations of a droplet in zero gravity. Our experiments show close agreement between the oscillation frequencies of a levitated water droplet and those in zero-g. There is a small effect on the resonant frequencies of the droplet owing to the cohesive force of the magnetic 'trap'. We have obtained an analytic expression for the perturbation, enabling high precision measurements of the surface tension to be obtained by this technique. RJA Hill and L Eaves, Phys. Rev. Lett. 101, 2340501 (2008); Phys. Rev. E 81, 056312 (2010).

Mechanical Behavior at Nanoscale I: Nanowires, Pillar, Multilayers and Nanocrystalline

Deformation Mechanisms in Cu-Nb Nanolamellar Composites Produced via Severe Plastic Deformation: *Nathan Mara*[1]; John Carpenter[1]; Weizhong Han[1]; Jon LeDonne[2]; Jian Wang[1]; Irene Beyerlein[1]; [1]Los Alamos National Laboratory; [2]Carnegie Mellon University

In this presentation, we report on the plastic deformation mechanisms in Cu-Nb lamellar nanocomposites processed via Severe Plastic Deformation as a function of decreasing layer thickness. We utilize Accumulative Roll-Bonding (ARB) to process bulk Cu-Nb nanolamellar composites from 1 mm thick high-purity polycrystalline sheet down to layer thicknesses of 10 nm. This processing technique has the advantage of producing bulk quantities of nanocomposite material, and also exposes the interface and bulk constituents to large strains (1000's of percent). These extreme strains result in rolling textures, interfacial defect structures, and deformation mechanisms very different from those seen in nanolamellar composites grown via Physical Vapor Deposition methods. Results will be discussed in terms of the effects of interfacial content on deformation processes at diminishing length scales, and defect/interface interactions at the atomic scale.

2:30 PM

Characterization of Defects Generated during the Martensitic Transformation in Pseudoelastically-Deformed NiTi Microcrystals: *Matthew Bowers*[1]; Michael Mills[1]; Sivom Manchiraju[1]; Peter Anderson[1]; [1]The Ohio State University

The present study investigates the effects of orientation and specimen size on the pseudoelastic response of NiTi shape memory alloy. The primary goal in this investigation is to determine the means by which the matrix accommodates the large strain associated with the martensitic transformation. This information is critical for extending the working life of components under cyclic loading/heating. It is theorized that the accommodation may take place by matrix plasticity and/or by inducing additional transformation variants, however no experimental verification exists. We demonstrate that micron-scale pillar testing can isolate individual martensite plates, allowing for the investigation of the microstructural evolution related to particular variants in the absence of interactions between competing plates. FIB-machined, micropillars of various crystal orientations have been tested in compression and analyzed via mechanical response measurements and post-mortem TEM observations. Crystallographic theory of martensite and micromechanics-based stress field calculations are used to explain the results.

2:50 PM
Deformation Behavior of a Dual-Phase Sheet Steel: *Hassan Ghassemi Armaki*[1]; Robert Maaß[2]; Julia Greer[2]; Shrikant Bhat[3]; Sriram Sadagopan[3]; Sharvan Kumar[1]; [1]Brown University; [2]California Institute of Technology; [3]ArcelorMittal

The deformation behavior of a dual-phase sheet steel consisting of ferrite and martensite was examined in uniaxial tension. Specimens tested to various strains were evaluated by nanoindentation of the coexisting phases to understand the behavior of the individual phases as a function of global deformation. The hardness of ferrite increases gradually with increased global plastic deformation. In contrast, the ferrite close to the ferrite/martensite interface is initially harder than in the interior but softens with increasing deformation. Martensite exhibits a larger scatter in nanoindentation hardness and only a modest change with global straining. A few micropillars were FIB machined in the ferrite and martensite in the as-rolled condition and after 7 percent global plastic strain and were deformed using a flat-punch nanoindenter to generate compression stress-strain curves. The microscopic deformation behavior of the individual phases and their relation to the macroscopic deformation response of the dual-phase steel will be discussed.

3:10 PM
Deforming Nanoporous Gold: Non-Size Effects: *Hai-Jun Jin*[1]; Xing-Long Ye[1]; Jörg Weissmüller[2]; [1]Institute of Metal Research, Chinese Academy of Sciences; [2]Institut für Werkstoffphysik und -Technologie,Technische Universität Hamburg-Harburg

Nanoporous metals exhibit a strong "size dependence" as other nanostructured materials: the strength increases with decreasing ligament size. Here we demonstrate that some non-size parameters have also great impact on the deformation behavior of nanoporous metals. Compression tests have been performed on crack-free, millimeter-sized nanoporous gold (npg) samples prepared by dealloying, with ligament size at nanometer scale. We found that the strength and brittleness of npg can be altered by changing the surface state (e.g., surface oxygen adsorption) via controlling the electrode potential while doing the compression in situ with potentiostatic controls (Jin and Weissmüller, Science 2011). We also found that the roles of initial lattice dislocation in deformation of npg are very different from that in massive Au. These observations have implications on the understanding of crystal deformation at nm scale, and may also lead to new strategies for making tougher (or less brittle) nanoporous metals.

3:30 PM Break

3:40 PM
Effects of Alloying, Temperature and Strain-Rate on the Mechanical Behavior of Nanocrystalline Palladium Alloys: *Thomas Neithardt*[1]; Oliver Kraft[1]; Ruth Schwaiger[1]; [1]Karlsruhe Institute of Technology, Institute for Applied Materials

It is now well accepted that for grain sizes up to about 50nm the dislocation activity is significantly reduced. Other deformation mechanisms were shown to gain importance, which is corroborated by the small activation volumes and increased strain rate sensitivity typical of nanocrystalline materials. We investigated nanocrystalline Pd und PdAu-alloys using indentation and microcompression tests. An increase of the hardness as well as the strain rate sensitivity for these nanocrystalline materials compared with coarse-grained Pd is typically observed. The alloying content has no significant effect on the strain rate sensitivity and the activation volume for grain sizes well below 100nm. To better understand the deformation mechanisms and their thermal activation, a heating stage was designed. The deformation behavior was studied in the temperature regime up to 90°C, for which no significant grain growth is expected to occur. First indentation and microcompression results as a function of temperature will be presented.

4:00 PM
Mechanical Behaviors of Nanostructures of Low Melting Temperature Metals as Revealed by Synchrotron Laue X-Ray Microdiffraction: *Arief Budiman*[1]; M. J. Burek[2]; G. Lee[2]; D.-C. Jang[3]; N. Tamura[4]; M. Kunz[4]; T. Tsui[2]; [1]Los Alamos National Laboratory (LANL); [2]University of Waterloo; [3]California Institute of Technology; [4]Advanced Light Source (ALS), Berkeley Lab

Mechanical behaviors at the nanoscales of low melting temperature metals, such as indium and tin, have not been much studied. Both indium and tin are key materials in advanced microelectronics and nanotechnology industry, and understanding their mechanical behaviors at nanoscales becomes increasingly important to ensure lifetime reliability of their nanoscale devices. Synchrotron X-ray microdiffraction has been utilized to examine defect structures of nanoscale materials. For indium and tin especially, this technique offers unique advantage as conventional methods such as TEM and EBSD will expose the structure to high energy electron beams that may significantly alter the microstructure and defect structure during analysis. Using this approach, we found interesting differences in term of X-ray peak broadening after deformation which indicates differences in plasticity mechanisms in the nanostructures of indium and tin. Understanding these differences could lead to better control of mechanical properties of low melting temperature metals at the nanoscales.

4:20 PM
Tensile Properties of Nano-Twinned Cu Nano-Pillars through Nano-Mechanical Testing, Electron Microscopy, and Atomistic Simulations: *Dongchan Jang*[1]; Xiaoyan Li[2]; Huajian Gao[2]; Julia Greer[1]; [1]California Institute of Technology; [2]Brown University

Nano-twinned materials have attracted great scientific interest because of their simultaneous attainment of high strength and ductility. While most reports on nano-twinned metals to date are polycrystalline, where randomly oriented nano-twins are embedded within grains, we developed a fabrication technique producing arrays of thousands of free-standing vertically-aligned Cu nano-pillars. Here, entire specimen consists of uniformly aligned nano-twins with {111} orientations at different inclinations and no grain-boundaries. Through in-situ uniaxial tensile testing, we are able to define the parameter space for dominant deformation mechanism and ultimate tensile strength. Microstructural changes due to plastic deformation were investigated via transmission electron microscopy. Results indicate that while nano-pillars containing orthogonally-oriented twin boundaries (TB) show intensive inter-TB dislocation activities, de-twinning was observed with TBs inclined by 20\176. Through molecular dynamics simulation, these findings are discussed in the framework of dislocation nucleation at the surfaces and subsequent glide along or across TBs.

4:40 PM
Dislocation Multiplication and Nucleation in Small Metallic Fibers under Stress: The Input of In Situ Transmission Electron Microscopy: *Marc Legros*[1]; Frédéric Mompiou[1]; Daniel Gianola[2]; Andreas Sedlmayr[3]; Oliver Kraft[4]; Daniel Caillard[1]; [1]CEMES-CNRS; [2]University of Pennsylvania; [3]Karlsruhe Institute for Technology ; [4]Karlsruhe Institute for Technology

Whiskers, thin films, and micro pillars display an increase of their strength as an inverse power law of their size. For sub-micrometre single crystalline pillars and fibers, where no external boundaries or interfaces are confining the dislocations, this trend has to root in the initial microstructure and its ability or not to nest dislocation sources. Despite a lack of detailed experimental investigations, dislocation multiplication is now widely recognized as the key parameter to explain the unusual mechanical behavior of these small objects. Here, we will show that determining a dislocation density may not be sufficient to fully predict the response of Al fibers fabricated by selective chemical etching of an eutectic lamellar Al/Al2Cu alloy. Combining in situ TEM and SEM tensile tests allowed us to relate yield stresses to intermittent spiral sources. As they operate closer to the surface, increasing stress values are needed, giving rise to the size effect.

5:00 PM

Deformation of Gold Nanowires: How Impurities Change the Game: *Francesca Tavazza*[1]; Lyle Levine[1]; Anne Chaka[1]; [1]National Institute of Standards and Technology

The role of impurities in Au nanowire deformation and quantum conductance has been heavily debated. We have used extensive density functional theory simulations to investigate the deformation of [110]-gold nanowires in the presence of light atomic or molecular impurities for several different tensile axes and effective strain rates. Substantial differences in both the wire evolution and the calculated conductance traces are found, with respect to the uncontaminated case. Different contamination mechanisms are investigated by changing the stage of deformation at which the impurity is added to the system. Lastly, the likelihood of an impurity being incorporated into a single-atom-chain is also examined.

5:20 PM

Deformation and Fracture of Color-patterned Pulsed Laser Oxides on Stainless Steel: *Samantha Lawrence*[1]; Douglas Stauffer[2]; Ryan Major[2]; David Adams[3]; William Gerberich[4]; David Bahr[1]; Neville Moody[3]; [1]Washington State University; [2]Hysitron Inc.; [3]Sandia National Laboratories; [4]University of Minnesota

Localized heating from a focused laser beam produces dielectric phases, creating unique metastable colored layers. Little research has focused on pulsed laser colorized films and none studied mechanical behavior. We have, therefore, begun to investigate the mechanical behavior of color-patterned oxides on polished 304L stainless steel where film and substrate properties control macroscopic wear and fracture processes. Quasi-static and dynamic nanoindentation probed oxide deformation and fracture, resulting in modulus and hardness values of approximately 160GPa and 12GPa, respectively. Conductive nanoindentation measured electrical contact resistance (ECR) for colored oxides indicating a correlation between laser exposure, current, conductance, and indentation response. In this presentation we will show that combining indentation and microscopy techniques provides a unique approach for defining mechanical behavior and processes. This work was supported by DTRA Basic Research Award #IACRO 10-4257, NSF Grant NSF/DMR-0946337, and Sandia National Laboratories, a Lockheed Martin Company for USDOE NNSA under contract DE-AC04-94AL85000.

5:40 PM

Strain Heterogeneities within a Sub-Micron Grain in a Polycrystalline Thin Film as Probed by X-Ray Coherent Diffraction during a Thermal Cycle: Nicolas Vaxelaire[1]; *Stephane Labat*[1]; Henry Proudhon[2]; Christoph Krichlechner[3]; Olivier Perroud[1]; Marie-Ingrid Richard[1]; Thomas Cornelius[4]; Jozef Keckes[3]; Samuel Forest[2]; Olivier Thomas[1]; [1]CNRS - Aix-Marseille University; [2]MINES ParisTech - CNRS; [3]Erich Schmid Institute of Materials Science; [4]ESRF

Strain heterogeneities in polycrystalline thin films are of great interest in technology because many fabrication and reliability problems are stress related. Nevertheless measuring local strains in sub-micron grains remains a real experimental challenge. This work is focused on the use of X-ray Coherent Diffraction Imaging. A 3D mapping of 111 Bragg reflection from a Au sub-micron grain was measured during a thermal cycle. Because of the difference in thermal expansion between the glass substrate and the film, the film undergoes a biaxial compression test. Coherent properties of the beam have been used to retrieve a component of the displacement field in 3D from a single grain with a resolution around $17 \times 17 \times 22$ nm via phase retrieval procedures. Besides, it has been possible to compute realistic FEM simulations and compare the displacement fields. These results pave the way to non destructive strain mapping at the nanoscale.

Mechanical Behavior Related to Interface Physics: Structure and Mechanical Behavior of Amorphous and Crystalline Nanocomposites

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Materials Processing and Manufacturing Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Nanomechanical Materials Behavior Committee

Program Organizers: Jian Wang, Los Alamos National Laboratory; Nathan Mara, Los Alamos National Laboratory; Izabela Szlufarska, University of Wisconsin-Madison ; Zhiwei Shan, Xi'an Jiaotong University

Tuesday PM — Room: Oceanic 1
March 13, 2012 — Location: Dolphin Resort

Session Chairs: Rozaliya Barabash, Oak Ridge National Laboratory; Alla Sergueeva, NanoSteel Company

2:00 PM Keynote

Crystal-Glass Interfaces: *Ju Li*[1]; [1]Massachusetts Institute of Technology

Unlike grain boundaries (GB) which have 3 mis-orientations and 2 inclinations degrees of freedom, crystal-glass interfaces (CGI) have only 2 inclinations degrees of freedom and constitute a different class of internal interfaces. Due to this essential difference in structure, the manners of inelastic deformation transduction at CGIs differ a great deal from those near GBs, which significantly impact the plasticity and fracture behaviour of nanoscale crystalline-amorphous aggregates. Recent experimental work have highlighted the importance of CGIs on the ductility of crystalline-amorphous multilayers (PNAS 104 (2007) 11155), and the cyclability and efficiency of Li-ion batteries (Science 330 (2010) 1515).

2:30 PM Keynote

Interface-Dominated Mechanical Properties of Layered/Fibrous Composites: *Rozaliya Barabash*[1]; [1]Oak Ridge National Laboratory

Interfaces play a crucial role in materials properties, in part because interfaces themselves possess unique physical properties distinct from the bulk constituent phases. In layered/fibrous composites, the overall interface area is very large. Interfaces between the phases are the key elements responsible for the unique micro-mechanisms of plasticity in composites. A predictive understanding of the interface interactions between the matrix and the lamellae/fibers under external fields would allow interface engineering to create the best combination of the materials properties. In this study the depth-dependent strain distributed in the layered/fibrous composite and partitioned across the interfaces is directly measured at submicron length-scales using X-ray microdiffraction and compared to a detailed micromechanical stress analysis. Interface strength is estimated from the near-surface depth-dependent strain gradients. Several examples for directionally solidified composites are presented. Research supported by the Materials Sciences and Engineering Division, Office of Basic Energy Sciences, U.S. Department of Energy.

3:00 PM

Dislocation-Interface Interaction in Crystalline-Amorphous Metallic Multilayers: *Christian Brandl*[1]; Timothy Germann[1]; Amit Misra[1]; [1]Los Alamos National Laboratory

The combination of amorphous nanoscale layers with crystalline nanoscale layers has exhibited extraordinarily high toughness, i.e. ultra-high strength in conjunction with high elongation-to-failure. The plastic deformation is confined by the crystalline-amorphous interface, which additionally has to maintain deformation compatibility to mediate homogeneous plastic flow. Contrary to crystalline-crystalline interfaces, where crystalline phases exhibit long range order, the amorphous structure is characterized by a lack of long-range order. Using molecular dynamics (MD) methods, the compensation mechanism of this reduced long-range order at the interface is studied for the Cu (FCC) / CuxZr(1-x) (amorphous) system. The ordering decreases with increasing distance from the amorphous-crystalline interface. The implication of the interface ordering on dislocations impinging upon the interface is studied via MD. The interface response is discussed in terms of (1) rearrangement of interface order, and (2) co-deformability of the amorphous and crystalline layers, and the resulting implications on layer size effects.

3:15 PM

Mechanical Characterization of Nanolayered Al/SiC Composites by High Temperature Nanoindentation: S. Lotfian[1]; J. Molina-Aldareguia[1]; K. Yazzie[2]; J. LLorca[1]; A. Misra[3]; *Nikhilesh Chawla*[2]; [1]IMDEA Materials Institute, 28040-Madrid, Spain; [2]Arizona State University; [3]Los Alamos National Laboratory, Los Alamos, NM

Multilayered Al/SiC composites exhibit extremely high strength and toughness. In this paper we discuss the high temperature nanoindentation behavior of these materials. The nanolaminates were processed by physical vapor deposition (PVD) using magnetron sputtering. Layer thickness and morphology was studied using a dual beam focused ion beam (FIB). The mechanical properties were characterized by high temperature nanoindentation at 100, 200, and 300oC. Finally, post-deformation microstructural analysis was carried by FIB and atomic force microscopy (AFM) to provide insight into the deformation mechanisms.

3:30 PM

The Interfacial Mechanics of the Thin Oxide Skin on Liquid Gallium Alloy: Ju-Hee So[1]; Rashed Khan[1]; *Michael Dickey*[1]; [1]NC State University

We describe the mechanics of the thin oxide skin that forms on a liquid metal. The alloy, eutectic gallium indium, is useful for moldable microelectrodes, stretchable antennas, and flexible solar cells. The ability to micromold the metal for these applications is enabled by the mechanical properties of a thin oxide skin that forms spontaneously on its surface; the material is therefore effectively a composite. The oxide skin is elastic and yields under a critical stress, at which point the metal flows. The ability to flow the metal is important for shaping (and re-shaping) it into useful geometries. We studied the mechanical properties of the oxide skin under different environments using a rheometer with a parallel-plate geometry. The rheological properties of the low viscosity liquid are dominated by the interfacial skin. These studies provide new tools to study thin films and engineer the forces under which the metal will flow.

3:55 PM Keynote

Tensile Ductility and Necking In Small-Volume Metallic Glasses: In the Limit of Suppressed Shear Banding: *Evan Ma*[1]; [1]Johns Hopkins University

In bulk samples of amorphous metals, shear banding is the norm upon room temperature plastic deformation. Almost all the plastic strains are localized in the quasi-2D shear band. When the sample size is on submicron- and nano- scale, however, such severe shear localization can be suppressed. Here we show new tensile testing schemes inside TEM that allowed quantitative evaluation of the intrinsic properties and deformation mode of ~100 nm diameter samples. We observe that the formation of the thin shear band, with "interfaces" that are energy-costing, gives way to distributed deformation followed by gradual necking. The resulting high strength (2.5 to 4 GPa), elasticity (up to 5%), and appreciable tensile elongation (~10%) make small-volume metallic glasses appealing for MEMS applications. This work is a collaboration with Lin Tian, Zhiwei Shan, Ju Li, Qingsong Deng and Xiaodong Han.

4:25 PM Keynote

Ductility Mechanisms in Glass Matrix Nanomaterials: *Alla Sergueeva*[1]; Sheng Cheng[1]; Brian Meacham[1]; Daniel Branagan[1]; [1]The NanoSteel Company

Metallic glasses and nanomaterials have shown great commercial promise due to their unique combination of properties which include very high strength (up to 50% of theoretical) and hardness. However, achieving usable ductility in these materials has been a compelling unsolved issue for several decades. Furthermore, operational theories on how this can be achieved, including the structure type and enabling mechanism of deformation, have not been clearly defined in theory or proven by experimentation. In this presentation, the ability to obtain usable ductility is shown in materials which combined features of both classes of the materials. Enabling metallurgical structure, mechanisms of ductility at room temperature as well as a role of glass/crystal interfaces in glass matrix nanomaterials are analyzed.

4:55 PM

Analysis of Heterogeneous Deformation along Grain Boundaries in Tensile Tests of Pure Tantalum: *Ian Jarvis*[1]; Thomas Bieler[1]; Martin Crimp[1]; Darren Mason[2]; Brad Boyce[3]; [1]Michigan State University; [2]Albion College; [3]Sandia National Laboratory

Deformation and failure of polycrystals results from heterogeneous deformation that accelerates after the ultimate tensile stress is reached. During the failure process, the difference in strain of hard and soft grains leads to formation of voids. In-situ deformation of pure tantalum polycrystals was monitored in SEM and EBSP maps were obtained at several stages of strain. Direct observation clearly shows how some grains deformed more than others, and distinct orientation gradients became evident along some boundaries. The sequential orientation maps were analyzed to identify locations where large gradients in deformation developed using grain boundary slip transfer concepts and a new modeling approach where the origin of grain boundary ledges arising from heterogeneous deformation was effectively predicted in titanium polycrystals. Simulation of this microstructure patch with crystal plasticity finite element models was used to obtain estimates of the local stress tensors. Agreement between model and experiment is assessed and discussed.

5:10 PM

Novel Design of Functional Nanoporous Metal Architectures: *Eric Detsi*[1]; Sergey Punzhin[1]; Patrick R. Onck[1]; Jeff T.M. De Hosson[1]; [1]University of Groningen

Nanoporous metals synthesized by dealloying have attracted considerable attention in recent years due to their potential for various applications including catalysts, sensors, actuators and drug delivery platforms. Downscaling the size of ligaments and pores to smaller dimensions is particularly interesting because this enhances the specific surface area as well as the material properties. Obviously, the size of microstructural elements cannot be scaled down indefinitely and in our work we address this limitation by searching for alternative nanoporous metal architectures. By exploiting grain boundaries misorientation in the alloy precursor, we have designed nanoporous metals with multilayer architectures during dealloying. The novel porous layers architecture displays intriguing functional properties. In particular giant charge-induced strains are measured, roughly two order of magnitude larger than in conventional nanoporous metals.

Mechanical Performance of Materials for Current and Advanced Nuclear Reactors: Characterization and Modeling of Microstructural Evolution in Nuclear Materials

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Nuclear Materials Committee

Program Organizers: Nicholas Barbosa, National Institute of Standards & Tech; Greg Oberson, United States Nuclear Regulatory Commission; Matthew Kerr, United States Nuclear Regulatory Commission; Elaine West, Knolls Atomic Power Laboratory; Stuart Maloy, Los Alamos National Laboratory; Osman Anderoglu, LANL

Tuesday PM Room: Swan 1
March 13, 2012 Location: Swan Resort

Session Chairs: Elaine West, Knolls Atomic Power Laboratory; Paula Mosbrucker, Los Alamos National Laboratory

2:00 PM Invited
Microstructures and Mechanical Properties in Carbide and Nitride Ceramics for Advanced Nuclear Systems: *Todd Allen*[1]; Yong Yang[2]; Clayton Dickerson[3]; [1]University of Wisconsin-Madison; [2]University of Florida; [3]Argonne National Laboratory

Many advanced nuclear systems aim to operate such that structures are exposed to higher irradiation dose, operate at higher temperatures, and use cooling media other than water. Interest in advanced ceramics comes from many areas including high-temperature gas-cooled reactors, fusion systems, and advanced water-cooled reactors. The radiation response and micromechanical response of two carbides, ZrC and TiC, and two nitrides, ZrN and TiN have been studied using controlled temperature high-energy proton irradiation. Following radiation microstructures have been characterized using x-ray diffraction and transmission electron microscopy while changes in mechanical properties have been estimated using deflection of micro-pillars machined from irradiated samples using a focused ion beam technique. In general, some lattice expansion is noted due to the accumulation of radiation-produced defects, a series of irradiation-induced dislocation loops is formed, and the fracture toughness increases relative to the unirradiated material.

2:30 PM
In-Situ Studies and Modeling of the Deformation and Fracture Mechanism for Wrought Zircaloy-4 and Zircaloy-2 as a Function of Stress-State: *Brian Cockeram*[1]; Kwai Chan[2]; [1]Bechtel-Bettis; [2]Southwest Research Institute

In-situ deformation and fracture studies were performed on wrought Zircaloy-4 and Zircaloy-2 over a range of stress-states using Compact Tension (CT) and smooth and notched tensile specimens to evaluate the mechanism for fracture initiation and propagation. Both annealed and beta-treated conditions were tested to understand both the role of microstructure and orientation. Unstable crack extension is shown to occur under plastic constraint by a process of void nucleation, growth, and coalescence under all stress-states. A constant value of critical local strain is shown to initiate void nucleation for all stress-states. The strain for failure is shown to be controlled by the process of void growth and coalescence that is strongly dependent on stress-state. A micromechanical model is developed for the mechanism of ductile tearing by void growth and coalescence. Excellent agreement between the model and experimental measurements of the critical strain for failure initiation and strain for fracture is observed.

2:50 PM
Mechanical Properties of Nanocrystalline Zr from Atomistic Simulation: *Zizhe Lu*[1]; Dong-Hyun Kim[1]; Mark Noordhoek[1]; Michele Manuel[1]; Susan Sinnott[1]; Simon Phillpot[1]; [1]University of Florida

Zirconium alloys are used as fuel clad because of their mechanical properties, and high resistance to corrosion and irradiation. Using molecular-dynamics simulation, we characterize the slip and twinning processes governing mechanical phenomena in fine-grained Zr. Two different descriptions of the interatomic interactions are employed: an embedded-atom method (EAM) potential [1], and a charge-optimized many body (COMB) potential recently developed by the authors. The modes of slip and twinning obtained using the different potentials are compared with those in experiments. Grain boundaries are found to act as heterogeneous nucleation sites of dislocations and twins. This work was supported by the Consortium for Advanced Simulation of Light Water Reactors (www.casl.gov), an Energy Innovation Hub (http://www.energy.gov/hubs) for Modeling and Simulation of Nuclear Reactors under U.S. Department of Energy Contract No. DE-AC05-00OR22725.[1] Mendelev MI, Ackland GJ. Philosophical Magazine Letters 2007;87:349

3:10 PM
Plastic Accommodation of Zirconium Hydrides: Cindy Smith[1]; *Ian Robertson*[1]; Mohsen Dadfarnia[1]; Petros Sofronis[1]; [1]University of Illinois

The formation of a field of dislocations around a gamma-hydride in a zirconium alloy is revisited by using electron tomography to determine the three-dimensional spatial distribution of the dislocation structure associated with the hydride. Electron tomography as applied to the studies of defects is a relatively new and challenging technique but the additional insight gain from moving from a projected to fully three-dimensional image is proving invaluable. Here this technique is coupled with conventional TEM analysis methods to explore the distribution of dislocations surrounding a gamma-hydride in a zirconium alloy. It will be shown that the dislocations associated with the hydride have the same Burgers vector, are coplanar, and originate from a common source on the hydride. These results will be considered in terms of proposed mechanisms for accommodating the misfit strain by generation of shear loops or reducing the interfacial energy through formation of emissary dislocations.

3:30 PM
Microstructural Evolution and Fracture Toughness Recovery by Thermal Annealing in HT9 Steel Irradiated to High Doses: *Osman Anderoglu*[1]; Thak Sang Byun[2]; Stuart Maloy[1]; [1]Los Alamos National Laboratory; [2]Oak Ridge National Laboratory

An HT-9 duct, ACO-3, was irradiated in a fast reactor to a maximum dose of 155 dpa at 380-505°C. Significant hardening and reduction of toughness at lower irradiation temperatures were observed. In an effort to recover the original mechanical properties, thermal annealing was performed at 550 and 650°C for up to 2 hours. Fracture toughness was measured at 22-600ºC after annealing using the TPB specimens. The results indicate that fracture toughness is completely recovered when annealed at 650ºC after low temperature irradiation, while it is partially recovered in other cases. TEM shows a high density of second phase precipitates at low temperature irradiations. It is thought that these precipitates are partly responsible from degradation of mechanical properties. We performed in-situ TEM annealing experiments to observe evolution of microstructure up to 500ºC. In this talk we will report the results of microscopic changes and discuss the effects on the macroscopic properties.

3:50 PM Break

4:05 PM
Molecular Dynamics Simulations of Cascade Evolution near Trapped Interstitial Clusters: *Nathan Capps*[1]; Aaron Kohnert[2]; Karl Hammond[1]; Donghua Xu[1]; Brian Wirth[1]; [1]University of Tennessee; [2]University of California

The overlap of displacement cascade is believed important in the development of visual defect clusters in thin film, in-situ ion irradiation studies. Here, we report molecular dynamics simulation results to investigate how impurities and damage induced by displacement cascades affect the mobility of pre-existing, interstitial-type dislocation loops in BCC iron. It is well known that impurities, such as oxygen, carbon, and nitrogen affect the ability of interstitial dislocation loops, and are likely responsible for differences in loop diffusivities between simulations and experiment. Molecular dynamics simulations with varying energy and direction of the primary knock on atom (PKA) reveal that cascades from PKAs with energy > 10 keV can cause the loop to detrap from impurities, but the loop may rapidly become trapped in the cascade debris. Furthermore, on several occasions, the cascade has induced a change in orientation or Burgers vector of the dislocation loop.

4:25 PM
Atomistic Modelling of Helium Trapping by Nanoscale Precipitates: *Niraj Gupta*[1]; Alfredo Caro[2]; Enrique Martinez[2]; Srinivasan Srivilliputhur[1]; [1]University of North Texas; [2]Los Alamos National Lab

Irradiation damage and helium generation pose a major challenge to the development of advanced materials for proposed fusion reactor designs. Recent experimental efforts have shown that nanostructured ferritic alloys exhibit exceptional helium tolerance due to defect recombination and helium trapping in small gas bubbles due to an ultrahigh density of oxide “nanofeatures.” The trapping mechanism is believed to be geometric in nature, and is modeled in our work using a prototype Cu-Nb system. Helium addition to FCC Cu precipitates in a BCC Nb matrix and vice versa were simulated using MD and Monte Carlo simulations. Both these simulations yield preferential interfacial helium trapping, illustrating that this behavior is general to any stable high-interface density material systems irrespective of chemistry. The role of coherency of the interface is also explored by contrasting with helium behavior in the Fe-Cr system wherein both Fe and Cr have body-centered-cubic structure and similar lattice constants.

4:45 PM
Influence of the Coherency of Nano-Oxides in ODS Materials on the Coarsening Kinetics: *Joel Ribis*[1]; Yann De Carlan[1]; [1]CEA

Ferritic/martensitic ODS alloys are candidates as structural materials for components subjected to very high irradiation doses at high temperature. They are reinforced by a homogeneous dispersion of nano-oxides within the matrix. Nano-oxides exhibit an amazing thermal stability. In the new Fe-14Cr1W CEA ODS alloy, after hot extrusion and annealing 1 hour at 1400°C there size remain close to 10 nm. Thanks to high resolution TEM observations, the coherency of the nano-phases has been shown. The interfacial and elastic energy have been determined. It explains the great thermal stability of the oxides but a recrystallization of the material breaks the coherency between the nano-phases and the matrix and increases the coarsening kinetics.

5:05 PM
Spinodal Decomposition in Duplex Stainless Steel: *Julie Tucker*[1]; George Young[1]; Michael Miller[2]; [1]Knolls Atomic Power Laboratory; [2]Oak Ridge National Laboratory

Duplex stainless steels are desirable for use in power generation systems due to their attractive combination of strength, corrosion resistance, and cost. However, thermal embrittlement at ~475°C limits upper service temperatures for many applications. New lean grade duplex alloys have improved thermal stability over standard grades and potentially increase their upper service temperature. The thermal stability of lean grade, alloy 2003 is compared to standard grade, alloy 2205, through isothermal aging between 280°C and 815°C for 1 to 10,000 hrs. Samples were characterized by microhardness, Charpy-impact toughness and atom probe tomography (APT). APT results indicated that α-α’ phase separation occured via spinodal decomposition for both alloys and identified a complex Cu-Ni-Si-Mn-P second phase in alloy 2205 that may contribute to the embrittlement rate. Research supported by ORNL’s Shared Research Equipment (SHaRE) User Facility, which is sponsored by the Office of Basic Energy Sciences, the U.S. Department of Energy.

5:25 PM
Elemental Solubility Tendency for the Phases of Uranium by Classical Models Used to Predict Alloy Behavior: *Van Blackwood*[1]; Travis Koenig[1]; Saleem Drera[1]; David Olson[1]; Brajendra Mishra[1]; Doug Porter[2]; Robert Mariani[2]; [1]Colorado School of Mines; [2]Idaho National Lab

Traditional alloy theory models, specifically Darken-Gurry and Miedema’s analyses, have been used to assist in predicting alloy behavior. These models will be applied relative to the three solid phases of uranium: alpha, beta, and gamma. These phases have different solubilities for specific alloy additions as a function of temperature. The Darken-Gurry and Miedema models, with modifications based on concepts of Waber, Gschneider, and Brewer will be used to predict the behavior of four types of solutes: 1) Transition metals that are associated with the containment as alloy additions in the uranium fuel 2) Transuranic elements in uranium 3) Rare earth fission products 4) Transition metals and other fission products. Using these solute map criteria, elemental behavior will be predicted and used to compare solute effects during uranium phase transformations. The solute map overlap is a convenient first approximation tools for predicting alloy behavior.

Nanocomposites: Nanocomposite Interfaces and Characterization

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Composite Materials Committee
Program Organizers: Garth Wilks, Air Force Research Laboratory; Jonathan Spowart, Air Force Research Laboratory; Meisha Shofner, Georgia Institute of Technology; John Zhanhu Guo, Lamar University

Tuesday PM — Room: Swan 8
March 13, 2012 — Location: Swan Resort

Session Chairs: Meisha Shofner, Georgia Institute of Technology; Javier Garay, University of California, Riverside

2:00 PM
Positron Lifetime Analysis of Polyurea-Nanoclay Composites: *Naidu Seetala*[1]; Danny Hubbard[1]; Gabriel Burks[1]; Alex Trochez[1]; Valery Khabashesku[2]; [1]Gramblimg State University; [2]University of Houston

Positron lifetime spectroscopy (PLS) is used to study 1-5 wt% nanoclay incorporated aliphatic polyurea films prepared by two different methods. Set-1 used aliphatic polyaspartate polyurea system consists of aliphatic diisocyanate resin, while set-2 used pre-made aliphatic-polyurea granules. PLS was used to study pore structure in polyurea samples. The third lifetime component, related to positronium formation in free spaces, provided the information on pore size and concentration of pores. The third lifetime component showed ~ 2 ns for set-1 and ~ 1.8 ns for set-2 with relative intensities of 16% and 19%, respectively; indicating that set-1 polyurea has larger pores with lesser concentration compared to set-2 polyurea. There is good correlation between positronium lifetime parameters (both lifetime and intensity) and % nanoclay in set-1 polyurea, but no correlation is observed for set-2 polyurea. The set-2 films showed bad quality and the polymer curing is not as good as set-1 films.

2:20 PM

Effect of Interfacial Reaction on Mechanical and Corrosion Properties of Oxide Nano-Particle Reinforced Aluminum Matrix Composites: *Jaehyuck Shin*[1]; Jiyeon Suh[1]; Donghyun Bae[1]; [1]Yonsei University

Interface characteristics, with their mechanical and corrosion properties, have been investigated for aluminum based composites reinforced with oxide nano-particles (TiO2, SiO2). The composites are produced by hot rolling the ball-milled mixture of Al powders and nano-particles. During a milling process, nano-particles are gradually dispersed and embedded within the Al powders. After the annealing process, interface of the composite is modified to be amorphous structure by inducing the formation of nanoscale diffusion layer between the nano-particle and the matrix. With increasing the annealing time, the composites show enhanced yield strength and ductility. Furthermore, interfacial reaction has beneficial effect on corrosion resistance of the composites due to the dispersion of oxide atoms into the matrix. Mechanical properties with increasing annealing time and their corrosion properties will be presented.

2:40 PM Invited

Interfaces in Functional Nanocomposites: *J. Garay*[1]; [1]UC Riverside

The influence of nano-scale defects (grain/phase boundaries, pores, etc) can be significantly different from micro-scale features. We will discuss how interfaces in nanocrystalline materials interact with light, electric and magnetic fields and how precise control of these defects can be used to tune materials properties. In particular we will concentrate on light transparency in the visible range, magnetic exchange coupling and magneto transport. We will also briefly discus our main processing technique, current activated pressure assisted densification has proven effective in overcoming the grain growth challenge. The materials produced have applications as magneto-optical diodes, magnetic sensors and permanent magnets.

3:20 PM Break

3:40 PM

Nano-Scale Characterization on the Metal/Carbon Nanotube Interface: Tushar Borkar[1]; *Junyeon Hwang*[1]; Sandip Harimkar[2]; Jaimie Tiley[3]; Soon-Hyung Hong[4]; Rajarshi Banerjee[1]; [1]University of North Texas; [2]Oklahoma State University; [3]Air Force Research Laboratory; [4]Korea Advanced Institute of Science and Technology

The properties of metal/carbon nanotube hybrid structures are critically dependent on the structure and chemistry of the metal-carbon nanotube interface. Therefore, the characterization of the interface at the highest possible resolution is of prime importance but rather challenging. In this study, interfaces of Ni/CNT nanocomposites fabricated by laser process and spark plasma sintering technique are characterized and compared with their mechanical properties. In addition, the interface deposited by vacuum process technique has been analyzed by analytical transmission electron microscope combined with three-dimensional atom probe tomography. The structural stability of the metal/CNT interface will also be discussed and related to potential implications on properties of these hybrid structures.

4:00 PM

Extended X-Ray Absorption Fine Structure (EXAFS) Studies of Radiation Damage-Tolerant Nanocomposites: *Simerjeet Gill*[1]; Avishai Ofan[1]; Lynne Ecker[1]; Amit Misra[1]; [1]Brookhaven National Lab

Nanocomposites such as Oxide Dispersion Strengthened (ODS) are promising fuel cladding materials for future reactors. One important challenge in ODS steels is that the atomic environment of the metal-oxide interface in a ferritic matrix is difficult to access due to the geometric complexity of the internal interfaces. In order to understand fundamental mechanisms of radiation-induced defect evolution and annihilation at interfaces of ODS steels with complex structure, model nanocomposite systems with regularly spaced interfaces in a multilayer geometry were studied. Nanocomposite layered systems with both metal-oxide/metal (Y2O3/Fe) and metal-metal (Cu/Nb) interfaces are reported. Nanocomposite systems have demonstrated high strength and good thermal stability, but local molecular structure at the interface is not clearly understood. In present studies, EXAFS is used to investigate changes in molecular structure and lattice distortions induced at interface in nanocomposite layered systems. The effect of annealing and irradiation conditions on the local molecular structure is reported.

4:20 PM

Structure and Transport Properties of Zeolite-Polymer Composite Membranes for Energy-Efficient Separations: Role of Interactions and Geometry: *Carson Meredith*[1]; Jung-Hyun Lee[1]; [1]Georgia Tech

We present measurements made with atomic force microscopy of the interfacial adhesion between key membrane-forming polymers and a model zeolite. These are used to determine the primary intermolecular interactions governing adhesion and are compared to transport and mechanical properties of polyamide- and poly(vinylacetate) (PVAc)-based composite membranes. Zeolite (all-silica MFI) adhesion to polyamides is governed primarily by acid-base interactions in which carbonyl groups on the polymer, as well as adsorbed surface water, play a key role. Models for these adhesion mechanisms are presented and compared as well. In particular, we find that adhesion can be correlated strongly with known surface tension values if measurements with a variety of solvents (protic and aprotic, polar and non-polar) are available. In addition, we present evidence of the beneficial effect of nanostructured roughening of the zeolite surface on adhesion, transport, and mechanical properties.

4:40 PM

Diffusion of Atmospheric Penetrants in Crosslinked and Uncrosslinked Polydimethylsiloxane Based Nanocomposites: Varun Ullal[1]; *Douglas Spearot*[1]; [1]University of Arkansas

Molecular dynamics (MD) simulations are used to compute diffusion coefficients for N_2 and O_2 penetrants in polydimethylsiloxane (PDMS) based nanocomposite models with metallic inclusions. PDMS is modeled using a hybrid coarse-grained interatomic potential which retains atomic distinction along the siloxane backbone but models the methyl side groups as united atoms. To validate the simulation methodology, diffusion data is computed for pure PDMS with different chains lengths over a range of temperatures and compared with experimental data. For nanocomposite simulations, both crosslinked and uncrosslinked PDMS models are constructed. Crosslinked PDMS networks are formed by mixing silanol-terminated PDMS chains with the molecule tetra(dimethylsiloxy)silane and employing a numerical algorithm to dynamically create crosslinks at the ends of the PDMS chains. Simulations show that nanoparticle volume fraction plays a primary role on the diffusion coefficient and that the interface between the PDMS and the metallic inclusions can influence the behavior of the diffusing species.

Neutron and X-Ray Studies of Advanced Materials V: Centennial: Dislocations, Strains, Deformation I

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Chemistry and Physics of Materials Committee

Program Organizers: Rozaliya Barabash, Oak Ridge National Laboratory; Xun-Li Wang, Oak Ridge National Laboratory; Gernot Kostorz, ETH Zurich; Lyle Levine, National Institute of Standards and Technology; Peter Liaw, Univ of Tennessee; Yandong Wang, Beijing Institute of Technology; Brent Fultz, California Institute of Technology

In-Situ Laue Diffraction during Mechanical Testing: *Helena Van Swygenhoven*[1]; Julien Zimmermann[1]; Cecile Marichal[1]; Steven Van Petegem[1]; [1]Paul Scherrer Institute

In-situ Laue diffraction during microcompression has been developed at the MicroXAS beamline of the Swiss Light Source. Diffraction patterns are obtained in transmission with a 4-24 keV Xray beam, FWHM of 0.5 -1 µm. Pillars with diameters up to a few microns can be deformed in-situ and Laue scans allow mapping of spatially distribution of strain gradients in the deformed pillars. The evolution of position and shape of the Laue reflections provides information on local crystallographic orientation and activated dislocation slip systems. Microcompression is a small testing device that is now widely used. The advantage of performing microcompression in-situ during Laue diffraction is demonstrated, emphasizing the boundary constraints of the test, the influence of sample shape and preparation on slip systems in single crystal fcc and bcc pillars. The first efforts towards the development of a computational bottom-up approach for the calculation of Laue patterns will be discussed.

2:25 PM Invited

Deformation Twinning in Mg Probed with Diffraction at Multiple Length Scales: *Donald Brown*[1]; Levente Balogh[1]; Bjorn Clausen[1]; Carlos Tome[1]; [1]Los Alamos National Lab

Diffraction is well suited to the study of microstructural evolution during plasticity. The length scale probed by diffraction is most strongly a function of the probe particle utilized. Electron diffraction provides information on a very short length scale, but also penetrates only a short distance into materials. Neutrons penetrate into the depth of most materials, providing a statistical sampling of the bulk of the material. The advent of high energy synchrotron x-ray diffraction over the last decade has bridged the gap between these two extremes. As part of a larger program to understand and model the deformation of hexagonal metals, we have utilized each of these probe particles to characterize deformation microstructures as the length scale has dictated. This talk will describe how the results obtained with distinct diffraction probes with length scales from sub-micron to cm's have been integrated to direct development of plasticity models in hexagonal metals.

2:45 PM Invited

Structure/Microstructure Analysis of Faulted and Modular Materials from Powder Diffraction Data: Beyond the Deterministic Approach: *Matteo Leoni*[1]; [1]University of Trento

Lattice parameters, asymmetric unit, symmetry elements and modulation vectors are usually employed for the description of a crystalline material. However, not always such information is sufficient to reconstruct the X-ray powder diffraction pattern (XRPD) of a real specimen, even if instrument and specimen-related broadening effects are properly taken into account. Odd profile shapes, deeply anisotropic broadening, extra features can in fact be present e.g. as the result of local breaking of the 3D periodicity of the lattice. The modular approach should be invoked in this case to move from a deterministic (regular) to a probabilistic (quasi-regular or irregular) description of the material. When single crystals are available, diffuse scattering and the Reverse Monte-Carlo approach are the ideal tools to analyse the extra intensity appearing in between Bragg peaks. It will be here shown how faulted structures and modular systems built with 2D symmetric modules can be analysed from XRPD data.

3:05 PM

Scientific Opportunities at the High Flux Isotope Reactor Neutron Powder Diffractometer: *Ovidiu Garlea*[1]; [1]Oak Ridge National Laboratory

The neutron powder diffractometer HB2a at the High Flux Isotope Reactor was designed to achieve an optimum balance between high neutron flux and high resolution. It is equipped with a vertically focused Ge monochromator that provides one of three wavelengths: 2.41A, 1.54A, and 1.12A. Due to its versatility, the instrument can be employed for a large variety of experiments, but it is particularly adapted for determining structures with large interplanar spacing, as well as complex magnetic structures. Furthermore, studies of phase transitions, thermal expansion, quantitative analysis, and ab-initio structure solution from powder data can be undertaken. A full range of ancillary environments can be used to provide a complete control of thermodynamic variables, which are essential to unravel the complex relationship between structure and materials properties. This presentation will give an overview of the HB2a diffractometer focusing on recent parametric diffraction studies on several new materials.

3:20 PM

Characterization of Superelasticity in a New Fe-Based Shape Memory Alloy Using Neutron and Synchrotron Radiation: *Saurabh Kabra*[1]; Klaus-Dieter Liss[1]; Kun Yan[1]; David Carr[1]; Yuuki Tanaka[2]; Toshihiro Omori[2]; Ryosuke Kainuma[2]; [1]ANSTO; [2]Tohoku University

A novel Fe-based shape memory alloy was recently discovered by Tanaka et. al. [1]. This material has shown one of the highest recoverable superelastic strains ever reported. In addition, it shows a very high strength of ~1.0 GPa and very large damping capacity. In this study, we have characterized both the parent austenite and the reversible martensite phase responsible for the superelasticity. The texture of the parent material was characterized using neutron diffraction while in situ tension experiments were conducted in a synchrotron, high energy x-ray beam to characterize the crystallography of the martensite phase and to quantify the amount of martensite phase. Furthermore, processing of these alloys was investigated by rolling the polycrystalline samples to varying amounts and measuring diffraction patterns at several orientations. [1] Y. Tanaka, Y. Himuro, R. Kainuma, Y. Sutou, T. Omori, and K. Ishida. Ferrous Polycrystalline Shape-Memory Alloy Showing Huge Superelasticity. Science 327, 1488 (2010)

Line Profile Analysis of Plastically Deformed Single Crystals: *Andras Borbely*[1]; [1]Ecole des Mines de Saint-Etienne

X-ray line profile analysis (XLPA) is an inverse method for quantitative microstructure determination. As all methods of this type it requires microstructural input obtained with imaging or other techniques. We present the momentum method of XLPA based on the asymptotic behavior of different order restricted moments of the intensity distribution, for which the extra required information is supplied by mathematics. The particularity of the method is related to the very simple analytical form of the moments when small crystallite size and dislocations are sources of line broadening. We apply the method to plastically deformed Cu and Al single crystals. The microstructure is evaluated not only in terms of usual parameters like: coherent domain size, average dislocation density and dislocation arrangement parameter, but also in terms of second order quantities like dislocation density fluctuation and dislocation polarization, pointing beyond the popular Wilkens approximation.

Structural Study of Textured Nanocrystalline ZnO Thin Films Prepared by Pulsed Laser Deposition: *Radomir Kuzel*[1]; Jakub Cizek[1]; Michal Novotny[1]; [1]Charles University in Prague, Faculty of Mathematics and Physics

Thin nanocrystalline ZnO films of thickness 40-80 nm were grown on sapphire (0001), MgO (100) and fused silica (FS) substrates. A combination of different XRD scans on the Eulerian cradle was required for revealing of main structural features. The film deposited on FS showed fiber texture but ZnO film grown on MgO was highly textured and exhibited local epitaxy in a form of domains with two different orientations. Surprisingly, 40nm thick film on sapphire didn't show expected (000l) texture but more complicated orientation of several domains epitaxially grown on the substrate. Extremely high compressive in-plane stress in the film on MgO was detected by mapping of diffraction spots. The films on sapphire and FS were stress-free and in tensile stress, respectively. Crystallite size and microstrain were estimated from the Williamson-Hall plots constructed for different asymmetric reflections. Positron annihilation revealed high density of open-volume defects in films on MgO and sapphire.

Residual Strain Tensor Determination from the Refinement of Multiple Diffraction Patterns: *Davor Balzar*[1]; Nicolae Popa[2]; Sven Vogel[3]; Donald Brown[3]; [1]University of Denver; [2]National Institute for Materials Physics; [3]Los Alamos National Laboratory

The determination of residual strain/stress and texture is a common but still challenging problem. One of the newer approaches is expanding strain and stress tensor components in series of spherical harmonics, which allows for accurate determination of strain and stress for arbitrary crystal and sample symmetries without making Voigt or Reuss approximations. The method yields the texture-weighted strain orientation distribution function (WSODF) and average strain and stress tensors that are usually of engineering interest. This approach requires the measurements of interplanar spacing of the several Bragg reflections or Rietveld refinement of the diffraction patterns at multiple sample orientations. Thus, energy-dispersive measurements and multiple detectors are very useful. We will present new results of the neutron time-of-flight (TOF) measurements carried out at the LANSCE SMARTS station on several samples.

Utilizing In-Situ Neutron Diffraction for Mesoscale Simulation of Recrystallization Texture in Polycrystalline Aluminum: *Bala Radhakrishnan*[1]; Sarma Gorti[1]; Grigoreta Stoica[1]; Alexandru Stoica[1]; Govindarajan Muralidharan[1]; Muth Thomas[1]; Xun-Li Wang[1]; [1]Oak Ridge National Laboratory

Direct modeling of nucleation during recrystallization is difficult because of our inability to capture the details of the complex deformation substructure and their rearrangement. Currently available nucleation models are largely empirically based. We illustrate an approach to model nucleation based on in-situ neutron diffraction to monitor the peak profile changes associated with recovery. Neutron diffraction data are obtained for straight rolled as well as cross-rolled Al-Mg alloy with or without an externally applied stress during annealing. The nucleation model is used in a mesoscale simulation of recrystallization of deformed microstructures calculated by a crystal plasticity based model in order to predict the dependence of the deformation path and the external stress on the recrystallization texture development in the alloy. Research sponsored by the Laboratory Directed Research and Development Program of Oak Ridge National Laboratory (ORNL), managed by UT-Battelle, LLC for the U. S. Department of Energy under Contract No. De-AC05-00OR22725.

Application of In-Situ Neutron and X-Ray Measurements at High Temperatures in the Development of Co-Re-Based Alloys for GasTurbines: *Debashis Mukherji*[1]; Juri Wehrs[1]; Joachim Rösler[1]; Pavel Strunz[2]; Ralph Gilles[3]; Michael Hofmann[3]; Markus Hölzel[3]; Helmut Eckerlebe[4]; [1]Technische Universitaet Braunschweig; [2]Nuclear Physics Institute ASCR; [3]Technische Universität München; [4]Helmholtz-Zentrum Geesthacht

There is a primary need to develop new alloys with very high melting point for future gas turbines. Presently, Ni-based superalloys are extensively used in the hot section of turbines but they are now reaching limits posed by their melting temperatures. High melting Co-Re-Cr based alloys introduced by the TU Braunschweig in 2007 [1] show promise as a new material class for high temperature application. In the Co-Re alloy development two main concepts of strengthening, namely precipitation hardening with MC carbides and composite hardening by Cr_2Re_3-type σ phase are explored separately. In-situ measurements at high temperatures by synchrotron and neutron scattering are used to study high temperature phase evolution and transformation. These new tools are providing vital information and guiding the alloy development. Selected results of microstructural characterizations by neutron and X-ray measurements are presented here. 5:25 PM

Evolution of Residual Strains in Nanocrystalline Metals Studied by Diffraction: *Steven Van Petegem*[1]; Lin Li[2]; Julien Zimmermann[1]; Peter M. Anderson[2]; Helena Van Swygenhoven[1]; [1]Paul Scherrer Institute; [2]The Ohio State University

For nanocrystalline f.c.c. metals the evolution of lattice strain as a function of applied stress is highly debated. In literature various trends are reported, which are seemingly inconsistent. However, the results are all different from what is expected for the coarse-grained counterparts. This often led to the conclusion that at the nanoscale intragranular slip is suppressed and grain boundary sliding mechanisms are responsible for the observed mechanical properties. In this work we present recent results obtained from in-situ mechanical testing during x-ray diffraction of several nanocrystalline metals. In particular we focus on electrodeposited Ni, Ni-20%Fe and Ni-50%Fe. The results are discussed in view of insights obtained from molecular dynamics and quantized crystal plasticity simulations. It is found that, due to the specific nature of plasticity mechanisms at the nanoscale, intragranular slip does not exhibit the same diffraction footprints compared to those observed at the microscale.

5:40 PM

Through-Thickness Distribution of Residual Stresses in One-Pass and Multi-Pass 70-mm Thick Welds: *Wanchuck Woo*[1]; Vyacheslav EM[1]; Ji Hyun Yoon[1]; Jeong-Ung Park[2]; Gyu-Baek An[3]; [1]KAERI (Korea Atomic Energy Research Institute); [2] Chosun University; [3]POSCO Steel

Two extra thick welds were prepared with the dimension of 300-mm wide, 230-mm long and 70-mm thick ferritic steel plates. One was joined using 1-pass electro-gas welding and the other was 60-pass flux-cored arc welding methods. Residual stresses were determined through the thickness of each plate along the weld centerline, heat-affected zone, and base material using neutron diffraction. Such a deep penetration capability was achieved by using the 211 and 110 reflections with the wavelengths of 1.55 and 2.39 Å, respectively. The wavelengths are located near the minimum total cross sections but off the Bragg edges. The gauge volumes were 4x4x8 mm^3 (longitudinal) and 4x4x20 mm^3 (transverse/normal), and 'stress-free' do were also considered. Significant amounts of tensile longitudinal stresses were developed along the heat-affected zone of the one-pass weld, while those were observed along the weld centerline of the multi-pass weld approaching the yielding strength (570 MPa).

5:55 PM
Strain-Induced Dimensionality Crossover in the Modulated Structure of Ferromagnetic Shape Memory Alloy Ni_2MnGa: *Zhihua Nie*[1]; Yandong Wang[1]; Yang Ren[2]; Dongmei Liu[3]; Zhenwei Huang[3]; [1]Beijing Institute of Technology; [2]Argonne National Laboratory; [3]Northeastern University

Structural modulations have been observed in a large variety of materials, including superconductors, ferroelectrics, and shape memory alloys, and their underlying physics is still not clear. A strain-induced dimensionality crossover of atomic modulation has been studied in a Ni_2MnGa single crystal by high-energy X-ray diffraction technique, showing that the 3D modulated structure of pre-martensite first transform to a 2D modulated phase before finally convert to the martensite with a quasi-1D modulation. First-principles electronic calculations show that the electronic states of the pre-martensitic phase have been significantly altered by the uniaxial stress field, showing an enhanced nesting feature of a single band before the martensite appears. The observation of the stress-induced dimensionality crossover of atomic modulation has broad impacts in understanding not only the mechanical properties of advanced shape memory alloys, but also the physical properties of condensed matter with heterogeneous structures.

Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Alternative Interconnects and Harsh Environmental Influences

Aligned Nanowires for Packaging and Circuit Interconnects: *Sungho Jin*[1]; [1]UC San Diego

Conductive nanowires offer interesting possibilities for new approaches of circuit interconnection and electronic packaging. Vertically aligned carbon nanotubes as well as metallic or conductive oxide nanowires can be considered for such interconnect applications. Control of the nanowire structure and geometry is essential for their successful electronic packaging applications including advanced solder connections, solderless connections, or thermal interfacing. In this talk, novel fabrication approaches to create vertically aligned nanowire configurations will be discussed, some of which exhibit solderability, enhanced electronic transport characteristics, and improved thermal conduction. Well controlled and processed vertically aligned semiconductor nanowire arrays can also be useful for solar cells and vertical nanotransistor arrays. Planarization of such periodically-arranged nanowire structures will be discussed in relation to circuit interconnection and construction of three-dimensional multilayer device configurations.

2:25 PM
Compliant Structures as Off-Chip Interconnects: *Suresh Sitaraman*[1]; [1]Georgia Institute of Technology

The high coefficient of thermal expansion (CTE) mismatch between an organic substrate and a silicon die creates thermo-mechanical stresses in flip-chip assemblies. These thermo-mechanical stresses could crack or delaminate on-chip low-k dielectric material and also result in early fatigue failure of off-chip interconnects. Epoxy-based underfill materials, although helpful for solder bump reliability, create additional die stresses and pose processing challenges for fine-pitch assemblies. To address these challenges, compliant structures can be used as off-chip interconnects that will decouple the die from the substrate, and thus, can reduce the thermo-mechanical stresses. In this presentation, we will discuss the status of several off-chip compliant interconnect technologies that are being pursued in academia and industry. The topics will include, but not limited to, electrical and thermo-mechanical performance of compliant interconnects, cost-effective wafer-scale fabrication process, uniformity in interconnect geometry, ease of assembly, operational reliability, scalability, and integration into existing infrastructure.

2:50 PM
Mechanical Stress Measurements in Cu Through-Silicon Via (TSV) Using Synchrotron X-Ray Microdiffraction for 3-D Integration: *Arief Budiman*[1]; H-A.-S. Shin[2]; B.-J. Kim[2]; S.-H. Hwang[2]; H.-Y. Son[3]; M.-S. Suh[3]; Q.-H. Chung[3]; K.-Y. Byun[3]; Y.-C. Joo[2]; R. Caramto[4]; L. Smith[4]; M. Kunz[5]; N. Tamura[5]; [1]Los Alamos National Laboratory (LANL); [2]Seoul National University (SNU); [3]Hynix, Inc.; [4]SEMATECH; [5]Advanced Light Source (ALS), Berkeley Lab

One key to enable the successful implementation of 3-D interconnects using Through-Silicon Via (TSV) is the control of the mechanical stresses. The synchrotron-sourced X-ray microdiffraction technique has been recognized to allow some important advantages compared to other techniques, namely stress measurement of individual Cu TSV as well as the silicon substrate surrounding it simultaneously at the submicron resolution, stress measurement in situ during annealing and while Cu TSV is still buried under the silicon substrate (mimicking the conditions of real device). Using this approach, we have studied Cu TSV samples from Hynix, Inc. as well as from SEMATECH and found interesting differences in the stress states of the Cu TSV. We studied the stress evolution throughout its thermal history, and proposed an explanation of the observed differences. This understanding could lead to improved stress control in Cu TSV as well as to reduce the impact to the silicon electron mobility.

3:10 PM
Conductive Anodic Filament Formation in Fine Pitch Halogen-Free Organic Substrates: *Koushik Ramachandran*[1]; Fuhan Liu[1]; Nitesh Kumbhat[1]; Raj Pulugurtha[1]; Venky Sundaram[1]; Rao Tummala[1]; [1]Georgia Institute of Technology

This study is aimed at investigating Conductive Anodic Filament (CAF) formation in laser-drilled through-vias at pitch sizes (< 200 \956m) in halogen-free glass reinforced package substrates. The need for high I/O density in 3D IC packages and multi-functional packages is driving the continuous reduction in through-via diameters and pitches. This fine-pitch requirement can potentially lead to reliability failures due to CAF that involves electrochemical migration of copper; this type of failure has been previously reported in brominated epoxy-glass composites (FR4) in printed wiring boards. However CAF reliability in "green" package substrates that incorporate halogen-free flame retardants such as inorganic fillers and phosphorus-based compounds has not yet been thoroughly investigated. In this study, accelerated testing method was used to investigate CAF formation in newly developed halogen-free package substrates. The test coupons were characterized using SEM and EDX to determine the nature and chemical composition of CAF in these advanced substrates.

3:30 PM

Investigations of Interfacial Features in Thick Al Wire Bonds: *Golta Khatibi*[1]; Brigitte Weiss[1]; Johannes Bernardi[2]; [1]University of Vienna; [2]Vienna University of Technology

This investigation includes detailed microstructural characterization of ultrasonic thick Al wire bonds as used in power semiconductor devices. The objective of the study is to understand the relationship between the bonding quality and microstructure of Al wire bonds. SEM-EBSD techniques are employed to characterize the size, distribution and orientation of the grains in the bonded region and to investigate the global substructure of the grains of the deformed Al wire bonds. TEM investigations highlight the microstructural features of the interface between the wire and metallization layer. The bonding interface shows an inhomogeneous structure consisting of highly deformed grains with dislocation cell structures, nanostructured grains, voids, amorphous particles and oxides. These results indicate that the reliability of the wire bonds is not affected by the strong inhomogeneity of the interface so far a sufficient bonded area has been formed.

3:50 PM

Effects of Combined Harsh Conditions on Wire Bond Reliability: *Maria Mirgkizoudi*[1]; Changqing Liu[1]; Paul Conway[1]; Steve Riches[2]; [1]Loughborough University; [2]GE Aviation Systems - Newmarket

The work focuses on the failure modes identification for wire-bonds under the combined conditions of thermal and vibration loadings. 48-pin DIL HTCC packages with Au/Ni plated surfaces were wire-bonded using Au and Al wires. Pull tests have been performed to evaluate the interfacial bonding strength and bonding adhesion of the wire-bonds. Electrical characterization has also been performed. The test packages have been subjected to sinusoidal and random vibration tests with the frequency ranging from 10Hz to 2000Hz, while keeping the temperature stable at 250°C. The analysis focused on the mechanical behaviour of the wires and microstructural characterization of the wire-bonds. Particularly, optical microscopy and SEM analysis have been performed to determine the mechanical deformation of the wires and, thermal and high speed cameras have been employed as well as laser interferometry for in-situ analysis. The results have contributed to further improve our understanding on interconnect failure under combined extreme loadings.

4:10 PM

Advances in Pressure-Less Sintering for High Temperature Electronic Applications: *Jiong (Jenny) England*[1]; Srinivas Chada[1]; Richard Kuder[1]; Julissa Eckenrode[1]; Javier Gutierrez[1]; Paul Gleeson[1]; [1]Henkel

During the past decade green initiatives have spearheaded implementation of lead-free solutions and recycling efforts in electronics packaging and interconnect industry. Although several lead-free alloys have successfully implemented for second level interconnects, there still is a need for a robust solution at first level. The current paper presents a lead-free first level interconnect material based on principle of low-temperature pressure-less silver sintering technology. This novel formulation enables achieving low bond-line porosity comparable to pressure-assisted sintering process. Also, compared to most pressure-less nano-silver technologies, the use of micro-scaled silver particles in this formulation offers a competitive balance among cost, performance, and processing capability. The proposed silver sintering paste can be sintered at a temperature as low as 200°C in a standard box oven without need for any specialized capital intensive equipment. Thermal and electrical properties as well as reliability tests that detail process-property-microstructure relationships will be explored in this paper.

4:35 PM Invited

Novel Sinter Paste Concept - A Lead Free Die Attach Alternative: Wolfgang Schmitt[1]; Thomas Krebs[1]; *Yvonne Loewer*[2]; [1]W.C. Heraeus; [2]Heraeus Materials Singapore Pte Ltd

Especially power electronic packaging industry has a need for new lead free interface materials which do not re-melt at the 2nd level packaging. In ideal case these materials can be processed at temperatures below 260°C. Additionally they have to provide highest reliability beside perfect thermal and electrical conductivity. Silver sinter materials do provide most properties mentioned before. But commercial available Silver Sinter Materials do have the need for very special processes or they are based on nano silver, which is expensive and problematic in handling. Heraeus has developed a novel concept for silver sinter pastes. The new concept uses micro scale silver particles combined with sinter additives. The novel pastes can be used in pressure free or low pressure bonding processes. Physical properties like shear strength at 260°C, electrical and thermal conductivity are outstanding. The paper describes the material properties and results in reliability testing.

5:00 PM

Effect of Solder Properties on Microstructural and Damage Evolution in Au-Sn Solder Joints: *Govindarajan Muralidharan*[1]; Kanth Kurumaddali[1]; Andrew Kercher[1]; Scott Leslie[2]; [1]Oak Ridge National Laboratory; [2]Powerex Inc

There is a significant need for next-generation, high-performance power electronic packages and systems with wide band gap devices that operate at high temperatures in automotive and electric grid applications. Au-Sn solder is a candidate for use in such packages with potential operating temperatures up to 200oC and higher. The results of a study on the damage evolution occurring in large area Au-Sn solder joints between silicon carbide dies and Direct Bonded Copper (DBC) substrates subject to thermal cycling between 200°C and 5°C is presented in this paper. Differences in the damage accumulation as a function of thermal cycling characterized using high resolution x-ray radiography in Au-Sn solder will be compared to that in Sn-3.5Ag solder. Effect of geometry and solder properties on observed damage will be presented. *Work sponsored by the U.S. Department of Energy, Office of Electricity Delivery and Energy Reliability.

5:20 PM

Microstructure and Sn Crystal Orientation Evolution in Sn-3.5Ag Lead-Free Solders in High Temperature Packaging Applications: *Bite Zhou*[1]; Govindarajan Muralidharan[2]; Kanth Kurumadalli[2]; Andrew Kercher[2]; Chad Parish[2]; Scott Leslie[3]; Thomas Bieler[1]; [1]Michigan State University; [2]Oak Ridge National Laboratory; [3]Powerex Inc

Understanding the reliability of Sn-3.5Ag and other lead-free solders in high temperature packaging applications is of significant interest in power electronics for electric vehicles, and the next generation electric grid. Large area (2mm×2mm) Sn-3.5Ag solder joints between silicon dies and direct bonded copper (DBC) substrates were thermally cycled between 5°C and 200°C. Initial microstructure including Sn crystal orientations, and its evolution due to thermal cycling were characterized using scanning electron microscopy (SEM) and electron backscatter diffraction (EBSD). Effects of the geometry of the solder joint, and stresses induced by differential thermal expansion on the evolution of microstructure and texture following thermal cycling will be discussed. Influence of the microstructural evolution on reliability of the solder joint will be evaluated. Work sponsored by the U.S. Department of Energy, Office of Electricity Delivery, and by the SHaRE User Facility supported by the Scientific User Facilities Division of the Office of Science.

5:40 PM

Comparison of Thermal Measurement Methodologies Used in Electronics Industry: *Dan Maslyk*[1]; Srinivas Chada[1]; Scott Allen[1]; Julissa Eckenrode[1]; [1]Henkel

The constant push for smaller and smaller footprints with faster and larger computing power has put thermal management into the forefront. Thermal management is fast becoming a necessity, requirement, and an integral factor needed to achieve the desired electrical performance and reliability. It is not uncommon for many an application engineer to use a material reported to have "good" thermal values, only to be disappointed by the poor performance during application at device level. This obvious gap between design and application values of many commercially available thermal materials can be attributed to the methods used in the gathering of data. Thus, it is imperative to understand the different methods used to gather thermal properties as well as the pertinent details that the data represents. In this paper we will compare and contrast the most popular measurement methods used in the electronic industry to evaluate thermal materials.

Phase Stability, Phase Transformations, and Reactive Phase Formation in Electronic Materials XI: General Issues in Microelectronics

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Alloy Phases Committee

Synthesis and Characterization of Low Temperature Sn-Cu and Sn Nanoparticles for the Fabrication of Highly Conductive Ink: Yun Hwan Jo[1]; Inyu Jung[1]; *Hyuck Mo Lee*[1]; [1]KAIST

A various size of Sn–Cu nanoparticles were synthesized by using a modified polyol process for low temperature electronic devices. Monodispersive Sn-Cu nanoparticles with diameters of 21 nm, 18 nm and 14 nm were synthesized. The eutectic composition shift was also observed in nano-sized particles as compared with bulk alloys. By controlling the size and eutectic composition, a significant melting temperature depression of 30.3C was achieved. These approaches will reduce adverse thermal effects in electronic devices. Additionally, we synthesized a gram scale of uniformly sized Sn nanoparticles and observed a significant size-dependent melting temperature depression. To improve the electrical property, we applied the surface treatments of hydrogen reduction and plasma ashing. The two treatments had the effect of diminishing the sheet resistance. In addition, conductive patterns (1 cm x 1 cm) were successfully drawn on the Si wafer using an inkjet printing instrument with conductive Sn ink.

2:20 PM Invited

Electrochemical Study on the Silica Particles Dispersed Permalloy Composite Coating: So-Yeon Park[1]; Myung-Won Chung[1]; *Jae-Ho Lee*[1]; [1]Hongik University

The composite electroplating is accomplished by adding inert materials during the electroplating. The surface wear resistance of a permalloy can be enhanced by incorporation of silica nanoparticles in its electroplated layer. In this study, the permalloy composite coating was obtained by electroplating. The dispersion of silica nanoparticles in the permalloy electroplated layer was reported with variation of current density, additives, sonication time, rotating speed and bath conditions. At high current density(40mA/cm2), the surface of coating has many cracks during electrodeposition. Additives change the surface morphologies of the electroplated layer as well as the silica nanopowder contents. In alkaline bath, smooth surface morphology and relatively high contents of silica nanopowder codeposition were obtained with addition of sodium lauryl sulfate. From zeta potential analysis, silica nanopowder has a negatively charged surface in an alkaline bath. Using a horn type sonicator promoted excellent silica dispersion in permalloy coating.

2:40 PM

Thermodynamic Stability and Diffusion Barrier Properties of Amorphous Ta-Rh Alloys for Cu Metallization: *Neda Dalili*[1]; Qi Liu[1]; Douglas Ivey[1]; [1]University of Alberta

Implementation of copper as interconnect/metal lines in electronic devices has created the problem of Cu reaction with and/or diffusion in Si/SiO2. Application of a barrier layer between the active region and Cu layer is, therefore, crucial. Refractory metal-transition metal alloys are a promising group of materials, as they offer a combination of good conductivity and high thermal stability together with high glass-forming ability. Thermodynamic calculations for possible supersaturated solid solutions and glassy phases were performed to find the glass-forming composition of the Ta-Rh binary system. Various compositions of the alloy were deposited by co-sputtering and the model was confirmed by structural characterization using XRD, TEM and XPS analysis. Thin layers of Ta-rich, Ta-Rh glassy alloys were then deposited on Si substrates followed by deposition of Cu. Barrier performance was studied after annealing in N2/H2 gas by employing resistivity measurements, XRD analysis, elemental depth profiling and electron microscopy.

2:55 PM

Application of High-Performance, Advanced Barrierless Cu Alloy Film in Cu Metallization: *Chon-Hsin Lin*[1]; [1]Asia-Pacific Institute of Creativity/Environmental Engineering

We developed a high-performance Cu alloy film for using it as an advanced barrierless interconnect. Cu diffuses rapidly into the Si layer and deteriorates device properties. Therefore, a diffusion barrier must be inserted between Cu and Si to prevent device failure. However, the challenge lies in reducing the size of these barriers, which make device miniaturization difficult. Herein, we propose a novel alloy-seeding technique for barrier-free Cu metallization. The Cu seed layer, which acts as a barrier to Cu/Si interdiffusion, was alloyed with small amounts of insoluble substances, e.g., VN, SnN, and HoN. The seed layer was characterized using X-ray diffraction, focused ion beam microscopy, secondary-ion mass spectroscopy, and transmission electron microscopy, and by film resistivity and current-voltage measurements. We assessed the reliability of the seed layer in copper interconnects by studying the time-dependent dielectric breakdown of MOS structures. The results show that the Cu film has enhanced thermal stability.

3:10 PM

Effects of Levelers on Copper Electroplating in Patterned Substrate: Myung-Won Jung[1]; In-Seok Kang[1]; Ki-Tae Kim[1]; *Jae-Ho Lee*[1]; [1]Hongik University

In recent days, the wire width of IC was narrowed and the degree of integration of IC was increased to obtain the higher capacity of the devices in semiconductor industry. However, the defects such as scratch or dent on FCCL(Flexible Copper Clad Laminate) and void in via filling process cause low reliability of the products. In this study, the behaviors of additives especially levelers in electroplating were investigated since the leveling action is very important to improve the properties of electrodeposits. The defectless and flat copper surface was obtained after optimizing concentrations of all additives such as accelerator, suppressor and leveler. The behaviors of five levelers in copper electroplating were investigated. Prior to copper electroplating on patterned substrate, the nucleation and growth behavior of copper with variation of additives were also studied. The electrochemical methods such as polarization plots, galvanostatic and potentiostatic plots were employed to analyze copper deposits.

3:25 PM
The Electrical Characteristics and Interfacial Interaction of Ti/Ni/Ag/Au Multilayers under Thermal Cycling Test: *Fu-Jung Yeh*[1]; Tsung-Chieh Chiu[1]; Kwang-Lung Lin[1]; [1]National Cheng Kung University

The Ti/Ni/Ag/Au multilayers combination was chosen for the metallization of AlN submount of flip chip high power LED. The interfacial interactions and electrical characteristics of the Ti/Ni/Ag/Au multilayers, under various periods of thermal cycling between -40°C and 125°C, were investigated by depositing on Si substrates. The electrical properties of the multilayer thin films were determined by two-probe nano-electronics measurement. The electrical resistance of Ti/Ni/(Ag,Au) and Ni/(Ag,Au) multilayer was founded to be 9MO and 8.5MO respectively, which shows that the Ni/(Ag,Au) determines the overall resistance of the multilayer combination. The results of XPS depth profile analysis indicate that Ag atoms diffused passing through the pure Au layer to the surface after thermal cycling. The outward diffusion of Ag atoms expands the mixed region of Ni, Ag and Au, resulting in higher resistance of the Ni/(Ag,Au) layer.

3:50 PM Invited
New Solution Method for SiC Crystal Growth: *Shigeto Nishitani*[1]; Yosuke Yamamoto[1]; Tadaaki Kaneko[1]; [1]Kwansei Gakuin University

Professor W. Shockley, a Nobel prize winner and the 'father' of the transistor, predicted in the 1950s that SiC would soon replace Si in devices because of its superior material properties. His prediction, however, has not yet come true because of the high cost of manufacturing SiC wafers. Very recently, the present authors reported a novel process for fabricating epitaxial SiC. This process has the potential to cost less and to provide SiC wafers with high crystalline quality. Here we present a new synthesis process for manufacturing SiC. In this process, the driving force for crystal growth is elucidated by considering a similarity -- the coexistence of the stable and metastable phases -- with the diamond synthesis process reported by Bonenkirk et al. of General Electric.

4:10 PM Invited
Method of Selective Electroplating having Strong Adhesion and Exceptional Uniformity by Nanoparticle Immobilization: *Shien Ping Feng*[1]; Bo Yu[2]; Shuo Chen[2]; Zhifeng Ren[2]; Gang Chen[3]; [1]The University of Hong Kong; [2]Boston College; [3]Massachusetts Institute of Technology

This research relates to a new method of selectively electroplating an electrically conducting material onto a substrate having strong adhesion and exceptional uniformity, with particular emphasis on transparent conductive oxide (TCO) substrates. A thin nanoparticle layer is initially deposited onto a TCO substrate by wet process. Cyclic voltammetry was used to define an optimum voltage range of selectively electroplating various metals on TCO with and without nanoparticles. AFM, SEM and puff-off test were used to evaluate surface topography and adhesion. Nanosphere lithography which is one of the cheap lithography methods was chosen to define a submicron pattern. A desired metal is then selectively electroplated onto the predetermined nanoparticle area by operating within an optimum voltage range during the exposure process of TCO substrate to an electrolytic solution.

4:30 PM
A Study on the Formation Mechanism of Ytterbium Germanide for Schottky Contact Applications: *Sekwon Na*[1]; Byunghoon Lee[1]; Hwayoul Choi[1]; Haseok Jeon[1]; Juyun Choi[1]; Yujin Seo[2]; Hyoungsub Kim[1]; Seok-Hee Lee[2]; Hoo-Jeong Lee[1]; [1]Sungkyunkwan university; [2]Korea Advanced Institute of Science and Technology

As the conventional method of improving the device performance of CMOSFETs by scaling-down the device size faces limitations, Ge-based FETs have gained attention. The development of Ge-based FETs requires challenging research endeavor in several fronts. Among them, a scheme to form a contact with low source/drain series/contact resistances is a critical issue. Here, we explored the possibility of using ytterbium germanide as a contact material. The ytterbium films were annealed for formation of germanide using RTA. Combination of HRTEM and EDS helped us to unravel several interesting aspects of the germanidation process. Interdiffusion between Ge and Yb was extensive even at low temperatures and led to the formation of an amorphous layer, followed by the nucleation of crystalline YbGe2-x. Upon annealing at a higher temperature, the germanide layer grew thicker as a flat layer of a uniform thickness with epitaxial relation with the underlying Ge lattice.

4:45 PM
Electrochemical Behavior of CIGS Electrodeposition for the Application of Photovoltaic Cell: *Hyunju Lee*[1]; Jae-Ho Lee[2]; Yangdo Kim[1]; [1]Pusan National University; [2]Hongik University

Cu(In1-xGax)Se2 (CIGS) have become attractive candidates for economic polycrystalline solar cells, due to their high absorptivity (>105cm-1) and stability against photo-degradation. In this study the electrochemical behavior of CIGS electrodepositions were investigated and the electrochemical conditions to prepare stoichiometric CIGS thin films were suggested. In acidic solutions containing Cu2+, In3+, Ga3+ and Se4+ ions, the CIGS films of different Cu/In/Ga/Se chemical compositions were electrodeposited on Mo/Glass substrate. The films were analyzed by XRD, SEM, and EDS. The results show that annealed films have pure CIGS phase with good crystallization and the morphology of the films are very uniform and dense.

5:00 PM
Intermetallic Compound Formation and Morphology Evolution in the Bi-xSn Solder Joint with Cu Substrate: *JinYi Wang*[1]; Chih-Ming Chen[1]; [1]National Chung Hsing University

Although lead (Pb)-free solders have been widely used in the electronic packaging industries, high-Pb solders are still used in some specific applications because high temperature Pb-free solders are still under investigation. In this study, high-Bi solders (Bi–10Sn, Bi–5Sn, and Bi–2Sn, in wt.%) were prepared as the high temperature Pb-free solders. The reactions between high-Bi solders and Cu substrate were investigated. The different composition of Sn in high-Bi solders influences the intermetallic compound formation at the interface during the soldering reaction. With increasing the reflow time, massive spalling of Cu-Sn intermetallic compounds between high-Bi solder and Cu substrates was also observed.

5:15 PM
Study of EM-Induced ENEPIG Bond-Pad Consumption at Sn(Cu)/ENEPIG Joint Interface: *Shih Han Wu*[1]; Cheng Yi Liu[1]; [1]National Central University

In this study, we investigated the EM effect on the joint interfaces of the Pb-free Sn(Cu) solder/ENEPIG solder joints at different annealing temperatures. The applied current density is 104 A/cm2. The compositions of Sn(Cu) solders joined with ENEPIG pad are SnxCu (x=0.2,0.7,1). According to the preliminary result, a serious EM-induced Ni(P) consumption. With increasing of the Cu content in the Sn(Cu) solders, the resistance to the EM-induced Ni(P) consumption wound be enhanced. In other words, the more Cu content in the Sn(Cu) solders, the less consumption of the ENEPIG pad. Also , we study the EM effect on the ENIG bond-pads joined with the same Sn(Cu) solder bumps at the same EM conditions. We found that, as compared to the previous Sn(Cu) ENEPIG results, the degree of the Ni(P) consumption is much serious and it also depends on the Cu content in the Sn(Cu) solder bumps.

Phase Transformations and Deformation in Magnesium Alloys: Deformation Twinning and Texture

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS/ASM: Phase Transformations Committee
Program Organizers: Jian-Feng Nie, Monash University; Sean Agnew, University of Virginia; Suveen Mathaudhu, Army Research Office

Generalized Approach for Analyzing Strengthening Effects of Twins in Polycrystalline Metals and Alloys: *Subhash Mahajan*[1]; [1]University of California

When a polycrystalline material deforms simultaneously by slip and twinning, stress concentrations can develop when a twin terminates within a crystal and during slip-twin, twin-twin, and twin-grain boundary interactions. We have developed a generalized approach to understand the relaxation of these stresses. We will present its salient features, and the supporting experimental observations from BCC, FCC and HCP metals and alloys. We will argue that the presence of twins will always strengthen a solid and the magnitude of strengthening will depend on the number of coherent twin boundaries per unit volume; the higher the number, the greater the strengthening. The author is grateful to Professors J.P. Hirth and Ke Lu for fruitful discussions.

2:25 PM
Interaction between Dislocation and Tensile Twin in Magnesium Single Crystals: Ming Zhe Bian[1]; *Kwang Seon Shin*[1]; [1]Magnesium Technology Innovation Center, Seoul National University

The objective of this study is to identify the effects of the tensile twin on the slip and twinning behavior of magnesium single crystals with various orientations by using multi-step compression (MSC) tests. Single crystal specimens with loading directions between [0001] and [10-10] were prepared and compressed along the <11-20> direction to activate the tensile twins. Then these compressed specimens were then rotated 90 degrees and compressed along the loading direction to generate slip dislocations and twins. It was found that tensile twin boundaries acted as barriers to dislocation motion and increased the flow stress of all specimens. A transmission electron microscopy (TEM) study also showed stacking faults within the tensile twin bands. The interaction process of the slip dislocation with the twin boundary was systematically examined with TEM.

2:50 PM
Deformation Twinning in Nanocrystalline Mg-Alloys: *Suveen Mathaudhu*[1]; Baolong Zheng[2]; Khaled Youssef[3]; Marta Pozuelo[4]; Laszlo Kecskes[5]; Yizhang Zhou[2]; Wei Kao[4]; Sungho Kim[6]; Bin Li[6]; Xiaolei Wu[7]; Carl Koch[3]; Jenn-Ming Yang[4]; Enrique Lavernia[2]; Yuntian Zhu[3]; [1]U.S. Army Research Office; [2]University of California - Davis; [3]North Carolina State University; [4]University of California - Los Angeles; [5]U.S. Army Research Laboratory; [6]Mississippi State University; [7]Chinese Academy of Sciences

Contrary to what is observed in nanocrystalline face-centered cubic metals, nanocrystalline hexagonal close-packed (hcp) metals are rarely observed to deform by twinning, although twinning is a major deformation mechanism in their coarse-grained counterparts. Here we report the use of novel, high-energy powder processing and consolidation strategies which produce bulk nanostructured Mg-alloys that remarkably show evidence of deformation twinning. Experimental results, including HRTEM observations of activated deformation twinning systems, and computational molecular dynamics simulations will be used to illustrate the thermomechanical processing environments and deformation mechanisms by which twinning may be activated in nanocrystalline Mg-alloys. These results point to a promising approach for the design of nanocrystalline hcp alloys with superior strength and concurrent ductility.

3:15 PM Invited
A Physically Based Phenomenological Model for Deformation Twinning in Magnesium Alloys: *Matthew Barnett*[1]; [1]Deakin University

A partial differential equation is developed that captures the evolution of key characteristics of tensile twinning in magnesium base alloys. The objective is to provide a framework for ascertaining the effects of hardening – due to grain refinement, precipitation and dislocation substructure – on twin volume fraction, thickness and length. The model is developed with the help of observations made on alloy AZ31. It is shown that it is necessary to consider the nucleation of twins at locations where neighbouring twins impinge on the grain boundary. The model provides a reasonable approximation for the role of grain size on twinning. It predicts a period of low apparent work hardening following yielding and shows that this should be more extensive for finer grain sizes, in agreement with experiment. Finally, some predictions are made on the effect of changing the resistance to twinning.

3:40 PM Invited
Effect of Particle Shape and Habit on Twinning in Magnesium Alloys: *Joseph Robson*[1]; Nicole Stanford[2]; Matthew Barnett[2]; [1]University of Manchester; [2]Deakin University

Precipitates in magnesium alloys typically take the form of plates or rods aligned on well-defined crystallographic planes. Such precipitates are known to have highly anisotropic behavior with respect to slip inhibition. This paper demonstrates that the same is also true for twinning. In particular, it is shown that basal plates of the type formed in Mg-Al-Zn alloys are highly effective inhibitors of {10-12} twin growth, and this can be understood by the large back-stress induced if the material surrounding such precipitates twins. Whilst twin growth is suppressed in precipitate containing alloys, nucleation may be promoted. This phenomenon is attributed to the additional stress driving twinning when precipitates suppress slip. The differences in the anisotropy of the slip and twinning modes in magnesium due to particle shape and habit suggest mechanical asymmetry can be manipulated by controlling these parameters. Experimental evidence confirming these predictions is presented for two precipitate forming alloys.

Structure Evolution in AZ61L along a Fine-Grain Sheet Processing Path: Tracy Berman[1]; William Donlon[1]; Victoria Miller[1]; Jack Huang[2]; Ray Decker[2]; Wayne Jones[1]; *Tresa Pollock*[3]; [1]University of Michigan; [2]nanoMag; [3]University of California Santa Barbara

Mg alloys, with the lowest density among all structural metallics, have substantial promise for lightweighting of structural systems. A significant challenge remains in defining alloys and processing paths that give sufficient combinations of strength and ductility. Structure evolution in AZ61L has been studied at each stage of a process which consists of (a) Thixomolding to establish an initially fine-grained structure, (b) partial solutioning and sheet rolling at ˜0.5Tm and (c) post-deformation annealing. Average grain size is refined from 4.1 µm to as low as 2.6 µm following final annealing. EBSD studies indicate only a weak development of texture along the processing path, resulting in tensile elongations of up to 22%. The evolution of the ß phase and its role in the process will be discussed.

4:45 PM Invited
Effect of Ca Addition on Texture Evolution and Deformation Behavior of Mg-Zn Alloy Sheets: D.-W. Kim[1]; J. H. Bae[1]; B. C. Suh[1]; M. S. Shim[1]; D. H. Kim[2]; *Nack J. Kim*[1]; [1]POSTECH; [2]Yonsei University

Wrought Mg alloy sheets typically exhibit strong basal textures, which have an adverse effect on ductility and formability at room temperature. It has been recently reported that the additions of rare earth elements or Y (RE/Y) can weaken the basal texture of Mg alloy sheets. However a rather strategic nature of these elements might prevent their widespread utilization as alloying elements for wrought Mg alloys. In the present study, the effect of an alternative element, Ca, on texture evolution and its concurrent effects on deformation behavior and mechanical properties of Mg-Zn base alloys have been investigated. It shows that Mg-Zn-Ca (ZX) alloys have much weaker basal textures than the other Mg alloys. These alloys also show not only higher yield strength but also better formability than Al 5052 alloy, showing their potential as highly formable wrought Mg alloys. The mechanisms responsible for such improvements will be discussed.

Effect of Deformation Structure on Static Recovery and Recrystallization of AZ31 Magnesium Alloy: *Qing Liu*[1]; Zhen Zeng[1]; Yunchang Xin[1]; [1]Chongqing University

In the present work, AZ31 Mg alloy sheets with initial texture of c-axis parallel to the normal direction (ND) and the transverse direction (TD) were rolled respectively at 150°C to different reductions followed by a static annealing at 250°C. It was found that both contraction and double twins dominated in the TD-sheet sample of 9% reduction and grains were preferred to nucleate near these twin boundaries. For the TD-sheet, {10-12} extension twins dominated in the sample of 9% reduction and new grains were preferred to nucleate at original grain boundaries instead of the twin boundaries. For both the ND and TD-sheets, large amount of shear bands were formed with increasing strain and acted as the new grains nucleates sites during annealing. Based on the experimental results, a static recovery and recrystallization mechanism was discussed by comparing the annealing behavior of the two types of rolling sheets with different deformation microstructures.

Work Hardening Behavior of the Magnesium Alloy AZ80 under Multi-Axial Loading: Philip Tomlinson[1]; Chad Sinclair[1]; Michael Gharghouri[2]; *Warren Poole*[1]; [1]University of British Columbia; [2]National Research Council Canada

The widespread application of magnesium alloys requires an understanding of their behaviour under complex loading paths. This work examines the deformation of alloy AZ80 under a variety of biaxial loading conditions. Multiaxial tests were conducted on thin-walled tubes using combinations of internal pressure and axial loading to produce a range of ratios of tensile stress to hoop stress. The effect of initial microstructure on mechanical response was examined using as cast material exhibiting a with weak initial texture and extruded and recrystallized material having a strong texture. The evolution of crystallographic texture was determined from neutron diffraction measurements. From the stress-strain response, the yield surface and its evolution with strain have been determined for the tension/tension quadrant of biaxial stress space. The results show that the kinetics of twinning are affected by the stress state and this has been interpreted using crystal plasticity simulations.

Processing to Control Morphology and Texture in Magnetic Materials: Role of Magnetic Fields and Texturing to Improved Magnetic Materials

The Role of Magnetic Energy in the Remnant State of Spinodally Decomposed Titanomagnetite-Magnetite Minerals: *Michael McHenry*[1]; Nicholas Jones[1]; Huseyin Ucar[1]; Amanda Velázquez[1]; Catherine Groschner[1]; Marina Diaz-Michelena[2]; David Laughlin[1]; [1]Carnegie Mellon University; [2]Instituto Nacional de Técnica Aeroespacial

Paleomagnetic minerals, like the magnetotitanates, are crucial in explaining the Martian crustal magnetization. A remnant magnetization comparable to magnetite could explain field anomalies as large as 200 nT. The magnetite must be monodomain with a mechanism for pinning the magnetization to prevent thermal switching. The pseudo-binary system between magnetite (Fe_3O_4) and antiferromagnetic Ulvöspinel ($TiFe_2O_4$) undergoes spinodal decomposition of a solid solution into lamellae of two monodomain phases. The lamellar width ensures monodomain behavior and the antiferromagnet pins the magnetization. We discuss the role of magnetic energy in determining the asymmetric miscibility gap and other changes in the phase diagram, which give rise to the decomposition, and its effect on the wavelength of composition fluctuations. We also discuss how the remnant state is set during the decomposition process and the micromagnetics of switching in this naturally occurring spring exchange ferromagnetic system.

Effect of Magnetic Field Annealing on the Random Magnetocrystalline Anisotropies in Nanocrystalline Soft Magnetic Alloys: *Kiyonori Suzuki*[1]; [1]Monash University

The effective magnetic anisotropy in nanocrystalline alloys is suppressed by the exchange softening effect. This softening effect is promoted dramatically by reducing the mean grain size and thus, the primary focus in the alloy development has been homogeneous fine-grained microstructures. However, there is a growing awareness that the exchange softening process in magnetic nanostructures is affected by macroscopic induced anisotropies (K_u). Our analytical solution to an extended random anisotropy model with K_u predicts that the grain size (D) dependence of the coercivity changes from D^6 to D^3 when the ratio of the random magnetocrystalline anisotropy $<K_1>$ and K_u is approximately 1 to 2. This suggests that the magnetic softness in nanocrystalline alloys could be improved dramatically by controlling K_u. This paper presents an overview of the effectiveness of magnetic field annealing on controlling the induced uniaxial and random magnetocrystalline anisotropies in nanocrystalline soft magnetic alloys.

2:50 PM

Neutron Scattering Analysis of Magnetostructural Phase Transformations of High Magnetic Field Textured Shape Memory Alloys: *Ben Shassere*[1]; Orlando Rios[1]; Khorgolkhuu Odbadrakh[1]; Jason Hodges[1]; Saad Elorfi[1]; Alex Melin[1]; Gerry Ludtka[1]; Boyd Evans[1]; [1]Oak Ridge National Laboratory

Magnetic shape memory alloys are important for both their shape memory properties and as magnetic refrigeration materials due to their coupled structural and magnetic phase transformations. Experiments to observe the structural and magnetic phase transformations were performed at the Spallation Neutron Source (SNS) at Oak Ridge National Laboratory (ORNL) on two magnetic shape memory materials, alloys of Ni-Mn-Ga and Fe-Ni-Co-Al-Ta. Both alloys are a first-order magnetocaloric material in which the structural and magnetic phase transformations are coupled and contribute to the giant magnetocaloric effect (MCE). The FeNiCoAlTa alloy that was solidification processed under high magnetic fields (20 Tesla) at the National High Magnetic Field Lab using a unique high temperature apparatus developed at ORNL's magnetic processing facility are characterized up to 16 Tesla using a split core magnet at the SNS. Data of the observations will be further presented and discussed.

3:05 PM

High Magnetic Field Effect on the Solid State PhaseTtransformation in Fe-Co Alloys: *Bianca Frincu*[1]; Sophie Rivoirard[1]; Olivier Geoffroy[2]; Thierry Waeckerle[3]; [1]CNRS/CRETA Grenoble; [2]Grenoble Electrical Engineering laboratory; [3]ArcelorMittal Research Center

Thermo-magnetic processing can be considered as a new technology for modifying phase equilibria and phase transformation kinetics, with the goal of developing novel microstructures and properties unattainable through conventional thermo mechanical processing. We investigated the high magnetic field influence on the α/γ phase transformation of Fe-Co alloys. An increase of the phase transformation temperature with magnetic field was experimentally observed using dilatation measurements. In order to quantify the effect of a high magnetic field on the α/γ transformation in Fe-Co alloys, a thermodynamics analysis was conducted. The magnetic contributions to the respective Gibbs free energies as a function of the applied magnetic field were calculated using magnetization measurements. These magnetic energy terms were found to account for the modification of the α/γ transformation temperature, which amounts to approximately 2 K/T. Thus, thermo-magnetic processing has proved to be interesting to tailor microstructure of Fe-Co alloy in view of their magnetic properties.

3:20 PM

Effects of FeCo Magnetic Nanoparticles on Microstructure and Mechanical Properties of Sn-Ag-Cu Alloy: Siyang Xu[1]; Ashfaque Habib[1]; *Michael McHenry*[1]; [1]Carnegie Mellon University

Sn-Ag-Cu (SAC) alloys are regarded as the most promising candidates for Pb-free solders in the electronic packaging industry. We have synthesized SAC solder-FeCo magnetic nanoparticles (MNP) composite paste with different MNP weight percentages and used AC magnetic fields to cause their localized heating for reflow. XRD patterns and optical micrographs indicate a decrease in the amount of primary Ag_3Sn and \946-Sn dendrites, and an increase in the amount of eutectic microconstituents with increasing weight percentage of MNPs. These microstructural feature impact the modulus and hardness data measured by nanoindentation. These show a parabolic and a linear increasing trend as a function of MNP weight percentage, respectively. The addition of FeCo MNPs is argued to promote the solidification of \946-Sn by providing more heterogeneous nucleation sites, at relatively low undercoolings, which results in the change of phase amount and enhanced mechanical behavior in the as-prepared solder joints.

Classical Nucleation Theory Description of Phase Selection and Compositional Partitioning in Co-Rich (Co,Fe)ZrB-based Nanocrystalline / Amorphous Nanocomposites: *Paul Ohodnicki*[1]; Michael Widom[2]; Samuel Kernion[2]; David Laughlin[2]; Michael McHenry[2]; [1]National Energy Technology Laboratory; [2]Carnegie Mellon University

(Fe,Co)-based nanocrystalline / amorphous nanocomposite alloys produced through rapid solidification processing and subsequent thermal processing will play an important role as advanced inductor materials in the next generation of high frequency power electronics. Co-rich alloys are of interest for these applications due to a large field induced magnetic anisotropy that can be developed through crystallization in the presence of a magnetic field. Similar free energies for BCC, FCC, and HCP phases in Co-rich Fe,Co-alloys results in the formation of multiple nanocrystalline phases during the crystallization process over a range of Fe,Co-ratios with a preferential tendency for BCC phase formation as compared to expectations based solely on the binary phase diagram of the Fe,Co system. Various factors governing phase selection and compositional partitioning between phases will be presented using classical nucleation theory supplemented with thermodynamic parameters obtained through ab-initio modeling. Recent and relevant experimental results will be discussed within this framework.

4:20 PM Invited

Nanostructuring and Texturing for Improved Magnetic Materials: *David Sellmyer*[1]; Y. Liu[1]; T.A. George[1]; Ralph Skomski[1]; [1]University of Nebraska

The concept of achieving a useful high-energy-product magnet through appropriate nanostructuring of known hard and soft phases has been tantalizing researchers since the idea was first proposed. The fabrication of exchange-coupled nanocomposite magnets faces several challenges including aligning the easy anisotropy axes of the hard-phase grains. Here we investigate experimentally and by model calculations two-phase nanostructures of hard $L1_0$-ordered FePt and soft iron-rich fcc Fe-Pt. The Fe-Pt thin films were produced by epitaxial co-sputtering onto MgO (001) which leads to a strong (001) texture. The experimental and theoretical hysteresis loops indicate nearly ideal exchange coupling, and excellent magnetic properties are obtained, including high values of coercivity (51k Oe), saturation magnetization (1287 emu/cc, J_s = 16.2 kG), and nominal energy product (54 MGOe). Extension to $L1_0$(Fe, Co) Pt and fcc (Fe, Co)-Pt shows high values of J_s and H_c, and this and other systems will be discussed.

4:45 PM Invited

Roles of Texture Formation and Grain Refinement on Nanocomposite Magnetic Alloys: *Matthew Willard*[1]; Lamar Minter[2]; Matt Brandes[3]; Maria Daniil[4]; [1]Naval Research Laboratory; [2]Tennessee State University; [3]The Ohio State Univeriswty; [4]George Washington University

Development of new magnetic materials capable of providing higher energy products for permanent magnets and lower core losses for soft magnets enable smaller, lighter, and more efficient devices. Over the past two decades, a major focus of research has been microstructure refinement to the nanoscale, which has advantages for each class of magnetic material – allowing permanent magnets to store more energy and allowing soft magnets to dissipate less energy than alternative materials. Texture development plays an important role in each of these areas, providing improvements in nanostructured permanent magnets and deteriorated properties in nanostructured soft magnets. This presentation will highlight recent work on nanocomposite magnetic materials produced by rapid solidification processing. The effect of nanostructure and the role of texture on the magnetic material performance will be shown experimentally with theoretical discussion.

5:10 PM Invited
High Pressure Crystallization of FeCo Based Alloys: *Matthew Lucas*[1]; [1]Air Force Research Laboratory

In crystalline materials the application of pressure alters the relative stability of alloy phases. For example, at ~13 GPa pure iron transforms from the body-centered-cubic (bcc) phase to the hexagonal-closed-packed (hcp) phase. Crystallization of amorphous metals may be significantly altered by application of pressure prior to heating. Diffusion is typically lowered, resulting in smaller average grain sizes. For Finemet, it was experimentally shown by Zhang et al. [J. of App. Phys. 84 (1998) 1918] that crystallizing at pressures up to 2 GPa results in both an increase in the volume fraction of crystallites and a decrease in the average grain size from ~12 nm to ~8 nm. According to Herzer [IEEE Transactions on Magnetics 26 (1990) 1397], the reduction in grain size should significantly lower the coercivity. Here we report results of high pressure crystallization on FeCo based magnetic materials. Initial results of in-situ neutron diffraction measurements are also presented.

Radiation Effects in Ceramic Oxide and Novel LWR Fuels: Experimental Characterization of Radiation Damage in Uranium Fuel and Surrogate Materials

Irradiation-Induced Defects in Oxide Nuclear Fuels: *William Weber*[1]; [1]University of Tennessee

Fundamental aspects of irradiation-induced defect production and migration in UO_2, PuO_2, and ThO_2 will be reviewed, along with similar behavior in the widely used surrogate material, CeO_2. Defect production and recovery from self-radiation (alpha decay), ion irradiation, and neutron irradiation (fission product damage) have been widely investigated over the years. Under irradiation at cryogenic and room temperature conditions, the measured defect concentrations increase with dose to saturation values. At least four distinct defect recovery stages are observed at temperatures from 77 to 1300 K. While the behavior of defects on the oxygen sublattice is reasonably understood, inconsistencies in interpretation remain for cation defects. In the case of fission, the electronic stopping power of fission products is below the threshold for track formation in UO_2; however, thermal spike simulations indicate the formation of isolated defects. This work was supported by the Materials Science of Actinides, an EFRC funded by U.S. DOE-BES.

2:35 PM
XPS Measurements of Radiation Damage in Thin Film Single Crystal UO2 and U2O3.: *Brent Heuser*[1]; Melissa Strehle[1]; [1]University of Illinois

We present x-ray photo-electron spectroscopy (XPS) measurements of the valence state of uranium in thin film single crystal UO2 and U2O3 grown via reactive-gas magnetron sputtering. XPS is sensitive to the cation valence state via the photo-electron binding energy; we observed changes photo-electron binding energy as a function of growth conditions, sputtering, impurity concentration, and heavy-ion bombardment. Discussion of our results will focus on the generation of point defects under Frenkel and Schottky equilibrium.

2:50 PM
Irradiation Damage of CeO2 with Xe and Kr Implantation: *Lingfeng He*[1]; Clarissa Yablinsky[1]; Mahima Gupta[1]; Todd Allen[1]; Jian Gan[2]; [1]University of Wisconsin-Madison; [2]Idaho National Laboratory

Microstructure, fission products, and lattice defects have great influence on the thermal transport in nuclear fuel and the mechanical integrity of both the fuel and cladding. CeO2 has a fluorite-type structure and serves as a surrogate material for UO2 and PuO2. This study is to investigate defect production and microstructural evolution of CeO2 under irradiation. To simulate fission fragments damage, 150 keV Xe and Kr ions were used to irradiate CeO2 to various doses. Thermal recovery of defects in irradiated CeO2 was studied by annealing the samples at 800°C and 1200°C for 1 hr. TEM was used to characterize the irradiation-induced mirostructural features in CeO2, such as dislocations and gas bubbles. The stoichiometry change of CeO2 versus dose was determined by XRD, XPS and WDS. This research was supported as part of the CMSNF, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science.

3:05 PM
Stoichiometry Dependence of the Evolution of Irradiated-Induced Defect Clusters in $Ce_xLa_{1-x}O_2$: *Weiying Chen*[1]; Bei Ye[1]; Aaron Oaks[1]; Yinbin Miao[1]; Brian Kleinfeldt[1]; Mark Kirk[2]; James Stubbins[1]; [1]U of Illinois at Champaign-Urbana; [2]Argonne National Laboratory

To study the stoichiometry dependence of irradiation effects in fluorite-type oxide nuclear fuel (UO_2), the technique of ion implantation in La doped ceria ($Ce_xLa_{1-x}O_2$) is used. Kr ions with energy 0.15-1 MeV were implanted into CeO_2 single crystals with 0%, 5% and 25% La concentration at 800°C. In-situ TEM was utilized to observe the damage process and the defects created by the ion beam irradiation. A substantial difference in the evolution of dislocation loops and bubbles for CeO_2 with different La concentration was observed at the same dose. For example, the dislocation loop growth rate in 25% La doped CeO_2 is about three times than that in 5% La doped CeO_2 during the low dose stage up to 8×10^{14} ions/cm^2. MD and KMC calculations were performed to study the diffusivity of each element. Calculation results show the diffusivity dependence on La concentration, which compliments the experiment results.

Microstructure Characterization and Thermal Annealing of Irradiated Oxide Fuels: Understanding Gas Behavior and Restructuring at High Burnups: *Thierry Wiss*[1]; Arne Janssen[1]; Bert Cremer[1]; Hatmut Thiele[1]; Ondrej Benes[1]; Jean-Yves Colle[1]; Dragos Staicu[1]; Vincenzo Rondinella[1]; Rudy Konings[1]; [1]EC - JRC - Institute for Transuranium Elements

The safe operation of a nuclear fuel imposes to understand its behaviour in normal operation but also in ab-normal operating conditions (temperature transient for example). The analysis of the release behaviour of fission products during laboratory thermal anneals of irradiated fuels is a convenient way to study migration and segregation of fission products in oxide fuels. Microstructure characterization by electron microscopy on irradiated fuels helps to understand their evolution after exposure to severe radiation damaging sources especially at high burnups.

The combined analysis of the microstructure, of the fission products behaviour and of other properties (e.g. thermo-physical) enables a good understanding and prediction on the nuclear fuel performance and safety. This work schematically discusses experimental results from Knudsen Cell mass spectrometry measurements of thermal release of fission gases and volatile fission products from irradiated fuels, coupled with electron microscopy (SEM and TEM) examinations.

4:15 PM Invited
TEM Characterization of Irradiated RERTR Dispersion Fuels: *Jian Gan*[1]; Dennis Keiser[1]; Brandon Miller[1]; Adam Robinson[1]; Jan-Fong Jue[1]; Pavel Medvedev[1]; Daniel Wachs[1]; [1]Idaho National Laboratory

The USA fuels program on Reduced Enrichment Research and Test Reactors (RERTR) is to develop low enrichment fuels to be used in the research and test reactors. Dispersion type plate fuels are popular for many research and test reactors, a special class of LWRs. A typical dispersion fuel plate in a test reactor consists of three layers with the outer layers of aluminum cladding and the middle layer of aluminum alloy dispersed with U-xMo (x=7-10 in wt%) or U_3Si_2 fuel particles. Fuel-Matrix Interaction (FMI) layer can develop as a result of fuel fabrication and reactor irradiation. The microstructural stability of the fuel under irradiation could strongly affect the fuel performance. This work reports the microstructure characterization using TEM on the irradiated RERTR dispersion fuels. The detailed microstrucural features will be analyzed and compared with the results in literature. The impact of the observed microstructure on fuel performance will be discussed.

4:45 PM
3D Microstructural Characterization of Oxide Nuclear Fuel Surrogates: Effect of the Processing Conditions on Grain Boundary Distributions: *Karin Rudman*[1]; Darrin Byler[2]; Harn Lim[1]; Robert McDonald[1]; Pedro Peralta[1]; Chris Stanek[2]; Kenneth McClellan[2]; [1]Arizona State University; [2]Los Alamos National Laboratory

The initial microstructure of an oxide fuel can play a key role in its performance. At low burn ups, the diffusion of fission products has a strong dependence on the grain size distribution and grain boundary (GB) characteristics (crystallography, geometry and topology), which in turn depend on processing conditions. Microstructural data are then needed as inputs for microstructurally explicit mesoscale simulations and atomistic models. Serial sectioning techniques were developed to obtain Electron Backscatter Diffraction (EBSD) data for depleted UO2 pellets. Samples were manufactured under different conditions, including oxygen stoichiometry variations. The EBSD data were used to create 3D reconstructions of the microstructure and GBs. These models were then used to gather statistical information on the grain crystallography, determine five GB macroscopic degrees of freedom, and to study the GB character (twist, tilt, mixed). The results were compared for the different samples to understand how processing conditions can affect microstructure evolution.

5:00 PM
Ion Irradiations in La Doped CeO2: the Effects of Impurity and Excessive Oxygen Vacancy Environment: *Di Yun*[1]; Aaron Oaks[2]; Jeffrey Rest[1]; Abdellatif Yacout[1]; Marquis Kirk[1]; Wei-ying Chen[2]; James Stubbins[2]; [1]Argonne National Laboratory; [2]University of Illinois at Urbana-Champaign

To evaluate impurity effects in nuclear fuels, systematic experiments have been conducted. CeO2 was selected as surrogate material for UO2 due to its many similar properties. Lanthanum (La) was doped in CeO2 to investigate the effect of impurities. The presence of La introduces a controlled concentration of oxygen vacancies, making it possible to investigate irradiation behaviors in a vacancy excessive environment. The influence of two La concentrations, 5% and 25%, were examined.Both in situ and ex situ TEM (Transmission Electron Microscopy) experiments were performed to study the evolution of defect clusters under irradiation with two common fission products: Xe and Kr. Irradiation damage caused formation of dislocation loops, segments and networks, cavities and bubbles. Quantitative results were obtained to characterize the fluence and temperature effects. The higher La concentration was found to induce both significant trapping reducing bubble swelling and higher sink strengths leading to slower defect kinetics.

5:15 PM
Analysis and Modeling of Swift Heavy Ion Irradiation Defects in CeO_2: *Clarissa Yablinsky*[1]; Anthony Schulte[1]; Peng Xu[2]; Jianguo Yu[3]; Jian Gan[3]; Todd Allen[1]; [1]University of Wisconsin; [2]Westinghouse Electric Company; [3]Idaho National Laboratory

The investigation of damage caused by fission fragments is often studied in the realm of nuclear stopping and cascade damage. However, damage created within the electronic stopping regime is studied to a lesser extent, and further insight into these mechanisms is important in studying fuel performance. In this study, cerium oxide was irradiated with gold ions at energies of 300MeV, 1GeV, and 2.1GeV to fluences above $1x10^{10}$ ions/cm^2. As-received and irradiated specimens were characterized using scanning electron microscopy, transmission electron microscopy (TEM), and high resolution TEM. Additionally, atomic ordering was investigated using high energy x-ray scattering at the Advanced Photon Source. Also a thermal-spike model will be applied to characterize and interpret the observed damage structure of the latent tracks generated by electron excitation mechanisms. This work is funded by the U.S. Department of Energy, Office of Basic Energy Sciences, as part of an Energy Frontier Research Center.

Randall M. German Honorary Symposium on Sintering and Powder-Based Materials: Powder Processing and Consolidation I

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Powder Materials Committee
Program Organizers: K. Morsi, San Diego State University; Fernand Marquis, Naval Postgraduate School; John Meyer, Iowa State University; Ahmed El-Desouky, San Diego State University; Eugene Olevsky, San Diego State University

Tuesday PM	Room: Oceanic 2
March 13, 2012	Location: Dolphin Resort

Session Chair: Z. Zak Fang, University of Utah

2:00 PM Keynote
A Tribute to the Breadth and Depth of the Influence of Randall M. German on Particulate Materials Processing: *John Smugeresky*[1]; [1]Sandia National Laboratories, Livermore, CA 94551

This paper traces the early work in the career of Randall M. German with examples of collaborations representing his insight into the then current as well as the then evolving rise in the interest and importance of powder metallurgy in the world of materials processing. It focuses on the pioneering expansion of his interests and that of the powder metallurgy community for fully dense and near-net shape metal processing. It starts with conventional press and sinter processing for fabricating controlled porosity stainless steel, expanding to use of hot isostatic pressing, atomization, and rapid solidification for creating new alloys and microstructures that have impacted one of his colleagues. Materials include 300 series stainless steels, maraging steels, iron base superalloys, titanium, and copper cermets. This progression summarizes ways to improve strength, compositional uniformity, grain refinement, and unique metastable microstructures all taking advantage of the rapid solidification capability of metal powder atomization.

2:30 PM Invited
Application of Metal Injection Molding to Soft Magnetic Materials: *Hideshi Miura*[1]; [1]Kyushu University

Soft magnetic materials need several characteristics to realize high performance. Powder metallurgy is an effective way to produce the complex shaped parts, and also decrease the eddy current loss in high frequency by subdividing the eddy current area due to the small grains. Especially, metal injection molding (MIM) process allows nearly full dense and net shaping of a variety of engineering materials. The application of MIM process to hard and brittle materials such as ferromagnetic materials demonstrates the potential of this novel process. This study considers the processing of three types of soft magnetic materials such as Fe-6.5Si, Fe-9.5Si-5.5Al and Fe-50Ni alloy compacts through the MIM techniques using different types of powders to obtain high performance of soft magnetic properties.

Novel Approaches to Powder Processing: Structure and Mechanical Properties: *Marc Meyers*[1]; C Wei[1]; E Olevsky[1]; Naresh Thadhani[1]; [1]UCSD

We present an overview of the contributions of our group to the production of compacts through quasistatic, dynamic, and shock compaction, reaction synthesis, and their combination. This work, carried out since 1980, has focused on the development of explosive consolidation methods, on combustion synthesis followed by quasistatic and dynamic densification, and on the combined densification-reaction of powders geared at producing defect-free compacts with unique compositions and structures. The mechanical properties and microstructures obtained are presented with emphasis on mechanistic aspects. A wide variety of ceramics, ceramic-based composites, and metals were investigated. We present the advantages and limitations of the techniques developed: hot explosive consolidation, double-tube explosive consolidation, SHS + QIP, SHS + dynamic densification, laser-induced reactions.

3:20 PM Invited
Dynamic Shock-Compression of Particulate Materials: Current Understanding and Possibilities: *Naresh Thadhani*[1]; [1]Georgia Institute of Technology

The response of powders or particulate materials to dynamic loading is dominated by the intrinsic and extrinsic properties of constituent materials which influence not only their densification behavior, but also the nature of interactions of particles with shock waves. The highly heterogeneous nature of particulate materials makes realistic predictions of their crush-up strength, compressibility, and overall consolidation response difficult. Preferential flow of particles into voids and variations in localized deformation, due to varying extents in which the void-collapse energy is dissipated at particle surfaces or in the interiors of particles, can lead to inter-particle bonding of inert powders, or alloying and release of energy. Current state of the understanding of the mechanisms of shock densification, shock-induced reaction, and particulate material interactions, will be described based on our recent work employing time-resolved gas-gun experiments and meso-scale particle-level simulations performed on imported micrographs of powders (and powder mixtures) using CTH multi-material hydrocode.

3:45 PM
Pressureless Sintering of Si3N4/SiC Nanopowders Prepared by High Energy Reaction Milling of Silica Fume: *Jyothi Suri*[1]; Leon Shaw[1]; [1]University of Connecticut

Due to their good mechanical and thermal properties at both room and elevated temperatures, Silicon nitride-silicon carbide nanocomposites are the promising materials for high temperature structural applications. The current work deals with fabrication of these nanocomposites using mechanically activated silica fume and graphite mixtures, for the first time. The obtained powder mixtures were subjected to carbothermal reduction and nitridation (CRN) at 1465°C to produce nano-Si3N4/SiC powders having particle sizes of 15-30 nm. These nano-Si3N4/SiC powders are thereby pressureless sintered using liquid-forming compositions in the Y2O3-Al2O3 system as additives, at 1700-1950°C in nitrogen atmosphere and their microstructure, phase composition, hardness, and fracture toughness were investigated. The effects of Y2O3 and Al2O3 as sintering additives on degree of densification, sample shrinkage and phase transformation of these nanocomposites were studied. The key emphasis is laid on the production of low cost Si3N4/SiC nanocomposites, in addition to producing a nanoceramic with superior mechanical properties.

4:00 PM Break

4:15 PM
Development of Solid Freeform Fabrication for Metallic Parts Using Selective Inhibition of Sintering: *Mahdi Yoozbashizadeh*[1]; Behrokh Khoshnevis[1]; [1]University of Southern California

The SIS-Metal process based on microscopic mechanical inhibition is a layer-based rapid prototyping process. In the process, salt solution is printed in the selected area of each metal powder layer; the salt re-crystallizes when water evaporates; salt crystals decompose and grow rapidly during sintering; the decomposed salt particles spread between metal powder particles and prevent the fusing of these particles together, hence inhibiting the sintering process in the affected regions. In this paper titanium and stainless steel powder in addition to bronze metal powder will be used in the SIS process. The reason behind inhibition of sintering will be presented followed by introducing sucrose as a new inhibitor. The factors affecting the SIS-Metal process based on microscopic mechanical inhibition will be identified. By the aid of response surface methodology the effective factors will be evaluated to improve the part strength, surface quality and dimensional accuracy produced by the SIS-Metal process.

4:30 PM
Numerical Simulation of Cold Pressing of Armstrong CP-Ti Powders: *Adrian Sabau*[1]; Sarma Gorti[1]; William Peter[1]; Wei Chen[1]; Yukinori Yamamoto[1]; [1]Oak Ridge National Laboratory

Numerical simulation results for the cold pressing of Armstrong CP-Ti Powders are presented. The computational model was implemented in the commercial finite element program ABAQUSTM. Several simulation cases were conducted for cylindrical samples with different aspect ratios and different compaction pressures. Numerical simulation results for the density distribution are compared against experimental data in order to validate the computational model.

4:45 PM
The Effect of Coke Particle Size on the Thermal Profile of the Sintering Process Product: *Nader Tahanpesarandezfuly*[1]; Ali Heidary Moghadam[1]; [1]Azad University

In this research, the effect of coke particle size on thermal profile in the production process is investigated in the laboratory environment. Baking process and sinter production was performed for different ranges of coke particle size while other parameter like, iron ore, lime and sintering mixture particle sizes, suction conditions and so on were kept constant. Thermal profile was achieved by measuring the temperature in different places of sintering bed. Investigating the thermal profile in different tests confirmed that coke grain size has a significant effect on thermal profile. The effect of coke particle size on coke combustion velocity, maximum temperature, the amount of produced melting phase as well as the flame front speed was understood by analyzing the achieved profiles and consequently the optimal grain size was known. The coke suitable particles size could have a great effect on quality of the produced sinter.

5:00 PM
Issues and Trends in Powder Injection Molding in Korea; Research and Applications: *Seong Jin Park*[1]; [1]POSTECH

Powder injection molding (PIM) is one of the most important manufacturing process. PIM is a net-shape fabrication technology that combines the complex shape-forming ability of plastic injection molding, the precision of die-casting, and the material selection flexibility of powder metallurgy. This paper discusses about many ongoing issues and trends of increasing attentions and interests on PIM research and applications in Korea. Furthermore, future research directions on simulation, optimization and informatics are discussed.

5:15 PM
Consolidation of Ferritic Oxide Dispersion Strengthened Alloys by Spark Plasma Sintering: *Kerry Allahar*[1]; Jatuporn Burns[1]; Brian Jaques[1]; Indrajit Charit[2]; Darryl Butt[1]; James Cole[3]; [1]Boise State University; [2]University of Idaho; [3]Idaho National Laboratory

The application of spark plasma sintering (SPS) for the production of oxide dispersion strengthened (ODS) ferritic alloys is presented. These alloys have improved resistance to radiation, thermally induced creep and swelling; properties that make them excellent candidates for cladding material in advanced nuclear reactors. Ferritic ODS alloys processed through conventional hot extrusion and hot isostatic pressing do not provide the advantages of SPS, which include faster heating rates, lower sintering temperatures and shorter dwell times. SPS samples were consolidated from a pre-alloyed Fe/Cr/Mo powder that was mechanically alloyed with Y2O3 (0 - 0.5 wt.%) in a high energy ball mill. SPS conditions included sintering temperatures from 900 oC to 1100 oC, dwell times from 0 to 60 minutes, heating rates from 50 oC/min to 200 oC/min and sintering pressures of 40 MPa and 80 MPa for process optimization. Microstructural characterization was performed using electron backscatter diffraction and transmission electron microscopy.

Control of Gas Emission during Pyrolysis of Waste Printed Wiring Boards: Alex Luyima[1]; Honglan Shi[1]; *Lifeng Zhang*[1]; Jaan Kers[2]; [1]Missouri University of Science and Technology; [2]Tallinn University of Technology

The rapid technological development has led to a substantial increase in the volume of waste Printed Wiring Boards (PWBs). Pyrolysis process has been suggested as one of the best methods for recycling PWBs. However, pyrolysis process generates a lot of toxic gases like HBr and CO. In current study, the pyrolysis of PWBs was investigated by a 50 gram-scale tube furnace at 300–1173 K. The kinetics and the control of emitted gas using different chemical additives for the pyrolysis of PWB powders were studied under various heating rates and gas flow rates. Moreover, the possibility of controlling toxic exhaust gases and recovering beneficial gaseous fuels like CH4 and H2 from pyrolysis process is discussed.

2:20 PM
Leaching Studies for Metals Recovery from Waste Printed Wiring Boards (PWBs): Alex Luyima[1]; Honglan Shi[1]; *Lifeng Zhang*[1]; [1]Missouri University of Science and Technology

Printed wiring Boards (PWBs) is a critical part of almost all electronic waste and accounts for ~3% of all e-waste by weight. Leaching process has been suggested to recover precious metals from waste PWBs. In this study, the leaching behavior of most metals present in waste printed wiring boards (PWBs) is evaluated. Different leaching acid reagents (hydrochloric acid, nitric acid and aqua regia) are compared. The effects of acid concentration, particle size of sample, leaching time and temperature are examined. Preliminary results revealed that most metals are present in small particle size and sequential leaching of PWBs with a combination of both nitric acid and aqua regia are capable of dissolving most of the metals content of PWBs.

2:40 PM
Effects of Inoculums Volume on Metals Extraction from Printed Circuit Boards of Computers by Bacterial Leaching: *Luciana Yamane*[1]; Denise Espinosa[1]; Jorge Tenório[1]; [1]Polytechnic School of São Paulo University

The present work investigated the effect of inoculums volume on bioleaching of metals from printed circuit boards of computers using *Acidithiobacillus ferrooxidans*-LR. Printed circuit boards from obsolete computers were mechanically processed by comminution followed by magnetic separation. In the non-magnetic fraction were concentrated base metals such as copper, lead, tin, zinc and aluminum. A shake-flask study was carried out on the non-magnetic fraction samples using a rotary shaker at 30°C, 170rpm and different volumes of oxidized solution culture as inoculum (%v/v): 5, 10, 20, 30, 40, 50 e 60. Leaching in acidic ferric sulphate media was also performerd. The analyzed parameters were pH, ferrous iron concentration and metals analysis (AAS). The results showed that using 10%v/v of inoculums were extracted 99.2% of copper and 60% of aluminum by bioleaching. Zinc, lead and tin extraction were not influenced by bacterial leaching and extractions rate were obtained by chemical leaching promoted by acid medium. Ferric iron leaching extracted less copper (35%) than bioleaching. SEM analysis shown difference on surface after bioleaching showing corrosion pits formed by the bacteria contact.

3:20 PM
Removal of Copper Cyanide Complexes from Solutions Formed in Silver/Gold –Cyanidation Recovery Process: *Jose Parga*[1]; Jesus L. Valenzuela[2]; Luciano Ramírez[1]; [1]Institute Technology of Saltillo; [2]University Hermosillo

An innovative process for removing copper cyanide complexes including silver and zinc from cyanidation circuits has been developed. The technology was based on the inducing the nucleated precipitation of copper and silver in a tube serpentine reactor, using sodium sulfide as the precipitate and sulfuric acid as pH control. The results showed that pH had a great effect on copper cyanide removal efficiency and the optimum pH was about 3 to 3.5. At this pH value copper cyanide removal efficiency could be achieved above 97 and 99 % , when influent copper concentration ions were 650 and 900 ppm respectively. In this process (sulphidizaton-acidification-recycle-thickening), the cyanide associated with the copper cyanide complexes is released as HCN gas under weakly acidic conditions, allowing it to be recycled back to the cyanidation process as free cyanide. This system was successfully commercial applied at Minera William in Mexico.

3:40 PM
Dissolution of Mixed Zinc-Carbon and Alkaline Battery Powders in Sulphuric Acid Using Ascorbic/Oxalic Acid as a Reductant: *Muammer Kaya*[1]; [1]ESOGÜ

The objective of this study is to investigate the effectiveness of H2SO4 and ascorbic/oxalic acids as a reducing agent for the simultaneous recovery of Zn and Mn from used AA and AAA sizes Zn-C and alkaline battery powder mixtures. Reductive acid leaching tests were conducted to evaluate the leaching behavior of Zn and Mn metals under different S/L ratio, temperature, H2SO4 concentration, mixing rate and leaching times. The effects of H2SO4, ascorbic/oxalic acid, temperature and time on metal dissolutions were investigated according to 2K full factorial design. Without a reductant, 99.42% Zn and 40.94 % Mn were dissolved; whereas, 74.88% Zn and 96.79% Mn were extracted using 30g/l oxalic acid. The optimum reductive acid leaching conditions were determined as 3h, 70°C, 0.5M H2SO4, 13 g/L ascorbic acid, 1/20 g/mL S/L ratio and 200 rpm. Under these conditions, the dissolution efficiencies were 99.99% for Zn and 99.25% for Mn.

4:00 PM
Selective Recovery of Precious Metals by Selective Adsorption on Garlic Peel Gel: *Kai Huang*[1]; Shuqiang Jiao[1]; Hongmin Zhu[1]; [1]University of Science and Technology Beijing

An adsorption gel was prepared by using garlic peel as the raw material, which is rich in amino- and thiol-groups, exhibiting a high affinity for Au(III). It was prepared by cross-linking garlic peel with concentrated sulfuric acid. Adsorption tests for different metal ions such as Au(III),Pd(II),Pt(IV), Fe(III),Cu(II),Ni(II) and Zn(II) from hydrochloric acid media found Au(III) to be selectively adsorbed on the cross-linked garlic peel gel over the other metal ions investigated. From the adsorption isotherms, this adsorbent was found to exhibit remarkably high adsorption capacity. The thermodynamic parameters indicated that the adsorption was governed by an endothermic reaction.

4:20 PM
Separation of Si/SiC Wiresaw Cutting Powder through Sedimentation by Adjusting the Solution pHs: *Kai Huang*[1]; Hao Deng[1]; Jichao Li[1]; Hongmin Zhu[1]; [1]University of Science and Technology Beijing

Silicon and silicon carbide mixing micropowders obtained from the saw cutting industry of polycrystalline silicon ingot is separated by a simple sequential sedimentation. The Zeta potentials of the powders in the aqueous suspension are adjusted by varying the pHs with dilute acid or alkaline reagents. The dispersion and aggregation content of the microparticles is significantly influenced by pHs, and so their settlement velocity in the same hydraulic conditions are quite different, and silicon powders tend to suspend in the upper section of the suspension for its finer size and smaller density under the stronger Zeta potential repulsion force. The original content of the cutting powders with 30%wt silicon are separated into the Si-rich and SiC-rich powder respectively, and 62%wt Si-rich powder can be obtained after 4 times of sedimentation under pH = 8.0, showing the great potential for Si and SiC powder separation and recovery in a cost-effective way.

Solid-State Interfaces II: Toward an Atomistic-Scale Understanding of Structure, Properties, and Behavior through Theory and Experiment: Mechanical Properties

Creep Deformation in Ion Irradiated Nanocrystalline Cu Alloys: *Robert Averback*[1]; Pascal Bellon[1]; Yinon Ashkenazy[2]; Kaiping Tai[1]; Jonathan Schäfer[3]; Karsten Albe[3]; [1]University of Illinois; [2]Hebrew University of Jerusalem; [3]Technische Universität Darmstadt

A straight forward strategy for designing materials with good radiation resistance is simply to include a large density of neutral sinks and traps for point defects. One means to achieve this microstructure is through the synthesis of ultra-fine grained materials, which can now be stabilized to temperatures approaching their melting points. Since materials with small grain sizes are susceptible to creep damage, a fundamental question that must be addressed concerns the dimensional stability of irradiated nanocrystalline materials at elevated temperatures. In this work in situ creep measurements on ion-irradiated nanocrystalline Cu alloys are presented which show that a random flux of point defects to grain boundaries can result in creep deformation. We also present MD simulations illustrating how defect relaxations in the grain boundaries make this possible. The simulations also show how thermal creep might be suppressed in these alloys.

2:30 PM Invited
Resolving the Contribution of Interfaces in the Deformation of Nanocrystalline Copper with Atomistic Simulations: *Garritt Tucker*[1]; Shreevant Tiwari[1]; Jonathan Zimmerman[2]; David McDowell[1]; [1]Georgia Institute of Technology; [2]Sandia National Laboratories

The deformation of nanocrystalline FCC metals involves activating various distinct deformation mechanisms. The interfaces between grains, or grain boundaries, in addition to dislocation nucleation/migration, fundamentally govern material plasticity in nanocrystalline metals. In this work, atomistic simulations employing volume-averaged kinematic metrics from continuum mechanics are utilized to elucidate the influence of grain size on the role of interfacial deformation during uniaxial tension. We show that the metrics offer insight into each deformation mechanism through reference configuration neighbor lists. In addition, lattice distortion due to atomic shear shuffling and rearrangement is captured using the microrotation metric. As average grain size is reduced, the influence of grain boundary deformation increases, and its contribution to the overall strain of the material is quantitatively computed using the Green strain metric. The ability of the metrics to capture fundamental mechanisms is illustrated, and we discuss the potential to translate nanoscale interface behavior into larger-scaled models.

3:00 PM
Heterophase Interface Character Distributions (HICDS) in Accumulative Roll-Bonded (ARB) CU-NB Multilayered Composites at Multi-Scale: *Sukbin Lee*[1]; Jonathan LeDonne[1]; Irene Beryerlein[2]; Nathan Mara[2]; Anthony Rollett[1]; [1]Carnegie Mellon University; [2]Los Alamos National Lab

Multilayered Cu-Nb composites are known to have exceptional strength, conductivity, and radiation damage resistance with decreasing layer thickness into the nano-scale and, hence, increasing heterophase interface area. Therefore, it is of great interest to characterize the types of heterophase interfaces and investigate their relationship to the desired properties. In the light of that, the full five-parameter heterophase interface character distributions (HICDs) in accumulative roll-bonded (ARB) pure Cu-Nb multilayer composites are presented as functions of layer thickness and annealing. The heterophase interfaces are segmented and smoothed on two-dimensional electron back-scatter diffraction (EBSD) maps or orientation maps from ASTAR techniques in the TEM, depending on the layer thickness (50 µm to 20 nm). Supports from the Center for Materials at Irradiation and Mechanical Extremes, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Basic Energy Sciences, the BES-supported CMIME and the NSF-supported MRSEC at CMU are acknowledged.

3:20 PM
Lithium Segregation at Matrix/Precipitate Interfaces in Al-Li-Sc and Al-Li-Sc-Yb Alloys: Thermodynamic Treatment, and Effects on Aging Microhardness: Matthew Krug[1]; David Dunand[2]; *David Seidman*[2]; [1]General Electric Aviation; [2]Northwestern University

Al-2.9 Li-0.11 Sc (at.%), and Al-5.53 Li-0.048 Sc-0.009 Yb (at.%) were isothermally-aged to peak-strength at 325 °C, followed by isochronal aging to 450°C. This resulted in precipitation of nanometer L12 alpha-prime–Al3(Li,Sc) and Al3(Li,Sc,Yb) precipitates, which exhibit significant excesses of Li at alpha-Al matrix/alpha-prime-Al3(Li,Sc,Yb)interfaces. As the aging temperature increases, the Li- and Yb-concentrations of the alpha-prime–Al3(Li,Sc,Yb) precipitates decrease, while the relative interfacial Li excesses increase. This result indicates that the alloys are not in thermodynamic equilibrium. The large interfacial excesses of Li at the aging temperature of 450°C, lead to interfacial free energy decreases of -81±3 and -160±8 mJ m-2 for Al-Li-Sc and Al-Li-Sc-Yb, respectively. These decreases influence the nucleation and coarsening of the strengthening precipitates. The effects on the evolution of mechanical properties is suggested by comparing atom-probe tomographic analysis of precipitates, to aging hardness data to a study on similar Al-Sc(-Yb) alloys with and without a Li addition.

3:45 PM
Intergranular Fracture Behavior in UO2: Molecular Dynamics Simulations: *Yongfeng Zhang*[1]; Xiangyang Liu[2]; Bulent Biner[1]; Paul Millett[1]; Michael Tonks[1]; David Andersson[2]; [1]Idaho National Lab; [2]Los Alamos National Lab,

The intergranular fracture behavior in UO2 is studied using molecular dynamics simulations with the Basak potential. A bi-crystal simulation cell is used with the <100> symmetrical tilt S5 grain boundaries (GBs). Uniaxial tension is applied normal to the GB plane to model the mode-I crack. In the absence of an initial crack, the deformation proceeds by phase transformations from the Fluorite to the Scrutinyite or the Rutile structures, with coherent boundaries in between them. The evolution of such metastable phases is also confirmed by separate density-functional-theory calculations. With an initial crack created at the GBs, these metastable phase transformations shield the crack at the onset of plastic deformation. At higher strain, cleavage crack propagation takes place preferably along the GBs, with rare exceptions along the newly formed phase boundaries. In addition, results with random GBs will also be presented to elucidate the effects of GB structure.

4:05 PM
On the Fracture Toughness of Polycrystalline LiCoO2: *Meng Qu*[1]; William Woodford[1]; John Maloney[1]; W. Craig Carter[1]; Yet-Ming Chiang[1]; Krystyn Van Vliet[1]; [1]Massachusetts Institute of Technology

LiCoO2 is a widely used cathode material in rechargeable lithium-ion batteries. The stress induced by reversible lithium-ion intercalation during electrochemical cycling is related directly to crack initiation and growth. In this study, we employed instrumented nanoindentation to probe the fracture toughness within individual grains of polycrystalline LiCoO2. We compared the crack length extrapolated from instrumented indentation load-displacement responses to those measured using direct imaging of surface cracks, and confirmed that these two approaches provide comparable crack length values. We found that the average fracture toughness varies among different grains in LiCoO2 over one order of magnitude. We also considered possible correlations between fracture toughness and grain misorientation, and found no conclusive correlation for the present sampling. This work demonstrates an efficient method to study the fracture toughness of lithium-ion battery materials. It can also be further applied to explore the fracture toughness of LiCoO2 particles in lithium ion battery electrodes.

4:25 PM
Rate Dependence Dissipation in Dynamic AFM: *Gabriela Venturini*[1]; Alejandro Strachan[1]; [1]Purdue University

Despite the growing importance of Atomic Force Microscopy (AFM) in material research, the link between the actual experimental observables and the underlying material properties remains tenuous. This talk will present a molecular dynamics (MD) approach to simulate the dynamics of tip-substrate interaction under conditions relevant to tapping mode AFM. We simulate a semi-spherical silica tip contacting an amorphous poly(methyl methacrylate) (PMMA) sample and study how deformation rate, indentation depth, and surface topology affect the effective tip-sample interaction. We find that interaction force curves depend strongly on local surface topology for small tip penetrations into the sample and these dependency decreases as the depth of the indentation increases. Interestingly, we find the total energy dissipated during the interaction to be rather independent of deformation rate when the interaction time varies from 0.040 to 4 ns.

4:45 PM
Mechanisms for the Nucleation of Lattice Dislocations from fcc/bcc Incoherent Interfaces: *Ruifeng Zhang*[1]; Jian Wang[1]; Irene Beyerlein[1]; Timothy Germann[1]; [1]LANL

Dislocation nucleation from fcc/bcc incoherent interfaces under mechanical deformation is studied using atomistic simulations. Two broad classes of interfaces are studied: ones containing intrinsic interface dislocations (i) with their Burgers vectors lying within the interface plane or (ii) with their Burgers vectors lying normal to the interface plane. We find that for the former type of interface, nucleation results from localized interface shear. The interfacial shear strain field that develops under stress is governed by the spatially non-uniform shear resistance of interface. For the latter class of interface, nucleation is attributed to the dissociation of preexisting interface dislocations. Using our single loop isolation method, the activation barrier for nucleation from these interfaces are found to be much lower than that for homogeneous nucleation in perfect fcc lattice, indicating that an incoherent interface, by virtue of its intrinsic defect structure, can act as a viable source of lattice dislocations.

5:05 PM
Molecular Dynamics Simulation of the Mechanical Behavior of Metallic Glass/Crystalline Composites: *Anupriya Agrawal*[1]; Logan Ward[1]; Katharine Flores[1]; Wolfgang Windl[1]; [1]The Ohio State University

Bulk Metallic Glasses (BMGs) represent a new class of metallic alloys with a wide range of potential applications. However, a major disadvantage of BMGs is the potential for rapid shear localization leading to catastrophic failure, particularly under tensile load conditions. Among the investigated solutions to this problem is the introduction of crystalline phases to control the propagation of shear bands in the glassy matrix. In this work, we have studied the mechanical behavior of a model crystalline metal-metallic glass composite system using Molecular Dynamics, with a focus on the c-Cu - a-(Cu-Zr-Ti) interface. The interface was studied under different applied stress states and with pre-formed dislocations on the crystalline side. We will present the effects of the system size, glass phase composition, annealing temperature and dislocation type and density on the dislocation motion and interaction with the interface, as well as the resulting mechanical properties of the composite.

Automated Materials Design of Metallic Glasses Using Genetic Algorithms: *Logan Ward*[1]; Katharine Flores[1]; Wolfgang Windl[1]; [1]The Ohio State University

Metallic glasses are a unique class of engineered materials with excellent properties for a wide array of applications ranging from hard-tissue implants to high-performance transformer cores. Before becoming a widely-used class of material, however, more alloy compositions need to be identified that are optimized for specific applications, which is experimentally a slow and expensive process. In this work, we propose a computation-only approach to designing optimized metallic glass alloys. Methods for predicting material properties using molecular dynamics were integrated with optimization using genetic algorithms to select the best alloy from millions of candidates. In our first test of this method, we were able to predict a low-density, fracture resistant metallic glass from first-principles that matched closely with an alloy experimentally known to have those properties. This versatile tool is in the process of being used to design glasses with more-complex properties and can easily be applied to different materials.

2:30 PM
Data-Driven Models Evolved through Multi-Objective Genetic Algorithms and Their MaterialsApplications: Nirupam Chakraborti[1]; [1]Indian Institute of Technology

This paper presents two recent Evolutionary Computational strategies for Data-driven modeling, developed in author's research group, and some of their materials applications. The first strategy is called Evolutionary Neural Net, where a flexible network architecture evolves as a Pareto tradeoff between the complexity of the model and its accuracy. A bi-objective Predator-prey type Genetic Algorithm locates an optimized Pareto frontier consisting of many such models, out of which one is selected by applying the Corrected Akaike Information Criteria. The second approach involves a similar strategy for Genetic Programming, where a tree encoding is used to evolve a suitable mathematical expression for the data in hand. Models developed this way tend to avoid overfitting and underfitting problems, and prune the insignificant inputs in a systematic manner. Coupled with established modeling strategies like Molecular Dynamics, these techniques lead to powerful meta-models for the materials systems, as will be demonstrated in this paper.

2:50 PM
Optimum Approximation for Three-Point Correlation Function: *Majid Baniassadi*[1]; Hamid Garmestani[2]; [1]Georgia Institute of Technology Materials Science and Engineering ; [2]Georgia Institute of Technology Materials Science and Engineering

Microstructural two-point correlation functions are among a well-known class of statistical descriptors that can be used for the characterization of microstructural heterogeneous systems. The main advantage of the statistical continuum approach is the direct link to statistical information of microstructure. Two-point correlation functions are the lowest order of correlation functions that can describe the morphology and the microstructure-properties relationship. In this study, a new optimized approximation has been developed based on Two-point correlation functions to predict Three-point probability functions. The optimum approximation for Three-point correlation functions is found and compared to the real probability functions. This comparison proves that our new developed approximation is capable of describing three-point correlation functions with the needed accuracy for materials with a wide variety of micro-structure. The ramification of the new procedure is investigated for the homogenization of the three-phase composite microstructure of Solid Oxide Fuel Cells for the prediction of the relevant transport properties ins.

Stochastic Geometry and Transformation Kinetics Theories: Basics and Results: *Paulo Rios*[1]; Elena Villa[2]; [1]UFF-EEIMVR; [2]University of MIlan

Aim of this talk is to show the important role played by Stochastic Geometry in Transformation Kinetics Theories. We generalize the early Kolmogorov, Johnson, Mehl and Avrami theory, to more general nucleation-and-growth processes. In particular the notion of point process will be introduced to model various kinds of nucleation processes, for instance inhomogeneous nucleation, cluster nucleation and nucleation on lower dimensional sets. Volume fraction, mean volume and surface densities of the transformed phase are studied by methods of Stochastic Geometry making use of the notion of causal cone.

3:50 PM
Forward and Inverse Analysis of Engineering Neutron Diffraction Data with Neural Networks: *Seung-Yub Lee*[1]; Hyuntae Na[2]; Ersan Ustundag[2]; [1]Columbia University; [2]Iowa State University

Integration of engineering neutron diffraction data analysis and solid mechanics modeling offers a powerful approach to deduce in-situ constitutive behavior of materials. Since diffraction data originates from spatially discrete subsets of the material volume, extrapolation of the data to the behavior of the overall sample is non-trivial. The finite element model (FEM) and self-consistent model (SCM) have been widely used for interpreting diffraction data by optimizing model parameters via iterative processes. In order to maximize the rigor of such analysis and to increase fitting efficiency and accuracy, we have developed an optimization algorithm based on the neural network architecture. In this presentation, I will discuss the programming concepts utilized in the development of this tool and show examples of analysis for actual samples.

4:20 PM
Probabilistic Modeling of Microstructure Evolution Using Finite Element Representation of Statistical Correlation Functions: *Veera Sundararaghavan*[1]; [1]University of Michigan

A probabilistic finite element scheme is presented for simulating evolution of polycrystalline microstructures during deformation. The microstructure is described using conditional orientation correlation function (COCF), defined as the probability density of occurrence of a crystal orientation g' at a distance r from a given orientation g. The COCF is represented using three interconnected layers of finite element meshes in the g', r and g spaces. As the microstructure evolves, the reoriented neighborhood and strain field close to an orientation (g) is captured by updating probability fields in these finite element meshes. For this purpose, a novel total Lagrangian approach has been developed that allows evolution of probability densities while satisfying normalization constraints, probability interdependencies and symmetries. The improvement in prediction of texture and strains achieved by the COCF approach over ODF-based methods is quantified through deformation analysis of a planar polycrystalline microstructure.

4:40 PM
Unsupervised Learning Algorithm for the Estimation of Crystallographic Texture from Discrete Orientation Measurements: *Stephen Niezgoda*[1]; Jared Glover[2]; Carlos Tome[1]; Rodney McCabe[1]; [1]Los Alamos National Laboratory; [2]Massachusetts Institute of Technology

Traditional methods for estimating the orientation distribution function (ODF) in polycrystalline materials, were developed as solutions to inferring the complete crystallographic texture from incompletely measured lower-order distributions (pole figures) obtained by diffraction. For discrete orientation data, produced using electron backscatter diffraction (EBSD) or used in polycrystal modeling, application of these methods relies on the, ad hoc, choice of filtering, smoothing and bandwidth. Here we present an unsupervised learning algorithm for ODF estimation from discrete orientations as a mixture of Bingham distributions over the rotation group. We formulate the fitting as an expectation-maximization algorithm which seeks to find the ODF that maximizes the probability of collecting the sampled data while minimizing the number of distributions needed to accurately represent the data. The framework eliminates the necessity of the ad hoc assumptions and is demonstrated to accurately capture a wide range of ODFs from sharp near single crystal to near uniform random.

5:00 PM
A Calibrated Monte Carlo Approach to Quantify the Impacts of Misorientation and Different Driving Forces on Texture Development: *Liangzhe Zhang*[1]; Anthony Rollett[2]; Timothy Bartel[3]; Di Wu[4]; Mark Lusk[1]; [1]Colorado School of Mines; [2]Carnegie Mellon University ; [3]Sandia National Laboratories; [4]Northeastern University

A calibrated Monte Carlo (cMC) approach, which quantifies grain boundary kinetics within a generic setting, is presented here. The influence of misorientation is captured by adding a scaling coefficient in the flipping probability equation, while the contribution of different driving forces is weighted using a partition function. The calibration process relies on the established parametric links between Monte Carlo (MC) and Sharp-Interface (SI) models. The cMC algorithm quantifies microstructural evolution under complex thermomechanical environment and remedies some of the difficulties associated with conventional MC models. After validation, the cMC approach is applied to quantify the texture development of polycrystalline aluminum with influences of misorientation and inhomogeneous bulk energy across grain boundaries. The results are in good agreement with theory and experiments.

Symposium in Memory of Patrick Veyssière: Understanding the Mechanisms Controlling Plastic Flow: Intermetallic Alloys

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division
Program Organizers: Georges Saada, LEM CNRS ONERA; Dennis Dimiduk, Air Force Research Laboratory; Hael Mughrabi, University Erlangen-Nuernberg; Haruyuki Inui, Kyoto University

Plasticity and Dislocation Structures in L12-Ordered Intermetallic Compounds and Transition-Metal Silicides: *Haruyuki Inui*[1]; Kyosuke Kishida[1]; Norihiko Okamoto[1]; [1]Kyoto University

Our recent results of investigations on plasticity and dislocation structures in L12-ordered intermetallic compounds and transition-metal silicides will be presented. The classification of L12 compounds in terms of the temperature dependence of yield stress is discussed in relation to the observed dislocation dissociation modes. The key issue is that although the rapidly decreasing yield stress at low temperatures observed for some L12 compounds is usually attributed to non-planar core structures either for 1/2[110] dislocations separated by APB on {001} or for 1/3[121] dislocations separated by SISF on {111}, the same yield behavior is observed for many L12 compounds even with dislocations dissociated into two 1/2[110] partials separated by APB on {111}. Some new strategies to improve the thermal stability of microstructures in two-phase MoSi2-based alloys will also be reviewed. The key issue is how the energy of interphase boundaries can be controlled with segregation of alloying elements on the boundary.

2:30 PM Invited
Some Long-Period Superstructures and the Related Motion of Dislocations in Al-Rich TiAl Single Crystals: *Takayoshi Nakano*[1]; Yukichi Umakoshi[1]; [1]Osaka University

Various long-period superstructures appeared in Al-rich TiAl are composed of three pairs of primitive cells, Ti_2Al, Ti_3Al and Ti_4Al with periodic atomic arrangements of unique shapes of lean rhombi, fat rhombi and squares, respectively, on the (002)Ti layers. These long-period superstructures play important roles on the operative deformation mode, configuration of dislocations and the related plastic deformation behavior in Al-rich TiAl, depending on the Al concentration. Fourfold ordinary dislocations, for example, often move as a group in Al_5Ti_3 superstructure based on the lean rhombi and squares embedded in the $L1_0$ matrix. In this paper, relationship between the periodic long period superstructures and dislocation motion will be discussed from the viewpoint of APBs formed in each superstructure. This work was partially performed with our unforgettable old excellent friend, Dr. Patrick Veyssière, ONERA-CNRS, France.

3:00 PM Invited
Determination of Fundamental Characteristics of Dislocations in Intermetallic Compounds Using γ-Surfaces: *Vasek Vitek*[1]; [1]University of Pennsylvania

Dissociated dislocations are planar while if a splitting cannot occur their cores may be non-planar and deformation characteristics may strongly differ in these two cases. In structures like FCC the stacking faults are determined by the symmetry and it is usually assumed that the symmetry also determines APBs in compounds. However, it will be shown here that that this is not the case. A powerful tool that can identify planar faults is the □-surface. It needs to be evaluated using the DFT in the case of compounds involving transition metals. Such calculations are relatively easy while studies of dislocations employing DFT are much more difficult. As examples we shall discuss stacking faults in a number of B2 intermetallics and demonstrate that metastable planar faults cannot be determined using simple models. Different faults are found in different B2 compounds and consequences for the plastic properties of B2 compounds will be discussed.

3:30 PM Invited
STEM Imaging and Analysis of the Fine Structure of Dislocations in Ni-Based Superalloys: Patrick Phillips[1]; Hallee Deutchman[1]; Yi Yun Li[1]; Ning Zhou[1]; Yunzhi Wang[1]; *Michael Mills*[1]; [1]The Ohio State University

Diffraction contrast scanning transmission electron microscopy and high angle annular dark field imaging have provided significant new insights into the rich variety of deformation processes that control deformation in Ni-based superalloys. At intermediate temperatures, the deformation mechanisms involve shearing by <112> type partials, and include microtwinning, a[112] dislocation ribbons, and superlattice intrinsic and superlattice extrinsic stacking faults. On the basis of high resolution imaging and ab initio calculations, these processes are thought to be mediated by reordering at the faults created in the precipitates. At higher stresses, shearing of precipitates by ½<110> dislocations on both {111} and {001} planes occurs. The importance of cube slip in superalloys and the relationship to the behavior of $L1_2$ single crystals will also be discussed in light of Patrick Veyssiere's seminal contributions. Examples will be provided where novel STEM imaging techniques have been instrumental in developing this fundamental understanding in these commercially important alloys.

Influence of Dislocation Activity in the Alpha 2 Phase on the Plastic Deformation of Titanium Aluminides: Jörg Wiezorek[1]; Michael Loretto[2]; *Hamish Fraser*[3]; [1]University of Pittsburg; [2]University of Birmingham; [3]The Ohio State University

Two-phase titanium aluminides (gamma TiAl and alpha2 Ti3Al phases) exhibit some interesting mechanical properties, but with usually somewhat low values of ductility. Detailed investigations, involving transmission electron microscopy (in concert with much of Patrick's experimental research!) reveal that while deformation in the gamma phase occurs readily, dislocation activity in the alpha 2 phase is somewhat restricted.

The present study has been aimed at understanding the influence of the deformation behavior of the alpha 2 phase on the limited ductility often observed in these two phase alloys. Three aspects have been considered: firstly, the intrinsic deformation behavior of the alpha 2 phase; secondly, the role of alloying elements on the dislocation activity in this phase; and, thirdly, the mechanisms and role of slip transfer through lamellae of the alpha 2 phase. This presentation will include French protests that Patrick would have made regarding some of the claims we make!

4:20 PM Invited
A Dislocation Dynamics Simulation of the Temperature Dependence of the Flow Stress of L12 Alloys.: *Ronan Madec*[1]; Patrick Veyssière[2]; Georges Saada[2]; [1]CEA, DAM, DIF; [2]LEM (CNRS/ONERA)

The part played by the thermally-activated formation of Kear-Wilsdorf locks in the positive temperature dependence of the L12 alloys flow stress is well established. KW locks are formed by cross-slip of dislocations from {111} slip planes to {001} planes in which slip motion is severely hindered. Several models based on this mechanism have been published which can be classified into two classes. In one, deformation is achieved by formation and destruction of the locks, the alloy strength is controlled by the lock stability. In the other, plastic flow proceeds from the kinks connecting the locks, the alloy strength is determined by the frequency of immobilization. These models exhibit varied agreement with the L12 flow stress anomaly set of mechanical properties. The present simulation investigation will explore the contribution of the lock formation frequency and of the lock stability to the mechanical properties of a model Ni3Al alloy.

4:40 PM Invited
A First Principles Study of the Effect of Ti and Ta on the SFE of the γ' Phase of Co-based Superalloys: *Alessandro Mottura*[1]; Anderson Janotti[1]; Tresa Pollock[1]; [1]University of California, Santa Barbara

Co-based superalloys are a potential candidate for use in the hottest parts of gas turbines. The presence of the γ+γ' phase field in the Co-Al-W ternary system allows for the casting of single-crystals which can be heat-treated to form the typical γ+γ' microstructure observed in traditional single-crystal Ni-based superalloys. The addition of Ta results in anomalously high yield strengths at high temperatures. This effect has been observed in conjunction with high densities of intrinsic stacking faults within the γ' precipitates. In this work, the Axial Ising Model is used in conjunction with Special Quasi-random Structures to study the effect of Ti and Ta additions on the intrinsic stacking fault energy from first principles. Results show that the strengthening effect observed at high temperatures may be due to Ta raising the γ' solvus, rather than Ta decreasing the SFE of the γ' phase of Co-based superalloys.

5:00 PM Invited
Cyclic Behavior of a Ni-Based Superalloy Characterized by Electron Microscopy: *Patrick Phillips*[1]; David Mourer[2]; Dan Wei[2]; Michael Mills[1]; [1]Ohio State University; [2]GE Aviation

The deformation behavior of the polycrystalline superalloy R104 has been characterized via scanning transmission electron microscopy (STEM). Specimens seeing either pure low cycle fatigue (LCF) or sustained-peak low cycle fatigue (SPCLF) were examined based on testing temperature, total strain range, and/or cycle number. In order to sufficiently characterize various damage mechanisms, both diffraction-contrast and high-resolution STEM imaging were performed, with the latter necessary given the fine-scale defects frequently present. The introduction of a dwell at maximum stress indeed influences the deformation modes, which are observed to vary from those observed in pure LCF – an effect which is likely a direct result of the dramatic cyclic softening the SPLCF specimens experience.

Characterization of Elongated Microtextures in Ti Alloys by Ultrasonic Backscattering: *Stan Rokhlin*[1]; Jia Li[1]; Oleg Lobkis[1]; Adam Pilchak[2]; [1]The Ohio State University; [2]US Air Force Research Laboratory

Theoretical and experimental analysis of a spectral representation of ultrasonic backscattering in polycrystalline materials with elongated grains is applied to inverse characterization of microstructure/microtexture in Ti alloys. It is shown that the dominant effect on the backscattering is the averaged ellipsoidal radius in the direction of wave propagation, instead of the ellipsoidal cross-section. The theory was applied to a simplified model of Ti alloy duplex microstructure and was compared with experiment. It is demonstrated that the grain size and grain morphology can be determined from directional measurements (morphological information is more accurate and easily obtainable). Also a new nondimensional parameter was introduced and measured. This parameter provides the relative contribution of the second phase (crystallites) to the backscattering signal, the effect of which is measurable and important. Comparison of the model with experiment shows there is significant advantage in using the directional ratios of backscattering coefficients for data analysis.

2:30 PM Invited
Quantifying Ti-6Al-4V Bimodal Microstructure Using Microstructure Informatics: *Ayman Salem*[1]; David Turner[2]; Dan Satko[2]; Joshua Shaffer[2]; Stephen Niezgoda[3]; Surya Kalidindi[2]; [1]Materials Resources LLC; [2]Drexel University; [3]Los Alamos National Laboratory

Microstructure Informatics tools, based on 2-point statistics, have been developed and applied successfully to quantify a broad range of Ti-6Al-4V microstructures. The applicability of the tools has been demonstrated on datasets captured by Electron Backscatter diffraction patterns (EBSD) and Backscatter Electron (BSE) images. Multiple filters and image processing techniques have been utilized to automatically segment various features of interest in the microstructure. Primary alpha grains, secondary alpha colonies, and secondary alpha laths have been quantified individually. The spatial correlations between various features have been captured in addition to morphologies and micro-texture attributes. Procedures have also been developed to extract legacy metrics from datasets. Comparisons between measured metrics using legacy standards and the ones computed by our novel methods revealed tremendous cost savings with the later.

3:00 PM
An Experimental Study on the Effect of Microstructure on Oxygen Ingress in Ti-6242S Alloy: S. Knox[1]; *G. Viswanathan*[2]; M. Chapman[1]; A. Shiveley[2]; J. Tiley[2]; [1]Southwestern Ohio Council for Higher Education/ Air Force Research Laboratory; [2]Air Force Reasearch Laboratory

Excessive oxygen ingress at high temperature has been known to adversely affect the mechanical properties of α/β Ti alloys. Although studies in the past have investigated oxygen ingress in Ti alloys, the impact of microstructure on the diffusion of oxygen and the formation of alpha case is only beginning to emerge. This study focuses on the roles of alpha orientation and morphology. Samples of Ti-6242S α/β alloy were solutionized in a vacuum furnace and held at temperature to produce large beta grains. Slow cooling was used to produce large colony microstructures. The samples were subsequently oxidized at 650C for 100 hours. The material was sectioned and analyzed using optical microscopy, SEM and EBSD techniques to investigate the effect of morphological orientation of (α+β) colony microstructure on oxidation. Additionally, the oxidized samples were examined for nucleation of surface cracks under tensile loads to determine effects of microstructure on mechanical performance.

3:20 PM
Characterizing and Exploring the Broad Utility of Kinetic Metallization, a Novel Subsonic Cold Spray Metal Deposition Technique: *John Sosa*[1]; Peter Collins[2]; Hamish Fraser[1]; [1]The Ohio State University; [2]University of North Texas

Kinetic Metallization (KM), a subsonic cold-spray metal deposition technique, avoids elevated temperatures and offers a promising way to produce unique titanium-based coatings and bulk material. However, there has been limited work to characterize the mechanisms of powder deformation and particle/particle interactions in the final product form. DualBeam™ (FIB/SEM) 3D characterization, incorporating EBSD, of single particles and particle-clusters has permitted a robust investigation of such mechanisms and interactions. Additionally, KM deposits have been subjected to both hot isostatic pressing and laser heat-treatments to probe the degree of recrystallization given their presumably high stored strain-energy. SEM, TEM, and FIB-3D have been used to characterize the phase transformations within binary metal composites and explore the influence of particle/particle interface character on such transformations. Finally, unique Ti/Mg metal-matrix composites have been fabricated using KM and their microstructure evaluated using multiple characterization techniques.

3:40 PM
Determining the Variance and Distribution of Quantified Microstructure in a + ß Processed Ti-6Al-4V and Their Contribution to the Accuracy of Property-Predictive Neural Network Models: *Meg Noble*[1]; Daniel Huber[1]; John Sosa[1]; Travis Presley[1]; Hamish Fraser[1]; [1]Ohio State University

The use of quantified microstructures as inputs to neural network models for property prediction has been pioneered by Center for the Accelerated Maturation of Materials at The Ohio State University to provide predictive tools for mechanical properties in titanium alloys while phenomenological models are developed. The work presented focuses on testing the neural network models, their predictive capability, and developing additional robust models. A generation of new automated tools developed by CAMM has permitted quantification of the variance and distribution of a + ß processed Ti-6Al-4V, which will provide inputs for testing the neural networks. The output accuracy of these models will be compared to the quantified variance and distribution to better understand the source of any model inaccuracy. The observed variations in quantified microstructures revealed variation in a host of Ti-6Al-4V microstructures, thus providing more precise prediction models.

4:00 PM
Calculation of Kearns Number Plots (KNP) and Kearns Number Maps (KNM) from EBSD Data: Application to Ti-6Al-4V with Bimodal Microstructure: *Ayman Salem*[1]; Adam Pilchak[2]; Surya Kalidindi[3]; [1]Materials Resources LLC; [2]Air Force Research Laboratory; [3]Drexel University

A method for calculating and presenting Kearns' texture factor from discrete orientations obtained by electron backscatter diffraction data was developed for titanium alloys. This form of quantitative texture analysis was visualized via new plots that display the Kearns numbers for all possible directions in the sample reference frame. In addition, new maps were generated to visualize the spatial distribution of Kearns number throughout the sample. The method is general and applicable to any material exhibiting hexagonal symmetry. The methods have been applied individually to the primary alpha grains and secondary alpha colonies in a hot rolled Ti-6Al-4V plate.

4:20 PM
The Study of Phase Transformation in Beta Titanium Alloys Using Electrical Resistivity Measurement, Image Processing Technique and Electron Microscopy: *Yufeng Zheng*[1]; Robert Williams[1]; Hamish Fraser[1]; [1]The Ohio State University

Due to the combination of high strength and great ductility, beta titanium becomes a promising candidate for the future use in the biomedical implants field as well as the aerospace application. Understanding the microstructural evolution in beta titanium alloys is essential to manipulating its properties. Using state of the art equipment, the phase transformation sequence of the beta titanium in the heating process and the kinetics of alpha precipitation in the isothermal treatment was studied by electrical resistivity measurement in the Electro-Thermal-Mechanical Tester(ETMT). With the high resolution transmission electron microscopy, the onset of the alpha precipitate formation in the material could be studied in details and with image processing technique, the TTT diagram of isothermal treatment could be plotted conveniently. The microstructure evolution in Ti-Mo binary alloy and Ti-5Al-5Mo-5V-3Cr will be introduced to illustrate the power of the method above.

4:40 PM
Phase Transformations and Mechanical Properties of Alpha-Beta Solution Treated Ti-6.8Mo-4.5Fe-1.5Al: *Jana Smilauerova*[1]; Petr Harcuba[1]; Miloš Janecek[1]; Josef Stráský[1]; Radomír Kužel[1]; Henry Rack[2]; Herbert Boeckels[2]; [1]Charles University; [2]Clemson University

Formation and growth of omega and alpha phase particles in TIMETAL LCB (Ti-6.8Mo-4.5Fe-1.5Al, wt. %) were examined by electrical resistivity and DSC measurements during linear heating. The influence of alpha-beta solution treatment between 700 and 745°C used to control the volume fraction, size and contiguity of grain boundary alpha and subsequent ageing at 450 and 500°C for times at 8 and 16 hours on mechanical and fatigue properties was studied. Related microstructure evolution – omega and alpha phase particle size and spatial distribution – was examined by transmission and scanning electron microscopy and by means of X-ray diffraction.

5:00 PM
Effect of Titanium Borides on the Formation of Equiaxed Alpha in Titanium Alloys: *Peeyush Nandwana*[1]; Soumya Nag[1]; Jaimie Tiley[2]; Hamish Fraser[3]; Rajarshi Banerjee[1]; [1]University of North Texas; [2]Air Force Research Laboratory; [3]The Ohio State University

Titanium boride (TiB) is a promising reinforcement phase in Ti alloy matrices that may lead to enhanced stiffness, strength, and wear resistance. Furthermore, during the solid-state precipitation of a in a matrix of ß titanium, the presence of TiB precipitates act as additional nucleation sites for a phase. Interestingly, the a that is nucleated on the TiB precipitates exhibit an equiaxed or globular morphology in contrast to the a precipitated on other nucleation sites such as grain boundaries, which exhibit a more lath-like morphology. The current study uses Electron Backscattered Diffraction (EBSD) and Transmission Electron Microscopy (TEM) techniques to investigate the effect of borides on subsequent nucleation and growth of a precipitates. For this, various cases were considered where the a phase was in close proximity to boride particles and different orientation relationships existing between a Ti, TiB and ß matrix were identified.

5:20 PM
Effect of Heating Rate on the Short Time Aging Kinetics of Ti-6.8Mo-4.5Fe-1.5Al: *Herbert Boeckels*[1]; Henry Rack[1]; [1]Clemson University

This investigation has examined the influence of heating rate on the short time, less than 4 h, kinetics of ω and a phase precipitation in beta solution-treated Ti-6.8Mo-4.5Fe-1.5Al utilizing measurements of the time dependent calorimetric response observed during aging in the temperature range 200-550°C. While transformations were observed at all aging temperatures for the lower rate, 5°C/ min., heating at 50°C/min. tended to suppress the observed transformations to higher aging temperatures. For example, single reactions, associated with the evolution of the ω phase, were found at aging temperatures = 400°C and = 450°C for 5°C and 50°C heating rate respectively. Above these temperatures duplex reactions involving both ω and a phase were observed. This behavior has been examined using the JMAK analysis methodology and will be discussed in terms of ω stability and a precipitation during isothermal aging as influenced by heating rate, aging temperature and aging time in Ti-6.8Mo-4.5Fe-1.5Al.

5:40 PM
Phase Evolution as a Function of Heat Treatment in Ti-48Al-16Nb Alloys: *Narayana Garimella*[1]; A. K. Singh[2]; N.K. Mukhopadhyay[3]; G.V.S. Sastry[3]; [1]University of Maryland School of Medicine; [2]Defence Metallurgical Research Laboratory Hyderabad India; [3]Department of Metallurgical Engineering Banaras Hindu University India

Several research works have focused on phase transformation in Ti-48Al based alloys with the aim of improving their formability characteristics. Precipitation, growth and distribution of B2 phase within the matrices of either 'Gamma' or lamellae of 'Gamma-Alpha2' or both Gamma and'Gamma-Alpha2' phases is found to be the important factor of contribution to enhance the room temperature formability of Ti-48Al-16Nb Alloys. In this work, phase evolution in Ti-48Al-16Nb alloys was evaluated as a function of aging time and temperature. The alloys were solution treated at 1400°C, and were aged at several lower temperatures ranging from 400°C to 1300°C for the descending durations of aging respectively. Relatively increased amount of B2 phase was resulted for the aging condition of 1200°C for 4 hrs sample with the subsequent decrease in vicker's hardness. Physical and mechanical metallurgy aspects of the results are discussed with the aids of phase transformation and mechanical strength.

T.T. Chen Honorary Symposium on Hydrometallurgy, Electrometallurgy and Materials Characterization: Transition Metal Processing

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Hydrometallurgy and Electrometallurgy Committee, TMS: Materials Characterization Committee

Tuesday PM — Room: Oceanic 5
March 13, 2012 — Location: Dolphin Resort

Funding support provided by: Rio Tinto Kennecott Utah Copper, ASARCO, and Freeport McMoRan

Session Chair: Michael Free, Univesity of Utah

2:00 PM
FeTi Alloy Production by Electrolytic Reduction of (Fe, Ti) Oxide Electrode in Molten Calcium Chloride: *Panigrahi Mrutyunjay*[1]; Atsushi Iizuka[1]; Etsuro Shibata[1]; Takashi Nakamura[1]; [1]IMRAM, Tohoku University

In this work, TiO_2 and Fe_2O_3 powder were mixed in proper molar ratio followed by preparing pellets and heat treated at (1000°C-1300°C) to increase the conductivity and strength. For electrolysis, the $CaCl_2$ was dehydrated to remove the moisture followed by pre-electrolysis at 2.6 V for the remaining amount of moisture and other volatile impurities. The heat treated (1000°C for 2 hrs.) pellet was electrolyzed by constant voltage electrolysis process (3 volt for 20 hrs) at 950°C. The conductivity of the electrolyzed pellet was measured and characterized by XRD, SEM and EDX. From these analyses, it is confirmed that the surface of the product contains FeTi, H_2FeTi and amorphous carbon and the cross section contains FeTi, $TiO_{1.04}$, amorphous carbon and TiO_2. However, more experiments should do with a longer electrolysis time to avoid the unwanted phases.

2:20 PM
A New Method for Production of Titanium Dioxide Pigment – Eliminating CO2 Emissions: *Scott Middlemas*[1]; Z. Zak Fang[1]; Peng Fan[1]; [1]University of Utah

Titanium dioxide (TiO2) has been widely used as pigment in paints, paper and cosmetic products, as well as high-tech applications such as PV Cells, semiconductors, biomedical devices and air purification. TiO2 pigment is primarily produced by the high temperature chloride process, resulting in considerable CO2 emissions. A novel hydrometallurgical process for making TiO2 pigment without CO2 emission is investigated. The new method promises to eliminate direct CO2 emissions, consume significantly less energy, and produce minimal environmental waste. The novel process involves molten salt roasting of titania slag, with subsequent washing, leaching, hydrolysis, bleaching, calcination and post-treatment stages, resulting in high-purity anatase or rutile pigments while realizing significantly reduced environmental impacts. Pigment whiteness is critically sensitive to trace amounts of discoloring impurities such as iron and chromium. Several methods for reducing the levels of these impurities are investigated. Energy consumption and emission models are also developed.

2:40 PM
Extraction of Titanium and Vanadium by Chloride Leach Processes: *Lucky V.I. Lakshmanan*[1]; R. Sridhar[1]; T. Sheikhzeinoddin[1]; Md. Halim[1]; R. Roy[1]; [1]Process Research Ortech Inc.

Chloride metallurgy is emerging as an alternative process for the production of base metals. Process Research ORTECH Inc. (PRO) has been at the forefront of technological development of chloride metallurgy. PRO has developed an innovative technology for the production of high purity titanium dioxide from ilmenite ores and concentrates. PRO is also developing its proprietary mixed chloride technology for the extraction of vanadium from different sources such as ilmenite and oil shales. In this paper, the developments in chloride metallurgy for the extraction of Ti and V will be reviewed and some results from the test work conducted at PRO will be presented.

3:00 PM
Formation of Titanium Liquid Alloy by Mechanical Mixing and Electrochemical Method: *Sho Maruyama*[1]; Shohei Hayashi[1]; Yuya Kado[1]; Tetsuya Uda[1]; Yoshitaro Nose[1]; [1]Kyoto university

We are trying to establish a new smelting process of titanium. The new process consists of two consecutive cells, Reduction cell and Refining cell. In the Reduction cell, titanium raw material is reduced to liquid alloy and in the Refining cell pure titanium is obtained by electrolytic refining. As the basic study, we made titanium liquid alloys by melting some metals or their alloys in titanium crucibles at 1173 K. But the titanium compositions in some liquid alloys (ex. Sn, Pb, Sn-Cu) were very smaller than those in reported phase diagrams. We found intermetallics is formed on the surface of the crucible with uniform thickness and it prevents titanium from disolving into liquid alloy. Only antimony alloys contained approximately 10 at.% titanium which coincided with the value in the phase diagram. Some results of electrochemical reduction of titanium raw materials to the liquid alloy will be introduced.

3:40 PM
Anion-Exchange Separation of Zr from Hf using Multi-Column Method: *Masahito Uchikoshi*[1]; Kouji Mimura[1]; Minoru Isshiki[1]; [1]Tohoku University

HfO_2 is expected to be a gate dielectric used in ULSI alternative to SiO_2. Although the materials used in ULSI are required to be sufficiently purified, commercial Hf contains > 2 mass% Zr. It is important to establish process of removing Zr from Hf. In the present study, anion-exchange separation using multi-column method was employed. The separation tests were carried out in variety of temperatures and flow rates. The decrease in the flow rate of the mobile phase made the elution curves of both Hf(IV) and Zr(IV) broadened contrary to the case of Co(II), Cu(II), or Fe(III). This is caused by the difference in adsorption rate on anion-exchange resin. In addition, more than one column were connected in series in order to enhance the separation ability. As a result, the content of Zr(IV) was successfully reduced down to 1/100 relative to the raw material.

4:00 PM
Recovery of Metals from Molybdenite Concentrate by Hydrometallurgical Technologies: *Yufang Wang*[1]; Kaixi Jiang[1]; Xiaoping Zou[1]; Lei Zhang[1]; Sanping Liu[1]; [1]Beijing General Research Institute of Mining and Metallurgy

Molybdenite concentrates are usually treated by roasting; but low concentration SO2 pollution is a problem. Extraction of Molybdenum and rhenium from molybdenite concentrates with pressure oxidative leaching and solvent extraction (SX) process was studied. A series of POX-SX lab and pilot tests were carried out on the molybdenum concentrate. In POX stage, more than 95% rhenium and 15-20% molybdenum were leached into solution. Solvent extraction extracted rhenium and molybdenum from POX solution. The extraction rate of Re and Mo reached above 98%. The loaded organic reagent is stripped with ammonia. The stripping ratio of Mo is more than 98%.Comparison with roasting process the total recovery of Mo can increase from 93% to 97%, and Re from 50% to 80%. In the coming five years POX-SX technology is competitive in China.

4:20 PM
The Effect of Phosphate Additions on the Microstructure and Performance of Cr_2O_3 Gasifier Refractories: *Kyei-Sing Kwong*[1]; James Bennett[1]; Jinichiro Nakano[2]; John Sears[2]; Xueyan Song[3]; [1]NETL, US DOE; [2]URS Corp.; [3]West Virginia University

Gasification is an efficient, environmentally clean, technology capable of processing coal, petroleum coke, or biomass into syngas used in the production of electric power or chemicals. However, the short service life of the Cr_2O_3 refractory used to protect the outer steel containment shell from coal slag attack and insulate it from the high temperature process is one of the factors limiting gasification technology. Post mortem analysis of Cr_2O_3 refractories has been conducted by XRD, ICP, SEM, and TEM to find failure mechanisms and to study the reaction between gasifier slags and refractories. Structure spalling caused by slag penetration has been identified as one of the major failure mechanisms. New improved phosphates containing Cr_2O_3 refractories were developed and successfully proven in gasifier field tests. The effect of phosphates has been characterized using TEM and SEM and its mechanism in decreasing slag penetration will be discussed.

4:40 PM
Extraction Impurities such as Fe, Ca and Mg from a Titanium Material in Chloride Acid System with Microwave Eenergy Leaching: *Shaohua Ju*[1]; Jin-Hui Peng[1]; Sheng-Hui Guo[1]; Wang Xin[1]; Lie-Xing Zhou[1]; Meng-Yang Huang[1]; [1]Kunming University of Science and Technology

This work intends to leach the impurities such as Fe, Ca and Mg out from a low grade Titanium mineral, to increase the grade. The original material contains 65% TiO2 , 16.12% Fe, 9.4% CaO + MgO, 4.2% SiO2, 1.25% Al2O3, and the particle size is between 0.053-0.045mm. The microwave energy was used to enhance the leaching effect. The result showed that when normal heating method was used to leaching the mineral, the extraction of impurities Fe, Ca and Mg are very low. However, when microwave energy is introduced to this system, the extraction of Fe, Ca and Mg increased dramatically. The optimized conditions are: relative power equals to 5W/g, the concentrate of HCl equals to 15%, leaching at 160□ for 20 min with a ratio of liquid to solid 12:1, and the material obtained contains 92.73% Ti, 0.207% Ca + Mg, and 0.8% Fe.

5:00 PM
Study on Sodium Roasting and Chromium Extracting of Fe-Cr Spinels: Hai-Xing Fang[1]; *Hong-Yi Li*[1]; Bing Xie[1]; [1]Chongqing University

In duplex melting process of converter, chromium forms chromium spinels, the study of which will help to explore Hongge ores (rich in chromium) in Panzhihua-Xichang area in China. Mimicked chromium slag was synthesized in experimental conditions. The oxidation and decomposition mechanism of Fe-Cr spinels was studied in sodium roasting process. Effects of temperature, roasting time and amount of soda addition on the convertion rate were investigated. The leaching-reduction-precipitation-calcination process to extract Cr2O3 was also optimized. Results showed that the optimized roasting temperature was about 1000□ with Na2CO3 addition in stoichiometric amount. Roasted materials were leached by distilled water and filtered to obtain chromium-containing solution, which was adjusted to pH 1.60~1.80. Reducing reagent NaHSO3 was added in stoichiometric ratio and the solution was then adjusted to pH 7.25~8.25. Maximum Cr(OH)3 precipitation was obtained and calcined at 1050□ for 2h to obtain Cr2O3 with recovery rate over 96%.

Ultrafine Grained Materials VII: Processing-Microstructure-Property Relationships: Al-, Mg- and Ti-Alloys

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Nanomechanical Materials Behavior Committee, TMS: Shaping and Forming Committee

Development of Ultra-High Strength Al–Mg Alloys Processed by Severe Plastic Deformation: *Hans Roven*[1]; Manping Liu[2]; Maxim Murashkin[3]; Ruslan Valiev[3]; Tamas Ungár[4]; Levente Balogh[4]; [1]Norwegian University of Science and Technology (NTNU); [2]Jiangsu University; [3]Ufa State Aviation Technical University; [4]Eötvös University

One of the recent interests applying severe plastic deformation to light alloys is the possibility to achieve ultra-high strength. The present work focuses on the strength potentials of the solid solution strength system Al-xMg applying high pressure torsion. The binary Al-Mg alloy system has been studied systematically in the range from commercial purity aluminium up to Al–10wt%Mg. Different post deformation characterization methods such as high-resolution transmission electron microscopy, X-ray diffraction and mechanical testing have been applied to reveal the embedded nanostructures and strengthening mechanisms. A remarkably high tensile yield strength of 830 MPa is obtained in an Al–

8.0wt%Mg alloy. This significant improvement in strength is attributed to the cooperative interactions of solute atoms, high dislocation densities, grain boundaries and planar interfaces.

2:20 PM
Dynamic Precipitation in AA6060 during HPT Processing at Different Temperatures: *Gang Sha*[1]; Xiaozhou Liao[1]; Kaan Tugcu[1]; Maxim Murashkin[1]; Ruslan Valiev[1]; Simon Ringer[1]; [1]The University of Sydney

Severe plastic deformation (SPD) is well known to be effective in modification of materials microstructures and achieving significant refinement on grain size. The SPD processing is able to have a significant influence on the formation of precipitate microstructures. In this contribution, AA6060 alloy quenched after a solution treatment has been processed using high-pressure torsion (HPT) at room temperature, 100 °C and 180 °C up to 10 revolutions under a pressure of 6 GPa. The precipitates microstructures of the alloy have been characterised systematically using both transmission electron microscopy and atom probe tomography (APT). In addition to the amount of strain applied by HPT processing, processing temperature has been found to have a significant influence on the formation of precipitate microstructures of the alloy. With the quantitative structural and chemical information of precipitates revealed by APT characterisation, this contribution will comprehensively address the kinetic and thermodynamic effects of the dynamic precipitation in AA6060 during HPT processing.

2:35 PM
ECAP Processing of Al5052 Alloys at Room and Cryogenic Temperatures: *Jung Singh*[1]; Garima Sharma[1]; Apu Sarkar[1]; V Basavaraj[2]; Jayanta Chakravartty[1]; [1]Bhabha Atomic Research Centre; [2]IIT Bombay

ECAP processing of Al5052 alloys has been carried out by deforming it at room and cryogenic temperatures. Samples were deformed using the Bc route up to 14 passes in a 120° angle die. Development of microstructure with number of ECAP passes has been monitored at intermediate intervals using transmission electron microscopy (TEM) and Electron backscatter diffraction (EBSD) techniques. Deformation temperature was found to have a strong effect on the substructure of the microstructure developed and consequently on the room temperature strength.

2:50 PM
Effects on Hardening and Ductility of Severe Plastic Deformation of Al-Cu-Li and Cu-Cr-Zr Precipitation Hardening Alloys: *David Morris*[1]; Kesman Valdes Leon[1]; Maria Muñoz-Morris[1]; [1]CENIM, CSIC

Severe plastic deformation of precipitation hardening alloys offers the possibility of processing the solutionised material at room or high temperature, with ageing before or after deformation. Different strengths and ductilities arise because of complex interactions between precipitates and dislocations. Such interactions have been examined by ECAP of two precipitation hardening alloys. ECAP of Al-Cu-Li at room temperature leads to moderate strength with poor ductility, with subsequent ageing improving both. ECAP at elevated temperatures gives good strength with moderate-to-good ductility, depending on processing conditions. Detailed microstructural analysis shows that precipitates play a major role in determining both strength and ductility. ECAP of solutionised and/or aged Cr-Cr-Zr leads to hardening but low ductility, while subsequent ageing increases substantially both strength and ductility. The role of ECAP temperature is complicated, determining the microstructural state. The balance of substructural refinement and dislocation and precipitate hardening is analysed here to explain the mechanical properties.

3:05 PM
Structural Evolution in Aluminium Alloy AA6082 during HPT Deformation at Increased Temperature: *Jozef Zrnik*[1]; Libor Kraus[1]; Reinhard Pippan[2]; Martin Fujda[3]; Karel Sperlink[4]; [1]Comtes FHT, Inc.; [2]Austrian Academy of Science; [3]Technical University in Kosice; [4]CSNMT

Aluminium alloy AA6082 of different initial structure was deformed by HPT at increased temperature of 150°C. The impact of various effective strain eef and temperature on fine grain structure evolution and mechanical properties was investigated. The refinement of coarse initial alloy structure, modified by thermal treatment performed prior deformation, was investigated using TEM of thin foils respecting the effect of different shear strain across the disc. The tensile tests and microhardness were performed with aim to evaluate mechanical properties changes as effect of straining. The torque versus number of turns was measured as well. The microstructure results showed that ultrafine grained structure was formed across the disc applying the first turn. Effectively homogenized ultrafine grained structure across the disc was attained. Tensile test results showed that effect of deformation strengthening was increasing as effective stress increased. The hardness results pointed out to the reverse dependence of strength across the disc.

3:20 PM
Effect of Short Annealing and Ageing on Microstructure and Mechanical Properties of Ultrafinegrained Al-Mg-Si Alloy: *Nageswararao Palukuri*[1]; Jayaganthan R[1]; [1]IIT Roorkee

In the present investigation, ultrafine grained Al 6061 alloy was developed through cryorolling(CR) by giving 90% reduction and further short-annealed(SA) for 10 min at 200ºC followed by low temperature ageing. Micro structural and Mechanical properties were characterized through (TEM), EBSD technique, Vickers hardness testing and Tensile testing unit. This has been compared with Al 6061 developed through cryorolling for 80% and hot rolling from 80 % to 90 % reduction at 200ºC with soaking time of 10 min followed by ageing. Cryorolling followed by hot rolling has shown improved Vickers hardness and UTS (115HV, 360MPa) compared to (96HV, 285MPa) of the samples subjected to CR+ SA.The post-CR hotrolling (200ºC) followed by ageing treatment (120ºC,) of the Al 6061 alloy has shown an improved strength and well defined ultrafine grain structure as compared to the samples subjected to post-CR short annealing (200ºC, 10 min) followed by ageing treatment.

Nanostructure Evolution in Pure Aluminum Heavily Deformed by Torsion: *Nobuhiro Tsuji*[1]; Sunisa Khamsuk[1]; Hiroki Adachi[2]; Daisuke Terada[1]; [1]Kyoto Univ; [2]University of Hyogo

Continuous torsion straining was applied to a commercial purity aluminum (JIS-1100) at various strain rates and temperatures. Elongated ultrafine grains having microstructural parameters comparable to those formed in other severe plastic deformation like ARB were found in the specimens deformed by torsion to high equivalent strains at room temperature. The effects of simple shear deformation, temperature and strain rate on the nanostructure evolution are experimentally shown and discussed.

4:10 PM
Effect of the Severe Plastic Deformation on the Wear Behavior of an Al-Mg-Si Alloy: Edgar Ortiz-Cuellar[1]; M. A. L Hernandez-Rodriguez[1]; *E. Garcia-Sanchez*[1]; [1]Universidad Autónoma de Nuevo León -Facultad de Ingeniería Mecánica y Eléctrica

With the aim to study the effect of the severe plastic deformation on the wear properties, grain refinement and mechanical properties in an aluminum alloy in this work a commercial Al-Mg-Si alloy under two initial microstructural conditions has been deformed at room temperature by multi-pass 90º equal channel angular pressing (ECAP). After the processing each sample was evaluated by means of microhardness tests and the microstructural condition was determinate by electron microscopy. Subsequently sliding wear test was undertaken in a ball on disk configuration under lubricated and unlubricated conditions using a steel ball. It was found a wear resistance increasing with the rise in the deformation promoted by the number of extrusion passes; the effect of the initial microstructure on the wear decreases with the level of strain in the material. The lubrication condition promotes changes in the response of the material. The dominant wear mechanisms were identified and correlated.

4:25 PM
Effect of Multi Directional Forging at Liquid Nitrogen Temperature on Microstructure and Mechanical Properties of Al-Mg-Si Alloy: *Jayaganthan R*[1]; Nageswararao P[1]; [1]IIT Roorkee

Multi directional forging was conducted on solution treated Al-Mg-Si alloy at liquid nitrogen temperature (-193ºC) with total number of cycles 6 and to the cumulative strain of 3.6. After every two cycles, the deformed microstructure was examined by EBSD and transmission electron microscopy (TEM). The results have shown that at lower strains in liquid nitrogen temperature, the microstructure exhibits higher dislocation density. Significant grain refinement was observed in miltidirectonally forged sample at cryogenic temperature. Grain refinement occurs due to effective suppression of dynamic recovery upon submerging the sample in liquid nitrogen during forging. The mechanical properties were studied through Vickers hardness testing machine and Tensile testing unit. Vickers hardness has been taken across the cross-section and it was observed that the hardness value of cryoforged alloy has increased from 45 HV to 110 HV by imparting 3.6 accumulated strains. Tensile strength of cryoforged sample was observed to be 340 MPa.

4:40 PM
Effect of Nano-Structural Modification on the Mechanical Behavior of Lamellar Gamma TiAl Alloy: *Yu Sun*[1]; Anil Sachdev[2]; Enrique Lavernia[1]; [1]University of California, Davis; [2]Chemical Sciences and Materials Systems Lab, GM Global R&D Center, Warren, MI

Lamellar gamma TiAl alloys exhibit high stiffness, specific strength and creep resistance for temperatures up to 1000°C, and have emerged as promising materials for high-temperature structural applications. The lamellar microstructure can be substantially varied by the modification of the length scale between γ-TiAl/α2-Ti3Al and the effect on mechanical properties. This paper describes the nanoscale modification of the lamellar phase microstructure on the mechanical behavior of these alloys. Cryomilling is utilized to generate nano-grained gamma powders, and the fully lamellar TiAl alloy, with the ultrafine colony size, is consolidated by spark plasma sintering. A careful design of the cooling route after sintering allows a manipulation of the lamellar γ-TiAl/α2-Ti3Al spacing, distribution and orientation, all of which are determined with TEM and EBSD. The size-effect of the lamellar colony, and the spacing, orientation and distribution of the lamellar γ-TiAl/α2-Ti3Al are investigated in terms of the macroscopic mechanical response and microscopic fracture mechanism.

4:55 PM
Development of Ultrafine Grained Mg-Y-RE Alloy by Multi PassFriction Stir Processing: *S. K. Panigrahi*[1]; R.S. Mishra[1]; R. DeLorme[2]; B. Davis[2]; R. A. Howell[3]; K. Cho[3]; [1]Centre for Friction Stir Welding and Material science and Engineering; [2]Magnesium Elektron North America Inc.; [3]Weapons and Materials Research Directorate

Rare earth containing magnesium alloys have received significant attention in aerospace and automotive industries due to their high strength to weight ratio, high damping performance and better creep resistance. The strength, ductility and superplasticity of these alloys can be enhanced further by refining the grain structure to the ultrafine regime. Friction stir processing (FSP) is emerging as an attractive technique for producing fine grained microstructure in Mg based alloys. Although a number of researchers have achieved ultrafine grained (UFG) microstructure on different Mg-Al-Zn alloy system by FSP, the development of UFG microstructure in Mg-Y-RE alloy has not been reported. In the present study, a multi pass FSP approach was used to develop UFG Mg-Y-RE alloy. The microstructure was refined to 240 nm after successful implementation of a three pass FSP. The influence of precipitates and heat input during FSP on microstructural refinement and texture modification were addressed in detail.

5:10 PM
Microstructure and Defect Structure Evolution in Commercial Magnesium Alloys Processed by Severe Plastic Deformation: *Miloš Janecek*[1]; Jakub Čížek[1]; Jitka Vrátná[1]; Julia Mueller[1]; Jeno Gubiza[1]; [1]Charles University

MgAlZn and MgZnZr were processed by hot extrusion and equal channel angular pressing (ECAP) known as EX-ECAP. Microstructure and defect structure evolution with strain due to ECAP was investigated by TEM, positron annihilation spectroscopy (PAS), and X-ray diffraction. Significant grain refinement was obtained in all alloys by EX-ECAP. The dislocation density evolution with strain as determined by PAS followed the same scheme in all three alloys. In the ex-extruded condition a very low density of dislocations was observed. Sharp increase of dislocation density occurred during the first two passes of ECAP, followed by saturation and even a decline manifesting the dynamic recovery at higher strains. XRD line-profile analysis confirmed the results of PAS with slightly higher values of dislocation densities in individual conditions. Detail analysis of contrast factors allows to determine the type of dislocations and to draw conclusions about slip activation and its variations with strain in individual alloys.

5:25 PM
Effect of HPT Processing Temperature on the Evolution of Strength in a Magnesium Alloy: *Yi Huang*[1]; Roberto Figueiredo[2]; Terence Langdon[3]; [1]University of Southampton; [2]Federal University of Minas Gerais; [3]University of Southern California

It is now well known that processing by severe plastic deformation can significantly increase the strength of metallic materials by refining the grain structure and increasing the density of defects. The rapid increase in strength observed in the early stage of deformation is expected to slow down and saturate at large strains due to an increase in recovery of the material. Therefore, a saturation of strength is expected to depend on the processing temperature. The present paper analyses this parameter by determining the evolution of hardness of a magnesium alloy processed by high-pressure torsion at different temperatures. Keywords: high-pressure torsion, magnesium alloys, microhardness test

5:40 PM
Some Studies on the Microstructural Changes in a Mg-Based AE42 Alloy Subjected to Friction Stir Processing: Brij Dhindaw[1]; Harpreet Singh[1]; *Harpreet Singh Arora*[1]; [1]I.I.T. Ropar

The study report microstructural changes taking place in a Mg-based alloy (AE42) subjected to FSP under different cooling conditions. FSP process was carried out with single as well as multipass options. It was observed that FSP tends to fragment the elongated precipitates and produces near homogeneous distribution of fine particles. The smallest particle size was observed to be produced by double pass FSP supplemented by rapid cooling, thereby generating in-situ nano-composites. Nearly two times increase in the micro-hardness of AE42 was observed in case of double pass FSPed AE42 with cooling at temperature of about -20°C. To further confirm these observations, another magnesium alloy AM50 was also FSPed under similar conditions. Fine submicron grain structure produced in FSPed AE42 alloy, immensely contributed towards grain boundary strengthening and Orowan strengthening had only marginal influence. Sub grain boundary pinning by in-situ nano-particles has contributed significantly in the strengthening process.

Structure and Properties of the Stainless Cr-Ni-Ti Steel after High PressureTorsion at T= 300-500°C: *Sergey Dobatkin*[1]; Ruslan Valiev[2]; Olga Rybalchenko[1]; Maksim Murashkin[2]; [1]A.A. Baikov Institute of Metallurgy and Materials Science of RAS; [2]Ufa State Aviation Technical University

The regularities of the structure formation in the stainless Cr-Ni-Ti austenitic steel (0.07%C, 17.3%Cr, 9.2%Ni, 0.7%Ti) upon high pressure torsion (HPT) under 6 GPa at 300 and 500°C have been studied. The HPT at room temperature leads to martensitic transformation. However, the martensitic structure deteriorates the corrosion resistance. The aim is to obtain fully austenitic structure after deformation. The electron-microscopic examination of the Cr-Ni-Ti steel after HPT at 300 and 500°C revealed the formation of nano- and submicrocrystalline structures with average sizes of structure elements of 87 and 123 nm, respectively. X-ray diffraction analysis revealed the presence of only austenitic phase. The HPT substantially increases the strength characteristics of the Cr-Ni-Ti steel: the YS and UTS increase almost by a factor of 6 and 3, respectively. The maximum yield strength (1740 MPa) is observed after HPT at T = 300°C. The work was supported by RFBR (project no. 10-03-00996).

2:20 PM
Effect of Alloy Composition on Mechanical Properties of Bulk Nanostructured Fe-Ni-Co-Ti Alloys Produced by High-Pressure Torsion: *Tadahiko Furuta*[1]; Shigeru Kuramoto[1]; Kaveh Edalati[2]; Zenji Horita[2]; [1]Toyota Central R & D Labs., Inc.; [2]Kyushu University

Microstructural evolution and mechanical properties were studied in Fe-(18.1-24.2)%Ni-(32.3-35.8)%Co-(3.9-9.3)%Ti (in at%) alloys after processing by high-pressure torsion (HPT) at room temperature with a rotation speed of 1 rpm under a pressure of 6 GPa. The HPT-processed alloys were composed of ultrafine grains having the sizes of less than 20 nm in diameter, regardless of the alloy compositions and of occurrences of phase transformation during HPT. However, the alloy compositions affect mechanical properties of these bulk nanostructured Fe-Ni-Co-Ti alloys: ultimate tensile strength (UTS) increases with decreasing Ni and increasing Ti contents and the highest strength is attained in the Fe-18.1%Ni-34.9%Co-9.3%Ti alloy with UTS of about 2.7 GPa. This result suggests that UTS of the present Fe-Ni-Co-Ti alloys is not determined wholly by the grain size after HPT. In this paper, possible strengthening mechanism in the Fe-Ni-Co-Ti alloys will be discussed.

2:35 PM
Synthesis and Characterization of Nanocrystalline High Entropy Alloys: *Koteswararao Rajulapati*[1]; P Chandrashekar[1]; M Sundararaman[1]; K Bhanu Sankara Rao[1]; [1]University of Hyderabad

High entropy alloys are a new class of alloys whose thermodynamic stability is achieved mainly by maximizing their configurational entropy and this can be maximized by making alloys of equi-atomic composition with large number of constituent elements. These materials have been reported to form as simple solid solutions than intermetallic compounds and have exhibited high thermal stability even at elevated temperatures. The present study reports the results of investigations carried out on the stability of two equi-atomic alloys of Al-Ti-V-Cu-Zn-Nb and Al-Cu-Co-Cr-V-Zn compositions processed by mechanical alloying. The milled as well as the aged powders are characterized by XRD, SEM, TEM and DSC to determine their crystal structure, microstructural and morphological changes occurring in them, their thermal stability and the grain growth kinetics. The influence of different synthesis routes on the nature and stability of these alloy powders has also been investigated in this work.

2:50 PM Invited
Influence of Strain Path on the Fracture Behavior of Severely Plastically Deformed Iron: *Anton Hohenwarter*[1]; Reinhard Pippan[1]; [1]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences

The fracture behavior of pure iron, deformed by equal channel angular processing was under investigation. The fracture toughness was determined for different crack plane orientations and additionally with respect to two different deformation routes, route A and route Bc, respectively. The results demonstrate that for route A the crack plane orientation has a tremendous influence on to the fracture toughness. For route Bc the crack plane influence is less pronounced, however, in comparison to route A a strong increase of fracture toughness was found. The relation between the microstructure depending on the deformation route leading to the same strength but to enormous differences in the fracture toughness will be in focus of this paper.

3:10 PM
Microstructure Evolution and of a F138 Austenitic StainlessSteel after Severe Plastic Deformation: *Andrea Kliauga*[1]; Sergey Dobatkin[2]; [1]Universidade Federal de São Carlos - UFSCar; [2]Baikov Institute of Metallurgy and Materials Science RAS

A F138 austenitic stainless steel was solution heat treated, deformed by equal channel angular extrusion (ECAE) at room temperature up to 2 passes and at 300°C up to 4 passes and deformed by high pressure torsion at 300 and 480°C, applying 6GPa pressure and 5 turns. Microstructure evolution was observed by transmission electron microscopy (TEM), electron back-scattered diffraction (EBSD) and X –ray diffraction. The ECAE processed material had a uniform distribution of deformation whereas the deformation of the HTP samples was much more intense at the outside diameter. At room temperature deformation twinning was the predominant deformation mechanism. Further deformation led to grain subdivision inside deformation bands and the onset of new grains formation after 2 ECAE passes. The deformation at 300 and 480°C lead to the formation of recrystallized grains of the order of 100 nm size. No martensite formation was observed by selected area and x-ray diffraction.

3:25 PM
Grain Size Effect on High Speed Deformation of Hadfield Steel: *Rintaro Ueji*[1]; Daisuke Kondo[1]; Yoshinori Takagi[1]; Takashi Mizuguchi[1]; Yasuhiro Tanaka[1]; Kazunari Shinagawa[1]; [1]Kagawa University

Hadfield steel with chemical composition of 12mass%Mn-1%C-bal.%Fe were rolled and subsequently annealed at various temperature to obtain the samples with various mean grain sizes ranging from 1.3 micron to a few 10 micron. Tensile test were conducted at wide range of constant strain rate from 0.001/sec (quasi-static) to 1000/sec (high speed). At the quasi-static test, the fractures of all samples took places without necking and the fracture surfaces indicates brittle like manners. When the strain rate changed to the high speed state, both the strength and the elongation improved largely in all the samples. The fracture at high speed in the samples with conventional grain size happens in ductile manner with necking, whereas that in the fine grained samples was similar to the brittle fracture at quasi-static state. These tendencies were discussed especially focused on twinning behaviors.

3:40 PM
Austenitization Process in a Nanostructured Ferritic Steel Produced by Means of Surface Mechanical Attrition Treatment: *Z.B. Wang*[1]; L.M. Wang[1]; K. Lu[1]; [1]Institute of Metal Research, Chinese Academy of Sciences

A nanostructured surface layer was produced on a ferritic steel (Fe-9Cr) by means of surface mechanical attrition treatment (SMAT). The mean grain sizes of ferrite and carbides in the top surface layer are ~ 8 and 4 nm, respectively. And they increase gradually with increasing depth. In-situ X-ray diffraction and differential scanning calorimetry were used to investigate the austenitization process in the nanostructured surface layer during heating. It was shown that the austenitization temperature decreases gradually with decreasing depth and is ~ 120 K lower in the top SMAT surface layer than in the original sample. In addition, the two-step austenitization process in the original sample becomes a one-step process in the SMAT surface layer. Further microstructural observations of the SMAT sample after annealing showed that an obvious reduction of ferrite grain size occurs after the austenitization during heating and the reversed decomposition of austenite during cooling.

Recent Progress in High-Entropy Alloys: *Ming-Hung Tsai*[1]; Jien-Wei Yeh[2]; [1]North Carolina State University; [2]National Tsing Hua University

It has been considered that alloys consisting of a greater number of principal elements will form complicated and brittle microstructures. Hence research regarding such alloys has received little attention. To overcome this misunderstanding high-entropy alloys (HEAs) have been proposed and explored since 1995. With the high mixing entropy HEAs tend to have simplified microstructures with solid-solution phases. This new alloy concept generates numerous alloys and activates a new research area beyond traditional alloys. In addition to high entropy effect, sluggish diffusion, severe lattice distortion, and cocktail effects are significant in affecting the structures and properties of HEAs. HEAs have been found to possess a wide spectrum of microstructures and properties, and hence provide a number of promising applications. This presentation reviews the recent progress in HEAs and also forecasts the future trend.

4:30 PM
Refinement of Second Phase Particles in Creep-Resistant Iron Aluminides using High-Temperature Severe Plastic Deformation: *David Morris*[1]; Maria Muñoz-Morris[1]; [1]CENIM, CSIC

Severe plastic deformation (typically by Equal Channel Angular Pressing or High Pressure Torsion) is useful for processing ductile materials to obtain fine grain sizes. This study uses multidirectional high strain forging at high temperatures in order to refine coarse second-phase particle dispersions. The materials examined are cast iron aluminide alloys containing different borides or Laves phase. Following forging to strains of about 4-6, materials have relatively coarse grain sizes with greatly refined second phase particles. It is easy to refine particles by fracture from elongated to equiaxed morphology, but further refinement requires strain levels well beyond the capability of the forging technique. The choice of alloy composition and casting conditions, as well as morphology and intrinsic mechanical behaviour of the second phase, are important for determining the evolution of particle size. Excellent creep resistance has been demonstrated after severe plastic deformation has led to extensive second phase particle refinement.

4:45 PM
Thickness Effect in Micro Drawing of Ultrafine and Coarse Grained Cooper: Andrey Molotnikov[1]; *Rimma Lapovok*[1]; Chengfan Gu[1]; Chris Davies[1]; Yuri Estrin[1]; [1]Monash University

The effect of the blank thickness in deep drawing operation was investigated by modelling and experiment. The thickness of a copper blank was varied and deep drawing was done for coarse grained and ultrafine grained material, leading to a change in the thickness-to-grain diameter ratio. For the coarse grained copper a decrease in maximum load was detected, which cannot be predicted by classical continuum plasticity models. The drawing force drops with decreasing thickness when the sheet thickness falls below a critical level (a fifteen-fold of grain diameter in our case). The proposed dislocation density based model, which accounts for the effects of specimen dimensions and grain size, was used to calculate the Limiting Drawing Ratio. It was found that in deep drawing process biaxial ductility does not suffer to the same extent as uniaxial tensile ductility after grain refinement to sub-micron levels, while strength of the material is improved significantly.

5:00 PM
Accumulative Roll Bonding of Cu-Mo Multilayers: MechanicalProperty-Microstructure Relations: Girija Marathe[1]; *Rainer Hebert*[1]; [1]University of Connecticut

The repeated rolling and folding of arrays of metallic foils produces bulk samples with nanoscale laminate- or particulate composite microstructures. Among the most interesting and challenging aspects is the mutual interaction between microstructures, deformation modes, and mechanical properties. Using Cu-Mo multilayers as an example of the technologically important class of Cu-bcc composites, the role will be highlighted of the initial temper condition of the starting foils and the difference in the mechanical properties of the starting foils on the microstructure- and hardness evolution. The formation of shear bands during the initial ARB stage is affected by the initial temper condition. By contrast, the hardness ratio between the component layers approaches a range between about 1.2 and 2.5 over an intermediate strain range irrespective of the initial hardness ratio. The results provide guidelines for the synthesis of nanolaminate or nanoparticulate composites with ARB processing.

5:15 PM
Combination of DRECE Process and Heat Treatment to Achieve Refining Structure of Brass: *Stanislav Rusz*[1]; Karel Malanik[2]; Jan Kedron[1]; Jan Dutkiewicz[3]; Lubomir Cizek[1]; Stanislav Tylsar[1]; Michal Salajka[1]; [1]VSB - Technical University of Ostrava; [2]VUHZ a.s.; [3]Institute of Metallurgy and Materials Science of Polish Academy of Sciences

Contribution concerned the whole production of UFG materials, using forming process DRECE (Dual Roll Equal Channel Extrusion) in brass. This research concerned the whole production of UFG materials, using Severe Plastic Deformation (SPD). Use of these materials is very versatile – either directly as semi-products for subsequent further processing with lower number of operations (created structure is preserved in final products), or for production of final products from semi-products. The heat treatment of part of sheet was applied after DRECE processing. Preliminary metallographic analysis was performed for indicative information, so as to find whether grains were really refined. Mechanical properties of studied samples were tested by Vickers hardness method. Keywords:DRECE machinery, hardness, structure

5:30 PM
Microstructural Evolution and Mechanical Behaviour of Warm Multi-Axially Forged HSLA Steel: *Aditya Padap*[1]; G Chaudhari[2]; V Pancholi[2]; S Nath[2]; [1]Bundelkhand Institute of Engineerring and Technology Jhansi, UP India 284128; [2]Indian Institute of Technology Roorkee, India

In the present work, detailed studies are conducted on the microstructural evolution and mechanical behavior of a high strength low alloy (HSLA) steel processed by warm multi-axial forging (MAF). After nine MAF strain steps, the initial ferrite grains of average 13 µm size reduced to submicron sized grains with over 0.7 fraction of high angle grain boundaries. Pearlitic cementite is fragmented and refined to about 50-100 nm size particles. The microstructure evolution with respect to fraction of HAGB with increase in number of strain steps is more sluggish in HSLA steel as compared to plain carbon steel of comparable carbon content. This is ascribed to the Zener pinning effect of (Ti, Nb) carbide particles. Tensile strength and hardness values of MAFed steel increased by more than 45% and 58 % respectively after nine warm MAF strain steps, whereas the fracture strain was reduced from 21 to 12%.

2012 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: Nanomaterials for Energy Technology

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Nanomaterials Committee
Program Organizers: Jiyoung Kim, University of Texas; David Stollberg, Georgia Tech Research Institute; Seong Jin Koh, University of Texas at Arlington; Nitin Chopra, The University of Alabama; Terry Xu, UNC Charlotte

Wednesday AM — Room: Pelican 1
March 14, 2012 — Location: Swan Resort

Session Chairs: Terry Xu, Univ. North Carolina at Charlotte; Deyu Li, Vanderbilt University

Selected Synthesis Techniques of Thermoelectric Nanomaterials and Their Role in Higher Performance Thermoelectric Materials: *Terry Tritt*[1]; Jennifer Graff[1]; Wenjie Xie[2]; Xinfeng Tang[3]; [1]Clemson University; [2]Wuhan University of Technology; [3]Wuhan University of Technology
This talk will give a brief introduction to thermoelectric (TE) phenomena with an overview of several former and current applications. Several methods will be discussed pertaining to the synthesis of nanomaterials that can be incorporated into a bulk matrix as well as methods that yield in-situ growth of nanodots. Both of these methods yield what is termed as a nanocomposite; nanomaterials incorporated into a bulk TE matrix. The compaction techniques, specifically spark plasma sintering allow these materials to be densified into a bulk pellet, that is typically very close to the theoretical density of the matrix. The ability to decouple the electron and phonon scattering mechanisms is very important in the development of higher efficiency thermoelectric (TE) materials, wherein the figure of merit, ZT, can be greater than unity. Recent results in TE nanomaterials as well as TE nanocomposites from several research groups, including my own, will be presented.

9:10 AM Invited
Thermal Transport Through Individual Nanowires/Nanotubes and Their Contacts: *Deyu Li*[1]; [1]Vanderbilt University
Nanoscale thermal transport attracts much attention over the past decade because of its important applications in thermoelectric energy conversion and thermal management of microelectronic and optoelectronic devices. Thermal transport through individual nanowires and nanotubes and their contacts is of particular interest because of the intriguing underlying physics involved. In this talk, I will present experimental measurements of thermal conductivities of individual nanowires and nanotubes and thermal boundary resistance between these nanowires and nanotubes. The effects of various factors, such as nanowire surface, alloying, and van der Waals interactions, on phonon transport through these nanostructures and interfaces will be discussed. Better understanding of these mechanisms will help to engineering thermal properties of nanostructured materials for different applications.

9:45 AM
Structure and Thermomechanical Behavior of Nanoporous Nickel Thin Films: *Lei Wang*[1]; Jiang Xu[1]; [1]University of Kentucky
High-purity nanoporous nickel (np-Ni) thin films with fine ligaments were successfully produced from NiMg precursor films using the dealloying method. The dealloyed films exhibit a microstructural length scale comparable to Raney nickel, with an average ligament width less than 7nm, and are thus potential candidates for catalytic applications. High-resolution scanning and transmission electron imaging was performed to characterize the structure and morphology of np-Ni films. Thermomechanical behavior was investigated with thermal cycling and stress relaxation experiments performed in a wafer curvature system. Np-Ni films exhibited linear, thermoelastic stress-temperature curves between room temperature and 250°C. Elastic modulus was calculated from these tests and combined with measurements of the films' relative density to investigate the scaling relationships for porous material mechanical behavior. Finally, activation energies for the stress relaxation mechanisms in films of various thicknesswere determined and will be discussed.

All Inorganic "Sensitized" Solar Cells Based on Large Bandgap Semiconductors: *Yong Zhang*[1]; [1]UNC Charlotte
Wide bandgap semiconductors are typically used as transparent conductive electrodes, passivation layers, and carrier transporters in optoelectronic devices. For a single junction solar cell, conversional wisdom would suggest to find a semiconductor with a bandgap in the range of 1.0 – 1.6 eV to serve as the absorber layer, based on the Shockley-Queisser detailed balance theory. However, it has been recently predicted that when two large bandgap semiconductors form a type II heterojunction, it can absorb a much broader spectrum of light than they are alone, due to the type II interfacial transition, as though the heterojunction has a much lower bandgap than any of the components. One could view this approach as two large bandgap components mutually sensitizing each other. The feasibility of this idea has recently been demonstrated using a ZnO/ZnSe core/shell nanowire array solar cell with a photoresponse threshold of ~1.6 eV.

10:50 AM
Catalytic Properties of AgCu Bimetallic Nanoparticles for PEMFC Cathode: DFT Study: Kihyun Shin[1]; Da Hye Kim[1]; Sang Chul Yeo[1]; *Hyuck Mo Lee*[1]; [1]KAIST
Noble metals such as Pt have been widely used for catalysts such as in fuel cells. However, due to the high price of Pt, there have been many efforts to reduce the Pt amount or substitute it. We considered AgCu bimetallic nanoparticles as an ORR catalyst. We studied firstly the structural stability of Ag, Cu, and AgCu bimetallic nanoparticles with different sizes and configurations by using DFT calculations. To evaluate the catalytic properties, we determined the oxygen adsorption site and the adsorption energy for each nanoparticle and obtained the energy barrier for oxygen dissociation. Oxygen dissociation is the rate determining step in ORR. As a result, we found the effect of size, configuration, and alloying effect on the oxygen adsorption energy and the energy barrier for oxygen dissociation. Through the comparison of the catalytic properties of each nanoparticle, we propose a new available catalyst for ORR.

11:05 AM
High-Performance Electrochemical Capacitors Based on Nanocomposites of Transition Metal Oxide Aero-Gel / Vertically Aligned Carbon Nanotubes: *Minsub Oh*[1]; Younghak Song[1]; Sangmin Kim[2]; Haseok Jeon[1]; Ju Hee Kim[3]; Haekyoung Kim[3]; Seungmin Hyun[2]; Hoo-jeong Lee[1]; [1]Sungkyunkwan University; [2]Korea Institute of Machinery & Materials; [3]Yeungnam University

Electrochemical capacitors have received much attention as a candidate for a next-generation battery. Nevertheless, the development has been hampered by their inherently-low energy density. Recent several studies have proposed nanostructured materials or hybrid materials that combine conductive carbon-based materials with nanostructured metal oxide to improve the energy density by utilizing the high surface areas of nanostructured materials. Here, we combined vertically-aligned carbon nanotubes grown using thermal CVD and aero-gel transition metal oxide ($NiCo2O4$) including several nanometer-sized pores. The hybrid structure was designed to enhance the electrical conductivity of the electrode while increasing the surface area. A careful characterization of the hybrid structure using various characterization tools such as XRD, SEM and TEM helped us elucidate the details of the morphology and microstructure of the aero-gel oxide coated on the VACNTs. The results underscore that the morphology and microstructure of the electrode critically determined the electrochemical properties of the electrode.

11:20 AM
3D Multiwall Carbon Nanotubes (MWCNTs) for Li-Ion Battery Anode: *Chiwon Kang*[1]; Indranil Lahiri[1]; Rangasamy Baskaran[2]; Mansoo Choi[2]; Won Gi Kim[2]; Yang-Kook Sun[2]; Wonbong Choi[1]; [1]Nanomaterials and Device Laboratory, Department of Mechanical and Materials Engineering, Florida International University, USA; [2]Department of Energy Engineering, Hanyang University, Seoul, Korea

Carbon nanotubes have attracted great attention as promising electrode materials for Li-ion batteries due to major advantages including large surface area and low resistance path. We developed novel multiwall carbon nanotubes (MWCNTs) based 3-dimensional anode for high-efficiency Li-ion batteries. The MWCNTs were synthesized through catalytic thermal chemical vapor deposition (CVD) on 3-dimensional Cu electrode. The 3D Cu electrode played a crucial role in accommodating much larger number of MWCNTs, leading to more amount of Li+ ion intake. Results from electrochemical characterization of Li-ion battery with 3D anode indicate better properties as compared to those with MWCNTs on 2D Cu foil anode. In addition, MWCNTs with sputtered amorphous Si (a-Si) layer on them (a-Si/MWCNTs core-shell structure) were also used as anode using a 3D geometry and improved electrochemical properties of these modified MWCNT anode were observed. Moreover, relation between electrochemical performance and structural properties of the MWCNTs and hybrid a-Si/MWCNTs composite on 3D Cu electrode is discussed.

2012 Symposium on Surfaces and Heterostructures at Nano- or Micro-Scale and Their Characterization, Properties, and Applications: I-Energy II-Magentic Materials III-Chemical Sensing and Surfaces

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS: Energy Conversion and Storage Committee, TMS: Nanomaterials Committee, TMS: Surface Engineering Committee, TMS: Young Leaders Committee, TMS: EMPMD Council

8:30 AM
Transport and Electrical Properties of Two Dimensional Hole Gas in δ-MIGFET in GaAs: *Outmane Oubram*[1]; Oracio Navarro Chávez[2]; Luis Manuel Gaggero-Sager[3]; [1]Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México ; [2]Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México; [3]Facultad de Ciencias, Universidad Autónoma del Estado de Morelos

Rapid and predictable scaling of planar CMOS devices is becoming difficult. As it is well known to conserve the MOORE's law within the conventional microelectronics technology is very hard, so searching for new alternative is critical. We study hole transport and electrical properties in a new alternative device δ-MIGFET (Delta-Multiple Independent Gate Field Effect Transistor) in GaAs. In this work we will analyze hole transport phenomena, due to ionized impurity scattering in a δ-MIGFET. We report theoretical results for hole transport in a δ-MIGFET using the hole structure of the device. The differential capacitance and resistivity are analyzed as well as the regions where the device is operating in digital or analog mode. The width of the Ohmic region and the Negative Differential Resistance (NDR) properties of the system are also characterized.

8:45 AM
Electrochemical Behavior of Nanoceria in Different pH Solution: *Shashank Saraf*[1]; Naveen Chandrasekaran[1]; Sudipta Seal[1]; [1]University of Central Florida

Cerium oxide has find its uses in many applications be it catalytic converter in automobiles, radiation protective coatings, solid oxide fuel cells, biosensors etc. All of these requires cerium oxide molecule to be electrochemically active which should have redox potential associated. In literature there are reports of redox potential of cerium ions in different pH and those plots are termed as pourbaix diagram. So it's imperative to measure redox potential of cerium oxide molecules as well. In this report we propose to find redox potential of cerium oxide in different pH by using ceria coating on platinum substrate by using cyclic voltammetry experiments. The redox potential of bulk will then be compared with nano cerium oxide molecules having different morphologies, chemical state and shape. Obtained ceria coatings will be first characterized by SEM, XPS and XRD to know their morphology and measure chemical state and crystallite size respectively.

9:00 AM

Facile Preparation and Advanced Characterization of ZnO Nanoparticles: *Hulya Kaftelen*[1]; Kasim Ocakoglu[1]; Emre Erdem[2]; [1]Mersin University; [2]Institut für Physikalische Chemie I, Albert-Ludwigs-Universität Freiburg

Zinc oxide (ZnO) nanoparticles have a great attention in recent years due to their potential and promising technological applications in gas sensors, light-emitting materials, nonlinear optics and field-effect transistors. In this study, elemental ZnO powders (Merck, 99.9%, particle size 7.4 μm) were milled for 0, 10, 20, 30 min in a FreezerTM Magneto/Mill. A significant broadening of X-ray diffraction peaks and decrease of their intensities with milling time were observed as a result of grain refinement and build up strain during milling. Crystallite size of nanoparticles after 30 min of milling was measured as ~35 nm by using TOPAS 3 (Bruker™ AXS) software whereas from scanning electron microscope analysis we obtained 45 nm mean particle size for the spherical ZnO particles for the same milling time. Electron paramagnetic resonance(EPR) results revealed strong surface effects by going to nanosize ZnO indicating the increase of concentration of defect centers at the surface.

Spherical Barium Ferrite (S-BaFe) Nanoparticles for Ultra High-Density Information Data Storage: *Yang-Ki Hong*[1]; Jeevan Jalli[1]; Sung-Hoon Gee[2]; [1]The University of Alabama; [2]Seagate Technologies

Recently, using ultra-fine hexagonal barium ferrite platelets (H-BaFe) tape media, a recording aerial density of 29.5 Gb/in2 was demonstrated [1]. H-BaFe platelets form poker-chip-like stacks, thereby, degrading the media recording capability, i.e. poor signal-to-noise ratio (SNR) [2]. To achieve better media recording performance, S-BaFe particle was proposed [3]. We converted spherical magnetite [4] and spinel barium-iron oxide [5] to 24 - 30 nm and 25 - 45 nm S-BaFe particles, respectively. Saturation magnetization (ss) and coercivity (Hc) of S-BaFe particles were higher than 40 emu/g and 4 kOe. To estimate the thermal stability factor (KuV/kBT) of the S-BaFe particles, dynamic coercivity measurement was performed. The thermal stability factor was measured to be greater than 80. This study suggests that S-BaFe nanoparticles are thermally stable and suitable for higher recording density media application than 29.5 Gb/in2 if other recording factors are optimized. *Supported by Information Storage Industry Consortium (INSIC).

Perpendicular Magnetic Tunnel Junctions for Spin-Torque Transfer Random Access Memory (STT-RAM): *Subhadra Gupta*[1]; Anusha Natarajarathinam[1]; Amritpal Singh[1]; [1]The University of Alabama

Fully perpendicular magnetic tunnel junctions have a clear advantage for non-volatile spin-torque transfer random access memory (STT-RAM). However, such perpendicular MTJ's have been seen to have limited tunneling magnetoresistance (TMR) compared to MgO-based in-plane tunnel junctions. We will present an overview of the science and technology of the fabrication and growth of perpendicular MTJ's, including an analysis of what limits the TMR. We will detail exciting new developments in this field that result in much higher TMR of about 40% and improved switching times that may make this technology a competitive and viable one for the future. Micromagnetic simulations that closely match the experimental results will be shown. Transmission electron microscopy (TEM) and local electron atom probe (LEAP) characterization were carried out on these MTJ's to understand better the correlation between structural and magnetic properties of these devices.

Nanocomposite Soft Magnetic Materials: Role of Composition on Properties(Invited): *Matthew Willard*[1]; Maria Daniil[2]; Keith Knipling[1]; [1]Naval Research Laboratory; [2]George Washington University

Over the past two decades, a major focus of research has been microstructure refinement to the nanoscale, which has enabled reduction in coercivity. These advantages originate in the exchange correlation length – a fundamental magnetic length scale determined by the strength of coupling between magnetic moments causing them to align – which has typical values with nanoscale dimensions. This presentation will highlight recent work on nanocomposite soft magnetic materials produced by rapid solidification processing over a broad composition range. The effect of nanostructure and the role of composition on the magnetic material performance will be shown experimentally with theoretical discussion.

11:05 AM Invited

Optical Thin Films for Gas Sensing in Advanced Coal Fired Power Plants: *Paul Ohodnicki*[1]; Thomas Brown[1]; John Baltrus[1]; Sittichai Natesakhawat[2]; Congjun Wang[3]; [1]National Energy Technology Laboratory; [2]National Energy Technology Laboratory and University of Pittsburgh; [3]National Energy Technology Laboratory and URS Corporation

The National Energy Technology Laboratory (NETL) is developing technologies for the next generation of higher-efficiency, lower emission fossil-fueled power plants, including oxy-fuel combustion processes for carbon capture and sequestration, and coal gasification to produce H2-rich synthetic gas which can be converted to electrical power using solid-oxide fuel cells or gas turbines. Improved sensor technologies that can operate under extreme conditions (high temperature, high pressure, corrosive gases) are needed for process monitoring and control. Optical sensors based on metal oxide thin films are important candidates, and an improved understanding of the fundamental link between structural/chemical changes in thin films and measured optical properties in the presence of various gas species under relevant conditions is needed to aid in sensor development efforts. Results of synthesis and characterization of metal oxide-based films will be presented, and future work plans that fully leverage unique expertise and facilities available at NETL will be discussed.

11:40 AM

Hierarchical Metallic and Ceramic Nanostructures via a Hybrid Approach Combining Laser Interference Ablation and Block Co-Polymer Phase Separation: *Taiwo Alabi*[1]; Dajun Yuan[1]; Suman Das[1]; [1]Georgia Institute of Technology

We report on a novel approach that combines pulsed laser interference ablation and block co-polymer phase separation to enable the formation of periodic metallic and ceramic nanostructures having a primary ordering (30-100 nm range) conforming with the domain spacing in a phase separated PS-P4VP polymer, and a secondary ordering (0.2 to 2 microns range) conforming with the periodicity of interfering laser beams. The primary domain spacing of the nano-structures was varied by tuning the loading time of the block copolymer thin films and changing the length of the P4VP chain of the block copolymer. The secondary ordering was varied by changing either the intensity of Nd:YAG nanosecond light source, angle of interfering beams, or number of interfering beams. The nanostructures were characterized with AFM, SEM, XPS and XRD characterization techniques. Data obtained indicates the formation of PtO2, PdO2, Au and Fe2O3 hierarchical features with some degree of crystallinity.

11:55 AM
Rapid Fabrication of Diverse Two-Dimensional and Three-Dimensional Gold Nanostructures Through Laser Interference Patterning: *Dajun Yuan*[1]; Suman Das[1]; [1]Georgia Institute of Technology

Gold nanostructures have been extensively studied. Here, we report on the development of a simple, one-step method for the fabrication of diverse 2D and 3D nanostructures through laser interference patterning on gold films over areas spanning 1 cm^2. Various periodic 2D and 3D nanostructures can be patterned on gold films of thickness 10-500 nm. The variety of possible structures including grooves and gratings with feature sizes ranging from 100 nm to 2 µm, hexagonal close-packed arrays of cavities and holes with feature sizes ranging from 100 nm to 2.5 µm, nanodomes, nanomushrooms, and nanoneedles with feature sizes ranging from 10 nm to 2 µm can be created through careful adjustment of the laser intensity and the interference period. Characterization of the fabricated nanostructures through AFM and SEM reveals the probable mechanisms of their formation through pulsed laser induced melting and resolidification, in combination with surface tension driven effects.

12:15 PM Invited
Development of Superhydrophobic Nano-structured Ceramics to Promote Dropwise Condensation: *Ghazal Azimi*[1]; Kripa Varanasi[1]; [1]MIT

Developing robust hydrophobic surfaces with improved water repellency and dropwise shedding condensation has been a subject of intense research over the past decades. Conventional approach of fabricating such surfaces include first, creating a rough or textured surface, and then modifying the surface with materials of low surface energy. Most cutting edge research in the field, however, have only focused on designing more complex structures, while overlooking the material aspect, which is equally, if not more important. Such developments, although promising, face major material-related hurdles that limit their scale up and industrial implications. To address these challenges, herein, we developed a novel hydrophobic ceramic that surpasses other ceramics in its ability to repel water droplets, while offering other unique properties, including thermal stability and chemical inactivity. The material developed in this work promoted dropwise condensation with remarkably improved heat transfer coefficient, when tested in a condensation chamber under simulated industrial conditions.

3rd International Symposium on High Temperature Metallurgical Processing: Sintering and Synthesis

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Energy Committee, TMS: Pyrometallurgy Committee

Program Organizers: Tao Jiang, Central South University; Jiann-Yang Hwang, Michigan Technological University; Patrick Masset, TU Freiberg; Onuralp Yucel, Istanbul Technical University; Rafael Padilla, University of Concepcion; Guifeng Zhou, Wuhan Iron and Steel

Wednesday AM — Room: Southern II
March 14, 2012 — Location: Dolphin Resort

Session Chairs: Mark Schwarz, CSIRO; Xiaohui Fan, Central South University

8:30 AM
A Study of Co-V-Al Alloys by Self Propagating High Temperature Synthesis: *Murat Alkan*[1]; Ozlem Altinordu[1]; Seref Sönmez[1]; Onuralp Yücel[1]; Bora Derin[1]; Vladimir Sanin[2]; Vladimir Yukhvid[2]; [1]Istanbul Technical University; [2]Institute of Structural Macrokinetics and Materials Sciences

Self-propagating high temperature Synthesis (SHS) process is one of the highly productive and economically reasonable methods for the metallurgical industry. This study covers information about a process based on self propagating high temperature synthesis to produce Co-V-Al alloys using a mixture of Co3O4-V2O5-Al powders. Different Co/V ratios are carried out in the SHS experiments; also addition of excess stoichiometric amount of Al2O3 between % 0 and % 20 is added to the mixture to decrease the adiabatic temperature of the system. The thermodynamic simulations and the calculations of adiabatic temperature were examined with FactSage program. The samples were characterized by the X-Ray Diffraction method (XRD) and Scanning Electron Microscope (SEM) techniques.

8:45 AM
Strengthening the Sintering of Iron Concentrate Fines by High Pressure Roller Grinding Pretreatment: *Yufeng Guo*[1]; Kelang Mu[1]; Jiang Tao[1]; Dao Su[1]; Jinghua Zeng[1]; [1]Central South University

The improvement in sintering of fine hematite-limonite concentrate by high pressure roller grinding (HPRG) were investigated in this paper. The results of sinter pot test show that, when HPRG is adopted to pretreate hematite-limonite concentrate, productivity is increased from 1.16t/(m2•h) to 1.53 t/(m2•h) dramatically, and tumbler index of sinter is able to be improved from 64.67% to 67.20%. It is found that ballability of hematite-limonite concentrate is dramatically improved and the ratio of fine particles increases greatly after being pretreated by HPRG, which contributes to better granulation property and higher reactivity in solid phase reaction of hematite-limonite concentrate in sinter process.Thus,the yield and quality of sinter increase accordingly.

9:00 AM
A Study of Ni-Cr-Al Alloys by Self-Propagating High Temperature Synthesis: *Bora Derin*[1]; Ozlem Altinordu[1]; Murat Alkan[1]; Seref Sonmez[1]; Onuralp Yucel[1]; Vladimir Sanin[2]; Vladimir Yukhvid[2]; [1]Istanbul Technical University; [2]Institute of Structural Macrokinetics and Materials Sciences, ISMAN

Self Propagating High Temperature Synthesis (SHS) has many advantages such as very short processing time, simple operation, low initiation energy requirement and low cost. After ignition of an SHS initial mixture, the combustion front is formed and propagates throughout the reactant mixture yielding the desired product. The present work proposed a process based on self-propagating high temperature synthesis to produce Ni-Cr-Al alloys using a mixture of NiO and Cr2O3, Al and Al2O3 powders. The addition of excess stoichiometric amount of Al2O3 is added to the mixture to decrease the adiabatic temperature of the system. The thermodynamic simulations and the calculations of adiabatic temperature were examined with FactSage program. The samples were characterized by the X-Ray Diffraction method (XRD) and Scanning Electron Microscope (SEM).

9:15 AM
Research on Sintering Properties of Vanadium-Titanum Magnetite Concentrate: *Xiaohui Fan*[1]; Qiang Wang[1]; Xuling Chen[1]; Min Gan[1]; Lishun Yuan[1]; Shan He[1]; [1]Central South University

The sintering properties of vanadium-titanium magnetite concentrate(VTC) was studied in this paper. Through the optimizing the sintering process of VTC, the suitable granulation moisture and coke proportion were determined. The sintering velocity decreased from 23.05 mm/min to 18.22 mm/min. With the increase of VTC proportion from 0 to 46%, the specific productivity and tumbler index were respectively decreased from 1.55 t/(m2•h) to 1.21 t/(m2•h), and 62.93% to 57.73%. The temperature of liquid phase formations of mixtures increased, the amount of liquid lowered, and the content and sharp of sintering mineral gradually changed with the increase of VTC ,these lead that sinter quality became worse.

9:30 AM
Influence of Limonite Proportion on Sinter Quantity and Quality: *Xiaohui Fan*[1]; Dao Su[1]; Ganghua Fu[1]; Xuling Chen[1]; Min Gan[1]; Tao Jiang[1]; Yufeng Guo[1]; [1]Central South University

Sintering properties and performances of typical limonite such as FMG and YD in the sintering of ore fine system and concentrate system are studied. The results show: limonite has big size, in the sintering of limonite and fine, content of small size of mixture reduces, relative basicity of small size of mixture increases, the fluidity of liquid phase is so good that the strength of sinters is bad especially proportion of limonite exceeds 55%. In the sintering of limonite and concentrate which has small size, the size of mixture is more reasonable that suitable fluidity of liquid phase can be produced, besides exothermic reaction of concentrate oxidation can make up heat loss by the remove of crystal water in limonite, data show that the sintering index is good when proportion of concentrate is about 35%~45%,and the coke rate is low.

9:45 AM
In Situ Observation of High Temperature Properties of Iron Ore during Sintering Process: *Pei Dong*[1]; [1]Shougana China

Confocal scanning laser microscope (CSLM) has been applied to carry out the in-situ observation of melting and solidifying characteristics during iron ore sintering process, accompanied with TG-DSC test. It can be found that apparent Liquid phase forming temperature(LFT) and ending solidifying temperature(EST) is about 1190°C and 1160°C, respectively. Forming liquid phase during sintering process go through four courses, that is shrinking, expanding, shrinking and expanding coexisting and expanding totally. For Yandi fine, the corresponding temperature of this four courses is about 1120-1160°C, 1190-1196°C, 1218-1220°C and 1233-1270°C, respectively. Although CAJ fine has more difficulty in forming initial liquid phase, but when liquid phase expands, it may have better fluidity and easier liquid phase formation. Adding enough CaO, CAJ fine takes on high fluidity like Yandi fine, because liquid phase during sintering process is formed mainly by reaction between CaO and Fe2O3.

10:00 AM Break

10:10 AM
The Influence of m(V2O5)/m(TiO2) on Compositions and Structures of V-Ti-Fe Alloys: *Bin Wang*[1]; Kuiren Liu[1]; Jianshe Chen[1]; Jilin He[2]; [1]Northeastern University; [2]Northwest Rose Metal Materials Research Institute

The preparation of V-Ti-Fe master alloys with metallothermic reduction method was studied. The influences of m(V2O5)/m(TiO2) on structures and compositions of the alloys obtained were investigated systematically. The results show that the compositions can be changed flexibly by variations of m(V2O5)/m(TiO2). With reducing m(V2O5)/m(TiO2) ratio, the recovery rate of Ti and V decreases along with an increase in contents of Al and Si impurity. Besides the V-based solid solution phase and the C14-type Laves phase, some impurity phases also exist in the V-Ti-Fe alloys. The results of energy spectrum analysis show that the elements of vanadium and iron distributed uniformly in the alloys. Segregation for titanium, i.e. the titanium-rich phase forms, was detected. It is mainly caused by the rapid cooling process. An appropriate heat treatment and refining process should be adopted to improve the quality of the alloys.

10:25 AM
Air Leakage Online Monitoring and Diagnosis Model for Sintering: *Fan Xiaohui*[1]; Jiang Lijuan[1]; Chen Xuling[1]; [1]Central South University

In order to solve air leakage of sintering testing cumbersome, inaccurate results, and other issues, the sinter machine air leakage characteristics were studied, and combining the mathematical modeling and the field detection. The temperature before air leakage was calculated by mathematical model, energy balance equation was established according to sintering process, using Adams prediction correction method which has stronge stability and high precision, to solve hyperbolic partial differential equation with astringency problem. The temperature after air leakage is detected by instruments, according to energy conservation calculation the sintering air leakage rate. According to the sintering continuity and periodicity, sintering air leakage location diagnosis expert system was established to judge specific air leakage locations.

10:40 AM
Investigation on the Interfaces of M42/45 Steel Bimetal Composites Sintered by Spark Plasma Sintering: Xu Jinfu[1]; You Hang[1]; [1]Institute of Materials Engineering, Ningbo University of Technology

The sintering of M42 P/M high speed steel and its jointed to 45 steel had been realized at the same time using Spark Plasma Sintering(SPS) technology, its contact surface's microstructure appearance, element density distribution, microhardness and interphase forming process have been tested and analysised. The analyzing results are as follows: The morphology and micro-hardness of M42/45 steel joints exist as a gradient distribution. The joint hasn't distortion and microcracks, the thickness of transition layer up to 10 ~ 20um. The interface connection of M42/45 steel is comprehensive synergy between fusion connection and diffusion connection, and fusion connection takes a priority at early sintering, while diffusion connection gradually becomes dominant at later sintering.

10:55 AM
Influence of MgO on the Strength of High Basicity Sinter: Xiaohui Fan[1]; *Wenqi Li*[1]; Min Gan[1]; Guohua Bai[1]; Tao Jiang[1]; Zhiyun Ji[1]; Zhiyuan Yu[1]; Xiaoxian Huang[1]; [1]Central South University

The influence of MgO on the tumbler index(TI) of high basicity sinter is studied. The result shows that TI of sinter decreases from 71.33% to 61.13% when MgO content increases from 1.15% to 3.5%. The mechanism research shows that the temperature of liquid formation of sintering mix increases and the content of liquid phase decreases with the increase of MgO content. And Mg2+ mostly dissolves in magnetite which diffuses into crystal lattice of magnetite and makes the magnetite more stable. So the content of magnetite in sinter increases and needle-like calcium ferrite decreases due to the retarding of magnetite oxidation, which is the main reason of MgO deteriorating TI of sinter. Experiments also indicate that the mineralization ability of dolomite is weaker than that of limestone. TI of sinter can be improved by optimizing the size distribution of dolomite which can facilitate the mineralization of dolomite.

Advances in Surface Engineering: Alloyed and Composite Coatings: Session V

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Surface Engineering Committee
Program Organizers: Sandip Harimkar, Oklahoma State University; Srinivasa Bakshi, Indian Institute of Technology Madras; Arvind Agarwal, Florida International University

Wednesday AM — Room: Macaw 1
March 14, 2012 — Location: Swan Resort

Session Chair: To Be Announced

8:30 AM
Tribological Behavior of Plasma Sprayed Al-Si Composite Coatings Reinforced with Different Carbon Allotropes: *Mingdong Bao*[1]; Cheng Zhang[1]; Debrupa Lahiri[1]; Arvind Agarwal[1]; [1]Florida Internatinal University

Al-Si composite coatings reinforced with nanodiamond, grapheme nanoplatelet, carbon nanotube and graphite were synthesized by plasma spraying. Effect of addition of carbon in different allotropic forms on the microstructure, hardness, and elastic modulus of the composite coatings is investigated. Tribological performance of different composite coatings and the wear mechanism in the presence of nanodiamond, graphene and graphiteare also studied.

8:50 AM

Evaluation of Brittle Layers Obtained on Boronized Cr-Mo Based Steels: *Noe Lopez Perrusquia*[1]; Marco Doñu Ruiz[1]; [1]Instituto Politécnico Nacional

In the present study, identify the fracture toughness and strength adhesion of borided layers on Cr-Mo based Steels by Boronizing, two commonly used steel AISI 4140 and AISI 9840 are considered, the steels contain 1.0, 0.8 wt% Cr and 0.20, 0.25 wt% Mo, respectively. The formation of the borided layers was carried out by the powder pack boriding process at a temperature range of 1123 -1273 K for 4, 6 and 8 h. X-ray diffraction analysis revealed peak of FeB, Fe2B and CrB, the Fracture toughness of the layers is estimated at 15 and 30 um from surface using four different Vickers indentation loads, using Palmqvist crack model, the adherence of the layer/substrate was evaluate in qualitative form though the Rockwell C. The fracture toughness of the borides depends strongly on temperature and time boronizing. Also, good adhesion is obtained around the Rockwell C indentation prints on the borided layer-substrate-interface.

9:10 AM

Evaluation of Residual Stress in Fe2B Coating on Ductile Cast Iron: *Marco Doñu Ruiz*[1]; Noe Lopez Perrusquia[1]; Victor Jorge Cortez Suarez[2]; David Leoncio Rosado Cruz[3]; [1]IPN; [2]UAM; [3]UPVM

The boriding thermochemical treatment enhances mechanical properties, depending on the condition under which it is produced the thin boride layer formed during a pack boriding process may be either Fe2B or FeB/Fe2B coatings that influences by the presence of residual stresses. The present study employ the finite element method for evaluate of thermal residual stress across Fe2B coatings produced on surface Ductile Cast Iron ASTM class 80-55-06, taking into account the power-pack boriding condition, the results of simulation was carried out in ANSYS environment were compared whit the experimental results determinate by means of X-ray Diffraction (XRD) shows that there is very good agreement. It was found that the residual stress varied regular with the heat treatment, globular graphites and the thickness of the coating, the distributions of residual stress determined in the Fe2B coatings are compressive with magnitudes ranging from -370 to -1537 MPa.

Regression Model of Oxidation Behavior of 6061 Al/SiC Composite: *Priyamvada Bhaskar*[1]; [1]National Institute of Technology, Surathkal

This paper analyses variation of weight gain, □m, of 6061 Al/SiC composite due to oxidation with time, t, using regression model. Using curve fitting technique, mathematical equations for oxidation behavior of the composite are formulated. The generated data are analyzed and compared with the experimental data. More specifically, regression analysis helps in understanding how the typical value of the mass gain (dependent variable) changes when the time of oxidation (independent variable) is varied, while the other independent variable (Temperature) held fixed. The effect of aging treatment and protective coatings like Aluminium and AlCrN on the oxidation behavior of the 6061 Al/SiC composite was studied. It was observed that coatings increase the oxidation behavior of the composite. The regression analysis carried out shows a two-fold linear variation of weight gain (Dependent variable) with respect to time and temperature of oxidation (Independent variables).

10:05 AM

An Alternative Solution for Aluminium Extrusion Die Surfaces: The Qualified Hard Coatings (AlCrN and AlTiN): *Behiye Yuksel*[1]; Yucel Birol[1]; [1]TUBITAK MAM Materials Institute

Extrusion is an important method frequently used in forming of aluminum products. The die materials used for the aluminum extrusion process should have a high level of hardness, yield strength and creep resistance as well as chemical resistance at elevated temperature. However the bearing surface of die during extrusion process is exposed to high temperature, chemical and tribological loads. Wear of the die bearing causes important technological and economic problems. Nowadays, scientists have studied on different applications to further improve the performance of the die. One of them is able to make the bearing surface more wear resistant by different surface treatments. The main aim of this study is the investigation of the wear behavior of AlCrN and AlTiN coatings which is coated by physical vapor deposition (PVD) on AISI H13 hot work tool steel as used almost on extrusion die material.

10:25 AM

On the Production of Mo-MoSi2 FGM by Diffussion Technology: *Ma Ruixin*[1]; Li Shina[1]; Zhang Juping[1]; [1]USTB

Mo-MoSi2 functionally graded material, FGM, was fabricated by diffusion the silicon into a molybdenum matrix under high temperature. The effects of temperature and the duration time on the Mo- Mo3Si5-MoSi2 gradient layer characteristics, such as thickness, components, phase and morphology are studied by means of metallographic microscope, XRD and SEM. The experimental results show that when heated at 1350°Cand duration time is 300 minutes, a FGM layer was fabricated with a thickness of over 200 μm. The composition of FGM layer, from surface to molybdenum base, was MoSi2, Mo3Si5, Mo5Si3 and Mo. A transition layer of about 5~10 μm exist between different layer.

Alumina and Bauxite: Energy and Processing Alternative Rawmaterials

8:30 AM

Decrease of Heat Consumption at Nepheline Processing to Alumina and By-Products: Vladimir Kazakov[1]; *Vadim Lipin*[2]; [1]St. Petersburg State Technologic University of Vegetable Polymers; [2]Saint Petersburg State Polytechnical University

It is resulted technological and heat engineering substantiation of the new original hardware-technological scheme of nepheline processing by sintering method. In this scheme the autoclave desilication of aluminate liquor and evaporation of a soda solution are united in one technological process. As a result the degree of thermodynamic perfection (exergic efficiency) raises from 70 up to 90 %, the charge of a steam from thermal power station decreases in 1,6 times, improve of ecological safety and operational reliability of equipment.

8:50 AM

Influence of Na2O on the Phase Compositions and the Alumina Leaching Properties of Calcium Aluminate Slag: *Yingjie Li*[1]; Z. F. Tong[2]; Lixiu Lian[1]; [1]Jiangxi University of Science and Technology; [2]Jiangxi University of Science and Technology

The influences of Na2O on phase composition,self-disintegrating and alumina leaching property of calcium aluminate slag were investigated by XRD, laser particle size analyzer and chemisty analysis, and the measures of eliminating the adverse impacts of Na2O on calcium aluminate slag were proposed. The results show that when the content of Na2O is 3% and less than 3%, the main phase are Ca12Al14O33 and γ-Ca2SiO4, the self-disintegrating rate of slag is above 90%, the alumina leaching rate is above 80%. The leaching rate is evidently decreased when Na2O is 4%, which is 75.56%. Decreasing the ratio of n(CaO) and n(Al2O3) of slag containing 4% of Na2O , the leaching rate is 83.5% when the ratio of n(CaO)and n(Al2O3) is 1.53, the adverse effects of Na2O on the slag is basically eliminated, the slag meets alumina leaching requirements.

9:10 AM

Influence of Titania on the Phase Compositions and the Alumina Leaching Properties of Calcium Aluminate Slag: *Z. F. Tong*[1]; Yingjie Li[2]; Lixiu Lian[2]; [1] Jiangxi University of Science and Technology; [2]Jiangxi University of Science and Technology

The influences of TiO2 on phase composition,self-disintegrating and alumina leaching property of calcium aluminate slag were investigated by XRD, laser particle size analyzer and chemisty analysis, and the measures of eliminating the adverse impacts of TiO2 on calcium aluminate slag were proposed. The results show that when the content of TiO2 is 2% and less than 2%,the main phases are Ca12Al14O33 and γ-Ca2SiO4, the self-disintegrating rate of slag is above 95%, the alumina leaching rate is above 85%. The leaching rate is evidently decreased with the content of TiO2 increasing when TiO2 is greater than 2%, the leaching rate was only 73.4% with 5% of TiO2. To add CaO into 5% of TiO2 of slag, the leaching rate is 84.1% when the ratio of n (CaO) added and n (TiO2) is 1.25, the adverse effects of TiO2 on the slag is basically eliminated, the slag meets alumina leaching requirements.

9:30 AM

Research of Al and Si Occurrence States on Acid Leaching Performance of High-Alumina Fly Ash: Zhang Ting'an[1]; *Lv Guozhi*[1]; Dou Zhihe[1]; Nan Xiangli; Song Dan[1]; Li Yan[1]; He Jicheng[1]; [1]Northeastern University

High-alumina fly ash is a kind of important materials for future alumina production. This paper researched the acid leaching performances of fly ash from Western Inner Mongolia, Chongqing and Shanxi of China. Effects of leaching temperature, acid concentration, leaching time and liquid-solid ratio on the leaching performance were investigated as well. Leaching experiments indicate that: the leaching rates of alumina in fly ash from Western Inner Mongolia, Chongqing and Shanxi provinces are 97.41%, 68.94% and 23.61% respectively, under the conditions of leaching temperature 150°C, liquid-solid ratio 20:1, stirring rotary speed 500rpm, leaching time 120min, sulfate concentration 20% and particle sizes -74µm. The effects of existing forms, crystallinity and coating situation of Al-Si phase on leaching performance of high-alumina fly ash were discussed by SEM and XRD. The results show that the crystallinity of fly ash from Western Inner Mongolia is about 75% which is worse than the others.

9:50 AM

Study on the Effect of Si and Silicide on Leaching Al_2O_3 from Magnesium Smelting Reduction Slag: You Jing[1]; *Wang Yaowu*[1]; Feng Naixiang[1]; Peng Jianping[1]; Di Yuezhong[1]; [1]Northeastern University

The main phases of the reduction slag from magnesium production by vacuum aluminothermic reduction using dolomite and magnesite as materials and using Al-Si alloy as reductant are $CaO•Al_2O_3$ and $2CaO•SiO_2$. It also has amount of unreacted Si. The Al_2O_3 content of reduction slag is about 60% and SiO_2 is about 10%. When leaching Al_2O_3 with a mixture solution of sodium hydroxide and sodium carbonate, Si and SiO_2 would enter into leaching solution and has a negative effect on Al_2O_3 leaching. The effect of Si and silicide on leaching Al_2O_3 from magnesium smelting reduction slag was studied in laboratory. The results show that total Si and partial SiO_2 would enter into leaching solution and react with $NaAl(OH)_4$ to form $(Na_2O•Al_2O_3•SiO_2)_6•27H_2O$ which is present in leaching residue and makes a loss of Al_2O_3.

10:10 AM

Extracting Alumina from Coal Fly Ash Using Acid Sintering-Leaching Process: *Kang Liu*[1]; Jilai Xue[1]; [1]Unversity of Science and Technology Beijing

Local shortages of bauxite in recent years present a challenge to develop a sustainable aluminum industry in China. Coal fly-ash from coal-fired power plants is rich in Al2O3 content with potential use as a resource for alumina refinery. This paper will describe our recent investigation on extracting Al2O3 from coal fly-ash using an acid sintering–leaching process. Thermal weight loss testing against temperature were first carried out to find an appropriate sintering temperature for avoiding heavy volatilization of the coal fly ash - H2SO4 (98%) mixture. Then, the mixture was subjected to sintering at 220°C, dissolving in water at 85°C, adjusting alkaline level in solution by CaCO3 addition, removing iron by KMnO4 and MnSO4, precipitating Al2(SO4)3•17H2O particles, and heating-treated at 850°C to produce Al2O3 powders. The rate of recycling Al2O3 can reach 70 – 90 % with relative lower processing temperature and fewer amounts of solid residues.

10:30 AM

Study on Secondary Reaction Mechanism during Alumina Leaching Process of Calcium Aluminate Slag: *Wang Bo*[1]; Sun Hui-Lan[2]; Yu Hai-Yan[1]; Pan Xiao-Lin[1]; Tu Gan-Feng[1]; [1]Northeastern University; [2]Hebei University of Science and Technology

SiO_2 of calcium aluminate slag exists in the form of γ-$2CaO•SiO_2$ which is more stable than β-$2CaO•SiO_2$. But it will also be decomposed by sodium carbonate solution during alumina leaching process, and this will cause the occurrence of secondary reaction. The occurrence degree of secondary reaction of calcium aluminate slag is studied in this paper, and its effect mechanism is discussed by the methods of XRD and SEM. The results show that the decomposition ratio of γ-$2CaO•SiO_2$ increases as leaching time and sodium carbonate concentration go up, and the main product of secondary reaction is hydrate garnet. SiO_2 concentration of solution rises at first then dropped with the increase of leaching temperature. XRD results indicate that the stable product of secondary reaction is hydrate garnet at lower temperature, but under higher temperature, hydrate garnet transforms into sodium hydrate alumina-silicate.

10:50 AM

Production of Novel Zeolite of Type Na-P from Sodium Aluminate Liquor/Spent Liquor/Alumina Tri- Hydrate of Nalco's Alumina Refinery, Damanjodi, Orissa, India: A Unique Builder Material for Detergent Formulation: *Chitta Mishra*[1]; [1]National Aluminium Company Limited

A process for production of novel synthetic crystalline porous alumino silicate Zeolite Na-P consisting of the oxides of silicon and aluminium represented by the formula a Na2O: Al2O3: b SiO2, wherein a = 0.1 -1.0 and b = 2.2 – 5.0 has been developed from three different raw materials viz. Sodium Aluminate Liquor/ Spent Liquor /Alumina Tri-hydrate of NALCO's Alumina Refinery, Damanjodi, Orissa. Zeolite Na-P was produced by preparing a gel by mixing Sodium Silicate, Sodium Aluminate Liquor/Spent Liquor/Alumina Tri- hydrate, autoclaving the gel at 80-150°C for a period of 2hrs to 4 days under static or stirred condition, quenching the resultant crystalline material in cold water , separating the catalyst formed , washing with water, drying the solid catalyst at a temperature of 80-120°C for a period of 3-12 hrs to obtain the product which can be used as a builder material for detergent formulation.

Aluminum Alloys: Fabrication, Characterization and Applications: Material Characterization

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Processing Committee
Program Organizers: Subodh Das, Phinix LLC; Tongguang Zhai, University of Kentucky; Zhengdong Long, Kaiser Aluminum

8:30 AM
Characterization of High Strength Wrought and Rapidly Solidified Al Alloys for Aero Engine Applications: *Eric Ott*[1]; [1]GE Aviation

Potential aero engine applications of aluminum are expected to be subjected to combinations of high static and cyclic stress, thermal cycles where aging effects may become a consideration, and the presence of salt-containing corrosive environments. Assessment of the properties, stability and corrosion resistance of several alloys including 7075, 7055, 2099, and selected dispersion and precipitation-strengthened, rapid-solidification processed alloys will be presented. Sensitivity to thermal exposure was assessed at times up to 2000 hours and temperatures up to 300°F. Environmental testing involved salt spray testing via ASTM B117 for times up to 168 hours followed by tensile testing and comparison to unexposed samples. Processing of rapidly solidified alloys was performed by several techniques and materials were subjected to extrusion prior to testing. Results and key considerations for aero engine applications of Al will be presented.

8:50 AM
Metallographic Identification of Phases in 5xxx Series Aluminum Alloys: *Young-Ki Yang*[1]; Todd Allen[1]; [1]University of Wisconsin

Nine different phases in 5083 aluminum alloys in H131 and H116 tempers were metallographically identified in a clear and consistent manner using scanning electron microscopy (SEM). Four Fe-rich, two Mn-rich, one Si-rich, one Cu-rich, and β phase (Al_3Mg_2) were found in as-received material. Cu-rich phase, in particular, was commonly observed in materials annealed at around 290 °C. β phase was found not only in material artificially sensitized, for example, at 100 °C but also in as-received material. Many of these phases were identified with SEM for the first time which sheds light on the overall characteristics of the microstructure. These accomplishments were made possible by the development of a new etching solution, dissolved ammonium persulfate in water. This solution can increase data gathering statistics of in-depth microstructure analysis in 5xxx series aluminum alloys significantly by allowing the use of SEM rather than transmission electron microscopy (TEM).

9:10 AM
Studies on Flow Characteristics at High-Pressure Die-Casting: *Christian Chimani*[1]; Richard Kretz[1]; Simon Schneiderbauer[2]; Stefan Puttinger[2]; Stefan Pirker[2]; [1]LKR Leichtmetallkompetenzzentrum Ranshofen GmbH; [2]JKU Johannes Kepler Universität

The flow and filling characteristics influence product quality of high pressure die castings. A planar jet of liquid aluminum is formed at the ingate due to its high inlet velocity. The ingate design triggers the flow characteristics of the jet. Analytical investigations show that the process of drop formation at the liquid planar free jet is dominated by atomization at the ingate. Numerically, high-pressure die casting is attacked by a Volume of Fluid approach. Drop formation at the phase interphase cannot be captured by the numerical model since drops are much smaller than feasible grid spacings. Global spreading of the free jet in the casting mold is well pictured by this first numerical simulation. Experimentally the process is studied by water modelling validating the numerical results. The observed flow characteristics are discussed in comparison to product quality results observed in Al pressure die casting parts of the similar design.

9:30 AM
Electrohydraulic Sheet Metal Forming of Aluminum Panels: *John Bonnen*[1]; Sergey Golovoshchenko[1]; Scott Dawson[1]; Alexander Mamutov[2]; Alan Gillard[1]; [1]Ford Motor Company; [2]Oakland University

In this paper, we present results of testing from sheet metal forming trials using pulsed electrohydraulic technology. Pulsed electrohydraulic forming is an electrodynamic process, based upon high-voltage discharge of capacitors between two electrodes positioned in a fluid-filled chamber. Electrohydraulic forming (EHF) combines the advantages of both high-rate deformation and conventional hydroforming, and electrohydraulic forming allows more uniform distribution of strains, widens the formability window, and reduces elastic springback in the final part when compared to traditional sheet metal stamping. This extended formability allows the fabrication of aluminum panels that are difficult to make by conventional stamping of EDDG steel, and it thereby vastly improves the number automotive weight reduction opportunities. The paper presents discoveries regarding die and chamber design, electrode erosion, forming, and results of finite element multiphysics simulations of system performance.

9:50 AM
Forming of AA7075 under Cryogenic Conditions: *Sebastian Fritsch*[1]; Stephanie Hunger[1]; Matthias Hockauf[1]; Martin F.-X. Wagner[1]; [1]Chemnitz University of Technology

As high strength aluminum alloys are generally hard to deform, the application of conventional severe plastic deformation methods, which in principle allow the generation of ultra fine grained microstructures and increasing strength, is limited. In this study, we explore cryogenic deformation as an alternative approach to deform a 7075 alloy, considering two different processing routes: (i) cryogenic rolling and (ii) cryogenic ECAP. Rolling is performed different low temperatures (minimum temperature: –196 °C) and different degrees of deformation. The cryogenic ECAP procedure uses a tool with an internal angle of 90°. We demonstrate that cryogenic rolling (followed by suitable heat treatments) results in increases of the degree of deformation, strength and ductility. Moreover, we present first results on the effect of cryogenic ECAP on microstructural evolution and mechanical properties of the same alloy that demonstrate the potential of cryogenic forming to produce improved properties of high-strength aluminum alloys.

10:10 AM Break

10:25 AM
Metallurgical Characterization of Aluminum Alloys by Matrix Dissolution: *Marcelo Paes*[1]; Francisco Pinheiro[1]; Miguel Borodiak[1]; [1]Votorantim Metais - CBA

Aluminum foils produced by cold rolling are able to show defects caused by primary particles that are formed along center line segregation. These particles are formed during casting process where some parameters are critical. In the same way, aluminum extruded parts are also able to show defects caused by intermetallic phases. They were used billets of AA6351 alloy (Al-Mg-Si) produced by "Direct Chill" and also sheets of AA8011 alloy (Al-Fe-Si) produced by "Twin Roll Casting". Samples were submitted to a chemical etching based on methanol and iode whose target is corrodes only aluminum matrix. Thus, intermetallic phases were analyzed using optical microscopy and SEM and EDS. On AA8011 alloy, they were identified the phases ß-FeSiAl5 and a- Fe2SiAl8 in as-cast samples, that are hazardous to final foil because they do not dissolve during homogenization treatment. On AA6351 alloy, they were identified the phases Mg2Si, a-(Fe, Mn)3Si2Al15.

10:45 AM

Effect of Silicon Particles on the Tensile Properties of Heat Resistant Al-Si-Cu-Ni-Mg Alloy Pertaining to Different Tensile Temperature: *Chuang Hsu-Chi*[1]; Lui Truan-Sheng[1]; Chen Li-Hui[1]; [1]National Cheng Kung University

The deformation behavior of Al-11Si and Al-11Si aluminum alloy in hot tensile procedure from 200 oC to 450 oC was investigated in this study. The results indicated that the flow stress was strongly dependent on second phase particles of d (Al3CuNi), Q (Al5Cu2Mg8Si6), t1 (Al9FeNi) and Si particles. At 200 oC to 300 oC, the yield and ultimate tensile strength of Al-11Si were higher than Al-1Si. It can be found that the mount of intermetallic d particles increasing will increase the deformation resistance whereas Si particle is detrimental. However, at elevated temperatures, Al-1Si would exhibit a higher elongation at 450oC but Al-11Si was higher than Al-1Si after 400oC. Microstructural observations showed Si particles would restrain the failure of matrix and increase the ductility.

11:05 AM

Work-Hardening and Flow Behavior of AA7055 Alloy Extrusions: *Geo Harrison*[1]; Rama Krishna[2]; Tejaswini[2]; Chandan Monadal[3]; [1]College of Engineering Guindy, Anna University; [2]JNTU College of Engineering; [3]Defence Metallurgical Research Laboratory, Hyderabad.

AA7055 is a high strength precipitation hardenable aluminium alloy and is widely used in compression dominated air-craft structures.In particular, extrudates of AA7055 alloy exhibits very high strength with reasonable ductility in the stress corrosion resistant RRA tempers. In the present work, mechanical properties of the AA7055 alloy extrudates having varying processing parameters (viz. initial billet temperature, extrusion ratio).Tensile properties of the extrudates have been characterized at room temperature for different heat treatment tempers.From the experimental data, plastic flow curves have been calculated and fitted to several semi-emperical flow curve models.It has been shown that a modified voce equation fits the data well for all the variants.The variations of the fit parameters with respect to the processing conditions and the heat treatment tempers are further discussed in collaboration with the microstructural features.

11:25 AM

Factors Influencing Tensile Mechanical Properties of Al-7Si-Mg Casting Alloys A356/7: *Heinrich Moller*[1]; Waldo Stumpf[2]; Gonasagren Govender[1]; [1]CSIR; [2]University of Pretoria

Conventional casting alloys Al-7Si-Mg A356/7 contain between 6.5 and 7.5% Si, together with 0.25-0.7% Mg and are used for critical castings in the automotive and aerospace industries. The tensile mechanical properties of these alloys are influenced by factors such as casting method, chemical composition variations and heat treatment. The casting method employed has an influence on the primary alpha-Al structure, which is dendritic using conventional liquid casting techniques and globular using semi-solid metal processing. The most important elements that influence mechanical properties are magnesium and iron. Temper condition dictates the degree of spheroidisation of eutectic Si-particles, as well as the strengthening precipitates formed. An equation to convert Vickers hardness to 0.2% proof stress in different temper conditions using the strain hardening exponent is proposed. Linear correlations between hardness, strength and (at% Mg-content available for precipitation hardening)1/2 are found. It is shown that ASTM Standard B969-10 needs to be revised.

Aluminum Reduction Technology: Cell Technology and Operation

DX+, An Optimized Version of DX Technology: *Abdalla Al Zarouni*[1]; Ali Al Zarouni[1]; Michel Reverdy[1]; Sergey Akmmetov[1]; Lalit Mishra[1]; Nadia Ahli[1]; Ibrahim Baggash[1]; [1]DUBAL

DUBAL has engaged in self-development of proprietary reduction technology since the 1990s. DX and DX+ Technologies in-house designed, modelled, tested and optimized are the products of this development process. In view of decreasing capital cost per tonne, DUBAL designed DX+ Pot Technology and started up five demonstration cells from June to August 2010. This paper summarizes the achieved targeted performance of the DX+ demonstration pots during their first year of operation at 420 kA. DX+ pots are similar to DX pots but larger in size: the productivity per square meter of potroom is increased by more than 17%. This paper describes the DX+ pot design evolution from DX Technology. The DX+ Technology has been selected for EMAL Phase-2 project. The FEED study completed in June 2011 is based on one potline of 444 DX+ pots. The design allows for operating amperage up to 460 kA.

8:50 AM

AP40 : The Latest of the AP Technology™ Solutions: *Laurent Fiot*[1]; Benedicte Champel[1]; Sylvain Fardeau[1]; Pierre Bon[1]; David Munoz[1]; Olivier Martin[1]; [1]Rio Tinto Alcan

Another significant step in the AP30 development has been successfully demonstrated; one that further enhances productivity. After AP39 technology validation, an enhanced operating point has allowed cells to operate above 400 kA without decrease in energy efficiency. Since July 2010, these cells, now referred to as AP40, operate at St Jean de Maurienne in the range of 400-405 kA with specific energy consumption below 13,150 kWh/t. To achieve this performance required an extensive review of operational aspects including busbar capability, operational quality, and process control. Also essential was the use of an "operating window" approach to determine the optimal operating point. By following a cell development methodology over two years, results have demonstrated a high level of process performance (anode effect frequency, current efficiency and energy consumption). Measurement campaigns have confirmed the excellent level of pot robustness.

9:10 AM

A Techno-Economic Optimization Model For Aluminum Electrolysis Production: Yanfang Zhang[1]; *Wangxing Li*[1]; Jianhong Yang[1]; Dengpeng Chai[1]; Shilin Qiu[1]; Jingyi Li[2]; [1]Zhengzhou Research Institute of Chalco; [2]Graduate School of Business and Law, RMIT

The major factors affecting the profit of an enterprise are the price of the product, the price of raw materials and energy consumed, depreciation of fixed assets, labor cost, output and process consumptions, etc. In this paper, based on a cost-volume-profit (CVP) analysis method and the process techniques of aluminium production, a series of techno-economic analysis and optimization models for the production of the aluminium smelter enterprises are built. The models can be used for the aluminium smelters in various market situations to get the optimum technical parameters of production, which are necessary for obtaining the greatest economic benefit. Thus, it will guide the aluminium smelters in different market environment, according to their own conditions, to adopt different technical parameters of production to maximize the gains and to minimize the losses. We also have studied the optimization of potline current of a 300 kA aluminium smelter by the models as an example

9:30 AM
The Successful Implementation of DUBAL DX Technology at EMAL: *Michel Reverdy*[1]; B. Kakkar[2]; David Spencer[2]; Walid Al Sayed[2]; Ali Al Zarouni[1]; Kamel Al Aswad[1]; Abdalla Al Zarouni[1]; [1]DUBAL; [2]EMAL

756 DX pots have been successfully commissioned at EMAL smelter in Abu Dhabi between 2nd December 2009 and 2nd January 2011. DUBAL DX Technology has gone through a fast track development from prototyping to large scale industrialization, with the design and engineering phase in 2004, followed by commissioning of five prototype pots in 2005, a demonstration line of 40 pots in 2008 and finally the commissioning of the giant smelter at EMAL in 2009/2010. The commissioning and normalization of the pots was very smooth without single lining incident. This has been achieved by the excellent team work and coordination between the various teams at all stages (pot preparation, preheat, start-up and normalization). It has also shown the robustness of the DX Technology. The potlines are operating at 353 kA with excellent performances exceeding 96.0% current efficiency and achieving 13.0 kWh/kgAl for more than 18 months since start-up.

9:50 AM
Commissioning of Emirates Aluminium Smelter Potlines: *B.K. Kakkar*[1]; Spencer[1]; Walid Al Sayed[1]; Salman Abdulla[1]; [1]Emirates Aluminum company

Abstract On the 2nd of December 2009 Emirates Aluminium (Emal) commenced its journey of starting 756 Dubal DX technology reduction cells. This undertaking was successfully completed on the 2nd of January 2011, thirteen months later, resulting in an average start-up rate of 13.3 pots per week. This sets a new benchmark for Greenfield Smelters. This remarkable achievement was possible due to an efficient work-organization, with committed and experienced employees. The pot start-up rate and pot technical results give measures of the success by which the task was accomplished. This article provides insights into the experiences gained and systems used by the Reduction Operations Team, in managing the organizational complexities of commissioning the largest Greenfield Smelter start-up to-date.

Update on the Development of D18 Cell Technology at Dubal: *Daniel Whitfield*[1]; Tariq Majeed[1]; Sergey Akhmetov[1]; Maryam Mohamed Al-Jallaf[1]; Kamel Al-Aswad[1]; Ibrahim Baggash[1]; Ali Al-Zarouni[1]; [1]Dubai Aluminium

Dubai Aluminium commenced operation in 1979 with 3 potlines, each with 120 P69 technology cells. After further refinement by Dubal (and renamed D18), a fourth potline of 144 cells was added in 1990. While more advanced cell technologies have since been developed and implemented at Dubal, the original cell technology has continued to be updated and improved so that it remains a vital contribution of the overall smelter production. The four D18 potlines have been combined into two potline circuits, and additional busbar added to all cells to reduce the specific energy consumption. Other changes such as improved noise control logic, resistance control, review of the anode set adder, and various changes to the alumina feed logic have enabled the D18 technology to reach the target amperage of 200kA and its subsequent stabilisation and optimisation at this milestone.

10:50 AM
Prebake Potline Restart after Power Supply Interruption: *Mikhail Lukin*[1]; John Johnson[2]; [1]Kubikenborg Aluminium AB; [2]RUSAL ETC

In early January 2011 the decision was taken to perform an emergency shutdown of the newly converted prebake potlines of Kubikenborg Aluminium AB (Kubal). This was due to power interruptions that resulted in bath shrinkage, which was followed by the onset of random anode failures in numerous cells when attempts were made to re-energize the potline. The present paper covers the methods for restarting the potline. These methods were first considered and tested on one or two pots to evaluate the individual method, taking into consideration the availability of trained personnel; cell limitations and logistics; metal purity for existing customer supply commitments; environmental regulations; and speed of restart.In addition, the paper will provide the criteria used to select the appropriate re-start procedure for different cell conditions and the results obtained by each of the methods used.

11:10 AM
The Restart of Two Idled Pot Lines at Ormet Primary Aluminum: *Cecil Smith*[1]; Mark Christman[1]; [1]Ormet Primary Aluminum

In November of 2010, Ormet Primary Aluminum Corporation announced an aggressive plan of restarting 2 potlines before the end of the 1st quarter of 2011. In order to accomplish this goal several key factors were utilized including the experience of the plant personnel, management of anodes and bath generation at start-up, initial power and chemistry control of the cells, and the fact that the shutdown of the lines was efficient and controlled. The total time from the restart announcement until all 344 cells were brought on took only 92 days, and the time from when the first line was energized until the final cell was cut in on the second line took only 71 days. This paper will discuss the key factors and obstacles that had to be overcome to allow Ormet to achieve this goal while also striving for safety as no recordable accidents occurred during the restart.

11:30 AM
Vertical Stud Søderberg Technology Development by UC RUSAL in 2004 -2010: *V.Yu. Buzunov*[1]; Victor Mann[2]; Evgeniy Chichuk[1]; Nikolay Pitertsev[2]; Igor Cherskikh[1]; Vladimir Frizorger[1]; [1]RUSAL ETC; [2]UC RUSAL

Due to considerable amount of VSS cells (more than 70 % of total capacity), RUSAL continues to develop the Søderberg process successfully. Alumina point feeding systems, dry gas scrubbers were introduced and anode paste production was modernized in Krasnoyarsk smelter. The amperage was increased in all RUSAL VSS potlines. Cell design has been permanently improved. These actions have increased an aluminium production efficiency and environmental sustainability. Besides, RUSAL Engineering and Technological Centre has successfully fulfilled the R@D program creating the new modification of VSS technology (so-called "colloid anode") with the reaching the new environmental standards. The results of these and other activities of the Company from 2004 to 2010 are shown in the article.

11:50 AM
Uniform Cathode Current Collection / Distribution Effect on Cell Stability (Nine Months of Continuous Treatment of a Sick Cell): *Hadi Fanisalek*[1]; [1]Hormozal

This paper describes a useful experience, which was conducted during last year's start-up and potroom operation regarding a sick cell treatment in an aluminum smelter in Iran, which we will call smelter X in this paper. Different parameters in the potroom have influence on cell stability, which need to be considered all together. Metal pad stability is the main concern for a smooth operation in an aluminum smelter to reach a low noise level and a high current efficiency. One of smelter X's aluminum reduction cells, which was started with good and smooth operating parameters, turned into a sick cell with a very high noise level two months after its start up. A special team started to monitor, test, analyze and try different strategies to bring the cell back to normal condition. This paper is a summary of the aforementioned challenge, team endeavor, possible solutions and final results to overcome this problematic issue.

Atomistic Effects in Migrating Interphase Interfaces - Recent Progress and Future Study: Modelling and Mechanisms of Interface Migration

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS/ASM: Phase Transformations Committee

Program Organizers: Tadashi Furuhara, Institute for Materials Research, Tohoku University; Sudarsanam Babu, Ohio State University; Hatem Zurob , McMaster University; Jian-Feng Nie, Monash University; Wen-Zheng Zhang, Tsinghua University; James Howe, University of Virginia

8:30 AM Invited

Effects of Alloying Elements on the Growth of Ferrite from Austenite In Multi-Component Fe-C Base Alloys: *Masato Enomoto*[1]; Ran Wei[1]; Guohong Zhang[2]; Dongwoo Suh[2]; [1]Ibaraki University; [2]Pohang University of Science and Technology

The nucleation and growth rates of ferrite in Fe-C alloys containing more than one alloying element are often different from the averages in component ternary alloys. For example the parabolic growth rate constant of ferrite in Fe-C-Mn-Si alloys was closer to that in Fe-C-Mn alloys than the average with Fe-C-Si alloys, whereas a similar tendency was observed with nucleation rate to a lesser extent. The deviation from the averages of ternary alloys can be produced by co-segregation (accumulation) of alloying elements at ferrie/austenite phase boundaries, diffusional interaction and change in partitioning of individual elements due to the change of transformation temperature. Experimental data on alloying element partitioning and parabolic growth rate constants recently obtained in Fe-C base quaternary and quinary alloys are compared with calculation and the possible mechanisms for synergistic effects are discussed.

9:00 AM Invited

Modeling of the Austenite to Ferrite Transformation in Fe-C-X Alloys: *Joakim Odqvist*[1]; Annika Borgenstam[1]; Henrik Larsson[2]; Lars Höglund[1]; John Ågren[1]; Mats Hillert[1]; [1]KTH (Royal Institute of Technology); [2]Thermo-Calc Software AB

The surprising results from experiments on Fe-C-Mn from Zurob et al. of a transition from LENP (local equilibrium-negligible partitioning) to PE (paraequilibrium) conditions during growth of ferrite at high temperatures have spurred new modeling attempts. In this work the dissipation of Gibbs energy approach is used to model the austenite to ferrite transformation in Fe-C-X alloys and the results are compared with experiments. Such calculations were performed by some of the present authors already 2002 but were based on very high ferrite/austenite interface mobility and indicated Ni segregation to the phase interface. Such segregation has not been confirmed experimentally and it has been found that the interface mobility may be many orders of magnitude lower than previously thought and thus the calculations will now be repeated. The simulations will also be compared with a more recent model by Larsson et al.

9:30 AM

New Model for Kinetics of the "γ" to "α" Transformation in Fe-C-X Systems: *Damon Panahi*[1]; Hatem Zurob[1]; Gary Purdy[1]; Christopher Hutchinson[2]; Yves Brechet[3]; [1]McMaster University; [2]Monash University; [3]Grenoble Institute of Technology

A newly developed model for growth of the proeutectoid ferrite has been employed to study the evolution of contact conditions at the ferrite/austenite interface during ferrite growth in Fe-C-X systems (X= Mo,Mn,Ni,Cr,Cu). The present model uses discrete atomic jumps to describe the diffusion of the substitutional elements across the interface. The free energy dissipation associated with these jumps is evaluated and its effect on contact conditions and interface velocity is taken into account. In line with this, recently obtained experimental observations and modeling results for the growth kinetics of the ferrite layer during decarburization of Fe-C-Mo and Fe-C -Mn systems will be presented. At the end, the compatibility of these experimental observations with the theoretical calculations will be discussed.

Precise Measurements of Phase Transformation Kinetics: What Can It Tell Us about the Atomic Mechanisms of Interface Migration?: *Christopher Hutchinson*[1]; Hatem Zurob[2]; [1]Monash University; [2]McMaster University

This symposium brings together two communities interested in phase transformations in solids. One community is interested in the local structure of phase interfaces. The other is interested in the transformation kinetics. The latter community acknowledges the key role of the interface structure but hides this in the interface mobility parameter. The former community similarly acknowledges that the structure and atomic mechanisms of interface migration may depend on the local chemistry and driving force acting on the interface but it is not clear how to include the effects.This presentation summarizes experiments that allow high precision measurements of the interface migration kinetics. The kinetics is interpreted using growth models and we discuss what conclusions regarding the atomic mechanisms of migration might be drawn. We attempt to highlight questions that would benefit from collaboration between the two communities to develop a description that couples thermodynamic, kinetic and structural aspects of interface migration.

Direct Computation of the Solute Drag on a Moving Interface using Atomistic Simulations: H. Humadi[1]; Y. Yang[2]; D. Buta[3]; B. B. Laird[2]; D.Y. Sun[4]; *Jeffrey Hoyt*[1]; M. Asta[5]; [1]McMaster University; [2]University of Kansas; [3]University of California, Davis; [4]East China Normal University; [5]University of California, Berkeley

Solute drag, or the dissipation of free energy arising from diffusional processes within the interfacial region of a moving interphase boundary, is an important phenomenon when describing microstructural evolution processes in alloys. In this work we show how atomistic simulations can be used to obtain quantitative values of the solute drag contribution of a moving crystal-melt interface for an embedded atom description of Cu-Ni. Molecular dynamics simulations have been used to extract both the interface velocity and the concentration profile for various driving forces. In addition, Monte Carlo simulations are utilized to determine the free energy of the system as a function of composition and temperature. From the free energy and velocity relationship the solute drag component is extracted and the results are compared with various theoretical treatments.

11:05 AM

Atomistic Simulations of Solute-Interface Interactions in Iron: *Hao Jin*[1]; Ilya Elfimov[1]; Matthias Militzer[1]; [1]The University of British Columbia

The kinetics of austenite-ferrite phase transformation is markedly affected by substitutional alloying elements. Therefore, it is of fundamental importance to quantify the interactions of solutes with interfaces in Fe alloys. In this study, the effects of common alloying elements (e.g. Nb, Ti, Mo, Cu, Mn, Si, Co, Cr, V, Ni) on structure, segregation and magnetic properties of Fe interfaces are systematically investigated using first-principles density functional theory (DFT). Minimum energy pathways for diffusion and associated saddle point structures were determined with the climbing image nudged elastic band method. Using the activation energies obtained with DFT self- and solute diffusivities along and across interfaces have been determined with atomistic Kinetic Monte Carlo (KMC) simulations. Calculated results confirm the strong interaction of Nb, Ti, and Mo with interfaces, and show that interface diffusion is faster than bulk diffusion.

11:25 AM
Atomistic Modelling of Interstitial Solute Interacting with Moving Interface: *Aulia Wicaksono*[1]; Matthias Militzer[1]; Chad Sinclair[1]; [1]UBC

A parametric study of the interactions between a moving solid-solid interface and mobile interstitial solutes has been performed using kinetic Monte Carlo (kMC) simulations. A new kink migration approach for the motion of an interface has been introduced and used to study the interaction with mobile interstitial solute. Above a critical temperature a roughening transition for the interface is observed that modifies the migration mechanisms, i.e. initiation-propagation for $T < Tc$ and stochastic fluctuation for $T = Tc$. It is found that the interaction between the interface and the solute depends on the simulation temperature relative to Tc. More generally, the velocity of the moving interface decreases with solute segregation to the interface, the level of segregation depending on the interface morphology, the binding energy between solute and the interface and the solute diffusivity. These observations are compared and contrasted with the classical mean field theory for solute drag.

Biological Materials Science Symposium: Biological and Bio-Inspired Materials III: Soft Biomaterials

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division, TMS: Biomaterials Committee

A Detailed Physicochemical Study of Peptide-Mineral Interactions; Importance of Peptide Composition, Particle Size, Surface Chemistry, pH and Buffer Identity: *Carole Perry*[1]; Valeria Puddu[1]; David Belton[1]; [1]Nottingham Trent University

The study of interactions occurring at the mineral- biomolecule interface is a subject of longstanding interest having implications in fields from biomimetic materials synthesis through to the development of drug delivery vehicles and nanodevices. Although extensive studies have been performed on a colloidal level to describe the interaction between organic species and inorganic materials, to date, a clear understanding of the processes occurring at a molecular level are still far from been achieved. A great challenge is the formulation of guidelines for the prediction of the functional groups that will preferentially interact with the surface, which forces will contribute to the interaction and to which extent. In this respect, we believe that to gain insights into the mechanistic aspects of the interaction, a comprehensive knowledge of the biomolecule and the inorganic material is of fundamental importance. In this contribution we show the results of studies on silica and titania.

9:00 AM
Specific Targeting Molecular Probes: From Materials to Cells: Hilal Yazici[1]; Marketa Hnilova[1]; Hanson Fong[1]; Hai Zhang[1]; *Candan Tamerler*[1]; [1]University of Washington

Molecular immobilization on inorganic surfaces has become an engineering consideration in a wide arrange of areas from sensing to biomaterials engineering. Requirements vary in each applications depending on the immobilization density, chemical and biological stability, material specific assembly, directionality. The characteristics of recognition, self assembly and ease of genetic manipulation make inorganic binding peptides an ideal molecular tool for addressable assembly of biomolecules. We therefore build upon the modularity of peptide domains and produce multifunctional peptides that can controllably bind to a given solid material, in particular to those relevant for nanomedicine. Here we will show specific examples on the flexible and modular use of peptides for biological surface functionalization and, demonstrate enhanced bioactivity as well as controlled antimicrobial property in the presence of different cells on a variety of biomaterials, i.e. implants and imaging agents. Research is supported the NSF-MRSEC at UW, NSF-BIOMAT, NSF IRES Projects.

9:20 AM
Possible Key Property of Nanoparticles that Can Maximize Its Cancer Killing Capacity: *Vanessa Moosavifazel*[1]; Soumen Das[2]; Sudipta Seal[2]; [1]University Central Florida ; [2]University Central Florida

Previously, we have reported the ability of dextran-coated nanoceria (Dex-CNP) to kill cancer cell (IC50 150µM). It is well known that physiochemical properties of a nanoparticle are crucial to the interaction of the particle with the cell. Therefore, to maximize the efficacy of the nanoparticles to kill the cancer cell we need to figure out which chemical or physical property is the key. In this study we have synthesized similar shape and size Dex-CNP with varying surface oxidation (Ce^{3+}/Ce^{4+}) state ratio, by exposing Dex-CNP to light initiating a color change from dark yellow to pale yellow which is an indication of Ce^{4+} to Ce^{3+} conversion. Nanoceria has been characterized by using uv-vis and x-ray photon spectroscopy. Interestingly, we have found that light exposed nanoceria coated with dextran loss it's cytotoxicity towards squamous cell carcinoma cell line (CCL30). Summarizing, lower surface Ce^{3+}/Ce^{4+} may be efficient for cancer killing.

9:40 AM
Response of Mice 7F2 Osteoblast and Porcine Dental Pulp Stem Cells to Substrate Topography: *Marian Kennedy*[1]; Xue Chen[1]; Terri Bruce[1]; Delphine Dean[1]; Julia Sharp[1]; [1]Clemson University

Currently, there are no restorative dental techniques capable of dentin fabrication. For this to become a reality, researchers must understand external influences to dental pulp stem cells (DPSCs). This work aims to identify the influence of substrate topography on DPSCs. Forty-eight unique micropatterns were produced with a range of feature heights (100-1000nm), widths (5-50µm) and shapes (lines, dots, holes and hexagons). Two types of cells were utilized- mice 7F2 osteoblasts and porcine DPSCs. The osteoblasts were plated as a control and confirmed earlier findings. The DPSCs did not show any cell alignment or proliferation (as indicated by cell density) with isotropic or anisotropic micropatterns. Significance of the osteoblast and DPSCs normalized densities were analyzed with statistical software (SAS, 2010). This analysis showed that there were no significant geometry effects. However, variation existed between each cell plating repetition and when repetition is taken into account, the feature height influenced average density.

10:00 AM
Determination of Mechanical Properties in Escherichia Coli by Nanoindentation: *Cody Wright*[1]; Abdelmageed Elmustafa[1]; Claretta Sullivan[2]; [1]Old Dominion University; [2]Eastern Virginia Medical School

The cytoplasmic membrane of Escherichia coli, a gram-negative bacteria, is shielded from the harsh environment by a cell wall which is comprised of a peptidoglycan and outer membrane. In hypoosmotic conditions, the peptidoglycan together with cellular proteins mitigate the osmotic stress which would otherwise cause lysis. Mechanical properties of E. coli and its individual layers have been investigated using atomic force microscopy (AFM). For precise measurements of elastic modulus and hardness, contact area and load should be well defined. The AFM cantilever spring constant can accurately describe the load however the contact area can only be estimated. This uncertainty in contact area can lead to propagating uncertainties in results. We propose a methodology for determining the nanomechanical properties of E. coli using nanoindentation. The mechanical properties of live bacteria will be determined in liquid in order to simulate biologically relevant conditions.

Measurement of the Cell Adhesion Strength of Patterned Fibroblasts Using Hydrodynamically-Confined Microfluidics: *Kevin Turner*[1]; Kevin Christ[2]; [1]Univeristy of Pennsylvania; [2]University of Wisconsin-Madison

Cell adhesion to the extracellular matrix (ECM) is a critical process that affects cell growth, differentiation, and fate. Here we present a new cell adhesion strength measurement technique using hydrodynamically-confined microflows that enables rapid analysis of the adhesion of single cells in open fluidic environments. Hydrodynamically-confined microflows (HCMs) are microfluidic flows that are confined on the top and bottom by solid walls, and on the sides by a surrounding liquid; hence, they can easily be created in common open cell culture environments, such as Petri dishes. Here we use HCMs to apply uniform mechanical stresses to detach adherent cells from protein-functionalized surfaces. We have designed and used an HCM device optimized for shear stress application to characterize the adhesion strength of patterned NIH3T3 fibroblasts as a function of shape. Details of the device design and fabrication as well as results from the experiments will be presented.

10:55 AM
The Role of Surface Free Energy of Cell Adhesion in TiO2 Systems: Eileen Gentleman[1]; Kyle Krzywosinski[2]; Matthew Scorsone[2]; *Molly Gentleman*[2]; [1]King's College London; [2]Texas A&M University

Titanium implants have gained popular use in orthopedic implants, specifically hip implantation. As a result, effort is being made to increase the osseointegration between these load bearing artificial implants and native bone. In previous studies the observed wettability of a surfaces has been shown to be a good indicator of the quality and rate of osseointegration. In this study, the role of surface energy on cell adhesion density and the quality of bone nodule growth are explored for a range of titanium dioxide samples. Modifications made to the acid and base surface energies of these oxides will be discussed with respect to the efficiency of cell maturation as measured by staining and Raman spectroscopic techniques.

11:15 AM
Mechanical Response of Brain Tissue Surrogate Material under Impact Loading: Marius Ellingsen[1]; *Deepthi Saini*[1]; Karim Muci-Küchler[1]; Brandon Hinz[1]; [1]South Dakota School of Mines and Technology

Brain tissue surrogate materials are necessary to study injuries related to head impacts which can occur during sports or accidents. Brain tissues are soft and weak materials with complex nonlinear mechanical behaviors, including hysteresis and strain softening. Acceptable surrogate materials must have similar dynamic properties to that of brain tissues. The primary objective of this study is to investigate the dynamic response of candidate brain tissue surrogate materials during high strain rate loading. Shear rheological characterizations of Perma-Gel and Agarose gel were conducted using a computer-controlled rheometer. The results showed that the Agarose gel had mechanical behavior similar to the porcine brain tissue as reported in the literature. Impact experiments were then conducted on Agarose gel to study its mechanical behavior at a high loading rate aimed at representing the scenario encountered in crash loading conditions. The results from the rheological and impact tests are compared and examined in detail.

11:30 AM
Photocatalytic Responses of Bacterial Cells: J. Zhang[1]; X. Wang[1]; P. Wu[2]; Q. Li[1]; *J. Shang*[3]; [1]Institute of Metal Research; [2]Superior Graphite Co.; [3]University of Illinois

Antimicrobial materials based on TiON visible-light photocatalysis have shown great potential in inactivating a wide range of microbiological species. However, there is a serious lack of basic understanding of the antimicrobial behavior of these materials. In this study, the photocatalytic responses of bacterial cells were examined, in "live" and post-mortem conditions, by a series of microscopic and microbiological techniques to investigate the mechanisms of bacterial inactivation by TiON photocatalysts. Significant alterations in the structure and morphology were observed in the bacterial cells. These changes are related to the antimicrobial properties of the photocatalysts.

11:45 AM
Polydimethylsiloxane Mechanical Properties and Their Effects on Cell Growth: *Zhixin Wang*[1]; Kranthi Elineni[1]; Nathan Gallant[1]; Alex Volinsky[1]; [1]University of South Florida

In this work, Polydimethylsiloxane (PDMS) network is used as a substrate to grow live cells. A series of PDMS network samples with different crosslink density were tested to obtain the relationship between their biological behaviors and mechanical properties. A macroscopic compression test instrument was designed for PDMS mechanical properties testing. The relationship between PDMS network elastic modulus and its base/agent ratio was established, where the PDMS network elastic modulus is linear with its percent of crosslinker. The same PDMS network samples were also tested with the Hysitron TriboIndenter to verify the elastic modulus and other mechanical properties. The ongoing work is to study the effect of substrate elasticity on the cell adhesion strength independently of the bio-chemical cues. This work would establish the relevance of PDMS as a biomaterial and more significantly in designing biomaterials by incorporating gradients of mechanical and bio-chemical cues.

Bulk Metallic Glasses IX: Fatigue and Corrosion

On the Fatigue Strength of Monolithic and Composite Bulk-Metallic Glasses: Bernd Gludovatz[1]; Marios Demetriou[2]; Maximilien Launey[3]; Douglas Hofmann[2]; William Johnson[2]; *Robert Ritchie*[1]; [1]Lawrence Berkeley National Laboratory; [2]California Institute of Technology; [3]NDC

High strength and ease of processing make bulk-metallic glasses (BMGs) promising candidates for many structural/functional applications. However, poor fatigue strengths in the form of low fatigue limits have been reported (in some alloys approaching 0.04 UTS), which clearly limits their utility as structural materials. This follows because the absence of microstructure provides no local arrest features for pre-existing cracks. Recently developed glass-matrix composite BMGs with crystalline second-phase dendrites, however, have displayed fatigue limits of ~0.3 UTS. Here, provided the inter-dendritic spacing does not exceed the critical crack size, the second phase can arrest incipient cracks leading to significantly higher fatigue strengths. The question that we now pose is whether such fatigue properties can be achieved in monolithic BMGs. In a 1.5 GPa strength Pd-Ag-based monolithic BMG we can achieve a fatigue limit comparable with that in composite BMGs, although the mechanisms underlying such high fatigue resistance are quite different.

8:50 AM
Surface Coating of Zr-Based Metallic Glass Film for the Fatigue Property Improvements of Ti-6Al-4V Alloy: *Cheng-Min Lee*[1]; J. P. Chu[1]; [1]National Taiwan University of Science and Technology

In this study, we propose the use of the Zr-based glass-forming material as a promising coating film for enhancing four-point bending fatigue property of Ti-6Al-4V alloy. A 200nm-thick $Zr_{50}Cu_{27}Al_{16}Ni_{7}$thin film was prepared by sputtering deposition system on Ti-6Al-4V substrate. The fatigue life is improved from 3.1 x 10^5 cycles for the uncoated sample by ~17.3 times to 5.3 x 10^6 cycles at a stress level of 1.3 GPa. Our Zr-based film is much thinner than traditional hard coatings but has a remarkable performance on the fatigue properties enhancement of the substrate. The excellent mechanical properties of the metallic glass thin film play a critical role. The mechanisms for the substrate fatigue property improvements have been studied and the results will be discussed.

9:00 AM Invited
Environment Assisted Cracking of Zr-Based Bulk Metallic Glass in the Region near Threshold: *Yoshikazu Nakai*[1]; Toyohiko Koyama[1]; [1]Kobe University

Crack propagation tests on a bulk metallic glass, Zr55Cu30Ni5Al10, were conducted in aqueous sodium chloride (NaCl) solutions under constant crack opening displacement tests where value of stress intensity factor decreased with crack extension. Tests were also conducted under cyclic loading of K decreasing test, and the effect of stress ratio was examined. Comparisons of the time based crack growth rate under cyclic loading and static loading will be conducted. The effect of environment on fatigue crack growth in the region near threshold (Region A) was also examined.

9:20 AM Invited
Statistical Modeling of Fatigue for Zr55Cu30Ni5Al10 Bulk-Metallic Glass: *D Gary Harlow*[1]; Yoshihiko Yokoyama[2]; [1]Lehigh University; [2]Tohoku University

Fatigue lives of bulk-metallic glasses (BMGs) exhibit large scatter in excess of four orders of magnitude especially for longer lifetimes. In order to be able to make meaningful lifetime predictions, sufficient data must be available to develop accurate probability and statistics models. The statistical properties of Zr55Cu30Ni5Al10 BMG are examined in the context of standard stress and fatigue-life cycles (S-N) response. The experimental data include stress amplitudes ranging from 500 to 1000 MPa for the as-prepared (no annealing) BMG. Subsequent comparisons to the BMG after annealing are made to evaluate its impact. For all these cases, the majority of the fractures were caused by fatigue damage initiation from the surface. Limited microstructural evidence will also be presented.

9:40 AM Break

9:55 AM Invited
Understanding Fatigue Resistance in Bulk Metallic Glasses: *Jamie Kruzic*[1]; [1]Oregon State University

Fatigue crack growth rates were measured for $Zr_{44}Ti_{11}Ni_{10}Cu_{10}Be_{25}$, $Zr_{58.5}Nb_{2.8}Cu_{15.6}Ni_{12.8}Al_{10.3}$, and $Zr_{52.5}Cu_{17.9}Ni_{14.6}Al_{10}Ti_{5}$ bulk metallic glasses (BMGs). The Zr-Ti-Ni-Cu-Be BMG was tested in different initial free volume states, different residual stress states, and in both ambient air and dry nitrogen environments. Fatigue crack growth rates were relatively unaffected by the initial free volume state. This was attributed to the formation of a fatigue transformation zone of increased local free volume at the fatigue crack tip. When casting residual stresses were annealed out it was found that the fatigue threshold and fracture toughness decreased. Finally, it was observed that testing in a dry nitrogen environment significantly increased the fatigue threshold, suggesting a corrosion fatigue mechanism in ambient air. A similar environmental effect was observed for the Zr-Nb-Cu-Ni-Al BMG while the Zr-Cu-Ni-Al-Ti BMG was immune to ambient air environmental effects and exhibited fatigue crack growth resistance comparable to crystalline metals.

10:15 AM
The Study of Fatigue-Induced Damage in Zr-Based Bulk Metallic Glasses: *Chih-Pin Chuang*[1]; Wojciech Dmowski[1]; Wei Guo[1]; Gongyao Wang[1]; Peter Liaw[1]; Takeshi Egami[1]; Yoshihiko Yokoyama[2]; Ran Li[3]; Tao Zhang[3]; [1]University of Tennessee; [2]Tohoku University; [3]Beihang University

It's well known that bulk metallic glasses (BMGs) will fatigue even when the applied cyclic-loading is far below its yielding stress, where the stress-strain curve indicated that the deformation should be macroscopically elastic. Yet, the mechanisms responsible for the fatigue-induced damage are varied and inconclusive. In the present work, we investigate the effect of "fatigue" on the fatigue behavior and atomic structure of Zr-based BMG. The compression-compression fatigue tests were conducted on the as-cast and the pre-fatigue-to-failure samples. The results indicated that pre-fatigued samples had similar or longer life (cycles-to-failure). The pair-distribution function (PDF) analysis of the as-cast, and post-fatigue samples using high energy synchrotron X-ray scattering showed no, or very small changes of local atomic structure. The results suggest that the fatigue life of these Zr-based BMG is dominated by the localized damage accumulated around crack tip. The sample will fail before globalized atomic structure changes were observed.

10:25 AM
The Atomic Structure Changes of a Metallic Glass under Creep and Fatigue Loadings: *Wei Guo*[1]; Wojciech Dmowski[1]; Andrew Chuang[1]; Gongyao Wang[1]; Yoshihoko Yokoyama[2]; Yang Ren[3]; Peter Liaw[1]; Akihisa Inoue[2]; Takeshi Egami[1]; [1]University of Tennessee,Knoxville; [2]Tohoku University; [3]Argonne National Lab

We studied the atomic structure evolutions in a Zr50Cu40Al10 metallic glass under room temperature creep and cyclic loadings below yielding point. The creep loading was held for 24hrs. and 72 hrs. at 60% and 80% of the yield stress (YS). The fatigue experiments were conducted for 105 and 106 cycles at mean stresses of 40% and 60%YS. The structure function S(Q) and the pair distribution functions (PDFs) were determined from high energy X-ray diffraction experiments. Results show that creep samples undergo greater changes than the fatigue samples indicated by the PDF peak sharpening and shifting. Significant difference was neither observed among samples loaded at different stress levels in creep experiments, nor in fatigue samples at different cycles. Loading direction influences the structure changes in the creep samples: The PDFs observed in the direction parallel to the loading have greater changes than in the normal direction.

10:35 AM Invited
Characterization of Shear Bands and Cracks Induced by Three-Point Bending Fatigue Test in Zr-Cu-Al Bulk Metallic Glass: *Pei-Ling Sun*[1]; Gongyao Wang[2]; Peter Liaw[2]; [1]Feng Chia University; [2]University of Tennessee, Knoxville

Zr50Cu40Al10 bulk metallic glass was deformed by three-point bending fatigue test in the air. Inhomogeneous shear bands/cracks were observed on the tensile and compressive regions after deformation. Characterization of shear bands by scanning electron microscopy reveals the presence of different fracture modes: river pattern and smooth fracture path on the tensile region. However, only a fracture path appears on the compressive surface. Cross sections of the shear bands/cracks were cut by focused ion beam for transmission electron microscopy (TEM) observation. Examinations of the shear band/crack microstructures reveal that nanocrystallites only appear on the crack fracture surface. Additionally, the compositions of matrix, shear band and nanocrystallite were found to be different. Shear bands contain more oxygen content but nanocrystallites have more copper content. These results are related to diffusion and thermally activated processes. The same sample tested in vacuum will be examined by TEM and the deformation mechanism will be discussed.

10:55 AM Invited

Static and Cyclic Deformation Effects on the Thermomechanical Behavior of Bulk Metallic Glass: *Rainer Hebert*[1]; Arif Mubarok[1]; Gongyao Wang[2]; Peter Liaw[2]; Yoshihiko Yokoyama[3]; Akihisa Inoue[3]; [1]University of Connecticut; [2]University of Tennessee at Knoxville; [3]Tohoku University

Static and cylic elastic loading of bulk metallic glasses yields unusual results. Static compression at about 70 % of the yield/fracture strength induces permanent length changes in a structurally-relaxed Cu50Hf41.5Al8.5 BMG at room temperature but only after about 25 hours of compression. Irreversible length changes during heating after static compression depend on the direction relative to the applied static load. Following cyclic tension-tension tests, i.e., fatigue tests, a Zr50Cu40Al10 BMG revealed a slight shift in the glass-transition temperature to lower temperatures, compared to the as-cast sample. Zr50Cu40Al10 BMG was conducted with a tension-tension cyclic loading at an R-ration of 0.1 and a frequency of 10 Hz. The fatigue lifetime is 7049 cycles with a maximum stress of 978 MPa. The thermal expansion data of the statically-elastically loaded Cu-based BMG is analyzed with an activation-energy spectrum approach. The results are coherent with a re-orientation of atomic bonds during deformation.

11:15 AM Invited

Fatigue Behavior of Zr-Based Metallic Glass at Micro- and Nano-Scales: *Dongchan Jang*[1]; Peter Liaw[2]; Gongyao Wang[2]; Julia Greer[1]; [1]California Institute of Technology; [2]University of Tennessee

Recent reports indicate that crystalline strength significantly increases when extrinsic sample dimensions are reduced to nano-scale. In some cases, metallic glasses have also been shown to attain increased tensile strength and ductility under quasi-static monotonic loading for sample sizes below ~100 nm. Size effects under cyclical loading have rarely been addressed. Here we present mechanical behavior and morphology evolution in Zr-based metallic-glass micro-/nano-pillars subjected to compression-compression fatigue. Cylindrical micro-/nano-pillars with diameters between several microns and ~200nm were fabricated via Focused Ion Beam (FIB) and tested in both G200 (Agilent) nanoindenter equipped with a flat punch tip and in the in-situ Scanning-Electron-Microscopy-based nano-mechanical instrument, SEMentor. The stress versus fatigue-life cycles (S-N) plots exhibit significantly enhanced lifetime and endurance limit compared with bulk, suggesting high fatigue damage tolerance in small-scale metallic glasses. These findings are discussed in the framework of unique microstructural deformation mechanisms occurring in micro-/nano-sized metallic glasses.

11:35 AM

Thermography Study of Fatigue on Different Amorphous Alloy Systems: *Gongyao Wang*[1]; Q. M. Feng[1]; M. D. Demetriou[2]; Y. Yokoyama[3]; P. Liaw[1]; W. L. Johnson[2]; A. Inoue[3]; [1]University of Tennessee; [2]California Institute of Technology; [3]Tohoku University

Zr-based bulk metallic glasses (BMGs) generally show shear failure during cyclic loading, while Fe-based BMGs demonstrate splitting failure during cyclic loading. This fact suggests that the fatigue mechanisms could be different between the relative "ductile" (Zr-based) BMGs and the relative "brittle" (Fe-based) BMGs. A state-of-art infrared (IR) thermography camera is employed to monitor the temperature evolutions of both Zr- and Fe-based BMGs during fatigue experiments. With the understanding of the temperature evolutions during fatigue, thermography could provide the direct information and evidence of the stress-strain distribution, shear-band formation and growth, and crack initiation and propagation. In-situ visualizations as well as qualitative and quantitative analyses of fatigue-damage processes have been performed using thermography results. Theoretical models combining thermodynamics and heat-conduction theory are developed to understand the fatigue behavior of BMGs. A mechanistic understanding of the fatigue behavior of Zr-based and Fe-based BMGs is suggested. The fatigue mechanisms of BMGs are discussed.

11:45 AM Invited

A Study of Corrosion Behavior of Zr-Based Metallic Glass Thin Films Deposited by Pulsed DC Magnetron Sputtering Technique: Yi-Chia Liao[1]; *Jyh-Wei Lee*[2]; Ching-Yen Chung[2]; Chia-Lin Li[3]; Jenq-Gong Duh[4]; Jinn P. Chu[3]; [1]Tungnan University; [2]Ming Chi University of Technology; [3]National Taiwan University of Science and Technology; [4]National Tsing Hua University

The Zr-based metallic glass thin films were fabricated on Si and SUS420 substrates by pulsed DC magnetron sputtering technique. Microstructures of thin films before and after corrosion tests were investigated by an atomic force microscopy (AFM), field emission electron probe microanalyzer (FE-EPMA) and transmission electron microscopy (TEM). The potentiodynamic polarization technique was carried out to study the corrosion resistance of thin films in HCl and H2SO4 aqueous solutions, respectively. Further analysis on the chemical compositions of corrosion products were explored using FE-EPMA. The pitting corrosion, crevice corrosion and filiform corrosion behaviors were observed. The possible corrosion mechanisms of Zr-based metallic glass thin films was discussed in the present paper.

12:05 PM

Utilization of Electrochemical Dissolution Processes for Micro-Machining of Bulk Metallic Glasses: Annett Gebert[1]; Jakub Koza[1]; *Ralph Sueptitz*[1]; Margitta Uhlemann[1]; Jürgen Eckert[1]; Ludwig Schultz[1]; [1]IFW Dresden

A recent trend in BMG research is the development of suitable techniques for production of micro-parts and micro-patterned surfaces. Thermo-mechanical processing is very promising but has also some limitations [1]. Here another approach operating at r.t. is introduced which utilizes the transpassive dissolution of metallic glasses. Electrochemical micro-machining (ECMM) with a micro-tool electrode is for the first time employed to generate micro-patterns on BMG surfaces by strict control of the local electrochemical process. The principal method is described and first experiments using a Zr-based BMG are presented for discussing the advantages and challenges of this advanced technique. Micro-hole structures were machined with significant aspect ratios at depths of ~40 µm. The effect of process parameters such as electrolyte, pulse voltage and pulse length was investigated and their influence on the machined structure morphology is established. [1] J. Schroers, *Adv. Mater.* 21, (2009) 1.

Cast Shop for Aluminum Production: Dross and Melt Quality Control

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee
Program Organizer: Trond Furu, Hydro

Wednesday AM March 14, 2012 | Room: Northern A4 | Location: Dolphin Resort

Session Chair: Gerd-Ulrich Gruen, Hydro

8:30 AM
A New Approach to Identify Aluminum Dross Reduction Opportunities Using an Integrated Weighing System: *Simon L'Heureux*[1]; Vincent Goutière[1]; Joseph Langlais[1]; David-Alexandre Tremblay[1]; Peter Waite[1]; [1]Rio Tinto Alcan

Cast house operations involving molten aluminum processing and furnace charging result in dross generation. This undesirable residue is composed mainly of metallic aluminum and oxides, and engenders costs exceeding 1000 US$ per MT of dross. Considering that no batch-to-batch measurements of dross weight are generally performed in the cast house, the task of dross reduction has always been complicated since the key process parameters and batch preparation practices affecting dross are not well known. As such, a new integrated weighing device was developed to continuously measure dross generation. The data generated will be used not only to follow-up on long-term furnace performance, with respect to dross generation, but also to complete a statistical analysis aimed at identifying key dross contributors. This paper describes the industrial dross weighing strategy that was developed, as well as the equipment that was installed in a RTA cast house.

8:50 AM
Statistical Analysis of Dross Data for Hydro Aluminium Casthouses: Christian Rosenkilde[1]; *Inge Johansen*[1]; Amanda Bowles[1]; [1]Hydro Aluminium

Reducing the formation of dross is important for a sound economic result in aluminium casthouses. In order to reduce the amount of dross the main drivers affecting the dross creation need to be identified. The first step towards identifying these drivers is to measure the dross amount on a charge basis. With a sufficiently large dataset it is possible to apply statistical methods to look for correlations between different parameters and the dross formation. It is also possible to rank the different parameters and identify those that are the most import for dross formation. In this paper multivariate statistical analysis is used to correlate the various input parameters and dross formation on a charge basis and to identify the most important driver/s for dross formation. Examples from a remelt extrusion ingot casthouse and a primary extrusion ingot casthouse are given and discussed.

9:10 AM
Wettability of Aluminium with Aluminium Carbide (Graphite) in Aluminium Filtration: *Sarina Bao*[1]; Kai Tang[2]; Anne Kvithyld[2]; Thorvald Engh[1]; Merete Tangstad[1]; [1]NTNU; [2]SINTEF

Graphite filters have previously been employed based on petrol coke. Wetting between molten aluminium and graphite is studied. Al3C4 is formed at the interface between aluminium and graphite. In filtration of aluminium inclusions such as Al3C4 formed in the hall electrolysis are removed. Wetting between aluminium and Al3C4 (graphite) is determined in kinetic studies in the higher temperature range 1000-1300°C. The results are extrapolated down to temperatures employed in the industry around 700°C. The contact angle between aluminium and graphite decreases with time. It may be divided into three steps: removal of an oxide layer on aluminium, formation of Al3C4 at the interface, finally giving an equilibrium value for the contact angle of Al- Al3C4. This value is found to be around 92.5° at 700°C.

9:30 AM
A New Fused Magnesium Chloride Containing Refining Flux Based on a Ternary System: *John Courtenay*[1]; [1]MQP Limited

The major cost factor in the production of fused refining fluxes is raw materials and in particular the cost of potassium chloride, which because of its role in fertilizer production has been subject to large price increases in the period 2008 – 2009, having risen by more than 350%. As demand for potash for world food production and bio-fuels is increasing again with the recovery in the global economy further price rises are expected, with the price having risen already by 43% from November 2010 to July 2011. A program of work has been undertaken to develop an alternative flux based on a ternary system comprising magnesium chloride and potassium chloride; where the potassium chloride is partially replaced with sodium chloride. The results of a study of the thermodynamics together with laboratory measurement of viscosity, interfacial tension and differential thermal analysis are presented.

9:50 AM Break

10:10 AM
High Frequency Electromagnetic Separation of Inclusions from Aluminum: *Lucas Damoah*[1]; Lifeng Zhang[1]; [1]Missouri University of Science and Technology

Electromagnetic purification method for the removal of inclusions has been proposed to complement the existing methods, and many researchers have devoted a lot of effort to studying the electromagnetic inclusion removal process. It has been widely published that high frequency electromagnetic field is limited in the depth of penetration into the molten metal thereby rendering the separation method ineffective. The contribution of the high circulatory fluid flow associated with such high frequencies has also been reported to be negative. The effect of wall temperature to the electromagnetic inclusion removal process has also not been clearly established. This study presents new results that show that, fluid flow contributes greatly in the presence of lower wall temperature to remove particles during high frequency (63 kHz) EM purification of aluminum, contributing to overcoming skin depth effect in small and large crucibles.

10:30 AM
Measurement of Non-Metallic Inclusions in the Size Range of 10-20µm by LiMCA: *Mark Badowski*[1]; Stephen Instone[1]; [1]Hydro Aluminium

Regular monitoring of the melt quality is employed in Aluminum cast houses production where optimized processes and high quality are required. A well established method for the quantitative measurement of non-metallic inclusions is the LiMCA system. In this method, inclusions flowing together with the liquid Aluminium through a 300µm orifice of a submerged glass tube are detected due to their high electrical resistance. The LiMCA system can identify the size, typically in the range between 20µm and 300µm and number of particles in the liquid Aluminium. Increasing product quality standards have resulted in demands to monitor particles even smaller than 20µm. This paper reports results of a parametric study to assess the capability of of the LiMCA system to monitor non-metallic inclusions in the particle size range of 10-20µm through changing the orifice hole size and by adjustment of the basic measurement parameters.

10:50 AM
Relationship between the Permeability of the Porous Disk Filter and the Filtrate Weight-Time Curves Generated with the PoDFA / Prefil® Footprinter Method: *Stephen Instone*[1]; Daniel Krings[1]; Gerd-Ulrich Gruen[1]; Roland Schmoll[1]; Mark Badowski[1]; [1]Hydro Aluminium Rolled Products GmbH

Current methods to quantify metal quality suffer from disadvantages in complexity, expense or response time. One method suggested to provide a real-time quantitative assessment of metal quality is the use of filtrate weight-time curves produced by filtering the metal through a porous disk filter. The slope and overall shape of this curve should indicate the level of inclusions present in the metal. Hydro Aluminium increasingly employs such methods to assess the quality of both Aluminium und Magnesium alloys. Several different types of crucible and porous disk filter are used. Due to the increasing importance of this assessment method a better understanding of the importance of variations in the permeability of the filter was considered necessary. This paper describes a device to measure the permeability of the filter discs and gives details of trials conducted to quantify the effect of variations in filter permeability on the filtrate weight time curves.

11:10 AM
Study of Ni-Impurity Removal from Al Melt: *Muhammad Akbar Rhamdhani*[1]; Mohammad Dewan[1]; Jason Mitchell[1]; Cameron Davidson[1]; Geoffrey Brooks[1]; Mark Easton[1]; John Grandfield[1]; [1]CAST CRC

Impurity control in the production of Al alloys is very important for achieving the desired properties of the products. There has been an increasing impurity concentration (particularly nickel and vanadium) in the coke used in the primary Al production which will end up in the Al. Vanadium can be removed in the casthouse through boron treatment. Nickel, however, is a non-reactive element and difficult to be remove. There is currently no technique available in the casthouse to remove nickel impurity. The current paper focuses on the study of nickel impurity removal from Al melt. A literature review on the available techniques for the removal of nickel and other elemental impurities from Al melt was carried out; followed by a systematic thermodynamic analysis of various Al-Ni-X systems for possible formation of Ni-containing phases in Al melt. Laboratory experiments were carried out to test the possible systems identified from the thermodynamic analysis.

CFD Modeling and Simulation in Materials Processing: Modeling of Casting and Solidification Processes II

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS Materials Processing and Manufacturing Division, TMS: Process Technology and Modeling Committee, TMS: Solidification Committee
Program Organizers: Laurentiu Nastac, The University of Alabama; Lifeng Zhang, Missouri University of Science and Technology; Brian Thomas, University of Illinois at Urbana-Champaign; Adrian Sabau, Oak Ridge National Lab ; Nagy El-Kaddah, The University of Alabama; Adam Powell, Metal Oxygen Separation Technologies, Inc.; Hervé Combeau, Institut Jean Lamour

Wednesday AM — Room: Asia 4
March 14, 2012 — Location: Dolphin Resort

Session Chairs: Laurentiu Nastac, The University of Alabama; Nagy El-Kaddah, The University of Alabama

8:30 AM
Modeling of Centrifugal Casting Processes with Complex Geometries: *Nicholas Humphreys*[1]; Diane McBride[2]; Nick Croft[2]; Dimitri Shevchenko[1]; Nick Green[1]; Mark Cross[2]; [1]University of Birmingham; [2]Swansea University

Centrifugal casting offers a route to high quality products in difficult to cast high temperature low superheat alloys and thin section molds. Under centrifugal forces metal is forced into thin sections and can fill thicknesses of less than a millimetre. However, due to the high liquid metal velocities there is a high risk of surface turbulent flow and air entrainment within the liquid metal. The combination of interacting flow-thermal-solidification phenomena and associated defects is a challenging modeling task which the authors have previously described and validated. Capturing the metal-air interface, on what are inevitably complex three dimensional geometries, results in highly computationally expensive simulations and simulating a single cast can take weeks on a single processor. This contribution reports on modeling a complex centrifugal cast, gas entrainment, bubble transport and solidification, employing meshes of up to a million elements and investigates the scalability of the model on high performance clusters.

8:55 AM Invited
Influence of Feeding Flow and Shrinkage Pipe Formation on Macrosegregation of Investment Cast -TiAl Alloys: *Sailei Zhang*[1]; Jeff Yanke[1]; David Johnson[1]; Matthew Krane[1]; [1]Purdue Center for Metal Casting Research, School of Materials Engineering, Purdue University

A single-domain multi-phase model is developed to predict macrosegregation of investment tilt cast γ-TiAl, considering the effect of both buoyancy and shrinkage induced flow. The model combines the volume of fluid method for tracking the gas/liquid and gas/solid interfaces during the formation of shrinkage pipe with continuum transport equations for velocity, temperature and composition. This model is used to investigate the influence of riser shapes and volume on the composition distribution and the shrinkage pipe shape in the final cast part. The influence of cooling conditions on fluid flow and shrinkage pipe formation during solidification is also studied.

9:20 AM
CFD Modeling of Macro-Shrinkage and Shrinkage Porosities in A356 Castings: *Laurentiu Nastac*[1]; [1]The University of Alabama

An advanced casting simulation approach was applied in this study to assist in the improvement of the mold design of aerospace components made of A356 alloy. By using this approach, mold filling and solidification related defects (including macro-shrinkage and shrinkage porosity) were significantly minimized and hence it helped in cost reduction, performance enhancement and quality assurance of complex A356 cast parts. An experimental validation and detailed calibration procedures of the models for prediction of macro-shrinkage and shrinkage porosities were performed using A356 plates cast in furan-silica sand molds using the Prometal Rapid Casting Technology (RCT) mold printing technology. Correlations between Niyama values and the pore percentage were also developed. Thus, the severity level of shrinkage porosity can be determined via the Niyama criterion. Predictions were then compared with the macro-shrinkage and porosity measurements in plates of various plate thicknesses and in other commercial A356 casting components.

9:40 AM
CFD Modeling of Microstructural Development in the Scanning Laser Epitaxy Process: *Ranadip Acharya*[1]; Rohan Bansal[1]; Justin Gambone[1]; Suman Das[1]; [1]Georgia Institute of Technology

This paper focuses on modeling of the scanning laser epitaxy (SLE) process that is currently being investigated and developed at the Georgia Institute of Technology. SLE is a laser-based manufacturing process for the creation of equiaxed, directionally solidified and single-crystal deposits of nickel superalloys onto superalloy substrates through melting and resolidification of alloy powders using a scanning laser beam. The thermal modeling of the system, done in a commercial CFD software package, simulates a heat source moving over a powder bed and dynamically adjusts the property values for consolidating CMSX-4 nickel superalloy powder. The associated melting and re-solidification process is modeled using an immediate consolidation approach, and the predicted melt depth is compared with the experimental data obtained. For a given position of the beam, geometrical parameters of the melt pool are used to estimate the resulting microstructure. The influence of the processing parameters on the microstructural evolution is also discussed. This work is sponsored by the Office of Naval Research through grants N00173-07-1-G031, N00014-10-1-0526 and N00014-11-1-0670.

10:00 AM Invited
CFD Modeling and Analysis of Casting of Energetic Materials in Cylindrical Ingots Controlled by the ACH Solidification Technology: *Laurentiu Nastac*[1]; Ruslan Mudryy[2]; [1]The University of Alabama; [2]U.S. ARMY

This paper investigates the solidification shrinkage problem in casting of energetic materials in cylindrical molds. An active cooling and heating (ACH) control solidification technology is applied to achieve unidirectional solidification during casting. The design parameters of the ACH technology are developed via Computational Fluid Dynamics (CFD) modeling. In particular, the media heating and cooling temperatures as well as the number of cooling/heating sections and their time sequences are optimized based on the mold diameter, thermo-physical properties of the energetic material, and mold thickness and type. It is demonstrated that the ACH technology can successfully be applied to significantly minimize the solidification related defects (including macro-shrinkage and shrinkage porosities) in cast energetic materials.

10:25 AM Break

10:45 AM
Defect Analysis by Casting Simulation Software in Rolling Roll Manufactured by GGG70: *Engin Tan*[1]; Ali Tarakci[1]; Derya Dispinar[2]; [1]Pamukkale University; [2]University of Istanbul

Nowadays, the casting industry is developing parallel with the information technologies (IT). Particularly the casting simulation software is being frequently used in foundry floors for casting quality control and optimisation. In this study, the filling and solidification analysis of a rolling roll manufactured by spherical graphite cast iron were carried out by Vulcan casting simulation software. The appropriate defect relieving suggestions were presented by anticipation of defects that may form during the casting process.

11:05 AM
SPH Model Approach Used to Predict Skin Inclusions into Semisolid Metal Castings: *Frédéric Pineau*[1]; Guillaume D'Amours[1]; [1]National Research Council Canada

Semisolid metal processing of metallic alloys takes advantage of the thixotropic behavior of material with non-dendritic microstructure to produce near-net-shape parts with improved mechanical properties. The much higher apparent viscosity of the semisolid billet limits the risk of oxide formed on the free surfaces to become incorporated into the casting during the process. But, the external-skin on the periphery of the billet, which is often partially solidified and contaminated with lubricants, should not be included into the casting, as this can be a cause of reject for most structural parts. In this paper, a preliminary model is set-up using the LS-DYNA SPH formulation to follow the paths of the skin. Calculations carried out show that this approach appears to be very promising to predict the paths of contaminated skins into semisolid castings. It can then be utilized to design suitable molds and gating systems.

11:25 AM
Influence of Mould Vibrations on the Solidification during a Horizontal Spin Casting: *Abdellah Kharicha*[1]; [1]University of Leoben

The aim of the present study is to investigate the influence of the vibrations on the flow and on the solidification during a centrifugal spin casting. A 2D shallow water model was built in order to simulate the dynamics of a liquid metal film under the influence of the centrifugal and coriolis forces. The mass transfer due to solidification was calculated using Stefan condition.The average dynamics of liquid metal film in a horizontal axially vibrating cylinder is studied. The different vibration and rotation frequencies are considered. The generation of toroidal vortices periodic along the rotation axis and the formation of quasi-steady interface relief are predicted. It is shown that quasi-steady wave shapes are induced by the tangential vibrations. These waves have considerable effects on the quality of the solidified layer.

11:45 AM
Inverse Modeling for Determination of Thermal Properties of the Investment Casting Ceramic Mold: *Mingzhi Xu*[1]; Simon Lekakh[1]; Von Richards[1]; Shelly Dutler[2]; [1]Missouri University of Science and Technology; [2]MAGMA Foundry Technologies, Inc

This study presents determination on the thermal properties of investment casting shell molds used in casting process modeling. Superheat and latent heat from solidification and cooling of a casting can either be accumulated by ceramic shell for thin-walled casting or transfer to environment for massive casting. Heat capacity and thermal conductivity both play important roles in casting solidification. Thermal properties of ceramic shell depend on shell composition and fabrication techniques as well as thermal history during shell preparation process due to multiple phase transformations. Inverse modeling was combined with corrected Laser Flash method to determine the applicable thermal properties of the shell during casting solidification. Pure nickel was poured into ceramic shells containing two thermocouples and experimental cooling curves were obtained. These curves were then fitted to the model by adjusting temperature dependent heat capacity and thermal conductivity.

Characterization of Minerals, Metals, and Materials: Characterization of Environmental and Construction Materials

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Materials Characterization Committee

Program Organizers: Jiann-Yang Hwang, Michigan Technological University; Sergio Montero, State University of North Rio De Janeiro; Chenguang Bai, Chongqing University; John Carpenter, US Department of Energy; Donato Firrao, Politecnico di Torino; Byoung-Gon Kim, Korea Institute of Geoscience & Mineral Resources; Mingdong Cai, Schlumberger

8:30 AM
Tile Production Using Wastes from Mining Industry of the Mining District Pachuca and Real Del Monte: Juan Hernandez[1]; *Eleazar Salinas*[1]; Francisco Patiño[1]; Isauro Rivera[1]; J. Flores[1]; Norma Trápala[1]; Miguel Pérez[1]; Mizraim Flores[1]; Iván Reyes[1]; [1]Universidad Autónoma del Estado de Hidalgo

This work is related with the production of tiles using wastes from mining and metallurgical industry of Hidalgo State, as raw material. These wastes present a majority particle size (60 %), minor than 53 m (mesh 270, in Tyler Series) with the following composition; 70.01 % wt. of SiO2, 12.82 % wt. of Al2O3, 3.80 % wt. of Fe, 0.70 % wt. of Mn, 3.98 % wt. of K2O, 3.34 % wt. of CaO, 2.50 % wt. of Na2O, 0.04 % wt. of Zn, 0.026 % wt. of Pb, 56 grams per ton of Ag and 0.6 grams per ton of Au. In this work, the partial results and experimental conditions for the preparation of some composites to produce tiles are shown. The composite that offers the best results in productions of tiles was that with 66.67 % wt. of mining waste, 26.67 % wt. of red mud and 6.67 % wt. of black mud.

8:50 AM
Concrete Using the Composite of Steel Slag and Granulated BF Slag Powders as Cementitious Material: *Honghui Fang*[1]; Jiannyang Hwang[1]; Gaifeng Xue[1]; Lijun Lu[1]; [1]Wuhan Iron and Steel Group Company R&D Center

Steel slag has been stockpiled in many steel mills due to its poor performance in various construction related applications. Free lime in steel slag has been considered as a major barrier for its utilization. Composite of steel slag and powders of granulated blast furnace slag have been found an excellent cementitious material for concrete. Portland cement is not required in this kind of concrete. Concretes with various amounts of steel slag and powders of granulated blast furnace slag additions have been investigated. Physical and chemical properties of the products were determined. High performance concrete can be obtained. Field testing of the concrete products was conducted for various applications, including buildings and pavements, and the results demonstrated the soundness of the concrete. Drill cores of field tested concrete, with ages up to 26 years, were examined for the microstructures under SEM.

9:10 AM
Setting Time of Concrete Material; Laboratory Measurements Versus Field Applications: *Mourad Riad*[1]; Samir Shoukry[1]; Gergis William[1]; [1]West Virginia University

Setting of concrete material is defined as the transitional period between states of true fluidity and true rigidity. Initial and final setting times are measured in the laboratory on the mortar sieved from the mix in a controlled environment where temperature and moisture values are constant. On the other hand, field applications are held in outdoor environments where environmental variations have direct impact on setting time values. In this study, initial setting time of class K concrete, usually used for bridge decks and concrete pavements, are investigated highlighting discrepancies between laboratory and field measurements. 72 mixes have been cast in variable environments and collected data from concrete mixes and the ambient conditions are reported. In light of the collected data, the effects of variable setting times on early age cracking of concrete material are studied and means to minimize such cracks are presented.

9:30 AM
Experimental Research to Improve the Soundness of Cementitious Material Blended with Cycled Fluidized Bed Ash: *Zhu Shu Jing*[1]; He Xinghua[1]; [1]Department of Water Supply in South Company of China Metallgical Group

Cycled fluidized bed ash, a significant portion of fly ash produced from coal-fired power plants and rejected from the ash classifying process,has remained unused due to its high free CaO and SO3 content. It is necessary to extend research on the method to reduce the expansion and improve the compressive strength by some effective chemical activator. This paper presents experimental results on the expansion by Le chaterlier tester and the compressive strength. Hydraulic ash-zeolite(HAZ) cementitious material was blended as the chemical activator to study the effects of the activator on the expansion and the compressive strength. The results show that HAZ can not only reduce the expansion, but also increase the prisms compressive strength. Scanning electron microscope observation and X-ray diffraction analysis indicate that the main hydrated products of the sample are calcium hydroxide, ettringite, zeolite and calcite, which can explain the results of the expansion and the strength tests.

9:50 AM
Characterization of Dust Generated in the BOF Converter: *Eduardo Junca*[1]; José Oliveira[2]; Denise Espinosa[1]; Jorge Tenório[1]; [1]University of São Paulo; [2]Instituto Federal do Espirito Santo

Steel industry has been expanding every year, consequently there has been an increase in waste generation in this area. Thus, companies in this sector are finding it difficult to give a correct destination of waste. For example, only in a blast oxygen furnace (BOF) converter are generated about 18kg of dust per ton of steel. The aim of this work was the characterization of dust generated in the BOF converter. The characterization was performed by chemical analysis (titration for iron and its oxides and Inductively Coupled Plasma Atomic Emission Spectroscopy for other elements), scanning electron microscopy, size analysis using Mastersizer 2000 equipment and X-ray diffraction. It was observed that dust is composed mainly iron in form of magnetite, metallic iron and wustite with approximately 99% of the particle size below 100µm.

10:10 AM Break

10:20 AM
Production of Apatitic Material Using Turkish Colemanite Mineral: *Cagatay Moral*[1]; Gulhayat Nasun-Saygili[1]; [1]Istanbul Technical University

The aim of this study is to prepare the apatitic material using colemanite mineral (2CaO.3B2O3.5H2O) which was obtained from Eastern Anatolia, Turkey. For this purpose, colemanite mineral was reacted with different phosphate sources, namely, dipotassiumhydrogen phosphate, ammoniumhydrogen phosphate and ortophosphoric acid at various temperatures and time periods. Experiments were run in batch system. The apatitic material was prepared by a wet method and followed by heat treatment at various temperatures. Structure of the samples were analyzed by XRD, FTIR, XRF and SEM. The particle size analysis was also made for the result product. The experiments showed that reaction temperature, contact time and heating temperature are important parameters to transform the colemanite into apatitic sturcture. Reaction of colemanite with dipotassiumhydrogen phosphate and ammoniumhydrogen phosphate results in amorphous, non-stoichiometric hydroxyapatite type structure, while acid based phosphate source gives brushite and monetite type product before and after heat treatment, respectively.

10:40 AM
Mercury Oxidation and Capture over SCR Catalysts in Simulated Coal Combustion Flue Gas: *Wei Gao*[1]; Qingcai Liu[1]; Jian Yang[1]; Wenchang Xi[1]; [1]University of Chongqing

The process of the reaction among elemental mercury and reactive flue gas components across the selective catalytic reduction (SCR) catalyst was studied in a laboratory-scale reactor. The SCR catalysts were tested for oxidation and capture of elemental mercury and its capture in simulated coal combustion flue gas representing those from combustion of low-rank coals. Experiments were conducted in a fixed-bed reactor at temperatures ranging from 100 to 350°C. The reaction mechanisms over the catalysts at SCR operating temperatures were investigated using individual flue gas components (HCl, NO) with O2 balanced in N2. The monomeric vanadyl sites on the catalyst surface were found to be responsible for the adsorption of both Hg0 and HCl, which means they are active for mercury oxidation. NO promoted Hg0 oxidation and capture in the presence of O2, but their promotional effects were insignificant in the absence of O2.

11:00 AM
Gas Emission and Structural Changes in the Firing of Red Clay Ceramics with Addition of Sanitary Ware Mass Wastes: *Roberto Faria*[1]; Vanessa Souza[1]; Shirley Cosin[2]; Rosane Toledo[1]; Helion Vargas[1]; [1]North Fluminense State University; [2]Federal University of São Carlos

With the purpose of decrease environmental impact, caused by industrial residues (just discarded in the environment) and clay extraction in the ceramic industry, sanitary ware wastes were incorporated into clay. In contrast, it is important to evaluate not only the technological essays but also gases emissions in the ceramic firing process. The pollutant gases emitted in ceramic with residues can be in much larger concentrations than that in a pure clay ceramic firing or, on the other hand, can decrease the pollutant gas concentrations. With the aid of thermal analyses and photoacoustical techniques it was observed that sanitary ware waste can reduce the CO2 emission. The gas emissions were shown as in function of firing temperature from 300 ºC to 1100 ºC. In order to analyse phase transformations during the firing process, clay samples and wastes were both analysed by x-rays fluorescent chemical analysis and x-rays diffraction mineralogical analysis.

Computational Thermodynamics and Kinetics: Molecular Dynamics: Potentials and Simulations

8:30 AM Invited

Recent Progress in Atomistic Computational Thermodynamics: *Byeong-Joo Lee*[1]; [1]Pohang University of Science and Technology

Computational thermodynamics, often associated with the CALPHAD technique, provides a thermodynamic basis to the phase field method simulation technique and contributes to predict phase transformations and microstructure evolution. For more accurate prediction, the phase field method needs wider range of fundamental materials properties as input data than provided by the CALPHAD technique. Typical examples of those properties are the grain boundary, interface and surface energy which are known to have a decisive effect on the microstructure evolution. In the present talk, recent progress in an empirical atomistic approach to provide such thermodynamic information will be outlined. This atomistic approach is based on the 2NN MEAM interatomic potential model which is highly applicable to multi-component alloy systems. A scheme to couple this atomistic computational thermodynamics with the phase field method and to extend the approach to multi-component systems and dynamic interfacial properties (diffusion and mobility) will also be discussed.

8:55 AM

A New Many-Body Potential Based on the Second-Moment Approximation of Tight-Binding Scheme for Alpha Hafnium: *Xidong Hui*[1]; Deye Lin[1]; Yi Wang[2]; Shunli Shang[2]; Zi-kui Liu[2]; [1]University of Science and Technology Beijing; [2]The Pennsylvania Sate University

In this work, we have proposed a new analytic function of the many-body potential based on the second moment approximation of the tight-binding scheme (TB-SMA) by introducing two polynomial factor functions into the original Finnis and Sinclair's (F-S) model for alpha-Hafnium. All the parameters of the new many-body potential have been systematically evaluated by fitting to ground-state properties including cohesive energy, lattice constants, elastic constants and vacancy formation energy. By using the present model, we also performed molecular dynamics simulations to predicate the melt point, thermal expansion coefficients, point defects and surface energy of a-Hf. It is shown that these properties can be reproduced well by the present model. Compared with previous works, some results calculated by present model are more closed to experimental data, indicating that this work has make substantial progress in development of TB-SMA for hexagonal close packed metals.

9:10 AM

Development of Concentration Dependent Interatomic Potential and Study of Deformation Mechanisms for Light-Weight Mg-Li Alloys: *Shivraj Karewar*[1]; Niraj Gupta[1]; Alfredo Caro[2]; Srinivasan Srivilliputhur[1]; Enrique Martinez[2]; [1]University of North Texas; [2]Los Alamos National Lab

The Mg-Li alloys are light weight-high strength candidate alloys for many automotive and aerospace applications. However, magnesium has low ductility and lithium additions increase its ductility as well as corrosion behavior. To study such effects, we need a reliable atomistic model for the Mg-Li system. Here, we present our newly developed, thermodynamically and mechanically reliable Mg-Li potential based on a concentration dependent method. We verify and validate our potential using alloy properties such as heat of mixing, elastic constants, and defect energetics available in the literature. Furthermore, we use this potential to create phase diagram for the Mg-Li system. This potential will be used to study clustering processes in the bulk, special grain boundaries and free surfaces of hexagonal-close-packed Mg-Li alloys using a Monte Carlo method.

9:25 AM

Charge-Optimized Many Body (COMB) Potential for Uranium: *Yangzhong Li*[1]; Tzu-Ray Shan[1]; Tao Liang[1]; Simon Phillpot[1]; Susan Sinnott[1]; [1]University of Florida

The prevalent phases of most metals have very symmetric ground state structures such as fcc or hcp. The low-temperature phase of uranium (a-U) has a low symmetry orthorhombic structure, a result of the strong correlations of the f electrons. As a result, it has proven very difficult to construct a classical empirical potential suitable for molecular-dynamics (MD) simulations. Here, a Charge-Optimized Many Body (COMB) potential for a-U is developed. The lattice parameters, elastic constants, defect formation energies and thermal expansion coefficients are compared to experimental values where available, and to the results of Density Functional Theory (DFT) calculations. This works was supported by the Center for the Materials Science of Nuclear Fuel, a DOE-BES Energy Frontiers Research Center.

9:40 AM

Structure of Martensite Phase in Free Standing Nano-Particles: *Zhen Zhang*[1]; Xiaobing Ren[2]; [1]Frontier Institute of Science and Technology, Xi'an Jiaotong University; [2]National Institute for Materials Science, Japan

The structure and morphology of martensite phase are important parameters in understanding the physical properties of shape memory alloys (SMA). For bulk SMA, the role of transformation strain and point defect have been revealed by observing the structure of self-accommodated martensite phase, adaptive phase, and strain glass state. For nanoscale SMA, however, the information on structure of martensite phase is still lacking. Therefore, the origin of size-dependent martensitic transition is still under controversial. We have studied the martensitic transformation in free standing nano-particles by molecular dynamics simulation method. This atomic approach enabled us to map the structure of martensite phase directly. It is found that the martensite phase in nano-particles is not homogeneous but tends to go back to parent phase when approaching surface. Moreover, a simple analytical model is established based on our direct observation and successfully reproduces the size dependent property of martensitic transition.

9:55 AM

Nano Phase Diagram, Structural Change and Catalytic Application of Ag-Au Bimetallic Nanoparticles: Sang Chul Yeo[1]; Da Hye Kim[1]; Kihyun Shin[1]; *Hyuck Mo Lee*[1]; [1]KAIST

Bimetallic nanoparticles (NPs) have attracted considerable interest due to their unique properties. One unique trait is that their physical and chemical properties can be modulated when their size is changed. This capability enables bimetallic NPs to have a wide application in areas such as catalysts. We study the structural evolution of 270 atom (2nm) Ag-

Au NPs with composition and temperature. The solid-to-liquid transition region and the solid-state structure were investigated using molecular dynamics simulations together with the caloric curve, mean square displacement and structural deviation. As a result, we constructed a phase diagram of the 2nm-scale AgAu nanoparticle. Additionally, we performed the density functional theory calculations to explore the CO oxidation, O2 adsorption and dissociation on the Ag-Au bimetallic NPs. In this way, we investigated their effect on the catalytic properties.

10:10 AM Break

10:30 AM
Molecular Dynamics Determination of the TTT Diagram For Crystallization of an Undercooled Liquid NiAl Alloy: Elena Levchenko[1]; Irina Belova[1]; Alexander Evteev[1]; *Graeme Murch*[1]; [1]The University of Newcastle

MD with an embedded-atom method potential is used to explore amorphous NiAl. First our recent MD results are summarized of the transient formation of amorphous NiAl that can form on reactive interdiffusion at the nano-level. Next, new MD results are described for the determination of the TTT diagram for crystallization of stoichiometric intermetallic NiAl. This diagram shows a typical nose-like shape. Analysis demonstrates that the critical cooling rate of liquid NiAl alloy to produce an amorphous state is very high, about 10**11 – 10**12 K/s and is comparable with similar estimations for pure metals. These findings reveal a low glass-forming ability of undercooled liquid NiAl and suggest why there is a lack of experimental data on synthesising of amorphous and nanocrystalline structures of this intermetallic by rapid solidification.

10:45 AM
Hybrid Deterministic and Stochastic Approach for Long Time Scale Atomistic Simulations: *Pratyush Tiwary*[1]; Axel van de Walle[2]; [1]Caltech; [2]Brown University

We propose a hybrid deterministic and stochastic approach to achieve extended time scales in atomistic simulations that combines the strengths of molecular dynamics (MD) and Monte Carlo (MC) simulations in an easy-to-implement way. The method exploits the rare event nature of the dynamics similar to most current accelerated MD approaches but goes beyond them by providing, without any further computational overhead, (a) rapid thermalization between infrequent events, thereby minimizing spurious correlations, and (b) control over accuracy of time-scale correction, while still providing similar or higher boosts in computational efficiency.We present two applications of the method: (a) Vacancy-mediated diffusion in Fe yields correct diffusivities over a wide range of temperatures and (b) source-controlled plasticity and deformation behavior in Au nanopillars at realistic strain rates (10^3/s and lower), with excellent agreement with previous theoretical predictions and in situ high-resolution transmission electron microscopy observations. In (b), we also calculate detailed temperature and stress dependence of activation free energy for surface nucleation of dislocations in pristine nanowires. The method gives several orders-of-magnitude improvements in computational efficiency relative to standard MD and good scalability with the size of the system.

11:00 AM
Spatially-Dependent Cluster Dynamics Modeling of Microstructure Evolution in Low Energy Helium Irradiated Tungsten: *Thibault Faney*[1]; Brian Wirth[2]; Niklas Juslin[2]; [1]UC Berkeley; [2]University of Tennessee

In fusion reactors, one key plasma facing component, the divertor, will face high fluxes of low energy (~100 eV) helium and hydrogen. The behaviour of Tungsten (the leading material candidate for the divertor) under high dose irradiation with coupled helium/hydrogen exposure remains to be determined. This study's aim is to understand and predict primary defect production and defect diffusion, clustering and interaction close to the inner surface of the divertor due to low energy helium irradiation. These defects can be interstitial and vacancy clusters, helium interstitials and helium-vacancy clusters.Molecular dynamics simulations have been performed in order to calculate mobilities and binding energies of the different types of defects. These results are then input into a spatially-dependent cluster dynamics model based on reaction-diffusion rate theory to describe the evolution in space and time of all of these defects. Modelling predictions are then compared with experimental data available in the literature.

11:15 AM
Reciprocal-Space Approach for Atomic Interactions and Configuration Correlations in Inhomogeneous Systems: *Mariya Rasshchupkyna*[1]; Volodymyr Bugaev[1]; Alexander Udyansky[2]; Miguel Castro-Colin[1]; Peter Wochner[1]; [1]Max Planck Institute for Intelligent Systems; [2]Max Planck Institute for Iron Research GmbH

Reciprocal space configurational thermodynamics of disordered systems [1,2] deals with cooperative concentration modes that take into account statistical coupling, which is essential for studies of highly inhomogeneous (liquid, amorphous) states. The main parameter of this theory is a Fourier component of the inter-particle potential function. The form of this function determines the structural and thermodynamic behavior of a system. Therefore, the right choice of the potential in statistical-thermodynamic modeling is of crucial importance. Coherent scattering data enables the extraction of parameters to construct an interaction potential, which is used to calculate two-body and, especially, many-body correlation functions. By this token, orientational pair-pair correlations are of particular interest in the present study since they describe bond-angle distributions as well as mid-range correlations[3].[1] V.N.Bugaev, A.Udyansky, O.Shchyglo, H.Reichert, H.Dosch, Phys.Rev. B74, 024202-1 (2006).[2]R.V.Chepulskii, Phys.Rev. B69, 134431 (2004). [3]P.Wochner, C.Gutt, T.Autenrieth, T.Demmer, V.N.Bugaev, A.D.Ortiz, A.Duri, F.Zontone, G.Grübel, H.Dosch, PNAS 106, 11511 (2009).

11:30 AM
Atomistic Simulation of Nucleation during Crystallization: *Ramanarayan Hariharaputran*[1]; Pavlo Rutkevych[1]; David Wu[1]; [1]Institute of High Performance Computing, Singapore

Crystallization from melt is a widely adopted materials processing route for various technological applications. Nucleation, an important step in the crystallization process, is altered by varying the thermodynamics and kinetics of transformation, to achieve varied microstructural outcomes with distinct material properties such as single crystal, fine grained polycrystal and glass.To gain insight into nucleation process, we present our studies of nucleation during crystallization using molecular dynamics (MD) simulation. Due to limitation in time and length scales accessible, MD simulations of nucleation are normally performed at high driving forces, which may introduce artifacts in the simulation. We propose non-equilibrium modifications of the boundary conditions to avoid artifacts arising from high driving forces. Our simulation results for a unary system are interpreted within the classical nucleation theory framework to yield parameters such as critical size, free energy barrier, and interfacial energy, to be used as inputs for mesoscale simulations of crystallization.

11:45 AM
Screening High-Performance Liquid Metal Anode for SOFC: Combining Ab Initio Molecular Dynamics Simulations and Experiments: *Michael Gao*[1]; Harry Abernathy[1]; Mike Widom[2]; Yves Mantz[1]; Kirk Gerdes[1]; [1]National Energy Technology Lab; [2]Carnegie Mellon University

The performance of liquid metal anode SOFC critically depends on oxygen transport through the anode, from the anode/electrolyte interface to the fuel/anode interface(s). The aim of this study is to efficiently and reliably screen alloy compositions that have the potential to outperform the benchmark alloy (pure liquid tin) with respect to enhanced oxygen diffusivity and solubility. We combine ab initio molecular dynamics simulations based on density functional theory and experiments that measure the density, solubility, diffusivity and current. NVT molecular dynamics simulations are performed for a series of Sn-based (binary, ternary and quaternary) liquid alloys at T=1073K. The phase stability of various hypothetical Sn16-xRxO32 alloys (prototype rutile titania) are also predicted. Down selected alloy compositions are recommended for experimental verification, and the predicted density, structure, and diffusivity are compared with available experimental values.

Computational Thermodynamics and Kinetics: Oxides, Steels, and Nuclear Materials

8:30 AM Invited
Thermodynamic Modeling of Oxide Systems – From Slags to Advanced Functional Materials: *Bengt Hallstedt*[1]; [1]RWTH Aachen University

Oxide materials are used in a huge number of applications. In many of them phase equilibria and phase transformations play an important role. It is clear that thermodynamic modeling will then be useful in order to design new materials, to develop process routes etc. The level of sophistication needed can be very different; sometimes just a rough idea under which conditions a phase is stable is needed and sometimes detailed knowledge about defect chemistry is needed. In this talk currently used models for liquid and solid phases will be discussed. For liquids associate, quasi-chemical and ionic sublattice models are in use. For solids the compound energy formalism (CEF) has become dominating. CEF can be used to model also defect chemistry, but it has some fundamental differences compared to traditional defect chemistry. This discussion will be illustrated with examples from solid oxide fuel cells, lithium ion batteries and high-temperature superconductors.

8:55 AM
Thermodynamic and Kinetic Calculations Supporting the Development of Tool Steels: *Karin Frisk*[1]; Greta Lindwall[1]; [1]Swerea KIMAB

Application of thermodynamic and kinetic calculations in the development of high nitrogen tool steels, and for understanding the secondary carbide precipitation in hot work tool steels is presented. New types of tool steel with high nitrogen contents (up to over 4%) have recently been developed. The substitution of C for N in these steels has a strong effect on the precipitate type, size, and on the compatibility with other steels, and these effects are described using thermodynamic and diffusion calculations combined with model alloy verifications. Modelling of the precipitation of secondary carbides based on a thermodynamic description coupled with kinetic parameters, through multi-component nucleation and growth models show that the effect of composition on precipitation can be described by the simulations. The most critical input to the calculations, for both applications, is the thermodynamic description of the individual phases.

9:10 AM
Thermodynamic and Elastic Properties of β-Fe from First-Principles Calculations: *Martin Friak*[1]; Fritz Koermann[1]; Alexey Dick[1]; Alexander Udyansky[1]; Tilmann Hickel[1]; David Holec[2]; Joerg Neugebauer[1]; [1]Max Planck Institute for Iron Research; [2]Montanuniversitaet Leoben

Understanding and tailoring the thermodynamic and elastic properties of paramagnetic body-centered cubic iron (β-Fe) is fundamental for developing Fe-based materials operating at elevated temperatures. We have therefore studied β-Fe, modeled by an antiferromagnetic supercell, with the internal distribution of local magnetic moments having the special quasirandom structure (SQS). In contrast to previously suggested antiferromagnetic models that were found to be mechanically unstable with respect to tetragonal deformations, the proposed SQS supercell is stable. Using this approach the thermodynamic stability of beta-Fe with respect to tetragonal and trigonal deformations has been studied. The corresponding total energies have been determined for a broad range of deformations and are compared with those calculated for feromagnetic (FM), non-magnetic (NM), and antiferromagnetic single-layer (AFM-1) magnetic states. The calculated single-crystalline elastic constants are found to closely reproduce experimental data detected within the temperature range of β-Fe.

9:25 AM
Thermodynamic Properties of Cementite Including Magnetic, Vibronic, and Electronic Excitations from Ab Initio: Alexey Dick[1]; Fritz Körmann[1]; *Tilmann Hickel*[1]; Jörg Neugebauer[1]; [1]Max-Planck-Institut für Eisenforschung GmbH

A profound knowledge of the thermodynamic properties of binary phases is critical for the construction of phase diagrams for steels. The experimental investigations for cementite, the most frequent carbide in steels, are, however, rather infrequent and difficult due to the presence of other phases. We have, therefore, performed a first-principles study of cementite employing density functional theory (DFT). Thermodynamic effects due to phonons and electrons are described within the quasiharmonic approximation and finite-temperature DFT. To account for magnetic excitations we have developed an effective model based on a numerically exact solution of a quantum spin Hamiltonian. Consistent with findings for nonmagnetic materials, the accuracy of the calculated free energies is mainly limited by the DFT T=0 K potential energy surface. Our approach reliably describes the temperature dependence of the heat capacity of cementite, and clearly demonstrates the importance of ab initio calculations to advance the calculation of Fe-based phase diagrams.

9:40 AM
Ab-Initio Calculation of High-Temperature Rare Earth Phases Using Large-Displacement Phonon Methods: *Nikolas Antolin*[1]; Oscar Restrepo[1]; Wolfgang Windl[1]; [1]Ohio State University

With recent developments in green technology, research into the previously under-utilized lanthanide series elements has become increasingly relevant. Ab-initio calculations have been hugely successful in the past in providing the necessary free energies to predict phase transformations and phase stability for elemental and alloyed materials. The application of ab-initio methods, however, is problematic when it comes to model metals and their alloys with mechanically unstable high-temperature phases, such as the bcc high-temperature phases of Ti, Hf, and rare earths. Using a novel large-displacement phonon method, the free energies and elastic constants of high-temperature phases of a model transition metal (hafnium) and several unexplored rare earth metals were calculated. We suggest a method to approximate the necessary displacement from the appropriate first principles calculation and demonstrate agreement with experimental data for several systems before extending the method to previously unmeasured high-temperature rare earth materials.

9:50 AM Break

10:20 AM
A Genetic Algorithm Approach to Maximize Austenite Volume Fraction in TRIP Steels: *Shengyen Li*[1]; Ruixian Zhu[1]; Ibrahim Karaman[1]; Raymundo Arroyave[1]; [1]Texas A&M University

The purpose of this work is to predict the optimum temperatures for two-step heat treatment to maximize the retained austenite in TRIP steel by employing a thermodynamic approach. TRIP steel consists of ferrite, bainite, martensite and retained austenite. Austenite contributes directly to the TRIP effect as its transformation to martensite during deformation provides additional plasticity. Under normal conditions austenite is metastable at room temperature but can be stabilized by saturation with carbon. Enrichment of austenite can be achieved through a two-step heat treatment. During intercritical annealing (IA) a dual phase structure (ferrite+austenite) is achieved. A further bainite isothermal treatment (BIT) leads to carbon enrichment of IA austenite through the formation of carbon-free ferrite. In this work, a thermodynamic approach is coupled to a Genetic Algorithm-based optimization procedure to design the treatment temperatures to maximize the volume fraction of retained austenite in a Fe-0.32C-1.42Mn-1.56Si alloy. The results are compared with experiments

10:35 AM
CarbonitridingTool© - Modeling the Carbonitriding Process: Yuan Xu[1]; *Liang He*[1]; Guannan Guo[1]; Huaxia Yu[1]; Laura Patricia Rivera[1]; Richard D. Sisson[1]; [1]Wocester Polytechnic Institute

Computational models have been developed to simulate the surface hardening of steel. The CarbonitridingTool© has been developed to model the carbonitriding heat treating process in the paper. The finite difference method is used to simulate the absorption and diffusion of carbon and nitrogen into several steels during carbonitriding processes. The diffusional interactions between carbon and nitrogen have been experimentally and theoretically determined and are included in the model. Carbon concentration, nitrogen concentration and microhardness in the carbonitrided layer can be predicted with the software. The experimental results will be presented along with the beta version of the validated model. The effects of carbon potential and ammonia addition in the endogas atmosphere will also be presented and discussed.

10:50 AM
Modeling of Low Alloy Steel Gaseous Nitriding Process: *Mei Yang*[1]; Richard Sisson[1]; [1]WPI

The microstructural development during the nitriding of quenched and tempered low alloy steels has been theoretically and experimentally investigated. The result is compared with the calculations from Thermo-Calc, which use thermodynamic data to predict multi-component phase behavior during nitriding. Customized Lehrer diagrams are developed to predict the relationship between the nitriding potential and the phase development at different temperatures. In addition, a computational model is developed to predict the nitriding kinetics. The methodology and preliminary results for this model will be presented and compared with experimental results.

11:05 AM
Advanced Stochastic Cluster Dynamics for Studying of Defect Evolution in Materials under Multi-beam Irradiation Conditions: *Tuan Hoang*[1]; Jaime Marian[1]; Vasily Bulatov[1]; Daryl Chrzan[2]; [1]Lawrence Livermore National Laboratory; [2]University of California, Berkeley

Stochastic Cluster Dynamics (SCD), a new modeling approach has been developed to study defect evolution and property degradation in materials subjected to particle irradiation in fission and fusion nuclear reactors and in various material testing facilities. More specifically, we seek to understand synergistic effects caused by the simultaneous bombardment of the material by energetic particle beams of different types, emulating the conditions in real nuclear reactors and multi-beam facilities. SCD is proposed as an alternative to the traditional rate theory (RT) approach which becomes computationally expensive when dealing with complex species comprised of more than two components as those present in the ODS steel and, still more expensive, kinetic Monte Carlo (kMC) method. Furthermore, to improve fidelity of our computational predictions we have enabled more consistent treatments of defect sinks, specifically, dislocations and grain boundaries, as opposed to drastic simplifications in the treatment of sinks presented in standard RT approach.

11:20 AM
Computational Modeling of Dislocation Loop Coarsening: *Andrew Boyne*[1]; Ximiao Pan[2]; Yunzhi Wang[2]; [1]University of North Texas; [2]The Ohio State University

Frank-type dislocation loops are common defects, for example as irradiation damage in nuclear reactor materials or “End of Range” defects in Silicon wafers. We have constructed a computational model of vacancy mediated climb in dislocation loops, and employed it to investigate the coarsening behavior of these defects. The model extends the previously developed microscopic phase field model of dislocations to consider coarsening and vacancy supersaturation driven climb in arbitraryconfigurations of vacancy loops. We compare the predictions of the model to previously developed analytical and line-tracking models of loop climb. The coarsening kinetics of populations of loops are simulated, including in the presence of vacancy sources (i.e. continuous irradiation). Straight-forward extensions of the model are possible, which would enable it to simulate multiple climb systems and the coupled evolution of both vacancy and interstitial point defects.

11:35 AM
Simultaneous and Sequential Transformations: Computational Simulation, Analytical Methods and Experimental Results: *Paulo Rios*[1]; Weslley Assis[1]; Tatiana Salazar[1]; Andre Alves[1]; Simone Oliveira[1]; [1]UFF-EEIMVR

In a recent work, Rios and Villa presented an analytical methodology suitable for the situation in which transformations take place simultaneously or sequentially. In this work, simultaneous and sequential reactions are simulated using cellular automata. The simulations are compared with published data on the recrystallization kinetics of IF steels and with the analytical methodology. It is shown how kinetic models reactions in isolation may be combined to predict the behavior of these transformations when they take place simultaneously or sequentially. It is also shown how one may extract theoretical information from the experimentally measured or computer simulated quantities.

11:50 AM
Identifying the Energetics of He-Point Defect Interactions in Fe: *Xunxiang Hu*[1]; Donghua Xu[2]; Brian Wirth[2]; [1]UC Berkeley; [2]University of Tennessee, Knoxville

Helium effects on the microstructural evolution and mechanical properties of structural materials are among the most challenging issues facing fusion materials research. In this work, we combine thermal helium desorption spectroscopy (THDS) with positron annihilation spectroscopy and a spatially-dependent cluster dynamics model to investigate the kinetics of helium-point defect interactions of helium implanted single-crystalline iron.This combination allows identification of possible mechanisms responsible for the He releasing peaks. Furthermore,the model predicts the depth dependence of the Helium and Helium – defect clusters as a function of time and temperature during the desorption measurement which can be identified by positron annihilation spectroscopy measurements at a variety of material conditions. This will provide an overview of the self-consistency of the model predictions based on the assumptions made in terms of the He-point defect binding and interaction energies, and diffusivities.

Defects and Properties of Cast Metals: Ductility, Creep, Stress and Cracks

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Solidification Committee

Program Organizers: Mark Jolly, University of Birmingham; Brian Thomas, University of Illinois at Urbana-Champaign; Carl Reilly, University of British Columbia

Wednesday AM — Room: Oceanic 4
March 14, 2012 — Location: Dolphin Resort

Session Chairs: Dai Xiaojun, The University of Birmingham; Mei Li, Ford Motor Company

8:30 AM
Thermal-Mechanical Model Calibration with Breakout Shell Measurements in Continuous Steel Slab Casting: Junya Iwasaki[1]; *Brian Thomas*[2]; [1]Nippon Steel Corp.; [2]University of Illinois at Urbana-Champaign

A thermal-stress model of continuous steel slab casting is calibrated with detailed measurements of a breakout and applied to simulate longitudinal off-corner cracks. First, a fluid mass balance is applied together with the measured slide-gate position, mold level, casting speed histories to reconstruct the transient events that occurred during the breakout, including the flow-rate and solidification time histories. A three-dimensional heat transfer model of the mold is calibrated to match the measured mold heat flux and thermocouple temperatures, with the help of an efficient 1D model, CON1D. Using these results, a 3D finite-element thermal-stress model of the solidifying shell and mold matched the measured shell thickness profiles, and was applied to reveal insights into the interfacial gap condition and the formation of off-corner longitudinal cracks.

8:55 AM
Transverse Creep Behavior of Superalloy Bicrystals: *Kaitlin Gallup*[1]; Tresa Pollock[1]; [1]University of California, Santa Barbara

Creep properties of bicrystals loaded normal to the boundary have been studied in the nickel-based superalloy René N4 and GTD444. Creep specimens were taken from directionally solidified bicrystals containing low and high angle boundaries (<10° misorientation, 20°, >30°). Alloy variants with and witout additions of boron and carbon, and those cast using the liquid metal cooled or Bridgman method were studied. Creep mechanisms are compared between single crystal bars and the bars containing a singular grain boundary at two testing conditions of 982°C/206MPa and 760°C/690MPa. Damage occurring along interdendritic regions at the grain boundary is quantified by use EBSD and correlated with shape parameters to measure the local degree of rafting. Light optical profilometry is also used to characterize boundary and fracture surface roughness. Additionally, instances where the orientation to the tensile axis has a larger effect on creep life the presenence of the boundary are discussed.

9:20 AM
Effect of Cooling Structure on Stress Distribution of Copper Plates of Slab Continuous Casting Mold: *Xiang-Ning Meng*[1]; [1]Northeastern University

A three-dimensional finite-element thermal-stress model of slab continuous casting mold is conducted to predict stress distribution on copper plates of mold. The results show that specific stress distribution of hot surface and cross-sections of copper plates of mold is determined by materials properties and casting conditions. It is recommended to select metal material that thermal properties close to copper to replace nickel as wear-resistant coating or to design copper-nickel transition region in mold waist to avoid abrupt stress. It is reasonable to design deep water slot in narrow face corner as slope, and a fillet or chamfer should be designed in upper part of slope slot. Also, design of slope deep slot in corner of narrow face is appropriate, while deepening slot is not helpful to control heat fatigue and avoid permanent creep of copper plates and original slot depth is suitable.

9:45 AM
An Integrated Methodology for Optimizing Al-Si Diecastings in Automotive Applications Part2 – Model Validation in Structural Components: *Nicola Gramegna*[1]; Franco Bonollo[2]; Giulio Timelli[2]; Stefano Ferraro[2]; Gianluca Quaglia[1]; [1]ENGINSOFT S.p.A.; [2]University Of Padova

An automotive safety component is studied in order to optimize the casting process and the mechanical characteristics. The design of the component follows the path that a good project manager would usually adopt, but at the virtual level before undergoing the final physical tests. A process simulation of original and optimized geometry of a structural component was made, in order to enhance the quality of the casting. The local mechanical properties and residual stresses were identified and transferred to FEA code for impact analysis, both in the initial version design and after the optimization cycle that was implemented using the new approach. Sampling of two different optimized geometries was made. The produced diecastings were analyzed (X-Ray, tomography, microstructure, etc.), in order to identify the distribution and amount of defects. Mechanical tests were also carried out and the experimental data were used to validate the results given by numerical simulations.

Embrittelement in Superaustenitic Stainless Steels: *Sermin Turhan*[1]; Barry King[2]; Eren Kalay[3]; Scott Chumbley[2]; [1]Cankaya University; [2]Iowa State University; [3]METU

Attributed to its extreme toughness and corrosion resistance, cast superaustenitic steels are widely used in extreme environments such as off-shore oil wells, seawater systems. However, according to recent time-temperature transformation diagram results, if the alloy is incorrectly heat-treated as little as 15 mins., it embrittles and the thoughness is decreased by 50%. In this study we've investigated possible reasons for this embrittelement by using a superaustenitic stainless steel CN3MN at relatively short annealing times. Specimens were heat treated at 927 for various annealing times and their impact strengths were tested.The fracture surfaces were investigated with using scanning electron microscope. A ductile to brittle failure transition was observed for a relatively short annealing. The corresponding microstructures for ductile and brittle specimens were investigated with using transmission electron microscope and electron back-scattered diffraction. The change in microstructure with respect to annealing and its effect on embtrittlement for CN3MN will be discussed.

11:00 AM
Deformation Prediction of a Heavy Hydro Turbine Blade During Casting Process with Consideration of Martensitic Transformation: *Jinwu Kang*[1]; Tianjiao Wang[1]; [1]Tsinghua University

Heavy hydro turbine castings are made of martensitic stainless steel, which undergoes martensitic transformation during casting process. Therefore, the residual stress and deformation are affected not only by uneven cooling but also by martensitic deformation. However, only thermal stress is processed during the usual numerical simulation of casting process. In this paper, the coupled thermo-martensitic phase transformation-stress model is established and it is implemented by secondary development in ABAQUS, which also incorporates the thermal and mechanical boundaries, the contact pair between casting and mold. The system is applied into the stress analysis of a heavy hydro blade castings. The stress, displacement and phase percentage are obtained. It is found that martensitic phase transformation has significant effect on the stress and deformation results. The simulated results are compared with measured results, and their agreement is improved with the consideration of martensitic phase transformation.

11:25 AM
Reasonable Temperature Schedules for Cold or Hot Charging of Continuously Cast Slabs: *Yang Li*[1]; Peng Lan[1]; Ke Liu[1]; Haibo Sun[1]; Hongzhi Chen[1]; Jiaquan Zhang[1]; [1]State Key Laboratory of Advanced Metallurgy, University of Science and Technology Beijing

There are occasionally transversely fracture problems for some continuously cast slabs during transportation or handling away from their storage state. There are also steel slabs being very sensitive to the formation of surface cracks during hot charging or following rolling process. It is revealed that steels with higher contents of pearlite delayed transformation elements have higher crack-sensitivity with room cooling condition, which should be slowly cooled down after cut to length from hot strand or charged to reheating furnace directly. Steels with higher contents of carbonitride forming elements, however, are even crack sensitive to hot charging temperatures due to the precipitation induced ductility tough. Based on thermodynamic theory for carbonitride precipitation in austenite and a solid-state phase transformation model, the CCT diagrams and the hot charging brittleness temperature range of related steels have been presented for the reasonable determination of their cold or hot charging temperature schedules.

11:50 AM
Affection of Charging Temperature on the Hot Ductility of Nb-Containing Steel: *Yongjian Lu*[1]; Qian Wang[1]; [1]College of Materials Science and Engineering, Chongqing University

The hot charging process for HSLA steel slabs was hindered by the formation of surface cracks in HSLA steel plate produced by hot charging rolling process. The hot ductility of a Nb-containing steel has been investigated by means of hot tensile tests simulating the charging process. It is indicated that the hot ductility of the steel is affected obviously by the charging temperature while there is less affection on the hot tensile strength. If the charging temperature is between Ar3 and Ar1, ductility as measured by reduction of area was generally low for all charging temperatures. This ductility loss can be explained in terms of finely precipitation of carbonitride at grain boundaries and the formation of duplex austenite grains during reheating process. The charging temperature controlled to be above Ar3 is favorable for avoiding plate surface cracking in Nb bearing steel with hot charging process.

Deformation, Damage, and Fracture of Light Metals and Alloys: Session IV

Influence of Deformation Path and Heating Rate on Recrystallization Kinetics in Al-2%Mg Alloy: *Grigoreta Stoica*[1]; G. Muralidharan[2]; B. Radhakrishnan[2]; S. B. Gorti[2]; A. D. Stoica[2]; S. Vogel[3]; H. M. Reiche[3]; K. An[2]; D.E. Fielden[4]; H. Cao[2]; H.D. Skorpenske[2]; R.A. Mills[2]; T. Ungar[5]; B.C. Chakoumakos[2]; X-L. Wang[2]; [1]ORAU/ORNL; [2]ORNL; [3]LANL; [4]UTK; [5]Eötvös University of Budapest

The effect of a tensile load on the recrystallization kinetics of a highly deformed Al-2%Mg alloy was investigated by in-situ time-of-flight [TOF] neutron diffraction at VULCAN [SNS]. The samples were annealed at temperatures of up to 350°C and at stresses ranging from 2 to 20 MPa. Peak profiles analyses were used to monitor: [1] the evolution of the energy stored in the dislocation substructure, and [2] the growth kinetics of recrystallizing grains. The results demonstrate that the heating rate and the presence of stress significantly affect the recovery rate, as well as, the grain growth. Texture measurements at HB-3A [HFIR] and HIPPO [LANSCE] showed enhanced or diminished texture components depending on the initial texture and the deformation path. Research was sponsored by the Laboratory Directed Research and Development Program of Oak Ridge National Laboratory (ORNL), managed by UT-Battelle, LLC for the U. S. Department of Energy under Contract No. De-AC05-00OR22725.

9:00 AM Invited
Deformation and Fracture Behavior of Magnesium Alloy WE43 at Temperatures and Strain Rates Relevant to Deformation Processing: *Sean Agnew*[1]; F Polesak[1]; [1]University of Virginia

Magnesium alloy, WE43, containing 4 wt% yttrium and 3 wt% rare earth elements (mainly neodymium), has superior ballistic behavior compared on an equal areal density to traditional Al alloy 5083 armor. In order to be implemented, it is necessary to optimize plate production. Hot torsion testing was used to simulate the rolling process. In the range of T = 150–250ºC, dynamic strain aging and deformation twinning are observed. At the highest temperatures (T≥400ºC), power law behavior typical of dislocation climb and glide is observed. The material undergoes power law breakdown at stresses above ~120 MPa. From 150–425°C, plate-shaped precipitates appear within the grain interiors during the deformation. Sparser, round precipitates are observed at temperatures above 425ºC, the temperature above which uniform dynamic recrystallization is observed. In order to achieve the desired refined microstructure and have sufficient ductility, deformation should be performed at a minimum of 450°C.

9:30 AM
An Investigation of Plastic-Deformation Dynamics on a Wrought AZ31B Magnesium Alloy Using Real-Time In-Situ Neutron-Diffraction Measurements: Wei Wu[1]; *Ke An*[2]; Peter Liaw[1]; [1]The University of Tennessee; [2]Oak Ridge National Laboratory

Investigations of plastic deformation are worth scientific efforts for structure applications of magnesium alloys, which exhibit the integrated properties of light weight, high strength-to-weight ratio, and high specific stiffness. In the present research, the plastic-deformation dynamics of a wrought AZ31B magnesium alloy has been studied, using real-time in-situ neutron-diffraction measurements at room temperature. We took advantage of the state-of-art VULCAN engineering diffractometer of the Spallation Neutron Source (SNS), Oak Ridge, Tennessee, to achieve the real-time in-situ neutron-diffraction measurement. Instead of using the "traditional" step-loading method, the neutron-diffraction measurements were performed under a continuous loading condition, while the neutron-diffraction data were collected, and then the data were sliced to small time bins. The lattice-strain and diffraction peak-intensity evolution of interested hkls were examined under the monotonic-loading condition. The new approach provides the detailed information related to the plastic-deformation dynamics, such as the twinning and detwinning behavior of the wrought magnesium alloy.

9:50 AM Break

10:00 AM
In-Situ Neutron Diffraction Study of Plastic Deformation in Solid-Solution-Strengthened Mg-Al and Mg-Zn Binary Alloys: Soo Yeol Lee[1]; *Michael A. Gharghouri*[2]; Huamiao Wang[3]; Ghazal Nayyeri[4]; Peidong Wu[3]; Warren J. Poole[4]; Wei Wu[5]; Ling Yang[6]; Ke An[6]; [1]Chungnam National University; [2]National Research Council Canada; [3]McMaster University; [4]The University of British Columbia; [5]The University of Tennessee; [6]Oak Ridge National Laboratory

Neutron diffraction has been employed to measure lattice strains and bulk texture evolution during tension and compression in a series of solid-solution-strengthened extruded binary Mg-Al and Mg-Zn alloys with composition ranges typical of common commercial alloys (Mg-1, 5, 9 wt.%Al and Mg-1, 2 wt.%Zn). Two starting textures were used: 1) the as-extruded texture, T1, in which the basal poles are preferentially oriented normal to the extrusion axis, and 2) a reoriented texture, T2, in which the basal poles were preferentially oriented parallel to the extrusion direction. The results provide insights into the effects of texture, load direction, and composition on the plastic deformation of the magnesium alloys investigated. The data are used to validate elastic-viscoplastic self-consistent models of polycrystal plasticity, from which the critical resolved shear stresses and hardening behaviour of the available slip and twinning modes can be determined.

10:20 AM
In-Situ Microstructure Evolution of Pure Aluminum Single Crystal under Plane Strain Tension: *Yong Seok Choi*[1]; Do Hyun Kim[1]; Hyun-Sik Choi[1]; Suk Hoon Kang[2]; Jun-Hyun Han[3]; Heung Nam Han[1]; Kyu Hwan Oh[1]; [1]Seoul National University; [2]Korea Atomic Energy Research Institute; [3]Chungnam National University

A novel micro deformation system to analyze plane strain tension behavior was designed, which can measure directly the plastic deformation behavior of sheet metals. Microstructural evolution of single crystal during deformation significantly depends on its crystal structure and potential slip systems related to the tensile direction. In this study, the microstructure and texture evolutions of pure aluminum single crystal during in-situ plane strain tension were investigated by high-resolution EBSD. The formation of slip bands and the orientation rotation behaviors of local areas were traced and analyzed during the deformation. The measured results were compared with the calculated ones based on a crystal plasticity theory. Furthermore, intersection behavior of subdivided slip bands inside of a single crystal was observed using a TEM. This result can be used for the study on the deformation behavior of sheet metals based on a FCC structure and the construction of FLD of aluminum single crystal.

10:40 AM
Low Temperature Superplastic Deformation of Mg-Bi-Si Alloys: Sergei Remennik[1]; *Alexander Katsman*[1]; Dan Shechtman[1]; [1]Technion - Israel Institute of Technology

Magnesium alloys with high room temperature ductility may find applications as biodegradable implant materials. A BS50 alloy with the composition of Mg-5%Bi-0.5%Si (wt%) and ~1.2 μm average grain size was prepared by rapid solidification and extrusion. Tensile tests were conducted at different strain rates in the range 10^{-4}-10^{-2} s^{-1} and at various temperatures in the range 20-150°C. Superplastic-like behavior, with up to ~ 200% elongation-to-failure and stress exponent values close to 2 at 150°C, was observed. The activation energy of the process, Q=91.9 kJ/mol, was related to a grain boundary sliding mechanism. The stress exponent increases with decreasing temperature and reaches the value n=3.6 at 20°C. This was addressed to the contribution of dislocation climbing which controls accommodation processes at grain boundary triple junctions. The threshold stress increases with decreasing temperature. A corresponding energy term, E=11.4 kJ/mol, was associated with the binding energy between solute atoms and grain-boundary dislocations.

Electrode Technology for Aluminium Production: Characterization of Anode Materials

Improving the Precision and Productivity of Green Coke VCM Analysis: Les Edwards[1]; *Kevin Hon*[1]; James Marino[1]; Marvin Lubin[1]; [1]Rain CII Carbon

Volatile and Combustible Matter (VCM) analysis of green petroleum coke is an important measurement for determining the calcination behavior and properties of calcined coke. Green cokes with high VCM (>12%) are more difficult to calcine and result in a higher porosity and lower bulk density in calcined coke. The paper will review current methods for measuring the VCM of green coke based on ASTM Quartz and Platinum crucible methods and Macro TGA methods. Detailed experimental results comparing the Quartz crucible and macro TGA methods are presented in the paper. When used in combination with a high speed knife mill, automated TGA equipment offers significantly improved speed and precision and the capability for simultaneous measurement of ash and moisture contents. As the range of green coke qualities used for calcination increases, the need for a more rapid and more precise measurement of VCM increases.

8:50 AM
Discrete Element Method Applied to the Vibration Process of Coke Particles: *Behzad Majidi*[1]; Kamran Azari[1]; Houshang Alamdari[1]; Mario Fafard[1]; Donald Ziegler[2]; [1]Laval University; [2]Alcoa Canada

Physical properties of coke particles including particle shape and size distribution have direct effects on their packing density. In the present work, effects of particle shape and size distribution on vibrated bulk density (VBD) of dry coke samples have been investigated. Discrete Element Method (DEM) has also been used to simulate the vibration process. Results showed that the shape and size distribution of particles influence the bulk density of coke and these parameters can be used to describe the packing density of coke particles. In general, mixed samples provide higher VBD than mono-size samples and as the fraction of coarse particles increases vibrated bulk density increases. However, existence of 10 wt.% of fine particles to fill the pores between coarse particles is essential. Simulation results were also reasonably consistent with experimental data. Finally, it is noteworthy that a well–tailored DEM model is capable of predicting the particle rearrangement and density evolution during the vibration process.

9:10 AM
Vibrated Bulk Density using Semi-automated Device: Simplifying Sample Preparation while Improving Accuracy and Precision: *Jignesh Panchal*[1]; Jeffrey Rolle[1]; [1]A.J.Edmond Company

Vibrated Bulk Density (VBD) of calcined petroleum coke is widely utilized as one measure of quality and is useful for quantifying binder demand in the anode production process of the aluminum reduction industry. ASTM D 4292-10 is one of the methods used widely by the carbon and aluminum reduction industries to measure VBD. Recently the carbon producer and consumer industries have jointly worked together to increase the competence and benefit of this method. Geopyc is a semi-automated device that potentially yields better precision compared to traditional vibrator device specified in D 4292. This paper presents an innovative use of the Geopyc instrument in measuring VBD, the results of which correlate well with D 4292; especially to the 28x48 Tyler Mesh size fraction. This novel sample preparation does not involve complicated roll crushing steps as specified in the ASTM method(s) and thus simplifies the method while improving the accuracy and precision.

9:30 AM

Characterization of Pre-Baked Carbon Anode Samples Using X-Ray Computerized Tomography and Porosity Estimation: *Donald Picard*[1]; Houshang Alamdari[1]; Donald Ziegler[2]; Bastien Dumas[1]; Mario Fafard[1]; [1]Aluminium Research Centre-REGAL, Laval University; [2]Alcoa Canada Primary Metals

Computed tomography has been used in the last years to gather information on carbon anodes which can be used to calibrate numerical models dedicated to simulating the anode forming process. To this end, samples with diameters varying from 50 mm up to 300 mm and cored from an industrial anode have been scanned in a Somatom Sensation 64. A correlation could be established between the CT scan results and the apparent density. To validate the correlation, an extended campaign was performed on 50 mm diameter samples cored in 20 different anodes, thus with possibly varying raw materials. In addition to the CT scan results, the apparent and real densities have been experimentally measured to estimate the porosity level. Similarly to the apparent density, a correlation between the CT scans results and the porosity has been proposed.

9:50 AM

Diagnosing Anode Quality Problems Using Optical Macroscopy: *Barry Sadler*[1]; [1]Net Carbon Consulting Pty Ltd

Anode quality assessment has become largely focussed on laboratory tests undertaken on anode core samples. This is important, giving valuable insight to many anode quality problems and their potential causes. Anode “structural integrity” is, however, a critical anode property that is not directly assessed by these traditional anode core tests. Structural integrity is best described as how well an anode has been made, as evidenced by the visual appearance of the anode structure. Several methods have been used previously to visually examine anode structures, including optical image analysis. While these methods can highlight individual structural features, they are not well suited to assessing overall anode structural integrity. This paper will outline a simple method for assessing baked anode structural integrity that uses USB microscopy to evaluate anode quality and diagnose problems.

10:25 AM

Properties and Production Conditions Affecting Crack Formation and Propagation in Carbon Anodes: *Odd Einar Frosta*[1]; Arne Petter Ratvik[2]; Harald A. Øye[2]; [1]Norsk Hydro ASA; [2]Norwegian University of Science and Technology

The objective of the present work is to achieve a better understanding of anode thermal shock fracture in the early stage after an anode change in the electrolysis cell. In order to better show the mechanisms leading to anode fracture and crack propagation, a thermo-mechanical model of the thermal shock experienced by an anode when it is positioned in the pot was developed. The model allows calculation of stresses and strains within the anode, as function of time. The time interval of the modelling lasts for 1 hour after the anode change.Baked anodes are inhomogeneous and anisotropic due to the raw materials and production process. Core samples from industrial scale anodes were analysed and the results provided gradient plots of physical and mechanical properties. The results were used as input to the model and together with a set of boundary conditions, the thermal shock resistance was calculated.

10:45 AM

New Method for Representative Measurement of Anode Electrical Resistance: *Marie-Josée Chollier-Brym*[1]; Denis Laroche[1]; Alain Alexandre[1]; Michel Landry[1]; Claude Simard[1]; Lucien Simard[1]; Danny Ringuette[1]; [1]RioTinto Alcan

Electrical anode resistance is more and more recognized as a key parameter for pot operation as the carbon material itself contributes to close to 50% of the anode assembly voltage drop. Factors such as raw materials, forming and baking conditions are sources of significant variation in anode properties, including anode resistance. Anode resistance will vary within an anode and between anode batches reaching voltage differences up to several tens of millivolts. The current method for resistivity measurement is based on core sampling on limited locations of a small population of anodes and may not be representative of the anode resistance. The current study proposes a non destructive method reproducing the current distribution in service and providing immediate results. Such results could be used to improve anode resistance and help potrooms cope with the anode batches variability.

11:05 AM

Increasing Coke Impurities – Is this Really a Problem for Metal Quality?: *Gyan Jha*[1]; Frank Cannova[2]; Barry Sadler[3]; [1]Tri-Arrows Aluminum; [2]BP Coke; [3]Net Carbon Consulting

Increases in the Vanadium and Nickel content of anode grade coke in recent years have predictably affected smelter metal quality. This has now reached the point where some smelters struggle to meet traditional metal purity specifications. New metallurgical studies have shown that metal specifications for impurities such as Vanadium and Nickel may be unecessarily restrictive. Increasing the levels of these impurities higher than the current specifications may provide opportunities to create new alloys in downstream processing. Given this, and the reality that any potential impact of these impurities on anode performance can be mitigated by maintaining adequate anode cover, there is a strong case to revise current metal and coke specifications

11:25 AM

Aluminum Electrolysis Anti-Oxidation Coating Carbon Anod: *Sh Yang*[1]; Fengli Yang[1]; Zhaowen Wang[2]; Zhongning Shi[2]; Bingliang Gao[2]; [1]Jiangxi University of Science and Technology; [2]Northeastern University

Anti-oxidation coating for carbon anode in aluminum electrolysis was studied in this paper. Different compounds of the anti-oxidation coating had different effects on carbon anode. The results showed that hot weight loss rate of coated anode was lower 10-30% than that of uncovered anode. The compounds of the anti-oxidation coating were optimized by SEM and tests of hot weight loss. It was proved that the anti-oxidation coating had great inoxidizable effects on carbon anode, and it was no influence on normal aluminum electrolysis.

Electrochemical Study of the Kinetics of Copper Metal Leaching with Ferric Iron: *Tomas Vargas*[1]; Rolando Espinoza[1]; [1]University of Chile

The kinetics of the oxidative leaching of copper metal with ferric iron at 60 ºC was studied using electrochemical techniques. Studies were conducted in a three-electrode cell using rotating disk electrodes made either of copper or platinum as working electrodes.The kinetics of anodic dissolution of copper was determined from i-E measurements conducted on copper disk electrodes in iron-free solutions containing 160 g/l sulphuric acid. The kinetics of ferric reduction was determined from i-E measurements conducted on platinum disk electrodes and mixed potential determinations conducted on copper disk electrodes in 160 g/l sulphuric acid solutions containing iron in the range 1-3 g/l and Fe+3/Fe+2 concentration ratios in the range 1-0.3. Experimental measurements were conducted at 60, 300 and 1000 rpm. A kinetic expression for the rate of copper leaching was obtained from the experimental data applying the mixed potential theory.

8:50 AM

Fundamental Reduction Kinetics of Fe(III) on Chalcopyrite Surface: *Guikuan Yue*[1]; Edouard Asselin[1]; [1]The University of British Columbia

Most of the chemical or electrochemical research on chalcopyrite leaching has focused on understanding the kinetics and mechanisms of the oxidative processes or the reduction reactions of chalcopyrite itself. However, the cathodic reduction of ferric ions on CuFeS2 is also of great significance because they can affect the overall leaching rate of the process, as predicted by mixed potential theory. In the present study, electrochemical measurements, especially cathodic potentiodynamic polarization and cyclic potentiodynamic polarization, have been employed to study the kinetics of ferric reduction in H2SO4 solution. Our work aims to explore the possibility of obtaining fundamental electrochemical kinetic parameters, such as exchange current density and transfer coefficients, thereby obtaining more detailed information about the electrochemical processes involved.

9:10 AM

Influence of Anodic and Cathodic Sub-Processes on the Rate of Copper Dissolution during Ferric Leaching of Chalcopyrite at 70 ºC: Hector Jordan[1]; *Tomas Vargas*[1]; [1]University of Chile

The influence of anodic and cathodic sub-processes on the rate of chalcopyrite dissolution during ferric leaching of chalcopyrite at 70 ºC was characterized using electrochemical techniques. Experiments were conducted in a three-electrode electrochemical cell using a working electrode made of chalcopyrite particles. Anodic dissolution of chalcopyrite was characterized from chronopotentiometric experiments conducted in deoxygenated iron-free sulfuric acid solutions at pH 1.7 at potential values of 0.55, 0.6, 0.7, 0.8 and 0.9 V/SHE. Reduction of ferric ion on chalcopyrite was characterized from linear sweep voltammograms conducted in deoxygenated sulfuric acid solution at pH 1.7 containing total iron concentrations in the range 0.005 – 0.3 M. The Fe+3/Fe+2 ratio was also varied in these experiments so that solution Eh ranged between 0.55 – 0.9 V/SHE. The obtained experimental results provided a better insight to explain the dependence of chalcopyrite dissolution rate on solution Eh and total iron concentration.

9:30 AM

Cathodic Reactions on Oxidized Chalcopyrite Electrode: *Ahmad Ghahremaninezhad*[1]; Edouard Asselin[1]; David Dixon[1]; [1]The University of British Columbia

In this study pertaining to the electrochemical dissolution of chalcopyrite, the active/passive behavior of a chalcopyrite in sulfuric acid solution was investigated. OCP measurements, potentiostatic and cyclic potentiodynamic polarization, and electrochemical impedance spectroscopy methods were conducted to analyze the electrodissolution parameters of the electrode. XPS experiments were used to study the composition of the passive film on the surface. The passive film was an n-type semiconductor with donor density of ~1023 m-3. The results of electrochemical experiments have proved that the surface layer (passive film) of chalcopyrite is a good electron conductor but a poor ionic conductor. Using electrochemical methods, the kinetics of the Fe3+/Fe2+ couple reaction on the surface of passive chalcopyrite was investigated. A kinetic model of the passivation process for chalcopyrite is proposed. The model was found to be in quantitative agreement with the results of the electrochemical impedance spectroscopy and steady state current vs. potential experiments.

9:50 AM

Investigation of Charge Transfer Resistance at Pyrite Electrodes Modified by Gold and Silver Nanoparticles: *Maziar Eghbalnia*[1]; David Dixon[1]; [1]University of British Columbia

Gold and silver nanoparticles (NPs) were deposited on pyrite at ambient temperature from colloidal solutions prepared by reduction of hydrogen tetrachloroaurate or silver nitrate by sodium sulfide or sodium tetrahydridoborate. The nanoparticles were characterized using Ultraviolet-Visible (UV-Vis) spectroscopy and the experimental spectra were fitted using Mie - Gans modeling. The modified pyrite was investigated using Electrochemical Impedance Spectroscopy (EIS). Electrodes were prepared from both natural and modified pyrite samples and were modeled using an equivalent circuit (EC) based on the EIS data. The comparison of the results revealed a decrease in charge transfer resistance for the ferric ferrous redox couple associated with the modified pyrite. From this behavior it is concluded that the electronic transport between the nanoparticles and the electrode surface over distances in nanometer scale is enhanced. Nanoparticles below a certain size act as quantum dots due to electronic confinement. Decreased charged transfer resistance at the nanometer scale may be caused by electron transport through tunneling mechanism via quantum dots.

10:10 AM Break

10:25 AM

Electrochemistry of Enargite: Reactivity in Alkaline Solutions: *Robert Gow*[1]; Courtney Young[1]; Hsin Huang[1]; Greg Hope[2]; Yasushi Takasaki[3]; [1]Montana Tech of the University of Montana; [2]Griffith University; [3]Akita University

The presence of enargite (Cu_3AsS_4) is problematic in gold processing as it is refractory, increasing cyanide and oxygen consumption, and environmentally hazardous. Selective leaching and treatment of the arsenic would prove advantageous to conventional gold leaching methods. The reactivity of enargite samples from Montana, US and Quiruvilca, Peru were studied under alkaline conditions, pH range of 8-13, using a cyclic voltammetry corrosion cell setup. Raman spectra of the surface were taken during and after cycling to compare surface species against theoretical predominance diagrams. Under slightly oxidizing conditions, covellite (CuS) peaks were found on the surface in a short matter of time, above ~0 V vs SHE for pH 9-13, suggesting arsenic leaching, but for longer conditioning times, elemental sulfur peaks were also found, which created a passivating surface layer. By operating above pH 12, under reducing conditions, ~-0.500 V vs SHE, arsenic can be leached as a thioarsenate ($AsS_{(4-x)}O_x^{3-}$), without sulfur formation.

10:45 AM

Electrochemical Evaluation of Petzite Leaching: *Laurence Dyer*[1]; Maziar Eghbalnia[1]; David Dixon[1]; John Rumball[2]; Edouard Asselin[1]; [1]University of British Columbia; [2]Barrick Gold Corporation

Gold and silver tellurides, such as calaverite (AuTe2), hessite (Ag2Te) and petzite (Ag3AuTe2), are commonly in many precious metal deposits. While gold and silver are easily leached via several processes (cyanidation, thiosulfate leaching, etc.), their telluride minerals prove far more difficult to treat. Petzite samples synthesized in the laboratory were examined using cyclic voltammetry to elucidate the reactions occurring during leaching in order to determine the factor(s) that inhibits precious metal dissolution.

11:05 AM

Effect of pH And Temperature on Meso-2,3-Dimercaptosuccinic Acid Mediated Dissolution of Polycrystalline Au Electrodes: Scott Smith[1]; *Eduard Guerra*[1]; Jeffrey Shepherd[1]; [1]Laurentian University

Electrochemical and spectroscopic evidence of alkylthiol-mediated Au dissolution is presented. Initial studies were performed on Au electrodes modified with a monolayer of meso-2,3-dimercaptosuccinic acid (DMSA), which was determined to be stable over a narrow range of potentials using cyclic voltammetry. However, at more positive polarizations, DMSA undergoes oxidative desorption. Electrochemical impedance spectroscopy suggested that part of the charge transfer reaction may be associated with Au oxidation. Gold dissolution was confirmed after holding the electrode at 0.8 V vs. Ag/AgCl for 12 hours in LiClO4 containing 10mM DMSA. This routine resulted in a small, but detectable quantity of Au in the electrolyte. Acidification of the electrolyte coupled with an increase in temperature to 50°C improved Au leaching kinetics, yielding an average rate of extraction 40.1 µg cm-2 hr-1. The implications of this process in the industrial leaching of Au will be discussed.

11:25 AM

Design and Commissioning of a Laboratory Scale Electrocoagulation Reactor: Eduard Guerra[1]; *Padmavathy Mahadevan*[2]; Samir Chefai[2]; [1]Laurentian University; [2]Barrick Gold Corporation

Electrocoagulation is a technique for treating wastewater streams from metallurgical plants whereby electrodes are corroded to generate gases (most notably oxygen at the anode and hydrogen at the cathode) and solid particulates which acts as substrates for coprecipitation of impurities. The performance of electrocoagulation reactors in terms their efficiency for removing a particular impurity is highly dependent on several factors, most notably: the nature of the electrodes, the spacing between electrodes, the current density, the height of the electrodes, the solution flow rate, and application of periodic current reversal. Because these variables have complex interactions, in order to ensure reliable scale-up of laboratory results, experiments should be conducted under conditions that closely match those that would be employed at an industrial scale. To that end, this article describes the design and commissioning of a versatile laboratory scale electrocoagulation reactor that allows for the control of all the aforementioned variables along with the ability to measure the instantaneous spatial distribution of current within the reactor.

Electrochemical Synthesis of Nanostructured Vanadium Oxides for Use as Supercapacitor Electrodes: Allison Engstrom[1]; *Fiona Doyle*[1]; [1]University of California, Berkeley

Nanostructured vanadium (V) oxide, V2O5, was deposited on planar platinum electrodes by potentiostatic anodic electrochemical deposition from an aqueous salt solution. Vanadium (IV) oxide, V2O4, and vanadium (III) oxide, V2O3, were then prepared by potentiostatically reducing the deposited V2O5 at appropriate potentials and pH. An agar gel layer, containing either water or 1.0 M KCl, was used to control dissolution and morphological change upon reduction. Cyclic voltammetry and galvanostatic charge/discharge cycling revealed that the deposited oxides initially exhibited pseudocapacitive behavior ideal for supercapacitor electrodes. The capacitance degraded markedly with cycling when tested in a standard three-electrode cell allowing transport of vanadium species into the bulk electrolyte. Degradation was significantly suppressed when the electrodes were tested in a two-electrode configuration acting as a symmetric supercapacitor device that confined the vanadium species in the gap between the electrodes. The electrochemical performance is correlated with the deposit morphology and mass transport during operation.

8:50 AM

Flexible Zn2SnO4/MnO2 Core/Shell Nanocable-Carbon Microfiber Hybrid Composites for High-Performance Supercapacitor Electrodes: Lihong Bao[1]; Jianfeng Zang[1]; *Xiaodong Li*[1]; [1]University of South Carolina

We demonstrate the design and fabrication of a novel flexible nanoarchitecture by facile coating ultrathin (several nanometers thick) films of MnO2 to highly electrical conductive Zn2SnO4 (ZTO) nanowires grown radially on carbon microfibers (CMFs) to achieve high specific capacitance, high-energy density, high-power density, and long-term life for supercapacitor electrode applications. The crystalline ZTO nanowires grown on CMFs were uniquely served as highly conductive cores to support a highly electrolytic accessible surface area of redox active MnO2 shells and also provide reliable electrical connections to the MnO2 shells. These results suggest that such MnO2/ ZTO/CF hybrid composite architecture is very promising for next generation high-performance supercapacitors.

9:10 AM Invited

Dealloyed Nanoporous Metals for Energy Storage: *Mingwei Chen*[1]; [1]Tohoku University

Growing demands for energy storage devices with outstanding sustainability and environmental friendliness have stimulated intensive research on electrochemical supercapacitors which can store and deliver energy at fast charging/discharging rates for high-power applications. Pseudocapacitive materials, such as metal oxides, offer higher levels of specific capacitance and energy storage via Faradic surface redox reactions, circumventing the key limitation of conventional electrochemical double-layer capacitors with low energy density. However, the limited cycle life and low power density, as the compromise of increased energy density, intrinsically restrict the applications of pseudo-capacitors in practical devices. In this talk, we will introduce nanoporous metal based nanocomposites, fabricated by dealloying and electroless plating, as robust electrodes for high-performance supercapacitors. The novel nanoarchitecture provides high electrochemical and mechanical stability and excellent electronic/ionic conductivity, giving rise to ultrahigh energy density and power density along with excellent cycling stability and ultrafast rate capability.

9:40 AM
Supercapacitive Properties of Hydrothermally Synthesized Co3O4 Nanostructures: *David Mitlin*[1]; Huatao Wang[1]; Li Zhang[1]; [1]University of Alberta and NINT NRC

A hydrothermal process was employed to create a variety of Co3O4 nanostructures. We demonstrate that nominally minor differences in the synthesis temperature (50, 70 or 90°C) yielded profound variations in the oxide microstructure, with lathe-like, necklace-like and net-like morphologies of different scales resulting. This in turn resulted in significant variations in the supercapacitive performance that ranged from mediocre to superb. Specifically, the mesoporous net-like Co3O4 nanostructures that were synthesized at 50°C exhibited very favorable electrochemical properties: The net-like Co3O4 had a specific capacitance of 1090 F/g at a mass loading of 1.4 mg/cm2. At this high mass loading such performance has not been previously reported. SEM and TEM analysis of these samples revealed an interconnected array of sub-10 nm crystallites interspersed with a high volume fraction of pores that were on the same scale. The poorer performing microstructures were both coarser and much less porous.

10:00 AM Break

10:30 AM
Graphene/Polyaniline Hybrids-Based Supercapacitor: Li Li[1]; *Shiren Wang*[1]; [1]Texas Tech University

Polyaniline demonstrates low cost, environmental stability, and unique doping/de-doping characteristics. Graphene also exhibits many exceptional properties, including exceptional mechanical, electrical, and thermal properties, as well as large specific surface area. Synergistic integration of them in a novel structure is anticipated to create high-performance supercapacitors for electrical energy storage. In this paper, polyaniline nanowires were synthesized in the presence of graphene sheets. The resultant hybrids were tuned into various morphologies and the morphology-effect on the electrical conductivity and surface area were investigated. The hierarchical hybrids were also utilized as an electrode of supercapacitor, and the galvanostatic charge-discharge tests were carried out. With optimized hybrid morphology, the specific capacitance is as high as 1100 F/g and it is stable for more than 1000 times. This research suggests that graphene/polyaniline hybrid has great potential for energy storage applications.

10:50 AM
Three-Dimensional Nanoporous Bulk Composite Electrodes Utilized in Battery-Like Electrochemical Capacitors: *Weifeng Wei*[1]; Xinwei Cui[2]; Weixing Chen[2]; Douglas Ivey[2]; [1]Central South University; [2]University of Alberta

Electrochemical capacitors (ECs), with rapid charge/discharge rates and higher energy density than conventional capacitors, have become a potential solution to various emerging energy applications. The commercialization of ECs, however, is restricted to much lower energy density than batteries, owing to the low utilization efficiency of active materials in ECs. A battery-like EC that combines the energy density of batteries with the rate capability of capacitors would considerably advance electrical storage technology. Nanostructured electrodes with desirable three-dimensional (3D) architectures are generally believed to enhance active material utilization through facilitating ionic/electronic kinetics and reducing inactive electrode components (e.g., current collectors, electrode binders, conductive additives, etc), although their realization is still challenging. Here we demonstrate a facile solution combustion synthesis process to prepare bulk 3D nanoporous composite sheets used as EC electrodes. Employing such composite electrodes, significant improvement in energy density over traditional bulk electrodes is demonstrated while maintaining the same charge/discharge rates.

11:10 AM
Interdigital Hybrid Graphene/CNT Micro-Electrodes for Supercapacitor Application: *Majid Beidaghi*[1]; Chunlei Wang[1]; [1]Florida International University

Recently, graphene has been introduced as an excellent material for Electrochemical Double-Layer Capacitors (EDLC). Theoretically, graphene is able to deliver a specific capacitance of 550 Fg-1 if its surface area is fully utilized. However, in practice agglomeration and restacking of single layer graphene sheets during electrode preparation limits their accessible surface area. Moreover, the conventional 2D stacking of the electrodes also limits the penetration of electrolyte ions between the graphene planes. In this work, we have tackled these problems by developing a process to fabricate interdigital micro-electrodes of hybrid graphene/CNT electrodes. The addition of CNTs between the graphene layers minimizes the restacking of graphene sheets, thus providing a higher accessible surface area. Moreover, the interdigital in-plane design of the micro-electrodes provides a better pathway for penetration of ions between the graphene layers. The micro-device also has high surface to volume ratio. The electrochemical performance of the micro-device will be presented.

11:25 AM
Nanostructured Manganese Oxide Supercapacitor Electrodes via Solution Precursor Plasma Synthesis: *Raghavender Tummala*[1]; Ramesh Kumar Guduru[1]; Pravansu S Mohanty[1]; [1]Univ of Michigan

Supercapacitors require high power densities with longer cycle life. Particularly, the metal oxide electrodes exhibit higher specific capacitance than carbon and conducting polymers. Manganese oxides (Mn2O3/Mn3O4) are one such inexpensive electrode materials with superior electrochemical characteristics. But, most of the conventional approaches involve powder synthesis with subsequent coating steps on the charge collectors, and thereby result in multi-step procedures. We present a single step and inexpensive synthesis technique for manganese oxide electrodes using solution precursor plasma deposition process. A solution precursor comprising manganese salt and deionized water was atomized into fine droplets for rapid thermo-chemical conversion in the plasma plume prior to deposition on the current collector. X-ray diffraction studies confirmed the desired phase and microstructures revealed rough morphology with porosity. Electrochemical characterization of these electrodes in aqueous KOH electrolyte will be reported.

Fatigue and Corrosion Damage in Metallic Materials: Fundamentals, Modeling and Prevention: Fatigue and Corrosion Interaction and Materials Corrosion

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee

Program Organizers: Tongguang Zhai, University of Kentucky; Zhengdong Long, Kaiser Aluminum; Peter Liaw, University of Tennessee

Wednesday AM | Room: Oceanic 6
March 14, 2012 | Location: Dolphin Resort

8:30 AM
Microstructural and Environmental Effects on Corrosion and Fatigue Crack Growth in 7075 Aluminum Alloy: Amir Bonakdar[1]; Jason Williams[1]; *Nikhilesh Chawla*[1]; [1]Arizona State University

The corrosion and fatigue behavior of aluminum alloys is greatly influenced by environment and precipitate structure. The driving force at the crack tip is clearly a combination of chemical and mechanical processes operating together. We have been conducting experiments in ultra high vacuum (UHV) and shown that the "intrinsic" material behavior can be extracted in a UHV environment. In this talk, the role of moisture on fatigue crack growth behavior of 7075 Al alloy will be presented. Rolled 7075 Al alloy was heat-treated to underaged, peak-aged, and overaged conditions. Fatigue crack growth rates were measured under various partial pressures of water vapor. Standard compact tension specimens were used, and testing was performed under load ratios of R = 0.1 and R = 0.8. The microstructure and morphology of the fracture surfaces were examined by scanning electron microscopy (SEM) and correlated with the crack growth behavior.

8:50 AM
Model for the Superimposed Effects of Stress-Corrosion Cracking and Environmentally Enhanced Fatigue in Aluminum-Magnesium Alloy 5083: *Ronald Holtz*[1]; Peter Pao[1]; [1]Naval Research Laboratory

Comprehensive studies have been completed of the fatigue crack growth behavior of aluminum-magnesium alloy 5083 in vacuum, air, and NaCl solution, for both unsensitized and sensitized conditions. At low load ratio, R, sensitization has no effect on the fatigue thresholds in vacuum, air or NaCl, and only small effect on crack growth rates. At high R, fatigue in air and vacuum does not depend on sensitization at all. However, in NaCl solution, the high R fatigue behavior depends very strongly on sensitization. To reconcile all observations, we consider a model of two superimposed environment effects: an environmentally enhanced cyclic mode acting in both air and NaCl solution, and a stress-corrosion cracking mode acting at high stress intensity in NaCl. The model details of the two modes are described. The two modes are combined within the "small-time-scale" approach of Lu & Liu [Int. J. Fatigue, 2010].

9:10 AM
Governing Factors for the Corrosion-to-Fatigue Transition in 7075-T651: *James Burns*[1]; Richard Gangloff[1]; [1]University of Virginia

Factors governing the drastic fatigue life reduction due to corrosion damage are poorly separated and understood. Crack surface markerbands quantify formation cycles (N_i) from a pit to a 10-20 micron crack in 7075-T651. N_i increases dramatically from 23°C to -90°C, and involves a complex interaction of macro-pit induced elastic stress concentration coupled with local micro-topographic plastic strain concentration, further enhanced by microstructure (sub-surface constituents). Such interactions leads to high variability in N_i. At high-applied stress N_i can be assumed to be nil, at low stress N_i is a significant portion of life as predicted by coupling macro-pit and micro-feature elastic-plastic stress-strain concentrations from finite element analysis with empirical fatigue life models. SEM-EBSD and stereology within 20 microns of pristine-specimen initiation sites shows no cracking on {111} slip planes, suggesting that slip-based crack initiation models are inadequate for environmental fatigue in Al alloys. A hydrogen embrittlement model perspective is proposed.

9:30 AM
Enhanced Corrosion Fatigue Resistance of AISI304 Bellows Expansion by Modifying the Bellows Shape: *Takafumi Ono*[1]; Hiroyuki Miyamoto[1]; Toshiyuki Uenoya[1]; Tomomi Fujikawa[1]; [1]Doshisha University

Bellows are widely used as the element of expansion joint in various piping systems. The U-shaped bellows is known as one of popular expansion joints which are widely used. Mostly, these bellows are made from austenitic stainless steel such as AISI304.Metastable austenitic SS such as AISI304 transforms to deformation-induced martensite (DIM) if it is subjected to the cyclic plastic strain range larger than 0.3wt%, and lose its corrosion resistance. In order to avoid the transformation, new µ-shaped bellows are proposed to extend the corrosion fatigue life by modifying the shape to have smaller plastic strain range than the critical value. It was demonstrated that µ-shaped bellows have 6 times higher fatigue life than conventional U-shaped counterpart. The austenitic stainless steels lose the resistance to localized corrosion when they are exposed to chloride solutions. The relations between the formation of cracks and DIM have been focused.

9:50 AM
Corrosion Fatigue and Crack Propagation of Different Austenitic Stainless Steels in High Chloride Solutions at Elevated Temperatures: *Clemens Vichytil*[1]; Gregor Mori[1]; Michael Panzenböck[2]; Reinhard Pippan[3]; Rainer Fluch[4]; [1]CD-Laboratory of Localized Corrosion; [2]Montanuniversität Leoben; [3]Austrian Academy of Science; [4]Bohler Special Steels

Different CrMnN stabilized austenitic stainless steels and CrNiMo austenites have been investigated in this research. Corrosion fatigue and crack propagation behaviour has been studied to determine damage and failure mechanisms in high chloride containing environments under cyclic loading. S/N curves and crack propagation rate curves have been recorded in 43 wt.-% $CaCl_2$ solution and in inert glycerine at 120 °C. Additionally electrochemical behaviour of all materials has been studied under testing conditions. CrNiMo steels are very chemically stable in high chloride environments and exhibit a minor reduction in fatigue strength compared to inert glycerine. Surprisingly crack propagation is significantly reduced in corrosive environment compared to inert glycerine. CrMnN steels have superior mechanical properties, but are very susceptible to stress corrosion cracking in test solution, resulting in a pronounced reduction in fatigue strength and increased crack propagation in this corrosive environment. Possible explanations of the different behaviours are critically discussed.

10:10 AM Break

10:20 AM
Creep-Fatigue-Environment Crack Growth Kinetics: *Jeffrey Evans*[1]; [1]University of Alabama in Huntsville

Several time-dependent damage mechanisms can operate during creep-fatigue loading. In the crack tip region creep deformation, stress relaxation, oxygen diffusion along grain boundaries, grain boundary oxidation, and surface oxidation are all occurring during the dwell period of a creep-fatigue cycle, and are influenced by temperature and microstructure. Each of these processes can be described in terms of kinetics. A comparison of kinetics can determine which mechanisms are operational and which mechanism is the rate limiting step in the time-dependent damage process during creep-fatigue crack growth. This paper will evaluate approaches to determining the kinetics of creep-fatigue-environment crack growth and discuss a graphical method that can be used for comparing the kinetics of various time-dependent crack tip processes operating during the dwell period of a trapezoidal creep-fatigue loading cycle. A comparison is shown that evaluates the kinetics for the superalloy 718.

10:40 AM
Effect of Corrosive Environment on High Cycle Fatigue of Friction Stir Welded Al-Mg Alloy: *Gaurav Argade*[1]; Nilesh Kumar[1]; Rajiv Mishra[1]; [1]Missouri University of Science and Technology

AA5083 plates were welded using friction stir welding and gas metal arc welding techniques. Microstructural characterization was carried out using electron backscattered diffraction technique. The influence of microstructure on fatigue life was studied in 3.5 wt% NaCl solution. For comparison the fatigue properties were also characterized in air. Fractography of tested samples was carried out using scanning electron microscope.

11:00 AM
Galvanic Corrosion Behavior of Ni-C Filled Conductive Silicon Rubber Coupled to Magnesium Alloys: *Hu Zhou*[1]; Zhidong Xia[1]; Zhe Li[1]; Fu Guo[1]; [1]Beijing University of Technology

The galvanic corrosion behavior of conductive silicon rubber (CSR) having a different resistivity couples of magnesium alloys were investigated in 3.5% sodium chloride solutions at different temperatures. Such investigation was carried out by means of mechanical measurement, electrochemical measurement, weight-loss determination, and surface characterization. The results showed that the lower the resistivity, the higher the potential of conductive silicon rubber, and then the larger the corrosion current density and the corrosion rate of magnesium alloys. The corrosion morphology from SEM suggested that the corrosion of magnesium alloys took place mostly along the grain boundaries and became increasingly severe as a function of corrosion time. However, the CSR coupled magnesium alloys were not corroded due to its zero corrosion rate. After corrosion, the resistivity of CRS was drastically increased, while the mechanical property change was not significant. XRD analysis also indicated that the major corrosion product of magnesium alloy was Mg(OH)2.

11:20 AM
Interfacial Reaction between Co-Based Alloy and Molten Al: *Ning Tang*[1]; Yunping Li[2]; Shingo Kurosu[2]; Hiroaki Matsumoto[2]; Yuichiro Koizumi[2]; Akihiko Chiba[2]; [1]Graduate School of Engineering, Tohoku University, Japan; [2]Institute for Materials Research, Tohoku University, Japan

In Al die-casting industry, the dies, which are currently made of hot-work tool steels, always suffer from the premature failure caused by corrosion of molten Al alloys and/or thermal fatigue during producing cycles. Therefore, Co-based alloys, whose corrosion resistance to molten Al and thermal fatigue resistance were reported to be higher than that of hot-work tool steels [1,2], are promising die materials. In this study, the Co-29Cr-6Mo (wt%) alloy was reacted with molten Al, and the interfacial reaction was investigated with the combination of interface structure and reaction kinetics. The results showed that two intermediate layers formed on the solid-liquid interface and thickness loss of the Co-based alloy followed a linear relationship with immersion time. These results may be applicable for enhancing the corrosion resistance of Co-based alloys to molten Al. [1] M. Yan, J Mater Sci 2001; 36: 285, [2] Y. Birol, Mater Sci Eng A 2010; 527: 1938.

11:40 AM
The Preparation Technics of a Alloy Coating with Special Properties: *Li Naijun*[1]; [1]Science Collge of Shenyang University

The treatment technics for substrate was researched and improved though out experimentations, the research of plating technics and additive for forming ornamental and functional multicomponents alloy was carried out completely, the optimum technics of plating three-components alloy was been found. The coatings made by optimum technics were excellent in corrosion-resistance, wear-resistance and oxidation-resistance, and also has a smooth, fine, shining surface. It was proved that phosphorus content in the coating is 8.4% by determinations, the coating is amorphous crystal. The properties of coating were test, the result shown that the combination force between the substrate and the coating was very good, the properties of coating to resist corrosion and abrasion were much better than that of others alloy by the tests. And the coating was finery in ornamentally also.

From Macro to Nano, Understanding Mechanical Behavior across Length Scales: A Structural Materials Division Symposium in Honor of Robert Ritchie: Environmental Effects and Hydrogen Embrittlement

8:30 AM Introductory Comments

8:35 AM Keynote
Models for Fracture in Lithium-Ion Battery Storage Particles: *Robert McMeeking*[1]; [1]UCSB

Models are developed for the transport of Li ions in the electrolyte, their diffusion through storage particles, and their kinetics at the interface between the electrolyte and the particles. As a consequence of Li intercalating in the storage particles, their lattice swells, leading to elastic stress when the concentration of Li ions in the particles is not uniform. The resulting model is used to compute stress in the storage particles, and to deduce the likelihood of fracture. The objective is to assess designs of porous electrode microstructures that permit rapid charging and discharging, but obviate the likelihood of fracture that limits the performance and reliability of the battery. The swelling associated with lithium storage, and the resulting stresses have interesting consequences for lithium transport and the crack tip stress intensity factor, analogous to other situations where transformation strain is a significant crack tip phenomenon.

9:15 AM Keynote
Understanding and Modeling Environment Effects on Intrinsic Fatigue Crack Propagation: *Richard Gangloff*[1]; [1]University of Virginia

Rob Ritchie has long championed similitude-based modeling of crack growth built on understanding mechanisms of crack tip and wake processes; this perspective is central to next-generation prognosis of fatigue in airframe aluminum alloys. Environment-produced hydrogen dominates intrinsic cracking rates and damage accumulation mechanisms, particularly in the low growth rate regime. In this regard, recent research results are highlighted: (1) prediction of the environmental exposure dependence of fatigue crack growth rate based on mass transport/reaction-rate modeling leading to better life assessment and alloy development, (2) high resolution characterization of fatigue crack path crystallography (SEM/EBSD) and crack tip dislocation structure (FIB/TEM) leading to a damage physics model which includes cyclic plasticity (\916K) and maximum tensile stress (K_{max}), (3) measurement of crack formation and

WEDNESDAY AM

growth from corrosion damage necessary for a validated microstructure-scale model of small-crack fatigue, and (4) ionic inhibition of H uptake leading to vacuum-like fatigue behavior and reduced prognosis complexity.

9:55 AM Keynote

Mechanism of Hydrogen Embrittlement in Fatigue: *Yukitaka Murakami*[1]; [1]Kyushu University/ International Institute for Carbon-Neutral Energy Research

The effect of hydrogen on fatigue crack growth rate was strongly dependent on load frequency both in BCC and FCC metals. Even very small amount of hydrogen of level of 2-3 ppm initially contained in commercial austenitic stainless steels accelerates fatigue crack growth rate under frequency of 0.0015Hz. The well known term 'hydrogen embrittlement' expresses undesirable effects due to hydrogen such as loss of ductility, decreased fracture toughness, and degradation of fatigue properties of metals. However, the experimental results on austenitic stainless steels show, surprisingly, that hydrogen can have an effect against HE. A dramatic phenomenon was found in which charging a supersaturated level of hydrogen into specimens of austenitic stainless steels drastically improved the fatigue crack growth resistance. The acceleration of crack growth rate due to hydrogen in a high strength steel was caused by nucleation of secondary cracks along grain boundaries and carbide boundaries ahead of main crack.

10:50 AM

Micromechanics of Hydrogen-Induced Fracture: From Experiments and Modeling to Prognosis: *Petros Sofronis*[1]; Mohsen Dadfarnia[1]; Brian Somerday[2]; Philip Schembri[3]; Dorian Balch[2]; [1]University of Illinois; [2]Sandia National Laboratories; [3]Los Alamos National Laboratory

Development and validation of a lifetime prediction methodology for failure of materials used for hydrogen containment components is of paramount importance for a hydrogen-powered society. In this presentation, we summarize recent developments on fracture prognosis for various materials by accounting for the deformation mechanisms at the microscale. Arguably the most devastating mode of hydrogen-induced degradation is the hydrogen embrittlement of high-strength steels. We present an approach to quantify the effect of hydrogen on the fracture strength and toughness of a martensitic steel through the use of a statistically-based micromechanical model for the critical local fracture event. To understand the mechanics of subcritical cracking in a gaseous hydrogen environment, we investigate crack propagation in the Fe-Ni-Co superalloy IN903. We identify the microstructural characteristic length that controls ductile fracture initiation in low pressures and make an effort to predict the threshold stress intensity for intergranular cracking at high pressures.

11:05 AM

Connecting Hydrogen Enhanced Plasticity to Fracture – A New Multi-Scale Approach: May Martin[1]; Akihide Nagao[1]; Mohsen Dadfarnia[1]; Petros Sofronis[1]; *Ian Robertson*[1]; [1]University of Illinois

Several different metallic systems have been subjected to various loading conditions, including fatigue loading, either in the presence of hydrogen or in the hydrogen charged state. The mechanical properties are as expected in that hydrogen reduces the ductility and in some systems causes a change in fracture mode. Focused Ion Beam machining has allowed samples for subsequent examination in the TEM to be extracted from site specific locations on the fracture surface. This approach has provided an unprecedented view of the dislocation substructure immediately beneath the fracture surface, which provides the missing connection between hydrogen enhanced plasticity and hydrogen-induced failure. Collectively the results from the different systems demonstrate the deformation structure accelerated by hydrogen provides the conditions to establish locally the fracture mechanism and fracture path. This claim will be supported by examples subjected to different loading conditions.

11:20 AM

The Effect of Trace Oxygen on Gaseous Hydrogen-Accelerated Fatigue Crack Growth in a Low-Strength Pipeline Steel: *Brian Somerday*[1]; Chris San Marchi[1]; Kevin Nibur[2]; [1]Sandia National Laboratories; [2]Hy-Performance Testing

Low-strength ferritic steels are commonly considered to be resistant to hydrogen-induced subcritical cracking; however, this resistance depends on material, environmental, and mechanical loading variables. For example, Suresh and Ritchie (e.g., *Metal Science*, vol. 16, 1982, p. 529) demonstrated that the threshold for gaseous hydrogen-induced subcritical cracking is dramatically lower under cyclic (fatigue) loading compared to static loading in low-strength steels. The onset of accelerated fatigue crack growth was associated with the maximum stress-intensity factor (K^T_{max}). Extending this foundation, the present study examines the effect of mixed hydrogen/oxygen gas (21 MPa H2 with 10 to 1000 vppm O2) on fatigue crack growth in the low-strength X52 pipeline steel. Results show that K^T_{max} systematically increases as the oxygen content increases but the absolute value depends on load-cycle frequency. These results are interpreted based on the competition between rates of bare-metal exposure associated with mechanical crack extension and rates of oxygen adsorption.

11:35 AM

Next-Generation Microelectronic Solder Joints and Their Mechanical Properties: Hyelim Choi[1]; *Heeman Choe*[1]; [1]Kookmin University

In recent years, the demand for special semiconductors packages used in harsh operating environment is substantially increasing in various industries. Being as equally important as electrical properties in microelectronic packages, the reliability and stability issue of solder joints therefore has attracted considerable attention. Furthermore, rapidly diminishing ball pitch and size of a solder joint has been regarded as a potential reliability concern for its mechanical and physical properties. Nevertheless, few systematic studies have been devoted to the microelectronic package used under harsh environment such as in automobile, aerospace industries. This study suggests potential solutions for a solder joint of the next-generation semiconductor package under extreme operating conditions. A trace amount of B or Y is added to lead-free Sn-1.0Ag-0.5Cu solder to significantly improve its mechanical properties. The pull test result indicates that B, Y-doped solder joints can retain high fracture strengths, regardless of the aging time and reflow frequency.

11:50 AM

Microstructre and Mechanical Properties of Electroplated Nickel-Cobalt Alloys with Cobalt Content Less Than 3wt.%: *Rong Yuan*[1]; Christopher Panichas[1]; Yi He[1]; Mitul Modi[1]; [1]Intel Corporation

This paper presents a comprehensive study of electroplated nickel-cobalt alloys on microstructure, mechanical strength and creep. Two types of alloys are investigated: high strength alloy (2 wt.% Co), and high hardness alloy (0.8 wt.% Co). Both alloys start with similar grain size at nano-scale. Following annealing at 200°C, 350°C, 500°C, and 700°C show that grain growth occurs from 200°C to 350°C based on FIB images although DSC curves do not show signal. Correspondingly, YS and UTS of the two alloys decrease with annealing temperatures, with high hardness alloy being stronger than high strength alloy. Tension test at elevated temperatures at 100°C, 150°C, 200°C, and 250°C show the same trend. However, high hardness alloy is subject to hydrogen embrittlement after annealing at 700°C whereas the high strength alloy seems not affected. Creep tests at 150°C and 200°C show that high hardness alloy has larger creep resistance than high strength alloy.

Integrating and Leveraging Collaborative Efforts for ICME Education: Session I

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Education Committee, TMS: Integrated Computational Materials Engineering Committee
Program Organizers: Laura Bartolo, Kent State University; James McGuffin-Cawley, Case Western Reserve University

Wednesday AM — Room: Europe 2
March 14, 2012 — Location: Dolphin Resort

Session Chairs: Laura Bartolo, Kent State University; James McGuffin-Cawley, Case Western Reserve University

8:30 AM Invited
Advances in ICME Education: *Greg Olson*[1]; [1]Northwestern University
Multiyear design education initiated in the materials curriculum at Northwestern employs an integrated research/education system in which funded graduate research in technical design provides the infrastructure for graduate student coaching of undergraduate design teams. A Materials Design Studio serves as a central teaching facility where software tools introduced throughout core courses are integrated in a required junior-level Materials Design course centering on computational design. Under a new Design Institute, cross-disciplinary concurrent computational engineering of materials and structures in multiyear engineering schoolwide "Institute Projects" now involve multidisciplinary undergraduate teams spanning freshman to senior level. At the graduate level, skills of multidisciplinary collaboration are fostered by a new cross-departmental doctoral "cluster program" in Predictive Science and Engineering Design, and an affiliated one-year MS program in ICME has been initiated.

9:15 AM
Computational Training in Design of Hot Strip Rolling: *Matthias Militzer*[1]; [1]The University of British Columbia
A state-of-the-art hot strip mill model (HSMM) is introduced to 4th year materials engineering students as an example to illustrate the power of integrated computational materials engineering tools. The students use the HSMM to design hot strip rolling process routes that will lead to a hot-rolled steel product with specified properties, e.g. for automotive applications. The design study includes the selection of a suitable steel grade, the identification of microstructure phenomena that markedly affect properties, the determination of critical processing steps and a sensitivity analysis to evaluate the robustness of potential processing paths. In preparation of using the HSMM, the students develop their own spreadsheet type models for individual microstructure phenomena, e.g. recrystallization and precipitation, and associated properties, e.g. yield stress.

9:40 AM
Centralized Computing Resources for Large or Dispersed Audiences: *David Gutschick*[1]; Peter Anderson[1]; [1]Ohio State University
A thorough understanding of many macroscopic phenomena requires familiarity with the underlying (3D) atomic-level phenomena. The wide variation in spatial and temporal intuition among students means that 2D, static illustrations are insufficient. They are effective primarily for those already familiar with the concept. Even 3D illustrations/animations are deficient if the student is unable to comprehend the 3D nature from a 2D display. An obvious solution is interactive applications. Consider, for example, a deformation mechanism map which associates a given stress and temperature with 3D, interactive animations of the macro and atomic-level processes. This tends to be computationally expensive, but technologies like server virtualization or application multiserving on a platform such as NanoHUB allows all members of an audience to individually interact with an application through the internet while the computational load is dealt with remotely.

10:05 AM
ICME in Transport Phenomena for Materials Processing: *James McGuffin-Cawley*[1]; [1]Case Western Reserve University
In teaching transport phenomena in materials processing a combination of approaches are used. These include: standard analytical approaches of the textbooks, numerical methods using computer programming, and a commercial mulitphysics software package. The relative advantages of each is discussed. In particular, the relative benefits of programming versus the use of a commercial package in the teaching environment is considered. The conclusion that is reached is that a mixed approach has advantages for the students.

10:30 AM Break

10:45 AM Invited
The 2011 Summer School for Integrated Computational Materials Education: *Katsuyo Thornton*[1]; Larry Aagesen[1]; Mark Asta[2]; Edwin Garcia[3]; John Allison[1]; Laura Bartolo[4]; Jon Guyer[5]; Paul Mason[6]; Anton Van der Ven[1]; Gregory Olson[7]; [1]University Of Michigan; [2]UC Berkeley; [3]Purdue University; [4]Kent State University; [5]NIST; [6]Thermo–Calc Software Inc.; [7]Northwestern University
The primary purpose of the NSF supported Summer School for Integrated Computational Materials Education was to "educate the educators" in order to enable rapid implementation of computational tools into undergraduate materials science and engineering curriculum around the world. This program allowed participants to return to their home institutions with the knowledge, skills, and materials to incorporate computational materials science and engineering (CMSE) in thermodynamics and kinetics courses. The Summer School curriculum also included an overview of CSME applications, the fundamental theory and advanced topics, as well as training for teaching the modules to undergraduate students. Twenty five faculty, postgraduate researchers, and graduate students from MSE departments and programs in the U.S. participated in this innovative program held at the University of Michigan in Ann Arbor, MI.

11:30 AM
Interactive Two-Dimensional Simulations as an Introduction to Core ICME Concepts: *Colin Ashe*[1]; David Yaron[1]; Laura Bartolo[2]; John Portman[2]; W. Craig Carter[3]; Donald Sadoway[3]; [1]Carnegie Mellon University; [2]Kent State University; [3]Massachusetts Institute of Technology
The 2008 NRC report on ICME exhorts universities to incorporate "ICME modules into a broad spectrum of materials science and engineering courses". While research- and industry-grade simulations are appropriate for upper-level courses, students in introductory courses would benefit from simulations of simpler systems that clearly convey central concepts. Combining efforts in MSE, chemistry, physics, and digital libraries, we have developed a web-based computational engine for simplified two-dimensional simulations of atoms and molecules that allows students to visualize and interact with simulations as they run. These capabilities provide a means to introduce students to both the underlying materials science concepts as well as to key concepts from computational science, such as choosing a suitable simulation time-step. In this talk, we will highlight the capabilities of our system, provide examples of its use with students, and discuss how educators interested in partnering with us might use it in their own ICME modules.

11:55 AM
Cyber-Enabled Materials Simulations via NanoHUB.org: *Alejandro Strachan*[1]; Bejamin Haley[1]; Ravi Pramod Vedula[1]; [1]Purdue University
Multi-resolution materials modeling and simulation have the potential to revolutionize the design of new materials and their certification. The materialization of this potential would be enormously accelerated by making advanced simulation tools and training material widely and easily available to researchers, educators and students. nanoHUB.org is a science web-portal created by NSF's Network for Computational Nanotechnology (NCN); it provides its users access to simulation tools and computational

resources free of charge and simply using a web-browser, with no need to download and install any software. Such a drastic reduction of the barriers to simulation opens significant opportunities in the education of a next generation of engineers and scientists and provides an efficient avenue to transfer advanced simulation tools from developers to materials scientists and engineers interested in design, optimization and certification. nanoHUB.org serves over 170,000 users annually and I will describe the key elements that contributed to its success.

International Smelting Technology Symposium (Incorporating the 6th Advances in Sulfide Smelting Symposium): Fundamentals: Thermodynamics, Phase Equilibria, and Kinetics

Sponsored by: The Minerals, Metals and Materials Society, The Metallurgy and Materials Society of CIM, TMS Extraction and Processing Division, TMS: Pyrometallurgy Committee

Program Organizers: Jerome Downey, Montana Tech of the Univ of Montana; Thomas Battle, Midrex Technologies, Inc.; Jesse White, Elkem Solar Research

Wednesday AM Room: Northern A3
March 14, 2012 Location: Dolphin Resort

Session Chair: To Be Announced

8:30 AM

Departure from Equilibria in Ilmenite Smelting: *Petrus Pistorius*[1]; [1]Carnegie Mellon University

Ilmenite smelting involves partial reduction of iron oxide from a slag consisting mainly of TiO_2, Ti_2O_3 and FeO, yielding as products iron (with approximately 2% carbon) and titanium slag. Slag purity requirements preclude any fluxing additions, and the aggressive nature of the slag necessitates a furnace freeze lining. Large departures from thermal and chemical equilibrium hold in the smelter, with implications for process stability. The slag is approximately 150K hotter than the metal, which means that the metal temperature is below the slag melting point; this has been shown to lead to formation of a solidified Ti_3O_5-rich layer between the slag and metal. Recent equilibrium measurements have confirmed that the slag and metal are not in chemical equilibrium either, with significantly more reducing conditions in the metal than in the slag. After solidification, the pseudobrookite slag structure is metastable below approximately 1400K, and may transform upon slight oxidation.

8:55 AM

Distribution of Boron and Calcium between Silicon and Calcium Silicate Slags: *Lars Klemet Jakobsson*[1]; Merete Tangstad[1]; [1]NTNU

Removal of boron from silicon by slag refining is one of the possible refining steps on a metallurgical route for production of silicon for crystalline silicon solar cells. The level of boron in silicon has to be brought down to 0.3 mg/kg or less if the silicon is to be used for solar cells, and boron is one of the hardest elements to remove from silicon. Slag refining is a promising method for boron removal, and in this work the distribution coefficient of boron, L_B, between slag and silicon was measured at 1600 °C for calcium silicate slags with a CaO/SiO_2 mass ratio between 0.6 and 1.3. The measured distribution coefficient can be approximated by the formula; $L_B = 0.437V + 1.93$, where V is the CaO/SiO_2 mass ratio within the range of the experiments.

9:20 AM

High Temperature Experimental Investigations and Thermodynamic Modelling in the $FeTiO_3$-Ti_2O_3-TiO_2 Ternary Slag System: *Stian Seim*[1]; Leiv Kolbeinsen[2]; In-Ho Jung[3]; [1]Eramet Titanium & Iron; [2]Norwegian University of Science and Technology; [3]McGill University

The current work presents new experimental data in the iron-unsaturated region of the $FeTiO_3$-Ti_2O_3-TiO_2 slag system. The samples are prepared by melting pure reactants in a high frequency induction furnace which employ a cold crucible. Such an experimental set-up have previously been described in literature and proven to suitable to investigate high titania slags. The FeO content of the samples range from 3.7 to 21.8 wt% and the Ti_2O_3 content range from 3.6 to 30.1 wt%. The liquidus temperature of the samples is measured in-situ by a spectropyrometer and range from 1450 to 1645 ºC. In addition an improved thermodynamic database for the FeO-Ti_2O_3-TiO_2 system has been developed. Ternary parameters have been included and optimized to fit previously published experimental data. This optimization minimizes the discrepancy between experimental data and thermodynamic calculations as previously discussed in literature. New liquidus projection plots are proposed for the FeO-Ti_2O_3-TiO_2 and the $FeTiO_3$-Ti_2O_3-TiO_2 systems.

9:45 AM

Reaction Mechanisms in Carbothermic Production of Silicon, Study of Selected Reactions: *Eli Ringdalen*[1]; Merete Tangstad[2]; [1]SINTEF ; [2]NTNU

The paper presents an overview over results from SINTEF/NTNU regarding new and ongoing Research in Silicon production. The main studies are related to condensation of SiO gas and cavity formation. Experimental work has shown formation of different types of condensates under different conditions, where temperature is the most important parameter. Development of cavity under industrial conditions has also been simulated. Physical apperance of zones in industrial furnaces and selected reactions in these will be discussed based on results from excavation of industrial furnace and results from laboratory experiments. This will be combined with some results from ongoing modelling work.

High Temperature Phases in Chromium Containing Cu-Fe-Ni-S Mattes: *Rauf Eric*[1]; Sanele Nkosi[2]; [1]University of the Witwatersrand; [2]Council for Mineral Technology

Experiments were conducted to determine the phases that develop when smelting and converter mattes of the Cu-Fe-Ni-S system containing chromium were solidified. These mattes are employed in the PGM smelting industry of South Africa. It is important to determine the phases that form and act as collectors for PGMs. Synthetic mattes representing were prepared from pure chemicals. They were sealed in evacuated quartz capsules and heated up to 1300°C. After equilibration they were quenched and examined using optical microscopy, SEM-EDX and X-ray diffraction. The effects of iron, sulfur and chromium contents were systematically examined on phase assemblages that developed during equilibration. One of the most noteworthy observations in mattes containing 1 to 5% Cr was the formation of (Fe, Cr) 1-XS phase,in addition to the metallic FeNi, bornite and the liquid phases at temperatures 1150°C and lower. Chromium did not dissolve in the FeNi and Cu sulfide phases.

10:55 AM

Stabilities of Phases in the Cu2S-FeS-PbS System: Hannu Johto[1]; *Pekka Taskinen*[1]; [1]Aalto University School of Chemical Technology

Copper sulfide concentrates contain often impurities such as lead and iron. The phase stabilities of the sulfide impurity systems in metallurgical process conditions are in many cases unsatisfactorily known. Thermodynamic information of a system gives better understanding of its behavior of metal making processes, but has also effects on the economic and environmental factors of the production process. In this study, isothermal equilibrium and quenching experiments of about the stable phases of the system Cu2S-FeS-PbS at 700 and 900 ºC were carried out and based on the experimental results, Gibbs triangle of equilibrium phases of the system was outlined.

11:20 AM
Experimental Thermodynamic Study of the Equilibrium Phase Assemblage $AgBi_3S_5$-Bi_2S_3-S: Fiseha Tesfaye[1]; *Pekka Taskinen*[1]; [1]Aalto University School of Chemical Technology

A thermodynamic study of the equilibrium phase assemblage $AgBi_3S_5$-Bi_2S_3-S was made by an EMF-technique, using the $RbAg_4I_5$ solid electrolyte. The ternary phase was synthesized from the pure Ag_2S and Bi_2S_3 in an evacuated silica ampoule and grinded in to powder and mixed with appropriate compositions of Bi and S, in a series of experiments, for pressing in to pellets. The pellets were assembled in a unique fashion to form the galvanic cells Pt(-) | Ag | $RbAg_4I_5$ | $AgBi_3S_5$ + Bi_2S_3 + S + (C) | Pt(+). The EMF-measurements were made in the temperature range 304 – 451 K. The EMF values for each equilibrium phase assembly were expressed as a function of temperature, in the different temperature regions of phase stabilities. In this article, thermodynamic functions of $AgBi_3S_5$ (pavonite) coexisting with Bi_2S_3 and S have been determined. The agreement between the obtained results and the literature values were established.

11:45 AM
Vacuum Distillation Refining of Crude Tin - Thermodynamics Analysis and Experiments on the Removal of Arsenic from the Crude Tin: *Yifu Li*[1]; Bin Yang[1]; Dachun Liu[1]; Baoqiang Xu[1]; Yongnian Dai[1]; [1]Kunming University of Science and Technology

The removal of impurity arsenic from crude tin is one of the major problems in the process of tin refining.Through the thermodynamics analysis on vacuum refining process of crude tin, the vapour pressure of impurity arsenic under different temperatures can be obtained, which demonstrates that it is possible to separate tin and arsenic by the vacuum refining process.This paper attempts to verify the behaviors of impurity arsenic.The experiment result shows that through vacuum distillation, crude tin with 0.16% arsenic can be refined from crude tin with 0.96% arsenic, and about 50% impurity arsenic can be collected in the form of metallic arsenic.

12:10 PM
Investigation of Removing Cadmium and Thallium from Crude Indium by Vacuum Distillation: *Jiang Wenlong*[1]; [1]National Engineering Laboratory of Vacuum Metallurgy, Kunming University of Science and Technology,

In usual,glycerin-KI and glycerin-NH4Cl were used to remove Cd and Tl in electrolysis method which products were In99.995%. Lots of polluted industrial wastewater cloud easily polluted environment was come into being. By calculated results the saturated vapor pressure of Cd and Tl between 1~200Pa were much larger than In, so study of removing Cd and Tl were carried out at the temperature range between 700~950^{o}C and pressure between 1~15Pa. In results, after vacuum distillation the content of Cd and Tl in crude indium cloud sharply fall blow 0.5ppm at least.

Magnesium Technology 2012: Alloy and Microstructural Design

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Magnesium Committee
Program Organizers: Suveen Mathaudhu, U.S. Army Research Office; Wim Sillekens, TNO; Norbert Hort, Helmholtz-Zentrum Geesthacht; Neale Neelameggham, U.S. Magnesium

Wednesday AM — Room: Southern V

8:30 AM
Age Hardening Behavior of Mg-1.2Sn-1.7Zn Alloy Containing Al: *Taisuke Sasaki*[1]; Tadakatsu Ohkubo[1]; Kazuhiro Hono[1]; [1]National Institute for Materials Science

Mg-Sn is a promising heat resistant precipitation hardenable system because of the higher melting temperature of the Mg_2Sn phase. Recent investigations also reported excellent extrudability of the alloy. However, previously studied Mg-Sn alloys require high solution treatment temperature above 500^{o}C because of the high solidus temperature for the Mg-2.2Sn base composition. In this work, we have investigated the age hardening behavior of Mg-1.2at.%Sn based alloys to reduce the solution treatment temperature. To enhance the age hardening response with the reduced Sn content, Zn and Al were alloyed. Mg-1.7Zn-1.2Sn-2.0Al alloy showed the peak hardness of 79 VHN at 200^{o}C. The peak aged Mg-1.2Sn-1.7Zn-2.0Al alloy consisted of cuboidal β_1' precipitates with the size of less than 50 nm, and fine lath shaped Mg_2Sn phase while Mg-1.2Sn-1.7Zn alloy was mainly strengthened by coarse rod shaped β_1' phase with over 500 nm in length.

8:50 AM
Evaluating the Effect of Pre-Ageing Deformation on β' Precipitate Size and Distribution in Mg-Zn(-Y) Alloys: *Julian Rosalie*[1]; Hidetoshi Somekawa[1]; Alok Singh[1]; Toshiji Mukai[2]; [1]National Institute for Materials Science; [2]Kobe University

The effect of pre-ageing deformation on the precipitate diameter and length distribution in Mg-Zn(-Y) alloys was examined. Extrusion and pre-ageing deformation were used to introduce dislocations while precluding twin formation. Dislocations provided nucleation sites for rod-like β' precipitates, resulting in a refinement of the precipitate size distribution. 5% strain reduced the average precipitate length from 450nm to 60nm, and average diameter from 14 to 9 nm. The average interparticle spacing of the rod-like precipitates was measured by Delaunay triangulation. The precipitate distribution was found to be significantly inhomogeneous, with measured interparticle spacings approximately 32% greater than predicted. For 5% pre-ageing deformation the yield strength approached 95% of the ultimate tensile strength.

9:10 AM
Effect of Zinc Content on the Microstructure and Mechanical Properties of Extruded Mg-Zn-Y-La Alloys with LPSO Phase: *Jonghyun Kim*[1]; Yoshihito Kawamura[2]; [1]Kumamoto Technology & Industrial Foundation; [2]Kumamoto University

Several wrought magnesium alloys such as AM- and AZ-series are structural materials which are suitable for use in the computers, mobile phone and automobile industries mainly because of their low densities. However, the number of commercially available Mg alloys is still limited especially for application at room and elevated temperatures.

For example, the above-mentioned alloys of AM- and AZ-series could not be applied to power train parts operating at temperatures higher than 130^oC due to their poor elevated temperature mechanical properties. The investigation reported here focused on the influence of Zinc, which was also effective in strengthening Mg-Zn-Y alloys at elevated temperature, on the microstructure and mechanical properties of the Mg-Zn-Y-La alloys.

9:30 AM
Effect of Ca Addition on the Microstructural and Mechanical Properties of AZ51/1.5 Al2O3 Magnesium Nanocomposite: *Md Ershadul Alam*[1]; Rowshan Rima[1]; Nguyen Bau[2]; Albedmagid Hamouda[1]; Manoj Gupta[2]; [1]Qatar University; [2]National University of Singapore

In the present study, new AZ51/1.5Al2O3-1Ca magnesium nanocomposite was successfully synthesized by simultaneously adding 2 wt. % aluminum, 1 wt.% Ca and 1.5 vol.% nano-sized Al2O3 (50 nm) into AZ31 matrix using an innovative disintegrated melt deposition technique. AZ51/1.5Al2O3 nanocomposite was developed following the same processing route except adding Ca. All nanocomposite samples were then subsequently hot extruded at 400 0C and characterized. Microstructural characterization studies revealed uniaxial grain size, reasonably uniform distribution of intermetallics and minimal porosity. Results also showed that the Ca addition into AZ51/Al2O3 nanocomposite helped to reduce the average grain size. Physical properties characterization revealed that addition of Ca reduced the coefficient of thermal expansion when compared to Ca free nanocomposite. The presence of Ca also assisted in improving overall mechanical properties including microhardness, 0.2% yield strength and ultimate tensile strength while the ductility was compromised.

9:50 AM Break

10:10 AM
Effect of Zn Concentration and Grain Size on Prismatic Slip in Mg-Zn Binary Alloys: *Nicole Stanford*[1]; Matthew Barnett[1]; [1]Deakin University

Mg-Zn binary alloys with concentrations between 0 and 2.8wt% Zn have been prepared and processed via hot rolling and annealing to produce specimens with a strong basal texture and a range of grain sizes. These have been deformed in tension, a condition in which the deformation is dominated by prismatic slip. This data has been used to assess the Hall-Petch parameter as a function of Zn concentration for deformation dominated by prismatic slip. Pure magnesium showed non-linear Hall-Petch behaviour at large grain sizes, and this is compared to the values for prismatic slip measured on single crystals. The differences between critical resolved shear stress measurements made through single crystal, polycrystal and mathematical modelling techniques are also discussed.

10:30 AM
Microstructural Characterization of Homogenised and Aged Mg-Gd-Nd Alloys Containing Zn, Y and Zr: Suzan Khawaled[1]; Menachem Bamberger[1]; *Alexander Katsman*[1]; [1]Technion - Israel Institute of Technology

Magnesium alloys containing heavy rare earth metals are very attractive candidates for the automotive industry including racing cars and aerospace applications, due to their high strength properties combined with low density. The microstructure of the Mg—6%Gd-3.7%Nd-0.3%Zn-0.18%Y-0.15%Zr (%wt) alloy has been investigated after solution treatment at 540°C for 24hr followed by isothermal aging at 175°C up to 32 days by X-ray diffraction and by SEM with EDS. It was observed that the homogenized alloy contained primary α-Mg solid solution, eutectic structures, cuboid shaped phases and Zr-rich clusters. The eutectic structures were the products of a 'quasibinary eutectic reaction' α-Mg+β-Mg_5 RE. The eutectic phase was characterized to be of Mg_5 Gd prototype with stoichiometry near Mg_5 (Gd_x Nd_{1-x} , x≈0.2). The cuboid shaped phases, with the composition Gd_4 (Nd_x Y_{1-x} , x≈0.6), grew during aging and reached ~3μm average size. The maximum microhardness was achieved after 16 days of aging.

10:50 AM
Mechanical Properties and High-temperature Oxidation Behaivor of Mg-Al-Zn-Ca-Y Magnesium Alloys: *Young-Min Kim*[1]; Bong Sun You[1]; Myeong-Shik Shim[2]; Nack Joon Kim[2]; [1]Korea Institute of Materials Science; [2]Pohang University of Science Technology

Simultaneous improvement in ignition resistance and mechanical properties of magnesium alloys can be achieved by the formation of protective oxide layer on the melt and the change in the morphology and volume fraction of secondary phases by alloying. In this study, the effects of alloying elements on the ignition resistance and mechanical properties of magnesium alloys were investigated. The results of this study show that the combined addition of calcium and yttrium can lead to significant increase in both ignition temperature and tensile properties, comparing to only Ca-added magnesium alloys with lamella-shaped eutectic phases. This is because the reduction of calcium content and the addition of a small amount of yttrium bring about a reduced amount Ca-containing phases and the formation of multi-layered protective oxides consisting of CaO, Y2O3, MgAl2O4, and MgO that effectively prevent oxygen penetration into the melt.

11:10 AM
Effects of Ca on Microstructure and Mechanical Properties of ZA62 Alloys: *Zhang Gang*[1]; [1]Shenyang University of Technology

Effects of Ca element on microstructure and mechanical properties of ZA62 alloys were investigated by using zeiss microscope, scanning electron microscope equipped with an energy dispersive spectrometer, X-ray diffractometer, and electronic universal testing machine. The results show that Ca can significantly refine microstructure and cause the precipitation of Mg2Ca and Al2Ca phases on grain boundary of ZA62 alloys. The addition of Ca can improve the tensile properties of alloys at room temperature. When the content of Ca is 2%, good properties are obtained, the tensile strength and yield strength of Mg-6Zn-2Al-2Ca alloy reaches 240.79MPa and 82.78MPa respectively.

11:30 AM
Effects of Si on Microstructure and Mechanical Properties of Mg-5Sn-2Sr Alloy: *Hao Shuai*[1]; [1]Shenyang University of Technology.

Phase constitution and microstructure of the Mg-5Sn-xSi-2Sr (x=0, 1, 2) alloys were analyzed by X-ray diffractometer, optical microscope and scanning electron microscope with an energy dispersive spectrometer. The tensile properties of the alloys were tested by electronic universal testing machine, and the fracture surfaces of the alloys were observed with scanning electron microscope. The results show that the microstructure of the Mg-5Sn-2Sr alloy consists of a-Mg, MgSnSr, Mg2Sn phases. The addition of Si element can promote the formation of Mg2Si phase on the grain boundary, and the content of Mg2Si phase increases with increasing the Si element. Mg2Si is a strengthening phase, it can effectively prevent grain boundary sliding and dislocation motion, and thus, the mechanical properties of the alloys were obviously enhanced. The mechanical properties of Mg-5Sn-2Si-2Sr alloy are better than other alloys, the tensile strength, yield strength, elongation and hardness are 147MPa, 110MPa, 5.0% and 47HB respectively.

Magnesium Technology 2012: Casting and Solidification

Twin Roll Casting of Thin AZ31 Magnesium Alloy Strip with Uniform Microstructure and Chemistry: Iman Bayandorian[1]; Ian Stone[1]; *Yan Huang*[1]; Zhongyun Fan[1]; [1]Brunel University

Magnesium alloys produced by the existing twin roll casting (TRC) technique have coarse and non-uniform microstructures and severe centre-line segregation. Consequenty, TRC strip is cast typically no thinner than 5-9 mm, relying on costly subsequent downstream processing to produce thin strip with an improved microstructure. In the research described herein melt conditioning by intensive melt shearing was used prior to TRC to promote heterogeneous nucleation and provide a refined and uniform microstructure without severe macrosegregation. Additionally, a TRC machine with small diameter rolls was used to cast AZ31 strip of less than 2 mm in thickness suitable for direct component manufacturing such as stamping, without the necessity of hot rolling. The effects of process parameters, such as casting speed and melt superheat, on as-cast microstructure were studied. Experimental results show that the melt conditioning process provided considerable reduction in as-cast grain size and elimination of centre-line segregation. The texture and mechanical properties of melt conditioned strips were much improved over conventional TRC strips, offering the potential for higher quality final components.

8:50 AM
Mathematical Modeling of the Twin Roll Casting Process for AZ31 Magnesium Alloy – Effect of Set-Back Distance: *Amir Hadadzadeh*[1]; Mary Wells[1]; Elhachmi Essadiqi[2]; [1]University of Waterloo; [2]CANMET Materials Technology Laboratory

A 2-D coupled thermal-fluid-stress model was developed and used to simulate the twin roll casting (TRC) of an AZ31 magnesium alloy using the commercial software package, ALSIM. The model was used to predict the fluid flow, temperature distribution and mechanical behavior of the AZ31 strip in the roll bite. An important parameter in controlling the TRC process is the set-back; distance between the nozzle entry to the kissing point of the rolls. There are two approaches to increase the set-back: 1) increasing the entry thickness and 2) decreasing the final strip thickness. In this study different set-back distances have been studied for different casting speeds to assess their effect, particularly the thermo-mechanical behavior of the strip during the process. The thermo-mechanical behavior of the strip has a significant effect on the final quality as defect formation depends on such behavior.

9:10 AM
Interdiffusion and Phase Formation in the Mg-Y System: *Katrina Bermudez*[1]; Sarah Brennan[1]; Yongho Sohn[1]; [1]University of Central Florida

Rare earths have been added to magnesium alloys in order to improve the creep resistance, corrosion resistance and strength. Solid-to-solid diffusion couples were assembled between Mg (99.9%) and Y (99.9%) to investigate the parabolic growth of intermetallic phases and interdiffusion in the Mg-Y system. The diffusion anneals were performed at 450, 500 and 550°C for 360, 240 and 120 hours, respectively. The intermetallic layers that developed were the d-Mg2Y and e-Mg24Y5 phases, however the MgY phase did not form. A substantial penetration of Y in Mg was observed, however along with Kirkendall porosity that indicates faster diffusion of Mg than Y in Mg solid solution. The activation energies for growth, assumed parabolic, in e-Mg24Y5 and d-Mg2Y were determined to be 89 and 77 kJ/mol, respectively. Relevant interdiffusion coefficients including activation energies in Mg-Y system were calculated for the e-Mg24Y5, d-Mg2Y, and Mg solid solution wherein reliable concentration gradients were observed.

9:30 AM
Microstructure and Mechanical Properties of High Pressure Die Cast AM50 Magnesium Alloy Containing Ce: Faruk Mert[1]; Ahmet Özdemir[1]; Karl Ulrich Kainer[2]; *Norbert Hort*[2]; [1]Gazi University; [2]Helmholtz-Zentrum Geesthacht (HZG)

Over the past decades, the necessity to decrease the weight of automobile parts has created a considerable interest in magnesium alloy. The need to develop magnesium die casting alloys for car components motivates R&D in high temperature magnesium alloy development. In order to improve magnesium alloys with low cost, high strength and with notable elevated temperature properties, the effect of Ce addition (0.5/1.0 wt.-%) on microstructure and mechanical properties of AM50 was studied. Results show that addition of Ce to AM50 resulted in grain refinement and the formation of the secondary phase $Al11Ce_3$. Mechanical properties of investigated alloys at both room and elevated temperature were remarkably increased. AM50 containing 1%wt. Ce showed relatively better refinement and mechanical properties compared to AM50 with 0.5%wt. Ce.

9:50 AM
Effect of Intensive Melt Shearing on DC Cast Ingots of Magnesium Alloys: Yubo Zuo[1]; *Zhongyun Fan*[1]; Bo Jiang[1]; Yijie Zhang[1]; [1]Brunel University

Direct Chill (DC) casting process is still one of the major methods to produce magnesium alloy ingots. A new melt conditioned DC (MC-DC) process, has been developed for producing high quality ingots of magnesium alloys by application of intensive melt shearing through a rotor-stator high shear device during the conventional DC casting process. The rotor-stator high shear unit can provide not only macro flow of liquid metal in the DC casting mould but also intensive melt shearing within the high shear device, which can enhance the heterogeneous nucleation and result in a uniform temperature field and a compositional filed. Experimental results have demonstrated that the MC-DC casting process can produce magnesium alloy billets with significantly refined microstructure and reduced cast defects. In this paper, we introduce this new MC-DC casting process, report the effect of intensive melt shearing on the DC casting process and discuss the grain refining mechanism.

10:30 AM
Effect of the Solidification Rate on Microstructure of Cast Mg Alloys at Low Superheat: *Gregory Poole*[1]; Nathan Rimkus[2]; Aeriel Murphy[1]; Paige Boehmcke[1]; Nagy El-Kaddah[1]; [1]The University of Alabama; [2]Los Alamos National Laboratory

This paper investigates the effect of cooling rate on the grain size and microstructure of Mg AZ31B alloy cast at a superheat of 8°C using the Magnetic Suspension Melting (MSM) process, which is capable of melting and casting at superheats less than 5°C. In this study, the Mg alloy was unidirectionally solidified in a bottom-chill mold with stainless steel and copper chill blocks. The solidification parameters, namely growth velocity (V) and temperature gradient (G), were determined from numerical simulation of the cooling curves, which was found to be in good agreement with measurements. For the investigated solidification rates,

WEDNESDAY AM

metallographic examination showed globular solidification morphology, and the grain size was inversely proportional to the square root of the cooling rate. Microprobe analysis of the cast ingots also showed that Al segregation occurs primarily at the grain boundaries, and the solidification rate affects the size and distribution of both the secondary a phase and the intermetallic Mg17Al12 phase

10:50 AM
Impact and Energy Dissipation Characteristics of Squeeze and Die Cast Magnesium Alloy AM60: *Sante DiCecco*[1]; Henry Hu[1]; William Altenhof[1]; [1]University of Windsor

High-pressure die cast (HPDC) magnesium alloy AM60 is recognized for its versatility in the manufacturing of weight sensitive components of relatively thin cross section. To further expand practical applications of the alloy, squeeze casting has been proposed to allow for thicker castings. In this study, AM60 alloy specimens of 10mm thickness were squeeze cast using a hydraulic press with an applied pressure of 60 MPa. Fracture energies, following a Charpy Impact Testing protocol, of the squeeze cast specimens were characterized in comparison with the HPDC counterparts using both experimental and numerical techniques. The experimental results show the squeeze cast alloy absorbing approximately 46.2% more energy during impact than its HPDC counterpart. Scanning electron microscopy fractography reveals the favourable quasi-cleavage fracture mode of the squeeze cast alloy AM60, relative to the decohesive rupture fracture mode present in the die cast alloy.

11:10 AM
Sliding Wear Behavior of Squeeze Cast Magnesium Composite AM60-9% (Al2O3)f: *Anindya Banerji*[1]; Henry Hu[1]; Ahmet Alpas[1]; [1]University Of Windsor

Increasingly stringent demands of improved fuel economy and emissions prompted the study of Mg and its composites as they provide and combination of properties of high strength and low density. In the present paper development of magnesium composites and their subsequent wear behavior is studied. Magnesium matrix composites were synthesized by reinforcing AM60 alloy with Al2O3 fibres using squeeze casting method with varying alumina fibre volume percentage. Lubricated wear tests were conducted on these composites under 1.0-5.0 N load at a constant sliding velocity against AISI 52100 steel balls. Mainly two mechanisms of wear were identified-ultramild wear and mild wear. The transition from ultramild wear regime to the mild wear regime was increasingly delayed as the applied load was decreased. The effect of Al2O3 fibre content on the wear resistance of AM60 composites was also investigated.

11:30 AM
Solidification Studies of Mg-Al Binary Alloys: *Manas Paliwal*[1]; Youn-Bae Kang[2]; Elhachmi Essadiqi[3]; In-Ho Jung[1]; [1]McGill University; [2]GIFT, POSTECH ; [3]CANMET-MTL

This study emphasizes on the evolution of as cast microstructure of Mg-3, 6 and 9 wt. % Al alloys solidified in the cooling rate range of 0.05 K/sec to 940 K/sec. The alloys have been solidified using different techniques like directional solidification (classical Bridgemann technique), sand mould casting, graphite mould casting, wedge casting, copper and steel mould casting and injection mould casting to obtain different cooling rates. The as-cast microstructures are characterized to reveal secondary dendrite arm spacing (SDAS), Primary dendrite arm spacing (PDAS) and second phase volume fraction as a function of cooling rate and composition. The microstructural features and different growth morphologies of Mg alloys have been systematically studied as a function of Al composition and it is found that increasing solute content can have a remarkable effect on the evolution of as cast microstructure.

Magnetocaloric Effect in Pr-Doped $La_{0.7}Ca_{0.3}MnO_3$: Magnetic and Calorimetric Studies: *Ramanathan Mahendiran*[1]; [1]National University of Singapore

Magnetic refrigeration using solid state magnetic refrigerants is currently attracting much attention because of its higher energy efficiency and environmental cleanliness. Pervoskite manganites are one of the candidates considered for magnetic refrigeration. Here, we report magnetocaloric effect in Pr-doped $La_{0.7}Ca_{0.3}MnO_3$ samples. The magnetic entropy change (ΔSm) was measured using a differential scanning calorimeter (DSC) working in a magnetic field environment. Temperature change in the sample during the magnetic field sweep was measured using a differential thermal analyser. The paramagnetic state of these compounds was found to be unstable with respect to magnetic field. The applied magnetic field induces a low to high moment transiiton (metamagentic transition) over a wide temperature range compared to other well known magnetocaloric systems such as Gd-Si-Ge, Mn-Fe-P-As and La-Fe-Si. As a result, these doped oxides show a large magnetic entropy and a refrigeration capacity.

9:00 AM Invited
Magnetocaloric Effect in GdFeCo-Based Melt-Spun Ribbons: Jozef Marcin[1]; Zbigniew Sniadecki[2]; Jozef Kovac[1]; Bogdan Idzikowski[2]; *Ivan Skorvanek*[1]; [1]Institute of Experimental Physics; [2]Institute of Molecular Physics

The magnetocaloric effect (MCE) is attracting a great deal of interest because it is a basis of the new environmentally friendly magnetic refrigeration technology. In this work, we report on a beneficial effect of partial Co substitution for Fe on the magnetocaloric behaviour in the melt-spun Gd(65)Fe(20-X)Co(X)Al(10)(Si,B)(5) (x=5,10 and 15) ribbons. The highest values of the maximal magnetic entropy change, ΔSM, and the refrigeration capacity, RC, for the Gd65Fe10Co10Al10B5 ribbon under 50 kOe reached 7.02 J/kg K and 766 J/kg, respectively. The markedly enhanced values ΔSM as compared to the Co-free compositions extended over a wide temperature range together with the good magnetic softness leading to the low hysteresis losses make the partially Co-substituted GdFeCoAl(Si,B) amorphous ribbons promising magnetic refrigerants in the temperature range from 80 to 220 K.

9:30 AM Invited
Novel $La(Fe,Si)_{13}$-Based Composites for Magnetic Refrigeration: *Julia Lyubina*[1]; Ullrich Hannemann[2]; Mary Ryan[2]; Lesley Cohen[2]; [1]Imperial College London ; [2]Imperial College London

Materials with a giant magnetocaloric effect (MCE) arising as a consequence of a first-order magnetic phase transition and in particular $La(Fe,Si)_{13}$-based alloys are attractive candidates for magnetic cooling application. It has recently been shown that introducing porosity in $LaFe_{13-x}Si_x$ alloys provides long-term mechanical stability and results in the desired reduction of the hysteresis [1]. However, the thermal conductivity of porous $LaFe_{13-x}Si_x$ decreases significantly. Here, we report the preparation and magnetocaloric effect of novel composite materials consisting of the active magnetic phase $La(Fe,Si)_{13}$ and a ductile, high thermal conductivity material, such as Cu or Ag. In the composites, giant MCE is successfully retained and at the same time the thermal conductivity is improved. The magnetic and thermal properties of the composites will be discussed. *This research was supported by a Marie Curie Intra European Fellowship within the 7th European Community Framework Programme.*[1] J. Lyubina, J. Appl. Phys. 109 (2011) 07A902.

10:00 AM
Optimizing the Magnetic Field Response of Magnetocaloric Materials by Nanostructuring: *Victorino Franco*[1]; Rafael Caballero-Flores[1]; Alejandro Conde[1]; Laszlo Kiss[2]; Laszlo Péter[2]; Imre Bakonyi[2]; [1]Sevilla University; [2]Hungarian Academy of Sciences

In order to be of practical use in magnetic refrigerators, magnetocaloric materials should have a large refrigerant capacity at moderate magnetic fields. In order to achieve this, two alternative approaches exist: a) the design of new alloys and compounds with such properties and b) the use of materials engineering techniques for the optimization of already existing materials. Although the first one is a highly desirable line of research, the expectations of success are limited due to additional restrictions on the materials' composition, operating temperature, etc. The materials engineering approach is a complementary line of research with larger certainty of its success due to the deep knowledge of the constituent phases that has been already achieved. We will overview how nanostructuring is a good strategy for obtaining magnetocaloric responses qualitatively different from the bulk materials and for controlling the field responsiveness in the magnetic field range appropriate for technological applications.

10:15 AM Break

10:30 AM
Comprehensive Study on Microstructure and the Magnetocaloric Properties in Mn-Substituted $La(Fe,Si)_{13}$: *Maria Krautz*[1]; Cristiano Teixeira[1]; Konstantin Skokov[1]; Jian Liu[1]; James Moore[1]; Paulo Wendhausen[2]; Ludwig Schultz[1]; Oliver Gutfleisch[1]; [1]IFW Dresden; [2]Federal University of Santa Catarina

$La(Fe,Si)_{13}$ intermetallic compounds are relevant materials for magnetic refrigeration, showing a large magnetocaloric effect (MCE) in the vicinity of T_C and consisting of abundant 3d-metal in contrast to other magnetocaloric materials, like Gd and Gd-based alloys. For application, T_C should coincide with the working temperature demanded in the refrigeration device. In $La(Fe,Si)_{13}$ T_C is about 200K and it is known that T_C can be raised above room temperature by hydrogenation. However, precise control of a partial H-content, to cover a range of T_Cs, is challenging. Fully hydrogenated $La(Fe,Si,Mn)_{13}$-compounds present a possible solution, since T_Cs ignificantly decreases with increasing Mn content. Here, we present a comprehensive study on $LaFe_{13-x}Mn_xSi_{1.2}$ and $LaFe_{13-x}Mn_x$Si1.4 (x = 0.0, 0.1, 0.2, 0.3 and 0.4) compounds and their hydrides. Results on magnetocaloric properties were obtained by magnetometry and direct \916T measurements. Finally, we assess the synthesis parameters to obtain near single-phase material in an economical manner.

10:45 AM
The Maximum Possible Cooling Power of $La(FeSi)_{13}$ and Gd Based Magnetic Refrigerators: *Konstantin Skokov*[1]; Alexey Karpenkov[1]; Oliver Gutfleisch[1]; [1]Leibniz Institute for Solid State and Materials Research

To comprehensively characterise magnetocaloric properties of potential magnetic refrigerant materials, adiabatic temperature change (\916T$_{ad}$), the heat capacity (c_p), the thermal conductivity and the magnetic entropy change need to be known. Yet, these parameters do not completely characterize the efficiency of the magnetic refrigerator which can be built on the basis of alloys such as $La(FeSi))_{13}$ and Gd. The magnetic refrigerator itself must simultaneously meet two basic criteria: large temperature span and large cooling power. The thermal span is strongly related to \916T$_{ad}$. But the cooling power depends on c_p and \916T$_{ad}$ in complex fashion and cannot be written analytically. In this work, by numerical simulation based on our \916T$_{ad}$ and c_p data we determined the temperature span and the maximum possible cooling power for reversible refrigeration cycles with $La(FeSi)_{13}$ alloys and Gd-metal as a working substances. The results clearly demonstrate the functional ranges of these refrigerators.

11:00 AM
Effect of W Substitution on the Magnetostrictive Behavior of [001] Fe-Ga Alloy Single Crystal: *Chai Ren*[1]; Biswadeep Saha[1]; Meenakshisundaram Ramanathan[1]; Sivaraman Guruswamy[1]; [1]University of Utah

Fe-Ga alloys have a large low-field magnetostriction and these alloys are attractive candidates in energy conversion and harvesting applications. Small additions of W also increase the magnetostriction of Fe. In this paper changes in magnetostriction by W substitution for Ga in various Fe-x at.% Ga alloys are presented. Fe-Ga-W single crystals were grown using vertical Bridgman Growth technique. [001]-orientated single crystal samples were prepared with faces within 1 degree off <100> orientation. The samples were annealed at 1150 degree C in the alpha-phase region and water quenched. The magnetostriction coefficient $(3/2)\lambda_{100}$ measurements were made on these Fe-Ga-W single crystals. The result on the effects of W substitution and annealing on the magnetostrictive behavior of these alloys are discussed. *Support of this work by NSF-DMR under the award DMR-0854166 is gratefully acknowledged.

11:15 AM
Influence of Deformation and Ga Content on Magnetostriction in Fe-Ga Alloys: *Biswadeep Saha*[1]; Meenakshisundaram Ramanathan[1]; Chai Ren[1]; Sivaraman Guruswamy[1]; [1]University of Utah

Influence of plastic deformation and gallium content is examined in Fe-Ga alloys. Fe-Ga single crystals were prepared using the vertical Bridgeman technique. Parallelepiped shaped samples were prepared with faces oriented within 0.5 degree off from the desired crystallographic orientation. Samples were annealed in alpha phase region and quenched in water. Annealed samples were plastically deformed to a predetermined strain level. Magnetostriction was measured in as grown, after annealing and after deformation. A decrease in magnetostriction is observed after deformation as compared to annealed sample at all Ga content examined. *Support of this work by NSF-DMR under the award DMR-0854166 is gratefully acknowledged.

11:30 AM
Modeling Magnetic and Structural Phase Transformations in Co-Ni-Al Ferromagnetic Shape Memory Alloys FSMA's: *Hassan Thawabi*[1]; Navdeep Singh[1]; [1]Texas A&M University

Ferromagnetic shape memory alloys FSMA's have shown promising features as high precision self-actuating materials with environmentally friendly energy conversion in diverse applications, specifically in the Aerospace and Bio-medical industries. In this study, we examine the effect of configurational ordering on the magnetic properties of Co-Ni-Al ordered ($L2_1$) and disordered (B2) austenite and martensite structures. The magnetic properties are analysed by means of employing Monte-Carlo simulations to get the magnetization, magnetic susceptibility, specific heat and entropy in response to temperature variation to obtain the Curie temperature and therefore alloy predicted operational temperatures. Magnetic exchange parameters are obtained using Ab-Initio and self-consistent field calculations and the results are used in the Monte-Carlo simulations. All the results are compared with experimental literature, and their overall effect on the martensitic structural transformation are elucidated.

Materials Development for the Traveling Wave Reactor: *Micah Hackett*[1]; Gary Povirk[1]; James Vollmer[1]; [1]TerraPower

The TerraPower Traveling Wave Reactor (TWR) concept envisions a fast reactor breed-and-burn core that initially starts on a combination of low-enriched uranium and depleted uranium, and then operates with additions of depleted uranium by in-situ breeding of its own fuel. TWRs can utilize depleted uranium stockpiles for fuel and produce significantly less spent-fuel waste than LWRs without reprocessing and with reduced enrichment. Perhaps the most significant constraint in TWR development, however, is the dose limit for the core materials and burnup limits for the fuel and clad. This talk will focus on present efforts toward TWR development, which includes: data analysis to support development of a creep and swelling model for HT9 ferritic/martensitic steel; an ion irradiation program for cladding and duct development, of both HT9 and, in the future, advanced materials; and a neutron irradiation test program to qualify materials to high doses.

9:00 AM
Materials Corrosion in Liquid Fluoride Salt for NGNP Applications: *Kumar Sridharan*[1]; Luke Olson[1]; Robert Sellers[1]; Brian Kelleher[1]; Wei-Jen Cheng[2]; James Ambrosek[1]; Mark Anderson[1]; Todd Allen[1]; [1]University of Wisconsin; [2]National Taiwan University of Science and Technology

Liquid fluoride salt FLiNaK (LiF-NaF-KF: 46.5-11.5-42 mol %) is being considered as the secondary coolant for fluoride salt-cooled high temperature reactor (FHR) and also as fluid for the transport of high temperature process heat from VHTR for the operation of chemical plants. Materials corrosion will be an important issue in high temperature liquid FLiNaK salt because of the inherent in reactivity of fluoride ion and the relative instability of the protective oxide layer on alloys in liquid fluoride salt environment. Corrosion performance of several high temperature alloys in liquid FLiNaK will be discussed. Chromium in the alloys is particularly prone to dissolution and electrochemical techniques have been developed for the quantitative detection of chromium in the liquid salt. Ni-plating was found to be remarkably effective in mitigating materials corrosion in liquid FLiNaK. Addition of zirconium to liquid FLiNaK alters its redox potential and can be used to control materials corrosion.

9:20 AM
Corrosion Behavior of a F91/Fe-12Cr-2Si Composite in Liquid Lead-Bismuth-Eutectic as a Function of Oxygen Potential in the Temperature Range 600-715°C: *Michael Short*[1]; Ronald Ballinger[1]; [1]MIT

The corrosion characteristics of the ferritic/martensitic alloys F91 and Fe-12Cr-2Si in liquid lead and Lead-Bismuth-Eutectic (LBE) have been investigated at low (600-615°C) and high (700-715°C) temperatures. Tests were performed at oxygen potentials above and below the potential for formation of iron oxides. Fe-12Cr-2Si alloys develop a multi-layered oxide film with a Si-rich oxide layer formed beneath a Cr-rich oxide layer. Fe-12Cr-2Si quickly forms a protective layer system of chromium, silicon and iron oxides. A thin inner layer of silica forms beneath the chromium oxide layer that acts as a powerful diffusion barrier to further corrosion. Extrapolated corrosion rates for Fe-12Cr-2Si are less than 1 μm/yr at 700°C. A composite system using F91 clad with the new Fe-12Cr-2Si alloy is shown to be highly resistant to corrosion in liquid lead or LBE at temperatures up to 700°C which represents enabling technology for the lead-cooled fast reactor or accelerator driven target system.

9:40 AM
Effects of Ordering Reaction on Lattice Variation in Alloy 690: *SungSoo Kim*[1]; Young Suk Kim[1]; [1]Korea Atomic Energy Research Institute

Alloy 690 is a standard steam generator tubing material in pressurized water reactor at present. It is known that the ordering reaction causes lattice variation during the reactor operation. In order to investigate the effect of thermo-mechanical treatment on dimensional stability in alloy 690, cooling rate variation and cold work are applied, and those are aged at 400°C up to 15,000 hours. The results showed that the lattice contraction is anisotropic; it is increased to be three times by cold work; however, the effect of cooling rate appeared little. The maximum lattice contraction appeared to be 0.05~0.07% according to lattice planes. The activation energy for the ordering reaction determined by differential scanning calorimeter was 240kJ/mol.

10:00 AM Break

10:10 AM
Effect of Coatings on the Corrosion-resistance of Fe, 9-14% Cr Steels in Supercritical Water: *Selçuk Kuyucak*[1]; Jian Li[1]; Wenyue Zheng[1]; [1]Dept. of Natural Resources Canada

Oxide dispersion strengthened ferritic steels having 9-14% Cr have been considered for in-core structural applications in the "next generation" nuclear reactor designs. These steels have high irradiation resistance because of their ferritic matrix and absence of nickel, high creep resistance, but moderate to low corrosion resistance. Higher chromium levels for greater corrosion resistance are not feasible as the steel becomes brittle in the absence of nickel. Application of coatings is one option to improve the corrosion resistance of such steels. The performance of a Fe-25Cr metallic coating applied by the cold-bonding process to various Fe, 9-14% Cr steels has been investigated with particular reference to the supercritical water-cooled nuclear reactor (SCWR) design.

10:30 AM
Studies on Stacking Fault Energy of Low Carbon Austenitic Stainless Steels: *Toshio Yonezawa*[1]; Ken Suzuki[1]; Suguru Ooki[2]; Hideshi Tezuka[2]; Shunichi Suzuki[2]; [1]Tohoku University; [2]Tokyo Electric Power Company

The stacking fault energy (SFE) for austenitic stainless steels has been studied by many researchers. The calculation equations of SFE value based upon chemical compositions have been also reported by some researches. But, these equations are not so well coincident with each other. Especially, the consensus is still not obtained about the effects of interstitial elements on SFE value. Recently, the calculation equation of SFE value based upon chemical compositions is attracted attention from the view point of decreasing of intergranular stress corrosion cracking susceptibility or radiation induced segregation for austenitic stainless steels in nuclear industrial field. SFE values for 56 heats of austenitic stainless steels were measured on width of isolated extended dislocations by dark field image of TEM, and the factors of main elements were verified by thermodynamics theoretical calculation. From these analyses, more reliable calculation equation of SFE value for austenitic stainless steels was discussed and proposed.

10:50 AM
Formation and Thermal Stability of Nanosized Oxide Precipitates in NiAl-(Y2O3,Ti) Alloys: *Yongdeog Kim*[1]; Hyon-Jee Lee[1]; Zuhair A. Munir[2]; Lizhen Tan[3]; Jeremy T. Busby[3]; Brian D. Wirth[4]; [1]UC BERKELEY; [2]UC Davis; [3]Oak Ridge National Laboratory; [4]University of Tennessee, Knoxville

NiAl oxide dispersion strengthened alloys were produced by mechanical alloying of NiAl with Y2O3 and Ti alloying powders, followed by spark plasma sintering, with the objective of improving the high temperature strength and creep resistance. These target properties are expected due to a presence of high number density of thermally stable nano-meter scale clusters, akin to those recently observed to improve creep strength and radiation resistance in nano-structured ferritic alloys. In this presentation, the alloy production process and characterization of the NiAl ODS alloys will be summarized. The improved mechanical properties will be explained in connection with the size, structure, and number density of the precipitated oxide particles, which are obtained using transmission electron microscopy, Atom Probe Tomography, and Small Neutron Scattering. Finally, the thermal stability of oxide precipitate will be discussed using the mechanical properties and microstructural characterization results of NiAl ODS alloys as a function of thermal annealing.

11:10 AM
Finite Element Creep Behavior Analysis in Welded Joints of Modified 9Cr-1Mo Steel: *Mehdi Basirat*[1]; Triratna Shrestha[1]; Gabriel Potirniche[1]; Indrajit Charit[1]; Karl Rink[1]; [1]University of Idaho

Modified 9Cr-1Mo steel is one of the first candidates for very high temperature reactor (VHTR) pressure vessels. Although modified 9Cr-1Mo steel has a good creep resistance, the material microstructure will degrade during welding process, hence material creep resistance investigation at the welded zone is essentially curtail. In this research, a microstructural creep model combined with a continuum damage mechanics model is developed. The numerical model has been implemented into Abaqus commercial finite element software by writing a User MATerial Subroutine (UMat). The creep behavior of the material was simulated at heat affected zone (HAZ) and the weld material. Furthermore, tensile creep behavior of the welded specimens at temperature range of 550-700 °C and stress level of 80-200 MPa was studied. Finally, the simulation results have been compared to the experiments and there is a good consistency.

11:30 AM
Study on Microstructural Changes and Corrosion Resistance of Ti-5Ta-2Nb/304L SS Explosive Clads in Concentrated Nitric Acid: *Sudha Cheruvathur*[1]; Ravishankar A[1]; Prasanthi T.N[1]; Kamachi Mudali U[1]; Saroja S[1]; [1]Indira Gandhi Centre for Atomic Research

Dissimilar joints of Ti-5Ta-2Nb and 304L stainless steel are fabricated using explosive cladding process. Detailed characterization of explosive clads confirmed (1) absence of intermetallic phases at clad interface and (2) deformation induced phase transformation in both 304LSS and Ti-Ta-Nb. Corrosion resistance of the clads was assessed in liquid (LP), vapour and condensate phases of 11.5M nitric acid. Except in LP, corrosion rate was <1mpy in other two phases. High corrosion rate in LP was explained based on intergranular corrosion of 304LSS. Nature of passive films forming on both alloys after exposure to nitric acid were identified using XPS. In LP, in the Ti alloy, more stable and protective oxides like TiO2, Ta2O5, Nb2O5 and NbO were detected whereas in 304LSS, Cr existed both in +3 and +6 oxidation states. This observation is in line with the conclusion drawn from corrosion experiments. Further details will be discussed in the paper.

Materials Design Approaches and Experiences III: Superalloys

The Alloys by Design Approach in Superalloy Development: *Nils Warnken*[1]; [1]University of Birmingham

The development of Ni-based Superalloys has reached a remarkable level of complexity. Current alloys consist of 10 and more mayor alloying elements, which have to be carefully balanced in order to achieve the desired alloy properties. This complexity makes it necessary to explore and utilise new approaches in alloy design. Newly designed alloys are not necessarily aiming at improving overall alloy performance, but also at finding the right balance of properties for a given task.In order to achieve these goals without the conduction of lengthy and costly experimental trials, a computational approach is presented which allows for the comparison of a large number of candidate alloy compositions; Merit-indices for characteristic properties such as for example creep and oxidation resistance, manufacturability, microstructure and density are used to identify promising alloys. Further virtual testing is illustrated by using computationally more intense techniques such as the phase-field method.

9:00 AM Invited
Development of Superalloy GTD262 at GE: Liang Jiang[1]; *Ganjiang Feng*[2]; Ji-Cheng Zhao[1]; [1]GE Global Research; [2]GE Energy

A project was initiated in 2002 and executed by GE Global Research and GE Energy to replace Ta in superalloy GTD222 which was widely used as nozzles in GE power generation gas turbines. By integrating computational thermodynamic predictions of phase equilibria with GE's property models and databases, we designed four alloys with Nb replacing Ta and with modifications to the concentrations of other elements to optimize key properties. Laboratory-scale tests were performed for mechanical properties, oxidation resistance, weldability and castability. The best of the four alloys doubled creep-resistance performance while maintained comparable other properties than the Ta-bearing GTD222; and it was subjected to a production trial and successfully passed the qualifications without any technical hurdles. The new alloy was named GTD262, was successfully introduced in GE gas turbines starting in 2006, and is experiencing much widened adoption today. The alloy development process and the lessons learned will be presented.

9:30 AM Invited
New Co-Base Superalloys Strengthened by γ' Phase - Alloy Design and Applications: *Kiyohito Ishida*[1]; [1]Tohoku University

Phase stability of intermetallic compounds in Co-base alloys are briefly reviewed and compared with those in Ni-base alloys focusing on the GCP (geometrically closed-packed) phase. Although only Co3Ti is known to be a stable γ'(L12) compounds, there are some metastable γ' phase in the Co-X binary system such as Co3Al, Co3W, Co3Ta, etc. Recently, we discovered ternary compounds of Co3(Al, W), Co3(Ge, W) and Co3(Ga, W) with L12 structure. The γ + γ' Co3(Al, W) two-phase alloys show the positive temperature dependence on flow stress. Therefore, the Co-Al-W base alloys have potential for new-type of superalloys strengthened by γ' phase. In this paper, the phase equilibria, alloy design and some properties of Co-Al-W base alloys will be shown. The applications of this new wrought and cast Co-base superalloys will also be presented.

10:00 AM Break

10:20 AM
High Temperature Microstructure and Properties of New $L1_2$-Containing Co-Al-W Alloys: *Michael Titus*[1]; Jun Zhu[2]; Alessandro Mottura[1]; Akane Suzuki[3]; Tresa Pollock[1]; [1]University of California, Santa Barbara; [2]University of Michigan; [3]GE Global Research

New cobalt-based alloys containing ordered $L1_2$ precipitates have been investigated. Alloying approaches for enhancing the two-phase **γ-γ**' microstructure have been indentified. Predictions of a new thermodynamic database on transformation temperatures and phases present will be compared to experimental observations. Single crystal tensile creep tests have been performed under vacuum at 900°C with stresses between 200 and 350 MPa. Based on minimum creep rates, the high temperature creep properties of the Co-base alloys are comparable to first-generation commercially available superalloy single crystals. The implications for design of new cobalt-base alloys will be discussed using the new thermodynamic database.

10:40 AM
Effect of Alloying Elements on Microstructure and Mechanical Property of Co-Al-W-Base Superalloys: Fei Xue[1]; Meiling Wang[1]; *Qiang Feng*[1]; [1]University of Science and Technology Beijing

The newly developed Co-Al-W-base superalloys with **γ**'-strengthening exhibit promising properties as candidates for aircraft engines and industrial gas turbines, but the knowledge of principal alloying effects has not been fully understood yet. In this study, the influence of Ti, Nb, Ta, V, Mo, Hf and Cr on microstructure and mechanical property of Co-9Al-10W-base alloys were investigated after heat treatment at 900°C. The results revealed that the morphology, size, volume fraction and solvus temperature of **γ**' precipitates were influenced by different alloying additions in different ways. The partition ratios of alloying elements were also examined to better understand the lattice misfit and **γ**' morphology, which were correlated with microstructural stability. The relationship of microstructure and mechanical property by the influence of alloy elements were analyzed based on the above experimental results. The present work will offer fundamental information to modify the compositional design for Co-Al-W-base alloys.

11:00 AM Invited
Accelerating Insertion of Materials at GE Aviation: *Deborah Whitis*[1]; Arturo Acosta[1]; Daniel Wei[1]; Liang Jiang[1]; [1]General Electric Company

Material and process development for aircraft engines has, in the past, required long and costly experimental programs, imposing a significant barrier to the insertion and exploitation of new materials and manufacturing processes. With the advent of computer modeling and simulation of materials processing, and the accelerated insertion of materials (AIM) approach, we have begun to provide the tools to industrial materials designers that they need to increase productivity and reduce cost of alloy and process development. This presentation will provide an overview of the implementation of the AIM approach at GE Aviation. The integration of materials models, historical databases, and analysis tools have allowed us to more rapidly downselect new alloys and manufacturing processes, responding quickly to the design requirements of a particular component and engine environment. Current progress in applying these techniques to nickel-based superalloys will be reviewed.

11:30 AM Invited
Development of High Temperature Capability P/M Disk Superalloys: Eric Huron[1]; Kenneth Bain[1]; David Mourer[1]; [1]General Electric Company

A study was conducted to optimize the major element chemistry of powder metallurgy (PM) alloys for the challenging goals of a High Speed Civil Transport (HSCT) application. Two iterations were performed. Subscale heats of experimental powders were atomized, consolidated by extrusion, isothermally forged, and supersolvus heat treated. Key relationships were identified between alloying elements resulting in the identification of an optimized alloy composition. The final alloy showed significant improvements in creep and in hold time crack growth compared to state-of-the-art commercial alloys.

12:00 PM
Computational Development of Polycrystalline Alloys Using Automated Importance Sampling: *Bryce Conduit*[1]; Gareth Conduit[1]; Paul Mignanelli[1]; Howard Stone[1]; Mark Hardy[2]; [1]University of Cambridge; [2]Rolls-Royce plc

Increasingly stringent demands are being placed on alloys used for high temperature structural applications. For such applications, the successful development of new alloys requires them to exceed numerous property targets. Combinatorial alloy design tools to achieve this are now available. However, efficient selection of optimal alloy compositions requires automated optimisation algorithms. In this work, an approach utilising importance sampling has been used to design a new Ni-based polycrystalline alloy. Neural network models have been built to describe various mechanical and thermodynamic properties for Ni-based superalloys. Minimum acceptable values for these properties were then specified, according to design criteria. The boundary of those compositions which satisfy these minimum requirements was then established by the automated importance sampling technique. On a standard desktop computer this technique can output up to ~100000 sets of compositions and design variables per second, which satisfy the design specifications.

Materials in Clean Power Systems VII: Clean Coal-, Hydrogen Based-Technologies, and Fuel Cells: Materials for Clean Coal Technologies, Turbines

8:30 AM Invited
Corrosion and Materials Degradation in Microturbines: *Wendy Matthews*[1]; Karren More[2]; [1]Independant Consultant; [2]Oak Ridge National Laboratory

Microturbines operate on a number of different gaseous and liquid fuels. Some of the fuels are standard fuels (natural gas, diesel, kerosene), while others are alternative/renewable fuels (sour gas, landfill gas, digester gas, bio-diesel). Variations in alternative/renewable fuel composition and the normal operating conditions of the microturbine, even with standard fuels, present many materials challenges. Hot corrosion/sulfidation has been found in microturbine components exposed to fuels containing high

Sodium and/or Potassium (such as bio-diesel). Accelerated oxidation of components may also occur, most notably in thin foil Primary Surface Recuperators (PSR), as a result of the presence of water vapor in the products of combustion. Microstructural and compositional analyses of these types of materials degradation will be presented and various possible solutions will be discussed.

9:00 AM
Development of Cast Alumina-Forming Austenitic Stainless Steel Alloys: *Govindarajan Muralidharan*[1]; Yukinori Yamamoto[1]; Michael Brady[1]; Larry Walker[1]; [1]Oak Ridge National Laboratory

There is significant interest in the development of alumina forming creep resistant alloys for use in various industrial process environments. Earlier studies have outlined the development of wrought Alumina Forming Austenitic (AFA) alloys. These alloys achieve good high-temperature oxidation resistance due to the formation of protective Al2O3 scales while multiple second-phase precipitation strengthening contributes to excellent creep resistance. This work will summarize the results on the development of cast AFA alloys. Oxidation resistance and creep properties have been evaluated in the as-solidified condition and compared with that achieved in the wrought alloys over the temperature range of 650°C to 800°C. This talk will summarize the effect of alloying element additions on the oxidation and creep properties of cast AFA alloys.Research sponsored by the U.S. Department Of Energy, Office of EERE Industrial Technologies Program, under contract DE-AC05-00OR22725 with UT-Battelle, LLC.

9:20 AM
Impact of Casting Superheat on the Mechanical Properties of Traditionally Wrought Ni-Based Superalloys for USC Steam Turbines: *Paul Jablonski*[1]; Jeffery Hawk[1]; Daniel Purdy[2]; Philip Maziasz[3]; [1]US Department of Energy; [2]GE; [3]ORNL

The high temperature components within conventional coal fired power plants are manufactured from ferritic/martensitic steels. In order to reduce greenhouse gas emissions the efficiency of pulverized coal steam power plants must be increased. The proposed steam temperature in the Advanced Ultra Supercritical (A-USC) power plant is high enough (760°C) that ferritic/martensitic steels will not work due to temperature limitations of this class of materials; thus Ni-based superalloys are being considered. The full size castings are quite substantial: ~4in thick, several feet in diameter and weigh 5-10,000lb each half. Small scale castings of alloys 263 and 282 with comparable section size and controlled cooling rate were cast with three levels of superheat. A multi-step homogenization heat treatment was developed in order to better deploy the alloy constituents. The mechanical properties of the alloys (tensile and fatigue) as well as the microstructure are reported here.

9:40 AM
Mechanical Behavior of Tempered Martensitic Steels for Ultrasupercritical Steam Applications: *Jeffrey Hawk*[1]; Paul Jablonski[1]; Christopher Cowen[2]; [1]U.S. Department of Energy, National Energy Technology Laboratory; [2]United States Department of the Treasury

Advanced 9-12% Cr tempered martensitic steels form the majority of tonnage of components used in coal fired power plants that operate in the temperature range of 570-620°C. Computational and experimental alloy development efforts at NETL have focused on raising the use temperature of this steel class to 650°C. An improvement in alloy high temperature capability would increase power plant efficiency while decreasing the carbon footprint. This presentation focuses on microstructure feature design considerations for typical high temperature martensitic steels, primary microstructural stability concerns, the preservation of strengthening mechanisms and their high temperature mechanical behavior. Tensile and creep properties for these alloys relative to commercially available 9% Cr steels will be discussed. Microstructure development during processing and post processing microstructural changes due to creep will be discussed for newly developed NETL alloys as well as for COST E, B2, and FB2 alloys.

10:00 AM Break

10:10 AM
Influence of SO2 and Water on the Corrosion in Oxyfuel Coal Power Plant: *Axel Kranzmann*[1]; Alexander Findeisen[2]; [1]Federal Institute for Materials Research and Testing; [2]BTU Cottbus

The flue gas of coal fired Oxyfuel Power Plants is characterised by the high partial pressure of CO2, water and SO2/SO3. Experimental simulations of the gas corrosion in the temperature between 490 °C and 620 °C including the mechanical stress under working conditions and ash were performed. Tubular specimen and plates from power plant steels were prepared from industrial parts. The tubes were loaded with an inner pressure of about 270 bar was applied by steam. The comparison between these different experiments indicate that the main influence of the ash is due the reaction between ash and oxide layer and and higher sulphur oxide fugacity within the ash layer. A simple heuristic model to describe the role of water supporting the diffusion of SO2 and CO2 through the oxide layer is included in the discussion of the corrosion effects.

10:30 AM
Microstructure Characterization of Crept Ni-Base Alloys for High Temperature Use: *Jeffrey Hawk*[1]; John Sears[2]; Paul Jablonski[1]; [1]U.S. Department of Energy, National Energy Technology Laboratory; [2]URS, NETL

High temperature alloys typically use a combination of matrix strengthening precipitates, carbides and high dislocation density to impart strength. In Ni-base superalloys for use at high temperatures the main strengthening phase is gamma prime. Volume fraction and precipitate morphology are two important factors in alloy strength and influence matrix strength and deformation behavior in the alloy. The character of the grain boundaries as well as phase found there are also important in generating high temperature creep strength and long-term microstructure stability. This presentation will examine two alloys, Haynes 282 and Nimonic 105 as potential candidate alloys for steam turbine components. The microstructure of each alloy will be discussed from the point of view of the unstressed versus the stressed state (creep deformation), with important high temperature strengthening mechanisms highlighted. These features will be related to the creep behavior of the alloy.

10:50 AM
Strengthening Concepts & Mechanical Behavior of Ni-Base Alloys in A-USC Steam Turbines: *Jeffrey Hawk*[1]; Paul Jablonski[1]; [1]U.S. Department of Energy, National Energy Technology Laboratory

Experience with nickel-base alloys for use at 1400°F has shown that commercial, "off-the-shelf" nickel superalloys exist for these applications, and while promising, the alloy in the off-the-shelf condition may not provide for all long-term mechanical needs in steam. One alloy, Haynes 282, has shown robust capability in terms of starting microstructure (gamma prime size & volume fraction). Another alloy, Nimonic 105, has exhibited the potential for improved creep behavior in the peak aged condition as well as when aged. These alloys are among several that offer the best potential for building steam turbine components for a power plant operating at =1400°F. Design strategy, strengthening concepts and creep behavior will be discussed for each alloy, highlighting differences in each alloy and their respective strengths relative to use as steam turbine components. Suggestions for improving alloy performance will also be discussed.

11:10 AM
The Effect of Temperature on Equilibrium of Coal-Petcoke Slag Mixtures under Gasification Conditions: *Jinichiro Nakano*[1]; Sudhir Ranjan[2]; Kye-Sing Kwong[1]; James Bennett[1]; Xueyan Song[3]; Seetharaman Sridhar[2]; [1]NETL; [2]Carnegie Mellon University; [3]West Virginia University

In gasifiers, molten slags forming from non-volatile impurities from carbon feedstock are known to cause wear of the protective liner materials. A recent industrial trend of increased use of petcoke to coal feedstock has drastically modified slag chemistry due to the high vanadium content, and caused new chemical equilibria in the slag system. In this work, synthetic slags corresponding to coal-petcoke fuel mixtures were studied for phases present under gasification conditions. Equilibration of samples (SiO2-Al2O3-Fe2O3-CaO-V2O5) exposed at 1425, 1500, and 1575°C in Po2=10-8atm for 72 hours, samples containing up to 9 wt% V2O5 was investigated by XRD, SEM-WDX, ICP, and TEM. Mullite, karelianite, and anorthite were found in equilibrium with slag at 1425°C, while mullite and karelianite were predominant at higher temperatures. The slag homogeneity expanded with increasing temperature. The presence of the solid phases is discussed in terms of its impacts on slag fluidity and refractory degradation.

11:30 AM

Nano-Scale Carbide Characterization in a Tempered Martensitic 9Cr Steel Used for Ultrasupercritical Steam Power Plants: *Niven Monsegue*[1]; Mitsuhiro Murayama[1]; William Reynolds[1]; [1]Virginia Tech

The 9Cr steel designated COST B2 is currently used in various USC coal power plant applications; however, microstructural stability under various service conditions such as evolution of strengthening factors has not been fully understood. In this study, three samples of COST B2 consisting of as-cast and two creep tested COST B2 were examined by transmission electron microscopy. The creep test parameters were: (1) 650°C for 655 hrs with 172 MPa stress and (2) 650°C for 2039 hrs with 138 MPa. Particular focus was placed on nano-size carbides, one of the major creep resistance factors in COST B2, and their correlating characteristics with varying stress and temperature.

Materials Research in Microgravity: Session V

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS Extraction and Processing Division, TMS: Process Technology and Modeling Committee, TMS: Solidification Committee

Program Organizers: Robert Hyers, University of Massachusetts; Hani Henein, University of Alberta; Valdis Bojarevics, University of Greenwich; James Downey, NASA; Douglas Matson, Tufts University; Achim Seidel, Astrium; Daniela Voss, ESA

Wednesday AM — Room: Asia 3
March 14, 2012 — Location: Dolphin Resort

Session Chair: To Be Announced

8:30 AM Invited

Solidification Modeling: from Electromagnetic Levitation to Atomization Processing: *Charles-Andre Gandin*[1]; D. Tourret[2]; T. Volkmann[2]; D. Herlach[2]; A. Ilbagi[3]; H. Henein[3]; [1]MINES ParisTech; [2]DLR; [3]University of Alberta

A segregation model for multiple phase transformations is presented together with solidification experiments using electromagnetic levitation. Comparison is made between predictions and measurements. Thanks to coupling with thermodynamic equilibrium calculations, as well as the treatment of dendritic, peritectic and eutectic reactions, quantitative agreement is found for the cooling curves and the fraction of microstructures measured, thus providing a validation of the kinetics of phase transformations. Application is then possible for the impulse atomization process. It reveals the importance of the competition between the various microstructures formed from the melt and the role of the nucleation and growth kinetics. Simulation for samples processed by electromagnetic levitation in the ISS in 2013 will be performed.

9:05 AM Invited

X-Ray Radiographic Observation of Directional Solidification under Microgravity: XRMON-GF Experiments on MASER12 Sounding Rocket Mission: *Guillaume Reinhart*[1]; Henri Nguyen-Thi[1]; Aboul-Aziz Bogno[1]; Bernard Billia[1]; Ragnvald Mathiesen[2]; Gerhard Zimmermann[3]; Ylva Houltz[4]; Kenneth Löth[4]; Daniela Voss[5]; Antonio Verga[5]; Fabio De Pascale[5]; [1]IM2NP - Université Paul Cézanne; [2]NTNU; [3]ACCESS e.V; [4]Swedish Space Corporation; [5]European Space Agency

The European Space Agency (ESA) - Microgravity Application Promotion (MAP) programme entitled XRMON (In situ X-Ray MONitoring of advanced metallurgical processes under microgravity and terrestrial conditions) aims to develop and perform in situ X-ray radiography observations of metallurgical processes in microgravity and terrestrial environments. The use of X-ray imaging methods makes it possible to study alloy growth processes with spatio-temporal resolutions at the scales of relevance for microstructure formation. XRMON has been selected for MASER 12 sounding rocket experiment, scheduled in autumn 2011. Although the microgravity duration is typically six minutes, this short time is sufficient to investigate a solidification experiment with X-ray radiography. This communication will report on the preliminary results obtained with the experimental set-up developed by SSC (Swedish Space Corporation). Results deal with the directional solidification of Al-Cu and they confirm the great interest to perform in situ characterization to analyse dynamical phenomena during solidification processes.

9:40 AM

Innovative Video Diagnostic Equipment for Material Science Experiments in Space

: *Giuseppe Capuano*[1]; Daniele Titomanlio[1]; Wolfgang Soellner[2]; Achim Seidel[2]; [1]Techno System Developments; [2]Astrium

Materials science experiments under microgravity increasingly rely on advanced optical systems to determine the physical properties of the samples under investigation. This includes video systems with high spatial and temporal resolution. The acquisition, handling, storage and transmission to ground of the resulting video data are very challenging. Since the available downlink data rate is limited, the capability to compress the video data significantly without compromising the data quality is essential. We report on the development of a Digital Video System for EML which provides real-time video acquisition, high compression using advanced Wavelet algorithms, storage and transmission of a continuous flow of video with different characteristics in terms of image dimensions and frame rates. The DVS is able to operate with the last generation of high-performances cameras acquiring high resolution video images up to 4Mpixels at 15 fps or high frame rate video images up to 1000 fps at 256x256pixels.

Three-Dimensional Interface Pattern Evolution in Directional Solidification under Mimcrogravity Conditions: Nathalie Bergeon[1]; Anthony Ramirez[1]; L Chen[1]; Bernard Billia[1]; Alain Karma[2]; Jiho Gu[3]; Min Xu[3]; *Rohit Trivedi*[3]; [1]Université Paul Cézanne; [2]Northeastern University; [3]Iowa State University

Experiments under low gravity conditions have been carried out on the International Space Station using the Directional Solidification Insert in the DECLIC facility to investigate the dynamic of spatially extended three-dimensional array of cells and dendrites under diffusive growth conditions. Experiments were conducted in a transparent system of succinonitrile-0.24 wt% camphor alloy, and the dynamics of three-dimensional interface pattern evolution under different growth conditions were visualized in situ through two cameras (bright field) and a laser interference technique. Several important results on the dynamics of three-dimensional pattern evolution will be presented with a detailed analysis of the time-evolution of their spatial arrangement. New observations on the formation of multiplets in three-dimensions will be described and novel oscillating modes were observed during the cellular growth at low velocity in which the hexagonal array split into three groups of cells showing oscillations in time with a phase difference of 1/3 with each other.

11:00 AM
Containerless Measurements of Density and Viscosity of Fe-Co Alloys: *Jonghyun Lee*[1]; Douglas Matson[2]; Robert Hyers[3]; [1]Tufts University and UMass Amherst; [2]Tufts University; [3]University of Massachusetts

During the past years, extensive collaborative research has been done to understand phase selection in undercooled metals using novel containerless processing techniques such as electrostatic and electromagnetic levitation. Of major interest is controlling a two-step solidification process, double recalescence, in which the metastable phase forms first and then transforms to the stable phase after a certain delay time. The previous research has shown that the delay time is greatly influenced by the internal convection velocity. In the prediction of internal flow, the fidelity of the results depends on the accuracy of the material properties. This research focuses on the measurements of density and viscosity of Fe-Co alloys which will be used for the fluid simulations whose results will support upcoming International Space Station flight experiments.

11:25 AM
TEMHD Effects On Solidification under Micrograviy Conditions: Andrew Kao[1]; *Koulis Pericleous*[1]; [1]University of Greenwich

An unexplored potential exists to control microstructure evolution through the use of external DC fields. Thermoelectric currents form during solidification and interact with this external field to drive microscopic fluid dynamics within the inter-dendritic region. The convective heat and mass transport can have profound changes on the dendritic structure. Levitation/confinement and control of the macroscopic fluid dynamics is often achieved through the combined use of both AC and DC magnetic fields. In the absence of gravity the effect of the AC field can be used purely for positioning, while the DC field can be chosen to be significantly large to interact with the thermoelectric currents. In this paper the effect of high magnetic fields on a solidifying droplet is demonstrated through the use of both 3-dimensional and 2-dimensional models. The results show that the application of a magnetic field causes significant disruption to the dendritic morphology.

Mechanical Behavior at Nanoscale I: Deformation/strength at Nanoscale and Li-induced Deformation

Unveiling the Strengthening and Toughening Mechanisms of Nacre – Lessons from Nature: *Xiaodong Li*[1]; [1]University of South Carolina

Nacre is a natural nanocomposite with superior mechanical strength and eminent toughness. What is the secret recipe that Mother Nature uses to fabricate nacre? What roles do the nanoscale structures play in the strengthening and toughening of nacre? Can we learn from this to produce nacre-inspired nanocomposites? The recent discovery of nanoparticles in nacre is summarized, and the roles these nanoparticles play in nacre's strength and toughness are elucidated. It was found that rotation and deformation of aragonite nanoparticles are the two prominent mechanisms contributing to energy dissipation in nacre. The biopolymer spacing between nanoparticles facilitates the particle rotation process. Individual aragonite nanoparticles are deformable. Dislocation formation and deformation twinning were found to play important roles in the plastic deformation of individual nanoparticles, contributing remarkably to the strength and toughness of nacre upon dynamic loading. This talk also presents future challenges in the study of nacre and nacre-inspired materials.

9:00 AM
Size Effect on the Mechanical Behaviour of GaAs Nanowires: *Yanbo Wang*[1]; Qiang Gao[2]; Xiaozhou Liao[1]; Yiu-Wing Mai[1]; Chennupati Jagadish[2]; [1]The University of Sydney; [2]The Australian National University

The mechanical properties of semiconductor nanowires (NWs) are of great importance for NW applications because they affect the reliability and functionality of NW-based devices. Recent investigations showed that mechanical strain in NWs can significantly change the optical, electrical and magnetic properties of the NWs. Here, we applied an in-situ transmission electron microscopy (TEM) nano-compression technique and finite-element analysis (FEA) to investigate the mechanical behaviour of GaAs NWs. Our results demonstrate significant size effect on the mechanical behaviour of the NWs: (1) the elastic strain limit of NWs with diameters of 50–150 nm is ~ 11%, which is 100 times higher than that of conventional bulk ceramics; (2) obvious plastic deformation occurs in NWs with diameters smaller than 25 nm; and (3) a repeatable self-healing process takes place in partially fractured NWs with diameters smaller than 15 nm that restores their original structure after the external compressive force is removed.

9:20 AM
Plasticity of Metal Nanoparticles in Nanoextrusion: *Antti Tolvanen*[1]; Karsten Albe[1]; [1]TU-Darmstadt

Recent transmission electron microscopy experiments have shown how nanoparticles can be encapsulated inside carbon onions and electron irradiation induced contraction of these onions can be used to apply pressure of tens of GPa to the encapsulated particle. If an orifice is opened to the carbon onion, this system can be used to study the extrusion of the encapsulated material and thus the plasticity of individual crystallites at the nanoscale. In this study, the results of molecular dynamics simulation of the extrusion of Cu, Pd and Al nanoparticles pressurised in spherical force field mimicking the behaviour of contracting carbon onion are presented. We compare the plastic behavior single-crystalline nanoparticles of Cu, Pd and AL with multiply-twinned nanoparticles. The effects of the different stacking fault energies of Cu and Pd, and the effect of twins on the dislocation nucleation and propagation is reported and a pressure driven athermal amorphisation process is presented.

9:40 AM
Anisotropic Swelling of Si Nanowires and Size-Dependent Fracture of Si Nanoparticles during Lithiation: *Xiaohua Liu*[1]; He Zheng[2]; Li Zhong[2]; Shan Huang[3]; Khim Karki[4]; Li Qiang Zhang[2]; Yang Liu[1]; Akihiro Kushima[5]; Wen Tao Liang[6]; Jiang Wei Wang[2]; Jeong-Hyun Cho[7]; Eric Epstein[4]; Shadi Dayeh[7]; Tom Picraux[7]; Ting Zhu[3]; Ju Li[5]; John Sullivan[1]; John Cumings[4]; Chunsheng Wang[4]; Scott Mao[2]; Zhi Zhen Ye[8]; Sulin Zhang[6]; Jian Yu Huang[1]; [1]Sandia National Laboratories; [2]University of Pittsburgh; [3]Georgia Institute of Technology; [4]University of Maryland; [5]University of Pennsylvania; [6]Pennsylvania State University; [7]Los Alamos National Laboratory; [8]Zhejiang University

We report direct observations of an unexpected anisotropic swelling of Si nanowires and a size-dependent fracture of Si nanoparticles during lithiation with advanced in situ transmission electron microscopy (TEM). Lithiation of the <112>-oriented Si nanowires resulted in anisotropic expansion (larger swelling along <110> than along <111>)

and a dumbbell-shaped cross-section, due to plastic flow and an ensuing necking instability that was induced by the tensile hoop stress buildup in the lithiated shell. A strong size-dependent fracture behavior of Si nanoparticles was discovered, i.e., there exists a critical particle diameter of ~ 150 nm, below which the particles did not crack, above which the particles first formed surface cracks and then fractured, due to lithiation-induced swelling and the buildup of large tensile hoop stress in the surface layer. These results provide direct evidence of the mechanical robustness of small silicon nanoparticles for their applications in lithium ion batteries.

10:00 AM Break

10:10 AM Invited
Physical Origin of Large Strain Bursts in Submicron Al Pillars: Zhangjie Wang[1]; Yuan Gao[2]; Qingjie Li[1]; *Zhiwei Shan*[1]; Ju Li[3]; Zhuo Zhuang[2]; Jun Sun[1]; Evan Ma[4]; [1]Center for Advancing Materials Performance from the Nanoscale (CAMP-Nano) & Hysitron Applied Research Center in China (HARCC), State Key Laboratory for Mechanical Behavior of Materials, Xi'an Jiaotong University; [2]Applied Mechanics Laboratory, School of Aerospace, Tsinghua University, Beijing; [3]Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, Massachusetts Institute of Technology; [4]Department of Materials Science and Engineering, Johns Hopkins University

Compression testing of micro- and nano- sized Al pillars indicate two sample size regimes with contrasting mechanisms underlying the large strain bursts. For small pillars the bursts originate from the inability to store dislocation network inside, characterized by ultrahigh collapse stresses and nearly pristine postmortem microstructure. For larger pillars the bursts result from the destruction of jammed dislocation configurations, featuring relative low stress level and retention of dislocation networks after bursts. Computer simulations reveal a critical pillar size required to form "junction-chain" structures for robust dislocation jamming.

10:30 AM
In-Situ Transmission Electron Microscopy Observation of Discrete Hopping Lithiation in ZnO Nanowire: *Akihiro Kushima*[1]; Xiao Liu[2]; Guang Zhu[3]; Ju Li[4]; Zhong Wang[3]; Jian Huang[2]; [1]Department of Materials Science and Engineering, University of Pennsylvania; [2]Center for Integrated Nanotechnologies, Sandia National Laboratories; [3]School of Materials Science and Engineering, Georgia Institute of Technology; [4]Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, Massachusetts Institute of Technology

The charging processes of individual ZnO nanowire (NW) electrode in Li-ion battery configuration were observed by in situ transmission electron microscopy. A unique reaction front morphology and dynamics, causing the single-crystalline NW to become a nanoglass (H. Gleiter, MRS Bulletin 34 (2009) 456), was discovered. First, partial lithiation of crystalline NW induces large stress and nanocracking ~70nm in front of the main lithiation front. This is followed by rapid surface diffusion of Li+ and solid-state amorphization along the open crack surfaces. Finally the crack surfaces merge, leaving behind an amorphous-amorphous interface and possibly residual voids. Such reaction front instability also repeats in the interior, further subdividing the NW into different nanoglass domains (nanoamorphization). Our observations lead to important insight for developing battery with better performance and cyclability. Furthermore, the results highlight the importance of lithium embrittlement in battery behavior.

10:50 AM
Multiple-Stripe Lithiation Mechanism of Individual SnO2 Nanowires in a Flooding Geometry: Jianyu Huang[1]; Scott Mao[2]; *Li Zhong*[2]; Xiaohua Liu[1]; Guofeng Wang[2]; [1]Center for Integrated Nanotechnologies, Sandia National Laboratories; [2]Department of Mechanical Engineering and Materials Science, Univ. of Pittsburgh

The atomic scale lithiation mechanism of individual SnO2 nanowires in a flooding geometry was revealed by in situ transmission electron microscopy. The lithiation was initiated by the formation of multiple stripes with a width of a few nanometers parallel to the (020) plane traversing the entire wires, serving as multiple reaction fronts for later stages of lithiation. Inside the stripes, we identified a high density of dislocations and enlarged interplanar spacing, which provided an effective path for lithium ion transport. The density of the stripes increased with further lithiation, and eventually they merged with one another, causing a large elongation, volume expansion, and the crystalline-to-amorphous phase transformation. This lithiation mechanism characterized by multiple stripes and multiple reaction fronts was unexpected and differed completely from the expected core-shell lithiation mechanism.

11:10 AM
Thickness Dependent Deformation Behaviour of Multilayer Metallic Nanopillars: *Mark Hoffman*[1]; Pranesh Dayal[1]; Nick Savvides[1]; [1]The University of New South Wales

The creation of metallic nanolayered structures leads to a significant increase in hardness with decreasing layer thickness. The exact mechanism of this nanohardening remains however contentious. In this study we have created Al/Pd nanolayered structures, based upon the theory of Koehler, with equal layer thickness of each material ranging from 1 to 20 nm thickness. A profound increase in hardness measured by nanoindentation is observed as layer thickness falls below 10 nm. We have then created nanopillars of 1, 10 and 20 nm thickness. It is found that the deformation changes from brittle cross-pillar shearing with high flow stress, to extrusion of the Al phase with increasing layer thickness at lower stress. TEM cross-sections of the compressed pillars reveals the presence of grain rotation within the layers of some thickness providing elucidation of the deformation mechanism and the nanohardening process.

11:30 AM
***In Situ* TEM Electrical Contact Indentation Observations in Doped Si Nanopillars**: *Douglas Stauffer*[1]; Sanjit Bhowmick[1]; Sergei Krylyuk[2]; Albert Davydov[2]; Ryan Major[1]; [1]Hysitron, Inc.; [2]Metallurgy Division, Material Measurement Laboratory (MML)

Shrinking dimensions of microelectronic devices and rapid development of nanostructured materials require novel techniques to measure electrical and mechanical properties of materials at the nanoscale. However, typical electrical measurements are done with very large probe radii or toxic materials such as mercury. Here, a depth sensing indenter is used to simultaneously probe the electrical and mechanical responses of silicon nanostructures. VLS-grown silicon pillars, with diameters from 120 nm to 160 nm and up to 800 nm in length are contacted in situ using both TEM and SEM to aid in positioning. Moduli values less than bulk Si, 121±16 GPa, are found. Absolute conductance measurements show increases in contact area as the probe meets the indenter followed by changes depending on the amount and type of plasticity caused by compression. From these measurements, true conductivity can be found knowing contact resistance and dimensions of the nanostructure.

11:50 AM
Multiscale Modeling of Anisotropic Growth in Lithiated Silicon Nanowires: *Sulin Zhang*[1]; Hui Yang[1]; Xu Huang[1]; Shan Huang[2]; Ting ZHu[2]; [1]The Pennsylvania State University; [2]Georgia Tech

We formulated a multiscale model to account for the anisotropic growth of lithiated silicon nanowires. On the atomic level, molecular dynamics simulations coupled with pathway sampling schemes were employed to compute the migration barriers of lithium ions in stressed silicon nanowires. The derived lithium diffusivity was then passed into a continuum-level diffusion equation, which is further coupled to the stress field calculations based on finite element analysis. The multiscale model provides atomistic mechanisms of lithiation of silicon nanowires, and explains well the anisotropic growth of lithiated silicon nanowires.

12:10 PM
Study of Dislocation Climb at Nanovoids in BCC Metal: *Mishreyee Bhattacharya*[1]; A. Dutta[2]; A. Giri[1]; N. Gayathri[1]; P. Barat[1]; [1]Variable Energy Cyclotron Centre; [2]Jadavpur University

Defects of the order of nanometer size, often created by radiation damage in metals in nuclear reactors form obstacles to dislocation glide and eventually affect the mechanical properties. Depending on the material and irradiation conditions, point defects agglomerate to form nanovoids and in-silico methods are most fruitful in providing detailed information about this dislocation-nanovoid interaction to model material properties. Here, we employ techniques of atomistic simulation to investigate the dislocation-nanovoid interaction in bcc Molybdenum, where the phenomenon of climb has occurred. Though void-mediated dislocation climb has been reported in recent molecular statics and dynamics simulations, the underlying mechanism is not yet revealed. We have performed simulations by varying depinning load and nanovoid size as well. These results suggest the possibility of a mechanism of dislocation climb, which can be fundamentally different from the conventional diffusion based process. In this work, the distinctive features of this void-mediated dislocation climb are highlighted.

Mechanical Behavior Related to Interface Physics: Interface Structures: Characterization, Theory, and Modeling

8:30 AM Keynote
Disconnection Mechanisms in Twin Growth: *Robert Pond*[1]; [1]University of Exeter

The basic mechanism of twin growth is the motion of dislocations along the twin plane. The Burgers vectors and step heights of admissible disconnections can be predicted using topological theory. However, for a fuller understanding, atomic-scale simulations are necessary, and recent progress is illustrated and discussed. The intrinsic mobility of a glissile disconnection is generally enhanced by a wide core structure, small step height, and minimal shuffling. Glissile disconnections are not necessarily blocked on encountering a sessile disconnection: modest applied stresses enable such obstacles to be overcome in a mechanism that is conservative overall. In a similar mechanism, a sessile disconnection under stress can act as a source for glissile disconnections, leading to irregular boundaries, as seen experimentally in Ti for example. Growth of deformation twins is suppressed by twin blunting: observations and simulations of this process in Al are presented, and contrasted with the low stacking-fault energy material Ni2MnGa.

9:00 AM Keynote
Exploiting the Atomic Structure of Interfaces in Crystalline Solids: *Richard Hoagland*[1]; Jian Wang[1]; Michael Demkowicz[2]; Amit Misra[1]; [1]Los Alamos National Laboratory; [2]MIT

The atomic structure of interfaces defines their properties and thereby the properties they impart to polycrystalline and polyphasic materials. This talk focuses primarily on the atomic structures of a few types of interfaces that have been observed in fcc/bcc composites. In spite of the relative simple crystallographic orientations, the differences in lattice parameter of the constituents leads to rather complex structures that are nearly periodic. Misfit dislocations in these structures are discussed and are shown to account for high strength by impeding slip, and to act as potent sinks for Frankel defects. The structure of interfaces is shown to depend on orientation and misfit strain, variables the may be adjusted to alter both mechanical strength and sink strength in controllable ways. This work was supported by Los Alamos National Laboratory Directed Research and Development project ER20110573 and the US Department of Energy, Office of Science, Office of Basic Sciences.

9:30 AM
Atomic Cu/Nb Interface Structures Characterized by Transmission Electron Microscopy: *Shijian Zheng*[1]; Weizhong Han[1]; Robert Dickerson[1]; Nathan Mara[1]; [1]Los Alamos National Laboratory

Cu/Nb nanosize multilayered composites have shown high strength and high ductility which are due to their high density of interfaces. In this work, Cu/Nb nanolayered composites were prepared by accumulative roll bonding (ARB). To understand the interface effect on mechanical behavior, atomic Cu/Nb interface structures were studied by (scanning) transmission electron microscopy (TEM). It was found that Cu and Nb often have {112} KS orientation relationship, and their interfaces are faceted. The faceted interfaces are closely linked to twinning in Cu. Also, composition gradients at the interfaces were characterized by scanning transmission electron microscopy (STEM), energy dispersive X-ray spectroscopy (EDS) and electron energy loss spectroscopy (EELS). The effect of deformation on intermixture of Cu and Nb, as well as O segregation at the interfaces will be discussed.

9:45 AM
Evaluation of Twin Boundary Interfaces to Strain Hardening by Electron Channeling Contrast Imaging: *Ivan Gutierrez-Urrutia*[1]; Dierk Raabe[1]; [1]Max-Planck-Institut for Iron Research

The formation of twin interfaces during deformation of FeMn alloys leads to an outstanding strain-hardening behavior, the so-called twinning induced plasticity (TWIP) effect. Because of the nanoscale size of the twins, the quantitative characterization of these interfaces and accordingly, their influence on strain hardening is still a challenging task. Conventional electron microscopy techniques, such as electron backscatter diffraction (EBSD) and transmission electron microscopy (TEM) are limited due to the low angular resolution and small field of view, respectively. We present a quantitative characterization of twin substructure by electron channeling contrast imaging (ECCI) in a FeMnC alloy. A novel ECCI set-up is used which makes use of EBSD to obtain twin and dislocations images at optimum contrast. The influence of initial grain size and crystal orientation on twin substructure is analyzed. The role of twin interfaces on strain hardening mechanisms and their interaction with the underlying dislocation substructure will be discussed.

10:00 AM
Ultra Fast Grain Boundary Segregation In Hot Deformed Nickel: *Marion Allart*[1]; Frédéric Christien[1]; René Le Gall[1]; [1]Université de Nantes

Hot deformation of nickel alloys (500-800°C) can lead to a dramatic loss of mechanical properties due to sulfur grain boundary segregation. In this work, both equilibrium and non-equilibrium sulfur grain boundary segregation in nickel were studied at 550°C. They were obtained respectively by simple annealing and by hot-compression. Segregation was quantified by Wavelength Dispersive X-ray Spectroscopy and was found to be thousands of times as fast during hot-compression as during annealing at the same temperature: it takes about 20 minutes at 550°C to saturate the grain boundaries with sulfur during compression at 3.10^{-5} s^{-1}, whereas three months are needed by simple annealing at the same temperature. Cross-section observations show that subgrains form during hot compression. A model based on sulfur diffusion along the subgrain boundaries (dislocation walls) enables to account for the observed ultra-fast segregation during hot-compression.

The Role of Interfacial Interaction Stresses and Crystallography on Deformation Mechanisms of Two-Phase Titanium Alloys: William Joost[1]; Zane Wyatt[1]; *Sreeramamurthy Ankem*[1]; [1]University of Maryland

The deformation mechanisms and mechanical properties of two-phase titanium alloys strongly depend upon the crystallographic relationship between phases. The crystallographic relationships, in turn, determine the nature of the interaction stresses that are needed to maintain compatibility at the interfaces. In this study, the interaction stresses at the alpha-beta interfaces were determined by the finite element method. It is shown that interaction stresses combined with the applied stress will influence the deformation mechanisms in two-phase titanium alloys. It was found that the deformation mechanisms in two-phase titanium alloys can be different than those found in the respective single-phase alloys. For example, during low-temperature creep a single-phase beta titanium alloy deforms by twinning, but the same beta phase in the presence of an alpha phase deforms by stress induced martensite. Details of the investigation will be presented. This work is being supported by the National Science Foundation under grant number DMR-0906994.

10:55 AM
Quantitative NanoSIMS Analysis of Grain Boundary Segregation in Bulk Samples: *Frederic Christien*[1]; Katie Moore[2]; Clive Downing[2]; Chris Grovenor[2]; [1]University of Nantes; [2]University of Oxford

Solute grain boundary (GB) segregation is an important metallurgical phenomenon that has been extensively studied, especially by Auger spectroscopy of fractured surfaces. More recently, it has been demonstrated that High Resolution SIMS (NanoSIMS) analysis can detect solute GB segregation on a simple polished cross-section. The aim of this work is to demonstrate the ability of NanoSIMS to achieve quantitative analysis of GB segregation. The material used in this study is high purity nickel containing 5 wt ppm of sulfur. Samples were annealed at different temperatures to get different equilibrium sulfur GB concentrations, ranging from about 1% to 50% of a monolayer. For each sample, about 20 GBs were analyzed by NanoSIMS. The measured GB sulfur concentrations range from ~0.02 to 0.5 monolayer and are in very good agreement with the data from literature. The potential advantages of this new technique with respect to Auger spectroscopy are discussed.

11:10 AM
Increased Adhesion of Cr-PI Interface at High Temperatures: *Megan Cordill*[1]; Aidan Taylor[1]; Gerhard Dehm[2]; [1]Erich Schmid Institute of Materials Science; [2]Dept. Material Physics

Metal films on polymer substrates are used in flexible electronics and gas barrier applications and the adhesion between films and substrates is essential. Chromium adhesion layers are used to enhance film adhesion for Cu and Au conduction lines. The use of conduction lines involves elevated temperatures making it important to understand how adhesion is affected by temperature. The adhesion energy of Cr-polyimide interfaces has been quantified using tensile straining and the resulting compression-induced buckles. This analysis has been made for films strained at 25C, at 350C and annealed at 350C and strained at 25C. Tensile straining at 350C caused an increase in the buckling strain and in the adhesion. TEM examination of the Cr/PI interface revealed a 3-4 nm interlayer prior to heating and after annealing indicates a change in the interface structure and chemistry. These changes in the interfacial microstructure and chemistry directly correlate to the measured adhesion values.

11:25 AM
Atomistically Informed Dislocation Dynamics Simulations on Dislocation-Interface Interactions: *Caizhi Zhou*[1]; Jian Wang[2]; Irene Beyerlein[2]; Curt Bronkhorst[2]; [1] Los Alamos National Laboratory; [2]Los Alamos National Laboratory

Atomic-scale modeling of unit processes suggests that the mechanical properties of nanoscale composites under deformation are dominated by defect-interface interactions. Discrete dislocation dynamics (DD) simulations, in which dislocations are the simulated entities, offer a way to extend length and time scales beyond those of atomistic simulations. In this study, we develop a DD simulation model based on experiment observation and atomic scale simulations to study the dislocation-interface interactions at micro- and nanoscales and provide a generic bi-metal interface model that represents the key characteristics of the structure and properties of the interface. In order to capture the fundamental physics of dislocation-interface interactions, dislocation annihilation, nucleation and emission from the interface are all considered in our simulations, which is different from traditional DD simulations on single-phase materials. Our DD-interface model can improve current knowledge of macroscopic mechanical properties of nanoscale composites with the knowledge gained from simulation results.

11:40 AM
The Periodic Unit of Doubly-diffracted Reflections from Periodic Grain Boundaries in Cubic Crystals and Its Relationship with Coincident Site Lattice: *Mohammad Shamsuzzoha*[1]; [1]University of Alabama

A geometrical formulation is provided of how double diffraction from a periodic grain boundary in a cubic crystal yields doubly diffracted reflection unit within the space of a coincident site of reciprocal lattice (CSRL). The doubly diffracted reflection unit is a primitive zero layer displacement shift complete (ZLDSC) unit of the coincident site of reciprocal lattice. Its reciprocal transformation yields a real space unit of coincident site lattices that includes the real zero layer coincident site lattice(CSL)of the periodic boundary. The formulation is applied in a case study on the determination of the CSL from the double diffraction patterns of a S3 [110]/ (111) grain boundary of Al.

Mechanical Performance of Materials for Current and Advanced Nuclear Reactors: Irradiation and Testing of Fuels and Cladding Materials

8:30 AM Invited
In-Situ and Post Irradiation Mechanical Testing of Ion Irradiated Materials: *Gary Was*[1]; Anne Campbell[1]; Vani Shankar[2]; Cheng Xu[1]; [1]University of Michigan; [2]IGCAR

Ion irradiation offers the capability to conduct well controlled, in-situ mechanical property experiments as well as ex-situ tests of the response of materials to irradiation and stress. In-situ irradiation creep provides a unique opportunity to track creep rate continuously in real time in the low dose regime. We have developed the capability to conduct irradiation creep on both metallic and non-metallic materials to study their behavior in their respective realms of application. Creep in ferritic-martensitic steels is measured in the 1-3 dpa range at dose rates up to 10-5 dpa/s and temperatures from 400-600°C relevant to fast reactor core structural materials, while creep in graphite, pyrolytic carbon and SiC are being studied in the temperature range 900-1200°C, appropriate to TRISO fuel particles in the VHTR. In addition, irradiation hardening, the evolution of localized deformation and stress corrosion cracking of irradiated austenitic alloys have provided important insights to their microstructural origins.

9:00 AM

Ion Implantation as a Neutron Analogue in Tungsten Alloys: Measuring Mechanical Properties: *David Armstrong*[1]; Steve Roberts[1]; Angus Wilkinson[1]; [1]University of Oxford

Tungsten and tungsten alloys are promising materials for plasma facing components, especially the divertor, for nuclear fusion power plants. The effects of neutron irradiation on mechanical properties are of great importance. Specimens of pure tungsten, and W-5%Ta and W-5%Re were irradiated using 2 MeV W ions, at 350°C, producing damage levels of 0.07dpa to 33dpa in a layer of depth ~300nm. Nanoindentation showed a significant increase in hardness in the implanted layer. The hardness increases are greatest in the W-5Ta alloy and smallest in the pure W. The hardness increases most rapidly in the low dose range, and appears to saturate by 13dpa. Atomic-force-microscopy was used to study plastic flow patterns around the nano-indents in W-5wt%Ta. Significant pile-up is seen in the unirradiated samples, however even damage levels of 0.07dpa causes pile up to be almost totally suppressed. This may indicate a change in work-hardening behaviour after irradiation.

9:20 AM

In-Situ Proton Irradiation Creep of Ferritic-Martensitic Steel T91: *Cheng Xu*[1]; Gary Was[1]; [1]University of Michigan

In-situ proton irradiation creep of F-M steel T91 exhibits linear dose rate and stress dependence at 500°C. Microstructure analyses of irradiation creep samples were conducted to relate microstructure evolution to macroscopic behavior to achieve full understanding of irradiation creep. Hardness measurements were made on the T91 sample to quantify hardening during irradiation creep. TEM investigation of irradiation creep T91 samples at different stresses and temperatures were made on the <100> and <111> zone axes using a JOEL 2010 TEM. Irradiation hardening occurred after irradiation creep up to 1dpa, and the amount of hardening decreased with increasing applied stress. Analysis of the microstructure of crept samples irradiated to 1 dpa revealed mainly ao<100> dislocation loops dispersed homogenously within the sample. The dislocation loop sizes at 1dpa are comparable to those found for unstressed irradiations at 3dpa. This talk will focus on the correlation of irradiation creep behavior and the irradiated microstructure.

9:40 AM

In-Situ Ion Irradiation TEM and Nanoindentation Studies of 316L and HT9: *Khalid Hattar*[1]; Alexander McGinnis[2]; Thomas Buchheit[1]; Luke[2]; [1]Sandia National Laboratories; [2]Naval Postgraduate School

To validate new cladding materials or predict the properties of existing reactors under extended life conditions, techniques are needed that permit insight into the microstructural and mechanical property evolution that occurs under these extreme environments. This presentation will highlight the recent improvements made to the in-situ ion irradiation TEM at Sandia and the resulting additional capabilities. To highlight these capabilities, in-situ ion irradiation of both 316L and HT9 samples prepared by FIB lift-out will be presented. In addition, the nanoindentation results from 316L stainless steel and HT9 irradiated under various conditions, as well as diffusion coupled with various refractory metals, will be presented. To relate the microstructural evolution to the nanoindentation results, a FEM incorporating a SRIM-based vacancy distribution profile will be provided. The combination of in-situ ion irradiation TEM and small scale mechanical property testing of ion irradiated materials provides a rapid method for characterizing microstructural evolution.

10:00 AM

On the Radiation Growth in HCP Metals: *Stanislav Golubov*[1]; Alexander Barashev[1]; Roger Stoller[1]; [1]ORNL

Many models of radiation growth proposed to date are based on the assumption that the primary damage produced by neutron irradiation is in the form of single point defects. These models do not account for the most important features of the primary damage under neutron irradiation, namely, intra-cascade clustering of self interstitial atoms and their one dimensional diffusion. During the last twenty years 'Production Bias Model' has been developed, which takes into account the cascade properties. Since the cascades in HCP metals, e.g. Zirconium, are found to be similar to those in cubic crystals, the PBM should provide realistic framework for the HCP metals as well. The main objective of the present work is to describe this model and demonstrate that all the usual growth stages are explained. The conditions leading to particular observations, such as the so-called "negative growth" and coexistence of vacancy and interstitial a-type loops are revealed.

10:40 AM

Grain Size Effect on Radiation Induced Defect Morphology in Nanocrystalline Iron: *Greg Vetterick*[1]; Chris Barr[1]; John Baldwin[2]; Khalid Hattar[3]; Mark Kirk[4]; Pete Baldo[4]; Amit Misra[2]; Mitra Taheri[1]; [1]Drexel University; [2]Los Alamos National Laboratory; [3]Sandia National Laboratories; [4]Argonne National Laboratory

Interfacial regions constitute up to 40 vol.% of a nanocrystalline material, providing a high number of annihilation sites for point defects during cascade events and subsequent diffusion. MD simulations in nanocrystalline Ni and Fe have shown reduced interstitial survival and excess vacancy production immediately following the cascade event. In Pd, Au, and Ni alloys, an absence of defect clusters has been found below a critical grain size proportional to their respective self-diffusion lengths. This work presents the study of point defect cluster formation in free standing nanocrystalline Fe films. Films were irradiated *in-situ* to approximately 5dpa at 300°C using 1MeV Kr^{2+} ions at Argonne and *ex-situ* using 20MeV Si^{4+} ions at Sandia National Laboratories. Dislocation loops displayed strong size dependence with grain size, and an approximate minimum grain size for cluster formation prevention was determined. This work is supported by DOE, Office of Science, Office of Basic Energy Sciences.

11:00 AM

Development of W-UO2/CeO2 CERMET Fuels for Ultra High Temperature Reactor Applications: *Jonathan Webb*[1]; James Werner[1]; Robert Hickman[2]; [1]Idaho National Laboratory; [2]NASA Marshal Space Flight Center

Historical and contemporary space reactor designs require the use of refractory materials to withstand steady state operational temperatures that range from 1000 K to 3000 K. This paper outlines the initial steps of a fuels program to recapture the technology required to fabricate W-UO2 fuel forms for hydrogen cooled nuclear rocket applications. The results and lessons learned from a robust literature search of the ANL CERMET fuels program and the General Electric 710 programs are detailed in this study. This paper also describes an initial effort to spheroidize particles of CeO2 which are also coated with tungsten to a 40 vol.% ratio. The particles are consolidated into fuel specimens and prototypic fuel element segments via Pulsed Electric Current Sintering (PECS) and Hot Isostatic Pressing (HIPing) techniques. Comparisons are made between the microstructure and basic properties of the specimens fabricated by PECS and HIP techniques.

11:20 AM

Structure and Property Relationship in Spark Plasma Sintered UO2 Pellets: *Ghatu Subhash*[1]; James Tulenko[1]; Ronald Baney[1]; Ge Lihao[1]; Andrew Cartas[1]; [1]University of Florida

UO2 powder has been sintered at a range of temperatures using spark plasma sintering technique. The sintered material density varied between 85-97% theoretical density. Ultrasonic measurements (both shear and longitudinal wave measurements) were conducted on sintered disks to determine their modulus and Poisson's ratio. The evolved microstructure was investigated using SEM and optical microscopy. Hardness measurements were conducted using a Vickers indentation tester. In addition, thermal conductivity measurements were also conducted. These measurements and their relationship to the evolved microstructure as well as a comparison to UO2 produced by other methods will be discussed in detail during the presentation.

11:40 AM
Non-Destructive Analysis of Microstructural Evolution after Irradiation of Zr2.5Nb Pressure Tubes Using Neutron Diffraction Line Profile Analysis: *Levente Balogh*[1]; Donald Brown[1]; Mark Daymond[2]; [1]Los Alamos National Laboratory; [2]Queen's University

Zr-2.5Nb samples removed from a CANDU reactor are investigated using the high resolution Neutron Powder Diffractometer at Los Alamos National Laboratory, to determine the microstructural changes induced by neutron irradiation. It is shown that Diffraction Line Profile Analysis (DLPA), performed here using the extended Convolutional Multiple Whole Profile (eCMWP) software, combined with time-of-flight neutron diffraction is a valuable tool for the characterization of irradiated materials. The dislocation density is observed to increase from $6x10^{14}$ to $24x10^{14}$ m^{-2} after 7 years of service. It is shown that this increase is due to $< a >$ Burgers vector type dislocations created by the neutron irradiation. DLPA also reveals a fundamental change in the arrangement of the dislocation structure induced by the irradiation compared to the cold worked, pre-irradiated state. Tensile tests indicate the activation of new deformation mechanisms in irradiated Zr-2.5Nb, the microstructural background of this effect is being explored by DLPA.

Nanocomposites: Nanocomposites for Magnetic and Dielectric Applications

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Composite Materials Committee
Program Organizers: Garth Wilks, Air Force Research Laboratory; Jonathan Spowart, Air Force Research Laboratory; Meisha Shofner, Georgia Institute of Technology; John Zhanhu Guo, Lamar University

8:30 AM
Removal of As(III) from Water and Decolorization of Methylene Blue by Mn3O4-Coated Magnetite Nanoparticles: *Gabriela Silva*[1]; Fabiana S. Almeida[2]; Nathália C. Pissolati[2]; Maria Sylvia S. Dantas[1]; Ângela M. Ferreira[2]; Virgínia S.T. Ciminelli[1]; [1]UFMG; [2]CEFET-MG

Mn3O4 magnetic composites were successfully synthesized by precipitating Mn3O4 in presence of previously obtained magnetite nanoparticles. Powder X-ray diffraction, Raman spectroscopy, Fourier transform infrared spectroscopy, Mössbauer spectroscopy, superconducting quantum interference device (SQUID) and nitrogen physical adsorption were used to characterize the composites. The composites are superparamagnetic at room temperature and can be separated by an external magnetic eld. The capacity of the composites to remove As(III) and methylene blue (MB) from aquatic systems was investigated. Oxidative decolorization of methylene blue (MB) by the synthetic materials was investigated by using UV-Vis absorption spectroscopy. The hybrids show a high binding capacity for As(III) probably due to the increased adsorption sites which occurs by oxidation of As(III) to As(V). Results show near complete (over 99.8%) arsenic removal within 10 ppm and near complete decolorization of MB from its aqueous solution on treating the dye in acidic media.

8:50 AM
Synthesis and Electrical Analysis of Nano-Crystalline Barium Titanate and PLZT Nanocomposites for Use in High-Energy Density Applications: *Christopher DiAntonio*[1]; Todd Monson[1]; Tom Chavez[1]; [1]Sandia National Laboratories

Ceramic based nanocomposites have recently demonstrated the ability to provide enhanced permittivity, increased dielectric breakdown strength, and reduced electromechanical strain making them potential materials systems for high energy density applications. A systematic characterization and optimization of barium titanate and PLZT based nanoparticle composites employing a glass or polymer matrix to yield a high energy density component will be presented. This work will present the systematic characterization and optimization of barium titanate and lead lanthanum zirconate titanate nanoparticle based ceramics. The nanoparticles have been synthesized using solution and pH-based synthesis processing routes and employed to fabricate polycrystalline ceramic and nanocomposite based components. The dielectric/ferroelectric properties of these various components have been gauged by impedance analysis and electromechanical response and will be discussed. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:10 AM
Conductive Polyaniline-Magnetite Nanocomposites: *Hongbo Gu*[1]; Yudong Huang[1]; Xi Zhang[1]; Jiahua Zhu[1]; Suying Wei[1]; John Zhanhu Guo[1]; [1]Lamar University

Polyaniline (PANI) nanocomposites filleded with magnetite (Fe3O4) nanoparticles (NPs) are fabricated by using surface-initiated-polymerization (SIP) method. The structures of PANI/ Fe3O4 nanocomposites are characterized by Fourier transform infrared spectroscopy (FT-IR). The thermal properties of the PANI/Fe3O4 nanocomposites are performed by thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC). Both transmission electron microscopy (TEM) and Scanning electron microscope (SEM) are used to characterize the dispersion of Fe3O4 NPs and the morphology of PANI/ Fe3O4 nanocomposites. The effect of the Fe3O4 NPs on the crystallization behavior of the PANI during polymerization is studied. The electrical conductivity, dielectric permittivity and magnetic properties of these nanocomposites are investigated in detail.

9:30 AM
Synthesis of Tailored Core-Shell Magnetic Microparticles for Intravascular Embolization: Gabriella Ferreira[1]; Alexandre Umpierre[1]; *Fabricio Machado*[1]; [1]Universidade de Brasília

Spherical core-shell microparticles of magnetic poly(vinyl acetate) / poly(vinyl alcohol) polymers intended for medical applications such as intravascular embolization procedures and hyperthermia treatment of injured areas were synthesized by in situ incorporation of surface modified magnetite nanoparticles through suspension polymerization process. The proposed experimental methodology showed to be very efficient for the synthesis of micro-sized magnetic particles with controlled morphology. Partially hydrolyzed magneto-polymeric nanocomposites exhibited good thermal stability that observed for the pure poly(vinyl acetate). It was also noted that the morphology of the precursor polymer is preserved when mild reaction conditions are applied during the hydrolysis reaction. Micro-sized polymeric particles showing good magnetic properties were obtained, which indicates that core-shell poly(vinyl acetate) / poly(vinyl alcohol) polymers can be successfully used as embolic agents.

9:50 AM Break

10:10 AM Invited
Electromagnetic Field Shielding Polyurethane Nanocomposites Reinforced with Core-Shell Fe-Silica Nanoparticles: Jiahua Zhu[1]; Suying Wei[1]; *John Zhanhu Guo*[1]; [1]Lamar University

A modified Stöber method is introduced to synthesize Fe@SiO2 nanoparticles (NPs) using 3-aminopropyltriethoxysilane (APTES) as a primer to render the metal particle surface compatible with silica. High resolution transmission electron microscopy and selected area electron diffraction results indicate a highly crystalline iron core coated with a uniform layer of silica. Polyurethane (PU) nanocomposites are fabricated via a surface initiated polymerization (SIP) method. Both Fe@SiO2 NPs and Fe@SiO2/PU nanocomposites exhibit better thermal stability and antioxidation capability than Fe@FeO and Fe@FeO/PU, respectively owing to the barrier effect of the silica shell, revealed by the thermalgravimetric analysis. Meanwhile, the silica shell greatly reduces the eddy current loss and increases the anisotropy energy. The Fe@SiO2/PU nanocomposites show good electromagnetic wave absorption performance (reflection loss, RL<-20 dB) at high frequencies (11.3 GHz), while the best RL of Fe@FeO/PU is still larger than -20 dB even with a larger absorber thickness.

10:50 AM
Hysteretic Magneto-Photoluminescence in Mn Ion Implanted Silicon Rich Oxide Thin Films: *Wei Pan*[1]; [1]Sandia National Labs

Spintronics, with combined magnetism and solid state electronics via spin-dependent transport processes, has generated much recent excitement. Such devices are expected lead to new electronic functionalities that will enhance the speed of information processing and storage density. The challenge lying ahead is to control magnetic phenomena at quantum length scales in reduced dimensions. Here we wish to report a hysteretic behavior in magneto-photoluminescence in Mn ion implanted silicon rich oxide (SRO) thin films. When the photoluminescence peak intensity is plotted against applied magnetic (B) field, surprisingly, a hysteretic behavior is observed for B sweeping up and down. This hysteretic behavior disappears when the temperature ~ 60 K. Similar measurements in the SRO sample without Mn-ion implantation was also carried out and no hysteresis is observable down to 1.3K. We propose that the origin of this hysteresis is probably due to a ferromagnetic order in Mn ion implanted thin films.

11:10 AM
Structure-Property Relationships Nanostructured Dielectric Materials: *Lawrence Drummy*[1]; Scott Fillery[1]; Hilmar Koerner[1]; Richard Vaia[1]; [1]Air Force Research Laboratory

The unprecedented control over organic-inorganic hybrid nanomaterial structure afforded by polymer synthesis and functionalization techniques provides a toolbox for materials property design. For applications such as high energy density dielectrics, a high volume fraction of inorganic material is desired while maintaining an appropriate interparticle separation distance, thus avoiding percolation which leads to dielectric breakdown. We have functionalized the surface of oxide (BaTiO3, TiO2, SiO2) nanoparticles with polymers (PS, PMMA) of controlled molecular weight and purified the resulting hybrid nanoparticles so that no unbound polymer remained. The resulting nanoparticles were assembled into films which showed increased dielectric constant with increasing volume fraction of inorganic, while maintaining their dielectric breakdown strength. Finally, 3D electron tomography and small angle X-ray scattering were used to develop structure-property relationships which showed that control of both the nano-structure (interparticle separation distance) and the meso-structure (void size) are critical to achieving the desired material properties.

11:30 AM
Effects of Thermal Processing on Crystallinity and Dielectric Properties of P(VDF-HFP) Nanocomposites: Hongxu Liu[1]; *Fiona Doyle*[1]; [1]University of California, Berkeley

Adding nanoparticulate fillers to polymers has been recently investigated as a way to enhance energy density for use in capacitors. This paper discusses the relationships between the thermal processing of polymer nanocomposites and the resulting crystal structures and dielectric properties. The polymer of interest is poly(vinylidene fluoride-co-hexafluoropropylene) (P(VDF-HFP)), a relaxor ferroelectric with high energy density and low ferroelectric hysteresis. Consistent with the literature, we have shown that the temperature at which the polymer solution is cast impacts the crystal phase of the polymer, and can greatly affect its breakdown strength. In addition, we have found that post-casting thermal treatments change crystallinity and can increase breakdown strength by five-fold. The addition of nanoparticulate fillers such as barium titanate and montmorillonite clays can increase the permittivity of the polymer film but also disrupts the crystallinity of the films.

11:50 AM
Soft Magnetic Nanocomposite for High Frequency Applications: *Matthew Lucas*[1]; [1]Air Force Research Laboratory

FeCo based nanocrystalline materials have excellent soft magnetic properties, but are limited to low frequency applications due to their relatively low electrical resistivity, which results in high eddy current losses. The alloy (Fe81Co19)84Ta9B7 was identified as having a high resistivity of 140 $\mu\Omega$-cm after annealing at the crystallization temperature of 552°C for 45 minutes. Results from in-situ x-ray diffraction as a function of temperature reveal that crystallization begins at 500°C, with the crystallite sizes determined from the Scherrer analysis growing from 13±4 nm at 525°C to 31±3 nm at 600°C. Resistivity measurements performed as a function of temperature cleary show a reduction of the resistivity with annealing temperature, as expected. These results indicate that the annealing temperature may be used to tune the electrical resistivity and grainsize, which may be used to optimize the high frequency magnetic properties for specific applications.

12:10 PM
Dramatic Expansion of Luminescence Region in GaP/Polymer Nanocomposites: *Sergei Pyshkin*[1]; John Ballato[2]; [1]Academy of Sciences of Moldova; [2]Clemson University

GaP nanoparticles were prepared using mild aqueous or colloidal syntheses at decreased temperature followed by ultrasonication and stored as dried powder or suspension in water-ethanol mixture or toluene. Selected mixtures of GaP nanoparticles, based on dimensions, exhibit at room temperature bright broad band luminescence from UV until yellow-red region with controlled band-width and spectral position of maximum. Poly (2-vinylpyridine) (P2VP), biphenyl vinyl ether (BPVE) and tetrahydrofuran (THF) polymers were used to prepare GaP based nanocomposites. The resulting nanocomposites showed pronounced quantum confinement effects and other discussed in this work important for application interesting phenomena leading to dramatic 1 eV expansion of GaP luminescence to the UV spectral region. These GaP nanoparticles and GaP/polymer nanocomposites provide significant enhancement of blue-shifted luminescence from which novel light emissive device structures may be fashioned.

Neutron and X-Ray Studies of Advanced Materials V: Centennial: Alloys, Correlations, Phase Transitions

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Chemistry and Physics of Materials Committee

Program Organizers: Rozaliya Barabash, Oak Ridge National Laboratory; Xun-Li Wang, Oak Ridge National Laboratory; Gernot Kostorz, ETH Zurich; Lyle Levine, National Institute of Standards and Technology; Peter Liaw, Univ of Tennessee; Yandong Wang, Beijing Institute of Technology; Brent Fultz, California Institute of Technology

8:30 AM Keynote
Structural Characterization of Complex Materials Using Total Scattering: *Thomas Proffen*[1]; [1]Oak Ridge National Laboratory

In this presentation an overview of experimental advances in neutron and x-ray total scattering measurements as well as the current state-of-the-art in modeling of disordered materials will be presented. Examples include local disorder in exotic oxides, hydrogen storage materials, nano-particles and their ligand structure as well as complex systems such as 'green' geopolymer concrete. Experiments were perfomed at the Advanded Photon Source at Argonne National Laboratory and at the Lujan Neutron Scattering Center at Los Alamos National Laboratory. New opportunities for total scattering experiments at the Spallation Neutron Source at Oak Ridge National Laboratory will also be discussed.

8:55 AM
Inelastic Scattering Studies of Iron Alloys: *Matthew Lucas*[1]; [1]Air Force Research Laboratory

Inelastic scattering provides quantitative information on the vibrations of atoms in materials, which is useful for understanding the relative stability of alloy phases. Using both neutrons and x-rays it has become a common practice to measure the phonon density of states of materials. Of particular usefulness is a combination of techniques which tells us information on the vibrations of particular elements in an alloy. Nuclear resonant inelastic x-ray scattering, a synchrotron Mossbauer technique, may be used to determine the vibrations of only the 57-Fe atoms. Combined with results from inelastic neutron scattering this information may be used to determine the vibrations of the other elemental species in binary alloys. The results of recent inelastic experiments of Fe alloyed with Ti, V, Cr, Co, Ni, Al, Pd, Pt, and Au are discussed along with general trends of alloying. Application of these techniques to more complex systems are presented.

9:10 AM Invited
Local Structure and Diffuse Scattering in Modern Ferroelectric Materials: *Marek Pasciak*[1]; Ross Whitfield[1]; Darren Goossens[1]; Richard Welberry[1]; [1]Australian National University

Modern ferroelectric materials are characterized by a complex structure frequently comprising occupational disorder and displacement correlations (polar fluctuations) on different length scales. Therefore, local structure probes are necessary for understanding structure–property relationship and facilitating the design of new materials. Diffuse scattering has become a main source of information on nanoscale phenomena in ferroelectrics, e.g. polar nanoregions. Yet its interpretation is often troublesome and advanced modelling techniques are necessary to explain observed patterns which usually host contributions from both dynamic effects and static disorder. We concentrate on the examples of $Pb(Mg_{1/3}Nb_{2/3})O_3$-$PbTiO_3$ and $Pb(Zn_{1/3}Nb_{2/3})O_3$-$PbTiO_3$ compounds. We show how, by using different modelling approaches, the pieces of information can be retrieved from the diffuse scattering, aiding the understanding of the excellent electro-mechanical properties of these materials.

9:30 AM
The PDF of Glassy Solids - Pitfalls and Traps of Experiment and Interpretation: *Wojciech Dmowski*[1]; Takeshi Egami[2]; [1]University of Tennessee; [2]ORNL

Structural characterization of glasses, liquids and disordered solids is challenging. The standard approach is to obtain the pair distribution function (PDF). PDF is obtained by a Fourier transformation of the structure function S(Q). The S(Q) has to be extracted from the diffracted intensity and normalized to absolute units to obtain a meaningful PDF. Frequently PDFs obtained for the same sample are different. Therefore it is important to establish procedures that put S(Q) on the absolute scale and allow obtaining reproducible PDF using different detectors and beamlines. We will discuss common traps and pitfalls of using high energy x-ray diffraction, area detectors and mouse and click GUIs and present some simple procedures to minimize normalization errors. We also will show x-ray and neutron data sets to illustrate our points. This work was supported by the U.S. DOE under DE-AC05-00OR-22725 and NSF-DMR-0906744.

9:45 AM Invited
X-Ray Cross-Correlation Analysis and Sample Ensemble Averaging Effect: *Miguel Castro-Colin*[1]; Peter Wochner[1]; Mariya Rasschchupkyna[1]; Volodymyr Bugaev[1]; Christian Gutt[2]; Gerhard Gruebel[2]; [1]Max-Planck-Institut fuer IS; [2]DESY

Disordered matter has been traditionally described using the pair-distribution function, which can, through modeling, extract coordination shell information about the sample and indirectly exhibit cluster symmetry existent within the sample. The cross-correlation technique is an alternative to study disordered matter, and can directly extract, cluster symmetry information by taking into consideration speckle intensity cross-correlations. These correlations are obtained from appropriate evaluation of the speckle intensity at constant momentum transfer Q, but variable azimuthal position , i.e. taking into account intensity diffraction rings. Such correlations can be Fourier decomposed and their individual coefficients analyzed. We seek to show the effect that ensemble averaging has in the value of those Fourier coefficients and contrast such results with the variance of the Fourier amplitudes of the intensities. For that purpose a disordered tri-dimensional sample was simulated via molecular dynamics and different subsets extracted and treated in the fashion indicated above.

10:05 AM Invited
Characterization of Complex Precipitation Pathways Using Small Angle X-Ray Scattering: *Alexis Deschamps*[1]; Frédéric de Geuser[2]; [1]Grenoble Institute of Technology; [2]CNRS

In realistic situations, precipitation processes in metals leading to useful mechanical properties usually show a high degree of complexity: precipitate systems are usually multi-component, with a compositional indetermination of the forming phases; precipitation occurs through a sequence of metastable phases with a variety of nucleation conditions; thermal paths are often non-isothermal, and may involve plastic deformation; in processes that involve welding, the precipitate microstructures may be spatially heterogeneous. This contribution will review recent advances in synchrotron small-angle X-ray scattering that address some of this complexity. Examples will be given in Aluminum alloys, with in-situ studies along non-isothermal paths, evaluation of precipitate compositions using anomalous X-ray scattering and precipitate mapping of heterogeneous microstructures. Emphasis will be made of the usefulness of combining these small-angle scattering approaches with complementary techniques (such as Atom Probe Tomography) to obtain a full quantification of the precipitation phenomena.

10:25 AM

Characterization of Nanostructures in Co-Pd-Si-O Soft Magnetic Nanogranular Film Using Compact type Small-Angle Neutron Scattering Spectrometer: *Yojiro Oba*[1]; Masato Ohnuma[1]; Shigehiro Ohnuma[2]; Michihiro Furusaka[3]; [1]National Institute for Materials Science; [2]Research Institute for Electromagnetic Materials; [3]Hokkaido University

Quantitative values of microstructure obtained from small-angle X-ray (SAXS) and neutron scattering (SANS) are useful to understand the origin of the materials' properties. Combined use of SAXS and SANS provides further information about the chemical compositions of nanostructures. Recently, owning to development of compact type SANS, which is called mini-focusing SANS (mf-SANS) spectrometer, the SANS of the nanostructures with a few nm has been able to be easily measured. In this study, the analysis of the morphologies and chemical compositions of the Co-Pd nanoparticles in a Co-Pd-Si-O soft magnetic nanogranular film using SAXS and mf-SANS is reported. The magnetic structures of the nanogranular is also investigated using the magnetic scattering contribution of SANS.

Synchrotron SAXS of Reverted Al-4wt.%Cu during In Situ Artificial Ageing: *Brad Diak*[1]; Marsha Singh[1]; Shig Saimoto[1]; Luke Westfall[1]; Lixia Rong[2]; [1]Queen's University; [2]Stony Brook Unversity

Stimulated by early developments in x-ray diffraction of metals, Guinier and Preston were the first "materials scientists" to successfully apply new x-ray tools to interpret diffuse scattering from decomposing Al-4wt.%Cu solid solutions as nano-sized clusters. Afterwards Al-Cu alloys became the model system to study GP zones [cf. Baur and Gerold, 1966]. Osamura, Otsuka and Murakami [1982] used laboratory SAXS to quantify the volume fraction and zone size of Al-4wt.%Cu single crystals after quenching and ageing. The rapid diffusivity of Cu in Al makes it experimentally difficult to study the as-quenched and early stages of ageing. More recent studies of GP zones have applied time resolved synchrotron SAXS [Okuda et al., 1997]. In the present study, reverted Al-4wt.%Cu, which is a more stable than the as-quenched condition, was artificially aged in situ while probing with SAXS configured at beam-line X27C at NSLS. Results of the phase decomposition will be presented.

11:05 AM Invited

Local Structure Models of Diffuse Scattering in Relaxor Ferroelectrics: *Branton Campbell*[1]; Benjamin Frandsen[1]; Va-Yee Vue[1]; Matthew Gardner[1]; Kevin Seppi[1]; [1]Brigham Young University

The lead-based relaxor ferroelectrics like $Pb(Zn_{1/3}Nb_{2/3})O_3$ - $PbTiO_3$ (PZN-PT) have exceptional piezoelectric properties. X-ray scattering techniques have recently been applied to investigate the local structures of these materials, in which marked changes have been observed upon the application of a strong electric field. We have reconstructed high-resolution reciprocal-space volumes of PZN-PT using single-crystal x-ray diffuse scattering images, which provide an excellent three-dimensional probe of this phenomenon. We will discuss quantitative fits of local structure models to this scattering.

11:25 AM

The Structural Relationship between Negative Thermal Expansion and Quartic Anharmonicity of Cubic ScF_3: *Chen Li*[1]; Xiaoli Tang[1]; Jorge Munoz[1]; Douglas Abernathy[2]; Brent Fultz[1]; [1]Caltech; [2]ORNL

Cubic scandium tri-fluoride ScF_3 has a large negative thermal expansion over a wide range of temperature. Inelastic neutron scattering experiments were performed to study the temperature dependence of the lattice dynamics of ScF_3 from 7 to 750 K. The measured phonon densities of states (DOS) show a large anharmonic contribution with a thermal stiffening of modes around 25 meV. Phonon calculations with first-principles methods identified the individual modes in the DOS, and frozen phonon calculations showed that some of the modes with motions of F atoms transverse to their bond direction behave as quantum quartic oscillators. The quartic potential originates from harmonic interatomic forces in the DO_9 structure of ScF_3, and accounts for phonon stiffening with temperature and a significant part of the negative thermal expansion.

11:40 AM

In-Situ Measurement of Crystalline Lattice and Amorphous Strains in Fluoropolymers by Neutron Diffraction: *Eric Brown*[1]; Bruce Orler[1]; Cynthia Welch[1]; Dana Dattelbaum[1]; Rex Hjelm[1]; Arthur Scholz[2]; Don Brown[1]; [1]Los Alamos National Laboratory; [2]UC Santa Barbara

Strain measurements by neutron diffraction are employed as an in situ technique to obtain insight into the deformation modes of crystalline and amorphous domains in a deformed semi-crystalline polymer. The SMARTS (Spectrometer for MAterials Research at Temperature and Stress) diffractometer has been used to measure the crystalline lattice displacements in polytetrafluoroethylene (PTFE). The chemical structure of PTFE makes it ideally suited for investigation by neutron methods as it is free of hydrogen that results in limited penetration depths and poor diffraction acquisition in most polymers. The LQD (Low-Q Diffractormeter) has been used to measure the amorphous response in PTFE and a (3:1) copolymer of PCTFE (polychlorotryfluoroethylene) and PVDF (polyvinylidenefluoride). Perturbations of the chain are determined by deviations of the scattering from the static result (I~Q–2), measurement of the radius of gyration, and a distorted form factor that is likely to be anisotropic.

11:55 AM

Lattice Defects Diffuse Scattering from Thin Films of Si-Ge System with Low Energy Ar+ and Xe+ Bombardments during MBE Growth: *Paul Rozenak*[1]; [1]Hydrogen Energy Batteries LTD

Growth of Si, Ge and SiGe layers using molecular beam epitaxy (MBE) was carried out with the Si and Ge (001) substrates, in the order to studied effects of ion bombardment on the crystalline strains of grown materials. Although, ion energies and ion/atom fluxes used in the experiments results to significant lattice distortions along the growth direction. High resolution X-ray diffraction (HRXRD) and transmission electron microscopy (TEM) characterizations of lattice distortion forms, caused by low energy Ar+ and Xe+ bombardment of grown thin epitaxial films on (001) substrates were investigated. The intensity distribution consists of two maxima, one from the distorted layer and the other from original un-effected lattice. The significant changes in the 2□ location, peak broadening and integrated intensity from the (004)* reflections were obtained as the function of aging temperatures. The effects to the ion bombardment induced formation and injection of different types of pointlike defects and defects clusters which modified new optical and electrical properties of grown layer.

12:10 PM

Vibrational Entropy of Amorphous Copper Zirconium: *Hillary Smith*[1]; Chen Li[1]; Glenn Garrett[1]; Matthew Lucas[2]; Matthew Stone[3]; Douglas Abernathy[3]; Brent Fultz[1]; [1]California Institute of Technology; [2]Air Force Research Lab; [3]Oak Ridge National Lab

Inelastic neutron scattering spectra were measured from 300 to 1020 K on equiatomic CuZr, initially quenched to form a bulk metallic glass at 300 K. The role of vibrational entropy in stabilizing or destabilizing the amorphous phase was determined by comparing the amorphous material above and below the glass transition temperature, in its equilibrium two-phase crystalline state at low temperatures, and at high temperatures in the B2 phase. Phonon density of states curves showed considerable softening of high-energy modes in the crystallized material in comparison with the amorphous state, indicating that the equilibrium two-phase mixture has a larger vibrational entropy than the glass. The vibrational entropy of the high-temperature B2 phase will also be reported.

Neutron and X-Ray Studies of Advanced Materials V: Centennial: Local Structure from Diffraction

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Chemistry and Physics of Materials Committee

Program Organizers: Rozaliya Barabash, Oak Ridge National Laboratory; Xun-Li Wang, Oak Ridge National Laboratory; Gernot Kostorz, ETH Zurich; Lyle Levine, National Institute of Standards and Technology; Peter Liaw, Univ of Tennessee; Yandong Wang, Beijing Institute of Technology; Brent Fultz, California Institute of Technology

Wednesday AM — Room: Northern E4
March 14, 2012 — Location: Dolphin Resort

Funding support provided by: Office of Basic Energy Sciences, U.S. Dept. of Energy, Dr. P. Thiyagarajan

Session Chairs: Emil Bozin, Brookhaven National Laboratory; Nidia Gallego, Oak Ridge National Laboratory

8:30 AM Keynote
Toward an Atomistic Interpretation of Diffraction Line Profile Broadening: *Paolo Scardi*[1]; [1]University of Trento

Even the most advanced methods of diffraction Line Profile Analysis (LPA) still rely on a theoretical background firmly established more than forty years ago, and mostly unchanged to this day. The traditional LPA approach deals with ideal continuous solids, in most cases simple geometrical shapes like spheres, cubes, cylinders, tetrahedra or octahedra, treated as perfect edifices made of a periodic arrangement of unit cells. Microstructural effects most notably those given by lattice defects are introduced as a perturbation to the coherency of such idealized perfect crystals, with more or less simplified assumptions whose reliability cannot be easily assessed on a general basis. An atomistic modelling can provide a realistic description of materials: nano-polycrystalline microstructures built from space tessellation algorithms, followed by atom filling and equilibration procedures provide test systems in which the role of each feature in determining the diffraction line profile can be clearly understood.

8:55 AM Invited
Local Structural Aspects of the Metal-Insulator Transition in Cu(Ir1-xCrx)2S4 from Total Scattering X-Ray Study: *Emil Bozin*[1]; [1]Brookhaven National Laboratory

CuIr2S4 cubic Pauli paramagnetic metallic spinel with mixed-valence Ir3+/Ir4+ state, undergoes at ~230K on cooling a metal-insulator transition, with simultaneous charge and orbital ordering and Ir4+ spin-dimerization, yielding temperature-independent diamagnetism, all within triclinic structure. Spin-dimerized Ir4+-Ir4+ distance is ~0.5 Angstroms shorter than for nondimerized Ir-Ir pairs. From insulating state, metallic state can be invoked by temperature, Cr-doping and X-ray irradiation. Atomic PDF study using 100 keV synchrotron X-rays [1] indicates that short-range ordered spin-dimers survive in the metallic state induced by X-ray irradiation, but are completely removed in the metallic state achieved by Cr-doping and temperature, emphasizing fundamental difference between the two metallic states. I will also discuss novel surprising local structural observations made in the high-T metallic state from the PDF. [1] E.S. Bozin et al., Phys. Rev. Lett. v.106, 045501 (2011).

9:15 AM Invited
Industrial Applications at Small Angle Neutron Scattering and Neutron Diffraction of HANARO Reactor: *Baek Seok Seong*[1]; Eunjoo Shin[1]; Young-Soo Han[1]; Chuck Woo[1]; [1]KAERI

Small angle neutron scattering (SANS) technique is used to characterize nano-sized (1 ~ 100 nm) fluctuations in the density and composition of the material. This is an excellent tool for obtaining the structural information about macromolecules and heterogeneities like precipitates, micro voids and magnetic inhomogeneities in the material. A new 40M SANS and a recently upgrade 18M SANS were installed in cold neutron facility building of HANARO and are under operational from last year. In this presentation, I would like to present the status and future plan of HANARO neutron scattering facilities and some scientific results carried out on HANARO neutron scattering facilities will be presented.

9:35 AM
Internal Stresses and Microstructure Studied by Neutron Diffraction Profile Analysis: Comparison with Other Techniques: *Vadim Davydov*[1]; Petr Lukáš[2]; Martin Petrenec[3]; Helena Van Swygenhoven[1]; Ondrej Man[4]; Pavel Strunz[2]; Radomír Kužel[5]; [1]Paul Scherrer Institut; [2]Nuclear Physics Institute; [3]Institute of Physics of Materials; [4]Brno University of Technology; [5]Charles University

The neutron and X-ray diffraction techniques combined with electron microscopy methods has been used to study the internal microstresses and micorstructure in low carbon steel. Since the real structure features affect the width and shape of the neutron or X-ray diffraction pattern, and, as these real structure aspects are very numerous and mutually superposed, diffraction effects in terms of real structure characteristics are not simple to interpret. Using the recently modified single-line profile analysis method, the dislocation content was addressed and compared in terms of dislocation density parameter with the results obtained by other microscopy methods. The single-line neutron diffraction profile analysis performed at NPI was extended using full diffraction patterns collected in time-of-flight mode at POLDI materials science diffractometer at PSI.

9:50 AM Invited
Microstructural Mapping Using High-Energy X-Ray Scattering: *Jonathan Almer*[1]; [1]Argonne National Laboratory

Advanced characterization methods at the APS permit unique in-situ studies of energy-relevant materials and processes. In this talk, use of high-energy x-rays at the 1-ID beamline for strain, phase and microstructural mapping will be presented. The combination of an undulator source, brilliance preserving optics and focusing lenses provides high-energy x-rays (E~50-120 keV) with transverse beamsizes down to the micron-level. Reconstruction of scattering data, together with sample translation/rotations, can be used to provide 3D information in select cases. Studies presented will include combined small- and wide-angle scattering measurements of strain partitioning under in situ loading, and strain and phase mapping of layered systems including batteries and fuel cells. Finally, recent advances will be discussed, including a new area detector configuration to permit simultaneous interrogation of materials under different measurement modes, and planned beamline upgrades to improve data fidelity and user access.

10:10 AM
New Approach to Measure Lattice Strains under Torsional Shear Using In Situ Neutron Diffraction for Polycrystalline Materials: Robin Woracek[1]; *Jeffrey Bunn*[2]; Dayakar Penumadu[2]; Camden Hubbard,[3]; [1]University of Tennessee & Helmholtz Zentrum Berlin; [2]University of Tennessee; [3]Oak Ridge National Laboratory

Torsion provides a unique opportunity to study the mechanical behavior of materials subjected to a state of pure shear stress and is of significance as most engineering components fail under the influence of shear, or combination of shear and axial stress. However, measurement of shear strain is limited to (near) surface measurements with most techniques. The authors introduce an experimental approach applying the concept of a "strain rosette" for the measurement of shear strain based on lattice spacing changes under in-situ torsional loading, using recent data obtained at ORNL-NRSF2 in conjunction with a custom developed axial-torsional loading-system. Aspects of the technique, such as required gauge volume size (=1mm3) and precise alignment using a Laser Tracker system are addressed. The lattice specific shear moduli for Fe(211), Fe(200) and Fe(110), which were experimentally determined while elastically loading a circular steel rod (d=6mm), are presented and compared to Young's moduli of the same sample.

10:20 AM Break

10:25 AM
Effect of Different Loading Condition on the Accumulation of Internal Strain in a Creep Resistant Bainitic Steel: *Michael A. Weisser*[1]; Steven Van Petegem[1]; Stuart R. Holdsworth[2]; Helena Van Swygenhoven[1]; [1]Paul Scherrer Institute; [2]EMPA

The strengthening mechanisms at both ambient and elevated temperatures in a creep resistant 1%CrMoV steel are governed by the interplay between the ductile ferrite matrix, cementite particles and a fine dispersion of carbides. These individual components have different mechanical properties and as a consequence, load-sharing between cementite/carbide and the plastifying matrix can yield large interphase stresses. Synchrotron and neutron diffraction measurements have been carried out in-situ during tensile deformation and ex-situ after deformation. Samples have been deformed under tensile load at room temperature and elevated temperature (565°C) and under creep conditions (565°C). The residual interphase strains are strongly reduced in the samples deformed at elevated temperature and this for both loading conditions. The character of the internal strain accumulation is discussed as function of the deformation strain, temperature and loading condition, shedding light on the role played by the different type of precipitates in the load-sharing. (Acta Mat 59 2011)

10:40 AM Invited
Verification of Site Occupancies in a Nickel Base Superalloy Using Synchrotron and Neutron Diffraction Techniques Coupled with Atomistic Modeling and High Resolution TEM: *J. Tiley*[1]; G. Viswanathan[1]; S. Knox[2]; A. Shiveley[1]; S Nag[3]; R Banerjee[3]; H. Fraser[4]; [1]Air Force Research Laboratory; [2]Southwestern Ohio Council for Higher Education/Air Force Research Laboratory; [3]Department of Materials Science, University of North Texas; [4]Department of Materials Science and Engineering, The Ohio State University

Creep behavior in nickel alloys is a critical property that impacts their use in propulsion systems. Previous research has shown that tertiary and secondary gamma prime precipitates dramatically influence the mechanical response for these alloys, and that chemical composition and location of elements within the gamma prime phases influence the lattice parameters and phase formation energies. Researchers in this investigation studied specific site occupancies of elements within Rene88DT using synchrotron and neutron diffraction techniques coupled with atomistic modeling, atom probe tomography, and hi-resolution EELS. Chemical compositions were experimentally measured and used in Rietveld analysis to determine site occupancies for major alloying elements within Rene88. Specifically, the models were validated using experimental techniques to determine changing structures within gamma prime precipitates and estimate phase volume fractions.

11:00 AM
Plastic Deformation of Nanocluster-Strengthed Ferritic Steel Studied by In-Situ Neutron Diffraction: *Alexandru Stoica*[1]; Grigoreta Stoica[1]; Zhongwu Zhang[2]; Xun-Li Wang[1]; [1]ORNL; [2]Auburn University

In-situ neutron diffraction data were recorded on nanocluster-strengthed ferritic steel specimens under uniaxial tensile loading. The tensile experiments were performed at RT and 8000C in displacement-controlled mode. The RT measurements reveal the evolution of lattice strains and intragranular accumulation of microstrains due to the plastic deformation. Both, the development of intergranular stresses and the increase of residual dislocation densities with the level of stress, prove that RT plasticity in nanocluster-strengthed ferritic steel is mediated by dislocation slip, and the material undergoes a strain hardening by dislocation pinning on nanoclusters. At high temperatures, the deformation process seems to be different. The absence of plasticity-induced intergranular strains, as well as, a modest intragranular broadening, suggest a diffusion-controlled grain-boundary sliding as the main plastic deformation mode at high temperatures. An unusually low creep rate was observed in constant load experiments and diffraction data confirm the outstanding stability of microstructure at high temperature.

11:15 AM
In-Situ Neutron Study of Phase Transformation Kinetics under Far-From Equilibrium Conditions in Advanced High-Strength Steels: *Zhenzhen Yu*[1]; Zhili Feng[1]; Wei Zhang[1]; Ke An[1]; Rebecca Mills[1]; Eliot Specht[1]; Xun-Li Wang[1]; [1]Oak Ridge National Laboratory

Advanced high-strength steels (AHSS) used in automotive industry rely on highly engineered microstructures to balance the strength and ductility for lightweight and crash-resistant structures. The characteristic microstructures are obtained through alloying and advanced thermomechanical processing, which typically involves phase transformations under far-from-equilibrium conditions. Subsequent vehicle assembly processes such as welding involve fast heating and cooling conditions, which can further alter the microstructures and cause unexpected property degradation. We designed and performed a novel in-situ real-time neutron diffraction measurement in two different AHSS (DP980 and DR210 steels), in order to understand the non-equilibrium phase transformation kinetics under various thermal cycles. The effects of heating rates ranging from 1C/s to 30C/s on phase transformation were clearly observed. The governing kinetics for such behavior are presented and compared with the phase transformation kinetic models. The roles of non-equilibrium phase transformation in developing the next generation AHSS and overcoming welding-induced property degradation are discussed.

11:30 AM Invited
SANS and QENS Studies of Phase Behavior and Dynamics of Hydrogen Confined in Nanopores: *Nidia Gallego*[1]; Cristian Contescu[1]; Dipendu Saha[1]; Lilin He[1]; Eugene Mamontov[1]; Alexander Kolesnikov[1]; Yuri Melnichenko[1]; [1]Oak Ridge National Laboratory

Room-temperature in-situ small angle neutron scattering (SANS) of hydrogen adsorbed in nanoporous carbon have provided for the first time information on extreme densification of hydrogen confined in carbon pores (0.9 – 3.5 nm) in equilibrium with the gas phase (up to 200 bar). The density of adsorbed hydrogen varies with pore size and pressure and approaches liquid hydrogen density in 0.9 nm pores at 200 bar, where internal pressure is many times higher than external gas pressure. In parallel, the dynamics of confined hydrogen was studied using quasi elastic neutron scattering spectroscopy (QENS) at cross-critical temperatures (10 – 35 K). The results showed an 8-10 K elevation of "melting" temperature for hydrogen extremely confined in 0.7 nm pores. Mobility increases on the increase of temperature, but remained lower than that of bulk liquid hydrogen. Sponsored by the Materials Science and Engineering Division, Office of Basic Energy Sciences, U. S. DOE.

11:50 AM

Strain-Rate-Effect on the Lattice-Strain Evolution of a Generation-IV-Reactor-Power-Plant Alloy: E-Wen Huang[1]; *Shan-Yu Wu*[1]; Wei Wu[2]; Ke An[3]; Yang Ling[3]; Chung-Hao Chen[4]; Peter K. Liaw[2]; [1]Department of Chemical & Materials Engineering and Center for Neutron Beam Applications, National Central University; [2]Department of Materials Science and Engineering University of Tennessee; [3]Neutron Scattering Sciences Division Oak Ridge National Laboratory; [4]Department of Mathematics and Computer Science North Carolina Central University

Inconel 617 is a structural-material candidate for the intermediate heat exchanger used in the Generation IV Reactor Power Plant. It is important to investigate its thermomechanical behavior. One of the key parameters is the strain rate. In this work, we use both the high-flux neutrons at the Spallation Neutron Source and the novel data acquisition and reduction technique at the VULCAN Engineering Diffractometer, Oak Ridge, Tennessee, to create an in-situ experimental environment. The dynamics of the structural evolution of the Inconel 617 subjected to three different strain rates of 4 x 10-4, 1 x 10-3, and 1 x 10-2 s-1 during the continuous monotonic tensile deformation at room temperature are recorded. The lattice-strain evolution is compared with the bulk-deformation behavior, such as the applied stresses and the thermal responses as a function of the elongation. The thermomechanical phenomena are analyzed by following the classic Zener-Hollomon concept. The refined neutron-diffraction results are used to modify strain-rate-dependent equations.

12:05 PM

In-Situ High-Energy X-Ray Study of Effect of High Magnetic Field on the Phase Transition of Antiferromagnetic CoO Crystal: *Gang Wang*[1]; [1]Northeastern University

The magnetic-field-driven preferential rearrangements of martensite multivariants in antiferromagnetic CoO crystal has been successfully observed in the previous experiments by the synchrotron high-energy x-ray diffraction measurement. A selection principle on martensite variants different from that found in the ferromagnetic shape memory alloys was deduced. In the present work, the effect of high magnetic field (6T) on the phase transformation of CoO crystal was studied by the synchrotron high-energy x-ray diffraction measurement at temperature between 180K-320K at Beamline 11-ID-C, Advanced Photon Source, Argonne National Laboratory. The results provided important information for understanding the magnetic-field-driven strain observed in the antiferromagnetic alloys.

Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Solder Alloy Design for Challenging Applications

Influence of Composition on the Morphology of Primary Cu6Sn5 in Sn-4Cu Alloys: *Kazuhiro Nogita*[1]; Stuart McDonald[1]; Jonathan Read[1]; Tina Ventura[1]; Motonori Miyaoka[2]; Keith Sweatman[2]; Testuro Nishimura[2]; [1]The University of Queensland; [2]Nihon Superior Co. Ltd.

Alloys from the composition range Sn-0.7 to 7.6wt%Cu consist of primary Cu6Sn5 surrounded by a eutectic Sn-Cu6Sn5 mixture and find applications as high temperature solder alloys (typically up to 400°C). The primary Cu6Sn5 intermetallics commonly adopt an elongated needle-like morphology, which is not optimal for the mechanical properties of the soldered joint. This report presents the results of an investigation into the effect of trace elemental additions on the size and morphology of the primary Cu6Sn5 in a Sn-4wt%Cu alloy with and without Ni additions. Elements investigated include ppm additions of Al, Ag, Ge and Pb. It is shown that Al has a marked effect on the solder microstructure and refines the size of the primary Cu6Sn5, even at very low addition levels. The effect of this refinement on mechanical properties is discussed with reference to the alloy microstructure.

8:55 AM

Relating the Microstructure to the Shear Strength of Fluxless AuSn Solder Bonds: *Jeffrey Florando*[1]; Ilya Golosker[1]; Barry Olsen[1]; [1]Lawrence Livermore National Laboratory

Solder joints consisting of 80Au20Sn solder are being develop to fluxlessly join Ni/Au metalized alumina substrates to flexible ENIG Cu cables using a heater bar. In optimizing the attachment process, the reflow time, temperature, and pressure were changed, which affected the ensuing solder microstructure. After attachment, the samples were shear tested and the cross-section of the bonds were examined in the SEM to compare and correlate the solder microstructure to the shear strengths observed. In addition, samples were aged at 90C and tested to understand the effects of aging on the microstructure and shear strength. The hardness of the phases that formed during the solder process was also measured using nanoindentation and correlated with the measured global shear strengths.

9:15 AM
The Initial Reflow Interaction between Sn3.0Ag0.5Cu Solder and Ni Metallization: *Yu-Wei Lin*[1]; Kwang-Lung Lin[1]; [1]National Cheng Kung University

The early stage interaction between Sn3.0Ag0.5Cu solder and Ni metallization was investigated at soldering temperature of 250 □ for 5 seconds followed by rapid quench in liquid nitrogen. The interfacial HRTEM (High Resolution Transmission Electron microscope) image reveals that Ni lattice distortion, a few atom layers, took place immediately adjacent to the Ni metallization. An amorphous Ni-Cu-Sn diffusion zone was formed next to the distorted Ni layer. Nano-crystalline Cu6Sn5 and metastable NiSn compounds exists within the amorphous diffusion zone. Meanwhile, a little NiSn also exists immediately adjacent to the distorted Ni layer. Homogeneous nucleation was proposed for the nanocrystals in the amorphous region while heterogeneous nucleation for the NiSn adjacent to the distorted Ni layer. The TEM inverse FFT (Fast Fourier Transform) image further shows the formation of many short-range-order structures within the amorphous diffusion region, showing the preliminary stage for the nucleation of the interfacial IMC.

9:35 AM
Intermetallic Compound Formation and Growth at the Lead-Free Solder/Cu Interface during Laser Reflow Soldering and during Isothermal Aging: *Hiroshi Nishikawa*[1]; Noriya Iwata[1]; Tadashi Takemoto[1]; [1]Osaka University

With the miniaturization of electronic productions and the use of heat sensitive electronic components, the laser soldering process brings several advantages in terms of localized heating, and rapid rise and fall in temperature. In this study, the formation and growth of an intermetallic compound (IMC) at the Sn-Ag-Cu solder/Cu interface during laser reflow soldering and during isothermal aging were investigated to clarify the characteristics of the laser reflow soldering. The results show that the rapid rise and fall in temperature strongly affected the IMC formation at the interface and the IMC thickness for the laser soldering was thinner than that for the traditional reflow soldering. During isothermal aging, the growth rate of IMC layer at the interface for the laser soldering was much faster than that for the traditional soldering. Then, after isothermal aging for 504 h, many voids at the Cu3Sn /Cu interface were formed.

9:55 AM
The Effect of Microstructure on the Reliability of Lead Free Solder Joints: *Babak Arfaei*[1]; Liang Yin[2]; Eric Cotts[1]; Peter Borgesen[1]; [1]Binghamton University; [2]Universal Instruments Corporation

We have shown the final solidification temperature after lead free solder joint assembly to vary systematically with the combination of joint size, shape, and contact pad metallurgies. This has consequences for the initial distribution of secondary precipitates, and Sn grain morphology. Overall, ball grid array (BGA) scale SnAgCu joints usually consist of either a single Sn grain or a 'beach ball' twinning structure, while smaller solder balls tend to undercool more, and may show an interlaced twinning structure. Systematic thermal cycling testing of specially designed model assemblies showed the smallest SAC305 joints to have a clearly superior fatigue resistance for a given cyclic strain range, a trend which was not observed for SnPb joints. The evolution of the microstructure during thermal cycling test was carefully characterized. The effects of the precipitate distributions and the Sn grain morphology on the eventual recrystallization and failure were reported.

10:15 AM
The Effect of Composition on the Thickness Morphology and Growth of Interfacial Intermetallic in Pb-Free Solders: *Keith Sweatman*[1]; Jonathan Read[2]; Tetsuro Nishimura[1]; Kazuhiro Nogita[2]; [1]Nihon Superior Co., Ltd.; [2]University of Queensland

Since the interfacial intermetallic compound is commonly identified as a factor in the reliability of solder joints the variation in its initial thickness and subsequent growth rate with solder composition could be a consideration in the formulation and selection of lead-free solder alloy. In work reported in this paper the thickness of the interfacial intermetallic layer in 8 alloys that are representative of solder formulations currently commercially available or under consideration was measured in the as-soldered condition and after 1000 hours ageing at 130°C, 140°C and 150°C. To deal with irregular morphology the average thickness was estimated by dividing the cross-sectional area by the length of interface. The alloys are based around the Sn-Cu and Sn-Ag-Cu eutectic with additions of Ni, Bi, Ce and Ge. While some additions have the greatest affect the thickness and morphology of the joint as-soldered others affect mainly the rate of growth during subsequent ageing.

10:35 AM Break

10:45 AM Invited
The Development and Validation of a New CALPHAD Thermodynamic Database for Lead Free Solders
: *Paul Mason*[1]; Pingfang Shi[2]; Andreas Markström[2]; Johan Bratberg[2]; Anders Engstrom[2]; Qing Chen[2]; Huashan Liu[3]; Zhanpeng Jin[3]; [1]Thermo-Calc Software Inc.; [2]Thermo-Calc Software AB; [3]Central-South University

This presentation describes the development of a new thermodynamic database for Pb free solders using the CALPHAD methodology based on various types of available experimental data and theoretical information. This new database contains all the important Au-/Ag-/Cu-/Sn-based solder alloy phases within a 16-element framework [Ag-Al-Au-Bi-Co-Cu-Ge-In-Ni-Pb-Pd-Pt-Sb-Si-Sn-Zn] and in total 150 phases (most of them as multicomponent alloy solutions and/or intermediate compound solutions, and the rest as intermediate stoichiometric compounds) are included. The database can be used with Thermo-Calc for predicting various thermodynamic properties, stable/metastable phase equilibria and phase transformations of Au-/Ag-/Cu-/Sn-based solder systems (Pb-containing/Pb-free), and for simulating the effects of non-equilibrium solidification and micro-segregation of various soldering/brazing processes. Such predictions can be used to screen candidate solder alloys and identify unsuitable freezing temperature ranges or the presence of undesirable precipitate phases and are a useful compliment to experimental studies.

11:10 AM
Investigation of Ti-Alloyed Sn-Ag and Sn-Cu Solders for Their Microstructure, Solidification, Mechanical Properties and Interfacial Reactions: *W. Chris Chen*[1]; Sung K. Kang[2]; C. Robert Kao[3]; [1]National Taiwan University; [2]IBM T.J. Watson Research Center; [3]National Taiwan University

To improve the integrity and reliability of Pb-free solder joints, minor alloying elements have been commonly added to Sn-base solders. In this study, Ti-added Sn-Cu and Sn-Ag solders were investigated for their microstructure, solidification, mechanical properties, high temperature aging, and interfacial reactions. Different cooling rates were employed to evaluate the effect of cooling rates on their microstructure and mechanical properties. DSC analysis was used to study their melting and solidification behaviors, confirming Ti addition being very effective in reducing their undercooling. The intermetallic compounds formed in Sn-Cu-Ti and Sn-Ag-Ti were identified by SEM/EDX analysis. The microstructure of Ti-added solders was found to be very stable in an extreme aging condition, such as 200°C, 100 h. This was also confirmed by the microhardness measurements of the aged vs as-reflowed solders. The interfacial reactions of Ti-added solders with Au/Ni and Cu were also investigated in comparison to the solders without Ti additions.

11:30 AM
Lead Free Solder Joint Void Growth during Multiple High Temperature Reflows: *Yan Li*[1]; John Moore[1]; Rajen Dias[1]; Deepak Goyal[1]; [1]Intel

Voids in lead free solder joints are formed by entrapped volatiles during the reflow process and they have a negative impact on product performance, mechanically and electrically. Post-SMT (Surface Mount Technology) cumulative voiding criteria in lead free solder joints is less than 25% according to IPC-J-STD-001E and IPC-A-610E specifications. For the solder joints that experience multiple high- temperature reflows process prior to SMT, it is important to understand and predict how any voids will interact during subsequent high temperature exposures. Both in-situ 2D X-ray and 3D X-ray were used to study the growth kinetics of the solder joint voids during multiple reflow cycles. The results suggest that the voids start to grow when solder get melted in each reflow cycle. The growth kinetics have been modeled and shown to follow a diffusion controlled law of out-gassing bubble growth in a supersaturated molten solder liquid.

11:50 AM
Effect of Temperature on the Mechanical Properties of Cu_6Sn_5 and $(Cu,Ni)_6Sn_5$: *Dekui Mu*[1]; Han Huang[1]; Kazuhiro Nogita[1]; [1]The University of Queensland

Sn-based alloys are important lead-free soldering materials for the modern electrical industry. During the interface reaction between Sn-based alloys and Cu substrates, a layer of Cu_6Sn_5 intermetallic is formed. This Cu_6Sn_5 has different mechanical and thermal properties compared to the adjacent Cu and Sn-rich alloys. When operating temperatures change, thermal stresses will be generated due to mismatches in thermal expansion coefficients. Thus a comprehensive knowledge of the mechanical properties of Cu_6Sn_5, especially at elevated temperatures, would be useful in the predictive modeling of solder joint behaviour. The effects of temperature and Ni content on the mechanical properties of Cu_6Sn_5 were investigated using nanoindentation at elevated temperatures, in combination with SEM and EDS. The elastic modulus and hardness of Cu_6Sn_5 were found to decrease with the increased temperature from room temperature to 175°C. The combined effects of temperature and Ni content on the mechanical properties of Cu_6Sn_5 were discussed.

12:10 PM
Effects of Minor Pd Doping on Microstructural Evolution and Interfacial Reactions in Sn-3.0Ag-0.5Cu-xPd/Cu during Isothermal Aging: *Hsiu-Chuan Chuang*[1]; Jenq Gong Duh[1]; Chih-Yuan Cheng[2]; Jim Wang[2]; [1]Tsing Hua University; [2]Shenmao Technology Inc. Micro Material Institute

Cu-based under bump metallurgy (UBM) has been widely used in flip-chip technology. The major disadvantages of Cu UBM are fast consumption of copper, rapid growth of intermetallic compounds and the formation of Kirkendall voids. In this study, the effects of minor Pd addition into Sn-3.0Ag-0.5Cu-xPd/Cu solder joints on the growth of IMCs during thermal aging were investigated. For minor Pd doped solder joints, the growth rate of Cu3Sn and Kirkendall voids was significantly suppressed during thermal aging. Elemental distribution and quantitative analysis demonstrated that Pd atoms would dissolve into Cu6Sn5 IMC. The Cu6Sn5 with Pd addition is regarded as a barrier to suppress the growth of Cu3Sn and the formation of Kirkendall voids. Furthermore, the high speed impact test was introduced to evaluate mechanical reliability. This study demonstrated that a novel Sn-3.0Ag-0.5Cu-xPd solder alloy is beneficial for retarding consumption of Cu UBM and improving the reliability of solder joints.

Radiation Effects in Ceramic Oxide and Novel LWR Fuels: Computational Modeling of Defect Evolution under Irradiation

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Nuclear Materials Committee

On the Problem of Void Growth in Irradiated Materials: *Anter El-Azab*[1]; [1]Florida State University

We present a continuum physics framework for the problem of void nucleation and growth in irradiated materials. This framework is based on the principles of non-equilibrium thermodynamics of heterogeneous materials with defects. From this general framework, the equations governing the evolution of voids will be extracted in both sharp and diffuse interface senses and the consistency of the sharp and diffuse interface models will be demonstrated. Numerical results will be presented for void nucleation and growth under irradiation and the results will be compared with experimental data for single- and multi-component materials. This research was supported as a part of the Energy Frontier Research Center on Materials Science of Nuclear Fuel funded by the U.S. Department of Energy, Office of Basic Energy Sciences under subcontract # 00091538 at Florida State University.

9:00 AM
Interactions of Voids and Grain Boundaries in UO2 by Molecular Dynamics Simulation: *Tsu-Wu Chiang*[1]; Aleksandr Chernatynskiy[1]; Bowen Deng[1]; Susan Sinnott[1]; Simon Phillpot[1]; [1]University of Florida

Uranium dioxide (UO2) is the most important fuel material for light water reactors. Its thermal transport properties are strongly influenced by defects and microstructure, which evolve considerably during burn-up. The large thermal gradient in the pellet and the high thermal stresses result in defect migration and interaction. Here we analyze the interactions between voids and grain boundaries using molecular-dynamics simulation. Specifically, we construct a UO2 bicrystal structure and place a void some distance away from it. Thermal and/or stress are used to drive the migration of each such that they interact. The nature of the interaction – including possible effects such as pinning, void dissolution, and GB microcracking are characterized. The effects of different void sizes and differ types of grain boundaries are explored. This work was supported by DOE Office of Nuclear Energy's Nuclear Energy University Programs.

9:15 AM
Computational Studies of the Formation and Migration of Atomic Defect Clusters in UO2 under Irradiation: *Xian-Ming Bai*[1]; Anter El-Azab[2]; Todd Allen[3]; [1]Idaho National Laboratory; [2]Florida State University; [3]University of Wisconsin-Madison

The production and migration of point defects and defect clusters in uranium dioxide (UO2) under irradiation are two important mechanisms of radiation damage and microstructure changes in this material.

Investigating the atomistic details of these two processes is critical for understanding the microstructural evolution of UO2 under irradiation. Here we first use molecular dynamics simulations to investigate collision cascade induced defect production at the picosecond timescale at both 300 K and 1000 K. The energy of the primary knock-on atom is 2 keV. Based on 200+ cascade simulations, we obtain the distributions of defect clusters in terms of their compositions and sizes at both temperatures. We then use temperature accelerated dynamics to investigate the migration barriers of these interstitial and vacancy clusters and determine their mobility. Finally we examine the interaction between different types of defect clusters and discuss their opportunities of forming larger clusters at long timescales.

9:30 AM
Atomistic Simulation of Radiation Effects in Nano-Grained Cerium Oxide: *Amit Kumar*[1]; Ram Devanathan[2]; Vaithiyalingam Shutthanandan[2]; Satyanarayana Kuchibhatla[2]; Suntharampillai Thevuthasan[2]; Sudipta Seal[1]; [1]University of Central Florida; [2]Pacific Northwest National Laboratory

We have used classical molecular dynamics simulations to study defect production in bulk and nanograined cerium oxide (CeO_2) under irradiation conditions chosen to represent nuclear stopping and electronic stopping separately. Our results show the formation of isolated point defects with a greater abundance of defects on the oxygen sublattice. In ceria, Ce can exist in Ce^{3+} and Ce^{4+} charge states. We augmented our MD simulations with Monte Carlo simulations of Ce^{3+} distribution in nano-grained ceria containing 10% Ce^{3+}. Simulations were performed in conjunction with irradiation experiments on single and poly crystalline CeO_2 thin films prepared using molecular beam epitaxy on 10 mol % yttria stabilized zirconia and sapphire substrates, respectively. We irradiated the ceria thin films with 2 MeV He^+ ions and characterized the Ce oxidation state change by in-situ x-ray photoelectron spectroscopy. We will discuss the findings of this integrated study in the context of radiation tolerance of ceramics.

9:45 AM
Electrochemistry of Defects in Irradiated UO_2: *Abdel-Rahman Hassan*[1]; Thomas Hochrainer[1]; Jianguo Yu[2]; Xianming Bai[2]; Todd Allen[3]; Anter El-Azab[1]; [1]Florida State University; [2]Idaho National Laboratory; [3]University of Wisconsin

Stoichiometric changes play a critical role in the dynamics of defects and microstructure evolution in oxides under irradiation. We investigate the electrochemistry of defects in UO_2 under irradiation, where both the atomic displacements by energetic collision cascades and the exchange of oxygen with the ambient drive stoichiometric changes in the material. The problem is cast in the form of balance laws of lattice and electronic defects under defect generation and diffusion, with boundary conditions dictated by the oxygen partial pressure at the free surface. Inherent to this problem is the electrostatic field resulting from the segregation of charged lattice and electronic defects. Thus, the scenario of dynamic stoichiometric changes in a UO_2 film under ion irradiation will be illustrated in detail. This research was supported as a part of the EFRC on Materials Science of Nuclear Fuel funded by the U.S. DOE, BES under subcontract #00091538 from INL to FSU.

Multi-Scale Modeling of Fission Gas Evolution in UO2: *Blas Uberuaga*[1]; David Andersson[1]; Xiang-Yang Liu[1]; Pankaj Nerikar[1]; Christopher Stanek[1]; [1]Los Alamos National Laboratory

Fission gases in uranium dioxide (UO2) nuclear fuels, of which Xe is one of the most prominent, influence fuel performance during reactor operation and have implications for accident scenarios. Their behavior, including the nucleation and growth of fission gas bubbles, is a multiscale problem. We use a multiscale modeling approach to understand the behavior of Xe in UO2 as a function of microstructure by considering the effect of different types of grain boundaries on the evolution of Xe. Using density functional theory we calculate the activation energies for Xe diffusion in UO2±x and we determine the interaction of Xe with different types of grain boundaries in UO2 using molecular statics. These results are then input into amesoscale model that predicts the evolution of Xe as a function of microstructure containing different distributions of grain boundaries. We find that the evolution of Xe depends significantly on the microstructure.

10:45 AM
Mesoscale Modeling of Intergranular Bubble Growth and Percolation: *Paul Millett*[1]; Michael Tonks[1]; [1]Idaho National Laboratory

The production of fission gas products, namely xenon and krypton, in irradiated nuclear fuel elements leads to a variety of phenomena that directly influence fuel performance. Central to the retention and release of fission gases is the evolution of bubbles existing on grain boundaries and grain triple junctions. Here, three-dimensional phase-field simulations of the growth and coalescence of intergranular Xe bubbles in UO2 bicrystal grain geometries will be presented. We investigate the dependency of bubble percolation on three factors: the initial bubble density, the Xe grain boundary diffusivity, and the bubble shape, which is governed by the ratio of the grain boundary energy over the surface energy. The simulations show that variations of each of these factors can lead to large discrepancies in the bubble coalescence rate, and eventual percolation, which may partially explain this observed occurrence in experimental investigations. This research was supported by the NEAMS program within DOE-NE.

11:00 AM
Self-Healing Response of Oxides to Irradiation: Dilpuneet Aidhy[1]; *Dieter Wolf*[1]; [1]Argonne National Laboratory

Molecular dynamics simulations of irradiated CeO2 (often considered a surrogate for UO2, the most widely used nuclear fuel) reveal the formation of charge-neutral interstitial dislocation loops identical to ones observed recently in experiments. Focusing on the kinetic phase that follows the initial damage cascade, our simulations of the cluster-formation mechanism reveal a self-healing response of the perfect crystal to the radiation-induced defects. Remarkably, the lattice responds to point defects created during irradiation with the spontaneous creation of new point defects. We demonstrate that these new 'structural defects', with a negative energy of formation, neutralize the cluster by screening its long-range Coulomb potential, thereby lowering the overall energy and localizing the damage. A similar lattice response was recently identified also in simulations of MgO and UO2, although very different types of clusters were formed, suggesting that this self-healing screening response may be an intrinsic reaction of all ionic crystals to irradiation.

11:15 AM
Computer Simulation of Dislocation Loop Evolution in Irradiated Cerium Oxide with Lanthanum Dopant: *Yinbin Miao*[1]; Aaron Oaks[1]; Wei-Ying Chen[1]; Bei Ye[1]; Brian Kleinfeldt[1]; James Stubbins[1]; [1]University of Illinois at Urbana-Champaign

Recent transmission electron microscope (TEM) experiments of irradiated ceria doped with lanthanum, which acts as a surrogate for the fluorite type mixed oxide of nuclear fuel, indicate the dislocation loops formed in {111} planes. Also, there exists prominent variation of loop growth rate in specimens of different lanthanum dopant concentrations. Static calculation is utilized to explore the energetic preference of defect configurations. Frenkel pairs (FP's) are introduced into ceria systems with various doping conditions to simulate defect evolution under irradiation via molecular dynamics. The dislocation loops observed are proved to be stoichiometric planar interstitial clusters. The loop formation and growth are dominated by cation FP's due to their resistance to recombination and assisted by anion FP's which neutralize local charge. Anion FP recombination is faster in higher dopant concentration cases whereas lanthanum FP's are energetically favored compared to cerium FP's, explaining the growth rate difference. Coalescence of close loops, observed in in-situ TEM, is also simulated.

11:30 AM
Segregation of Ru to Edge Dislocations in Uranium Dioxide: *Anuj Goyal*[1]; Bowen Deng[1]; Minki Hong[1]; Aleksandr Chernatynskiy[1]; Susan Sinnott[1]; Simon Phillpot[1]; [1]University of Florida

Mechanical behavior of nuclear fuel during irradiation depends on a great number of individual phenomena, but only a few of which are adequately understood. Dislocation behavior is therefore significant in understanding the formation and clustering of defects on atomic scale. We used atomistic simulation methods to investigate the interaction of Ru fission products with the core of an edge dislocation in UO2. Molecular static simulations are employed to study the {110}<110> and {100}<110> slips systems in stoichiometric UO2. Segregation behavior of Ru with various charge states at various cationic substitution site is examined and characterized in terms of the charge state, ionic radius and local stress state. This research is being performed using funding received from the DOE Office of Nuclear Energy's Nuclear Energy University Programs.

Powder Material Principles Applied to Additive Manufacturing: *David Bourell*[1]; [1]University of Texas

Laser Sintering (LS) is an additive manufacturing process in which a part is constructed from powders without the use of part-specific tooling. Production of metallic, ceramic and composite parts in some cases requires some form of pre-processing or post-process sintering to achieve full density. Powder Densification Maps are a tool for optimizing the pre- and post-processing parameters. Such maps are computational representations of part density as affected by time, temperature, pressure and materials properties. This paper summarizes LS developments with emphasis on the utility of powder densification mapping of powder pre-processing and part post-processing. Specific emphasis includes developments in Powder Densification Map production for zirconia, Ti 6Al 4V, nickel-based Alloy 625 and copper. A comparison of theoretically predicted and experimentally determined densities for a variety of processing conditions is presented.

Optimizing Ductility and Strength of Ultrafine Grained Nickel via Cryo-Milling and Ceracon Forging: *Yonghao Zhao*[1]; T.D. Topping[1]; J.F. Bingert[2]; E.J. Lavernia[1]; [1]University of California Davis; [2]Los Alamos National Laboratory

When bulk nanostructured (NS) materials are prepared via consolidation of individual particles, agglomerates or clusters, extraneous defects, such as porosity, insufficient bonding, and impurities are sometimes introduced leading to the degradation of ductility. In this study we prepared bulk ultrafine grained Ni with high density and purity via optimizing cryomilling, degassing and Ceracon forging processes. As a result, the consolidated fine-grained Ni have good combinations of a yield strength of 470 MPa and a ductility of 42%, and a yield strength of 310 MPa and a ductility of 49%. The combination of strength and ductility of our Ni is superior to those of the nanocrystalline/ultrafined-grained Ni prepared by eletrodeposition, cryo-rolling, and equal-channel angular pressing methods. The microstructural origins for such combinations of good strength and high ductility will be discussed (Advanced Materials 20, 3028).

9:20 AM Invited
Powder Metallurgy and Terabytes: *Pavan Suri*[1]; [1]Heraeus Materials Technology

Powder metallurgy processing is typically associated with Fe-based, refractory metal based and super alloy based near net shaped products. Precious metal based products are typically not well known. This presentation gives and introduction to the materials and fabrication methods of Platinum based products made via powder metallurgy and used in the magnetic data storage industry to make hard disk drives.

9:45 AM Invited
Controlling Performance of PM Consolidation in Extrusion: *Wojciech Misiolek*[1]; [1]Lehigh University

Extrusion gives flexibility in consolidation of metal powders while applying hydrostatic compressive stresses in the deformation zone. The extrusion parameters can be adjusted to obtain the desired process performance. The selection of the extrusion process and its parameters depends on powder and material characteristics. Ductile metal powders like Aluminum and Copper can be cold consolidated to theoretical density under specific conditions of powder extrusion without the need for sintering when plastic deformation follows the consolidation stage. This leads to the retention of initial microstructure of the powders and at the same time achieving the desired density and mechanical properties. A review of studies performed on different grades of Aluminum and Copper powders is presented. The consolidation behavior of each grade of powder was analyzed and determined from the density / porosity 2D and 3D contour maps of billets and extrudates as well as from the extrudates' hardness measurements.

Advances in Synthesis and Densification of Heterogeneous Materials: *Fernand Marquis*[1]; [1]Naval Postgraduate School

Because the strength, toughness and other engineering properties of heterogeneous materials are strong dependent on their grain size and density, the quest to achieve simultaneously dense and fine/ultrafine grain size materials has been one of the most important in materials science and engineering. In this work we explore novel approaches for producing dense and fine/ultrafine heterogeneous materials. Typical approaches consist of reaction synthesis, combustion synthesis and shock synthesis followed by dynamic and static consolidation and densification pre and post reaction synthesis. Typical heterogeneous materials covered in this paper consist of tungsten heavy alloys, coated graphite powders, metal silicides and multiphase, multi microstructural constituent ceramic armor materials. The synthesized and densified materials were fully characterized by OM. SEM, TEM, EDX analysis, quantitative image analysis, X-Ray diffraction and mechanical testing. This paper presents and discusses the effect of reaction and processing parameters on the microstructure, densification and strength and toughness of typical heterogeneous materials.

10:50 AM
Processing Challenges of Dual-Matrix Carbon Nanotube Aluminum Composites: *Amal Esawi*[1]; Khaled Morsi[2]; Ihab Salama[1]; Hany Saleeb[1]; [1]The American University in Cairo; [2]San Diego State University

The interest in nanostructured materials has grown considerably in recent years. Significant enhancements in strength have been reported. A common problem, however, is the associated reduction in the materials ductility. Efforts to overcome this ductility challenge by designing multi-modal or hierarchical microstructures have recently been reported. In this work, we report on the processing of dual matrix carbon nanotubes composites in which composite particles of aluminum reinforced with carbon nanotubes are embedded within a soft aluminum matrix. Such approach aims at combining the high strength of the CNT-reinforced region with the ductility of the soft aluminum matrix. Preliminary results, however, show that the interface quality is pivotal in promoting bonding between the two dissimilar particles since a poor interfacial bond is found to lead to deterioration in the composite properties; thus making it impossible to achieve the desired paradox of strength and ductility. Processing-related challenges in this regard are discussed.

11:15 AM
The Versatility of Combustion Synthesis Processing: *K. Morsi*[1]; [1]San Diego State University

Over the past few decades the process of combustion synthesis (CS) has been combined with other processes and effects. This has lead to level-1, level-2 and higher new CS-based hybrid processes with the potential to improve on conventionally produced CS products and eliminate some of inherent disadvantages of CS. This presentation discusses fundamental aspects of CS in light of new research, and provides an overview of single and multi-level hybrid processes exemplifying the versatility of combustion synthesis processing. Research work by the author in this context is also discussed.

Recent Developments in Biological, Electronic, Functional and Structural Thin Films and Coatings: Process-Properties-Performance Correlations I

8:30 AM Introductory Comments

8:35 AM
Atomic Scale Characterization of the Nanoscaled Structure of Sputtered Fe-C Thin Films: *Xavier Sauvage*[1]; Amélie Fillon[1]; Jean Marie Le Breton[1]; Ben Lawrence[2]; Michel Perez[3]; Colin Scott[4]; Arnaud Weck[5]; Chad Sinclair[2]; [1]University of Rouen, CNRS; [2]Department of Materials Engineering, The University of British Columbia; [3]Université de Lyon - INSA de Lyon, MATEIS; [4]ArcelorMittal Research Maizières; [5]Mechanical Engineering Department, University of Ottawa

Sputtered Fe-C thin films were deposited on Si and Fe substrates with various carbon contents, from 10 to 40at.%. Depending on the carbon concentration, the as-deposited films exhibit an amorphous (high C content) or nanoscaled structure (low C content). Films were characterized by conventional Mössbauer spectroscopy, conventional and High Resolution TEM. The spatial distribution of carbon atoms was measured thanks to Atom Probe Tomography. During isothermal annealing, the super saturated solid solution of the nanoscaled thin films decomposes giving rise to the nucleation and growth of carbides and carbon free ferrite nanoscaled grains. Thin films with a higher C content and that are amorphous, do crystallize and also decompose into ferrite and carbides nanoscaled grains. A special emphasis was given on the influence of the carbon concentration on the decomposition kinetics.

9:05 AM
Dependence of Tribology of Carbide Derived Carbon Films on Humidity: *Marcin Tlustochowicz*[1]; [1]CTLGroup

Tribologically advantageous films of carbide derived carbon (CDC) have been successfully synthesized on binderless tungsten carbide by reacting it with chlorine at 1000°C. Some of the treated samples were later dechlorinated by an 800°C hydrogenation treatment. The results of detailed characterizations of the CDC films and sliding contact surfaces were correlated with the friction and wear behavior of the CDC films in various tribosystems, including CDC-steel, CDC-WC, and CDC-CDC and in two specific environments: moderately humid air and dry nitrogen, as well as in an environment of changing water vapor pressure. Friction coefficient values as low as 0.11 in moderately humid air and 0.03 in dry nitrogen were obtained. A model of tribological behavior of CDC has been proposed that takes into consideration the tribo-oxidation of counterface material, the capillary forces from adsorbed water vapor, the carbon-based tribofilm formation, and the lubrication effect of both chlorine and hydrogen.

9:35 AM
Structural and Optical Properties of Silicon Carbonitride Thin Films Deposited by Reactive DC Magnetron Sputtering: *Okan Agirseven*[1]; Tolga Tavsanoglu[1]; Esra Ozkan Zayim[1]; Onuralp Yucel[1]; [1]Istanbul Technical University

In this study, silicon carbonitride thin films of variable compositions were deposited on glass and AISI M2 high-speed steel substrates by reactive DC magnetron sputtering of high purity silicon target using CH_4 and N_2 as reactive gases. The composition of the coatings has been modified by the change in the reactive gas flow ratios. Microstructural properties were investigated by cross-sectional SEM analyses. Spectrophotometer has been used to measure the optical transmittance and reflectance of silicon carbonitride thin films over the spectral range from 280 to 1000 nm. The optical constants and band gap values of the films are further evaluated with respect to the gas flow rate. The results of analyses and calculations provided the information about the relationship between the reactive gas flow rates, microstructure, optical constants and band gap values of silicon carbonitride films.

9:55 AM
Influence of TIG Re-Melting and RE (La2O3) Addition on Microstructure, Hardness and Wear of Ni-WC Composite Coating: Bal Mukund Dhakar[1]; *Dheerendra Dwivedi*[1]; Satpal Sharma[2]; [1]Indian Institute of Technology Roorkee; [2]Gautam Buddha University

Influence of re-melting and lanthanum oxide (La2O3) addition on microstructure, hardness and abrasive wear behavior of Ni-WC composite coating developed by flame spraying has been presented in this paper. The Ni-WC coating was modified with the addition of La2O3. Unmodified and modified coatings were subjected to re-melting by gas tungsten arc welding. EDS and XRD analysis were carried for elemental and phase analysis of the unmodified and modified coatings. Vickers microhardness of various coatings was carried out to study influence of the La2O3 addition and re-melting on hardness of the coatings. Abrasive wear was carried out at different normal loads against two abrasive grit sizes 120 and 600. SEM analysis of worn out surfaces was carried out to understand operating wear mechanism. The La2O3 addition and re-melting result in finer grain structure, increase in hardness, improvement in abrasive wear resistance of the coating as compared to that of unmodified coating.

10:40 AM
Evaluation of Mechanical Properties of Ni-Ti Bi-Layer Thin Film: Maryam Mohri[1]; *Mahmud Nili-Ahmadabadi*[1]; [1]University of Tehran

Shape memory thin films are attractive candidates for micro-electro-mechanical-system because of their large deformation and strong recovery force. In the present study Ni-Ti thin films have been deposited on glass substrates by dc magnetron sputtering source fitted with an alloy target, which prepared in vacuum arc remelting (VAR). In this study, three types of thin films have been deposited; Ni45Ti50Cu5 and Ni50.7Ti49.3 thin films were separately deposited on glass substrate and also a composite bi-layer of Ni50.7Ti49.3 and Ni45Ti50Cu5. The as deposited Ni-Ti thin films were crystallized to change the amorphous to a nano-structured material to characterize shape memory and superelastic behaviors. The composition of targets and films were determined by energy dispersive X-ray spectroscopy. The crystallization, surface morphology and structural features were studied using X-ray diffraction (XRD), atomic force microscope (AFM).Mechanical properties were characterized by nanoindentation analysis and compared to each other.

11:00 AM
Anodic TiO2 Nanotubular Arrays with Pre-Synthesized Hydroxyapatite - A Promising Approach to Enhance the Biocompatibility of Titanium: *Luning Wang*[1]; [1]University of Alberta

Hydroxyapatite (HA) coating is widely applied on metallic implant substrate to enhance the bioactivity for orthopaedic and orthodontic application. Highly ordered titanium dioxide (TiO_2) nanotubular arrays on titanium obtained via electrochemical anodization has been shown a certain bioactivity for biomedical application. In the present work, an alternative immersion method (AIM) is applied on the TiO_2 nanotubular to rapidly preload synthetic HA. The AIM treatment promised to dramatically enhance the HA coating formation on TiO_2 nanotubular. To study the effect of AIM treatment, the different of geometrical and crystal structure of the TiO_2 nanotubular was carried out. The as-treated specimen and as-formed HA coating was evaluated for HA formation and cell culture test to evaluate its biocompatibility. Results showed that AIM is a promised treatment to highly enhance the biocompatibility of TiO_2 nanotubular arrays in comparison with non-treated TiO_2 nanotubular arrays.

11:30 AM
Preparation and Properties of Cu2ZnSnS4 Thin Films by Electrodeposition and Sulfurization: *Chao An*[1]; Huimin Lu[1]; Xi Chen[1]; [1]Beihang University

The environmental-friendly Cu2ZnSnS4(CZTS) thin film is a promising alternative to semiconductors based on Ga or In as solar absorber material for its beneficial properties like good optical properties, high absorption coefficient and an ideal band gap for photovoltaic applications, not to speak of abundant and cheap raw materials. In this paper, Cu2ZnSn precursor films were electrochemically deposited on Mo-coated glass substrate at room temperature from the air-and water-stable ionic liquid based on chloride/urea eutectic mixture. Then the precursor films were sulfuretted in a tube furnace at a series of sulfurization temperatures using argon as the carrier gas to successfully form CZTS thin films. The films prepared were characterized by X-ray diffraction (XRD), scanning electron microscope (SEM) and energy dispersive spectroscopy (EDS). The CZTS thin films having good tin pyrite-type phase structure with the preferential grain orientation along (112) were obtained as revealed in XRD analysis.

12:00 PM
HR-STEM Characterization of Sr2FeMoO6 Thin Films Possessing Both High Saturation Magnetization Values and Tc: *Manisha Dixit*[1]; Robert Williams[1]; Adam Hauser[2]; Fengyuan Yang[2]; Hamish Fraser[1]; [1]Materials Science and Engineering Department, The Ohio State University; [2]Department of Physics, The Ohio State University

Thin films of double perovskite Sr2FeMoO6 (SFMO) were grown along <001> and <111> on SrTiO3 substrates by magnetron sputtering. Initial characterization using Rutherford back-scattering spectrometry showed the presence of stoichiometric SFMO while X-ray diffraction data indicated pure phase SFMO. These films also exhibited the unusual characteristic of both a high Tc of ~850K and a high saturation magnetization value close to 4uB per formula unit. To further characterize the structure of these thin films, TEM samples were prepared using a FEI Helios™ Nanolab FIB and characterized using a FEI-TitanTM 80-300 aberration-corrected scanning transmission electron microscopy (STEM) using high-angle annular dark-field mode. STEM imaging was complemented with electron energy loss spectroscopy, energy filtered TEM and energy dispersive x-ray spectroscopy. The films were found to have regions of iron lean and iron rich phases with variable oxidation states that adapt to the double perovskite crystal structure and lead to enhanced magnetic properties.

8:30 AM
Ecological Recovery Process for Textile Waste: *Eftalea Carpus*[1]; Emilia Visileanu[1]; Michaela Dina Stanescu[1]; [1]The Research-Development National Institute for Textile and Leather

Humanity must learn from the global financial and economic crisis experience - is the conclusion of the policy makers who should develop a strategy designed to reinvigorate the economy and make possible an" intelligent, sustainable and favourable to inclusion" growth, by a better coordination of national and European policies.The recovery and reintroduction into the economic circuit of the textile material resources must be considered as component parts of the strategies of harmonizing the relationships between the economic growth, consumption of natural resources and environmental protection. It is obvious that at the origin of pollution there are the technological processes of textile processing with impact on air, water, soil, as well as the storage processes. Ecological methods were tested on the basis of separating the respective components of polymers-cellulose blends, for example the removal of cellulose fibers with enzymatic products for isolating the polyester component for subsequent processing.

8:50 AM
Technical Tools for Increasing the Eco-Efficiency of Textile Products: *Emilia Visileanu*[1]; Eftalea Carpus[1]; [1]The Research-Development National Institute for Textile and Leather

Textile industry is one of the most important sectors of the global economy, both in terms of exports and in terms of employment. It is an active and innovative sector, consisting of a large number of sub-sectors, covering the entire production cycle, from the production of raw materials as semi-finished products (fibers, yarns, woven fabrics, knitted fabrics, nonwovens) to multifunctional, interactive, intelligent textile products and systems. Adapting infrastructure and logistics that encourages the marketing of "sustainable", "fairly traded" and "green" products will facilitate the transition towards dematerialization and eco-efficiency among producers. The ecological recovery of textile waste requires the use of new management tools (life cycle analysis, clean production, environmental cost management, etc.), as well as new methods of training and ecological education (the development of ecological consciousness, sense of responsibility, ability to make decisions).

9:10 AM
Characterization of the Chemical Changes and Surface Properties of Carbonated Waste Cement: *Kwangsuk Yoo*[1]; Seong-Ho Lee[1]; Sun-Ho Hwang[1]; Ji-Whan Ahn[1]; [1]Korea Institute of Geoscience and Mineral Resources

This study investigated changes in the chemical properties of carbonated waste cement, including the phase transformation, gel polymerization, and specific surface area, as well as cation exchange capacity (CEC) and the adsorption ability of heavy metal ions (Cr6+ and Cu2+). Highly crystalline calcite and highly polymerized silica gel with a three-dimensional network were found to form in carbonated waste cement. The specific surface area and the CEC of waste cement increased with an increase in the carbonation percentage. In addition was a linear relationship between the specific surface area and the carbonation percentage of the waste cement. When the carbonation percentage of waste cement was 35%, the CEC of the carbonated waste cement reached approximately 22 meq/100g. The increase of the CEC confirmed that carbonated waste cement could adsorb heavy metals.

9:30 AM

Recycling of Flat Glass Waste into Clayey Ceramic: Thais da Costa Caldas[1]; Alline Cordeiro Morais[1]; Sergio Neves Monteiro[1]; *Carlos Fontes Vieira*[1]; [1]State University of the North Fluminense Darcy Ribeiro

This work has as its objective to evaluate the firing behavior of a kaolinitic clayey body from Campos dos Goytacazes-RJ incorporated with flat glass waste (FGW) from civil construction. Incorporations of the waste, with a particle size less than 74 μm (200 mesh), were performed in the red ceramic in the following amounts: 0%, 2,5%, 5% and 10wt.%. Specimens were prepared by uniaxial press-molding and then fired at 850 and 1050°C. The characterization of FGW was done by X-ray Fluorescence. The physical and mechanical properties evaluated were: linear shrinkage, water absorption and flexural rupture strength. The microstructure of the fired ceramics was evaluated by optical microscopy (OM). The obtained results showed that the flat glass waste can be used as a component of ceramic bodies once it was noticed tolerable modifications of technological behavior.

A Study on Waste Packaging Containers Generated by Household in Taiwan: *Esher Hsu*[1]; Chen-Ming Kuo[2]; [1]National Taipei University; [2]I-Shou University

This study aims to estimate the amount of waste packaging containers generated by household in Taiwan and also explore its spread based upon the estimation of recycled and un-recycled amount. A sampling survey with ratio estimation is conducted for estimating the recycled amount and the refuse sampling method for municipal solid waste composition is employed to estimate the un-recycled amount. Total amount of waste packaging containers in 2009 generated by household in Taiwan is estimated to be 708,532 m.t. which is much larger than the amount declared by importers and producers. It implies that the amount of waste packaging containers is underestimated around 1/3. In which, 70.3% of the waste packaging containers are recycled and 29.7% are landfilled or incinerated. 94% of the recycled waste packaging containers are recycled through official certified recycling system. The declaration mechanism for products with packaging containers in Taiwan has to be improved.

10:30 AM

Manufacture of Calcium Sulfoaluminate with Alumina Waste: *Ji-Whan Ahn*[1]; Sun-Ho Hwang[1]; Seong-Ho Lee[1]; Kwangsuk Yoo[1]; [1]Korea Institute of Geoscience and Mineral Resources

The high functional cements have been focused on, with increase on the need for multistoried building, complex constructions and so on. The calcium sulfoaluminate is a representative cement with high functions. The aluminate resource, such like bauxite, is used as main raw material to manufacture calcium sulfoaluminate. Unfortunately, the aluminate minerals are almost not buried in south Korea. Therefore, This study proposes a method to manufacture a calcium sulfoaluminate with industrial by-products, which are containing a large amount of aluminate. This study proposes the modified calcium modulus quantitatively to deduce the optimum mixing condition of raw materials before sintering process. This calcium modulus represents the relative proportion of calcium oxide, iron oxide, sulfate, alumium oxide, and silica on the form of the calcium oxide. When the modified calcium modulus was applied to synthesis CSA with alumina waste, CSA with high quality was formed with dicalcium silicate phase.

10:50 AM

Recycling of Styrene-Divinylbenzene Copolymer through Sequential Mass-Suspension Polymerization Process: Nathália Campelo[1]; Alexandre Umpierre[2]; *Fabricio Machado*[2]; [1]Universidade Católica de Brasília; [2]Universidade de Brasília

The present work illustrates the reuse of macoporous anion exchange resins (employed for decolorization of solutions of organic substances such as sugar syrup and fruit juice concentrates in the soft-drink and beverages industries), based on crosslinked styrene-divinyl benzene copolymer (Sty-DVB) to the production of polymeric materials. Micro-sized particles of polystyrene and poly(styrene-ethyl acrylate) were obtained by mass-suspension sequential polymerization process. The proposed experimental technique was able to perform proper dispersion of the Sty-DVB in the thermoplastic matrix of polystyrene. The final material showed good thermal stability, showing degradation profile similar to that observed for the pure polystyrene. It was also noticed that polymer particles with spherical morphology can be obtained. In addition, the incorporation of ethyl acrylate monomer into the polystyrene chains minimizes the undesirable effect of fracture in polymeric particles, improving the mechanical and end-use properties of the final polymeric composite.

11:10 AM

Modeling of Heavy Metals Ions Adsorption by Polyamidoamine Dendrimers: Mohamed Barakat[1]; *J Kuhn*[2]; [1]KAU University; [2]USF

Polyamidoamine (PAMAM) dendrimers have potential for many environmental, applications including separations. This study presents a kinetic model of metal ions by generation 4 PAMAM-OH with ethylenediamine core based on data obtained from ultraviolet-visible (UV-Vis) spectroscopy. This work will discuss aspects related to characterization of the dendrimer before and after adsorption using nuclear magnetic resonance (NMR) spectroscopy, gas chromatography/mass spectrometry (GC/MS) characterization of the metal structures, molecular simulations using quantum mechanics/molecular mechanics (QM/MM), and immobilization onto titanium (IV) dioxide (titania). The results of this study will be used in the development of separation processes that employ PAMAM dendrimers for adsorption of heavy metals from wastewater. The produced samples will be evaluated by adsorption of heavy metals such as Cu(II), Ni(II), and Cr(III) from electroplating wastewater (in a separate article).

11:30 AM

Mullites Bodies Produced From the Kaolin Residue Using Microwave Energy: *Maria Brasileiro*[1]; Romualdo Menezes[2]; André Rodrigues[1]; Gelmires Neves[3]; Lisiane Santana[3]; [1]Universidade Federal do Ceará; [2]Universidade Federal da Paraíba; [3]Universidade Federal de Campina Grande

Mullitization behavior of a mixture of kaolin residue and alumina as the starting materials was examined by microwave heating. X-ray diffraction results showed that in times of 15 minutes was possible to obtain mullite. Microstructure of samples heated in a microwave oven and conventional electric furnace were compared. Results showed that the grain growth of mullite was sharper by microwave heating. It was observed that with the increase of the processing variables of the peak intensity of mullite phase increased.

Refractory Metals 2012: W and Mo Alloys | Structure, Microstructure and Properties

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS: Refractory Metals Committee
Program Organizers: Eric Taleff, The University of Texas at Austin; Todd Leonhardt, Rhenium Alloys Inc; Rachel DeLucas, H.C. Starck; Gary Rozak, HC Starck Inc

Wednesday AM — Room: Mockingbird 2
March 14, 2012 — Location: Swan Resort

Session Chairs: Todd Leonhardt, Rhenium Alloys Inc.; Gary Rozak, HC Starck Inc

8:30 AM
Brittle to Ductile Transition in Forged Tungsten and Tungsten-Tantalum Alloys: *David Armstrong*[1]; J Gibson[1]; J Lachanary[1]; Angus Wilkinson[1]; Steve Roberts[1]; Michael Rieth[2]; [1]University of Oxford; [2]Karlsruhe Institute of Technology

Tungsten alloys are considered the most likely materials for the divertor of a fusion power plant due to tungsten's high melting point, low sputtering yield and low activity. There is a critical need to understand their fracture properties. Four point bend tests have been performed on millimetre-scale specimens of forged W5wt%Ta, W1wt%Ta and UHP tungsten at temperatures from 290K to 1273K. These alloys have highly anisotropic microstructures, with "pancake" grains following the forging direction.In the L-T direction (parallel to the "pancakes") failure is by brittle, intergranular fracture at all temperatures. In the L-S direction (normal to the "pancakes") below 600K, brittle fracture occurs, but with the fracture path predominantly along the long axis of the bar. EBSD shows that the fracture follows specific grain boundaries. Above 600K mixed mode failure occurs by delamination of the specimen along these weaker boundaries.

8:50 AM
The Re Effect on Fracture Toughness of Mo- and W-Based Alloys for Nuclear Applications: *Mikhail Sokolov*[1]; Evan Ohriher[1]; Roger Stoller[1]; [1]ORNL

The refractory alloys are always considered as attractive structural materials for high-temperature nuclear applications due to high melting point, good thermal conductivity and excellent high temperature strength. Unfortunately, these advantages are coupled with very low fracture toughness and serious difficulties associated with fabrication. In this study, the alloy compositions of Mo-15% Re and Mo-25% Re (by weight) were produced by vacuum arc remelting. The melt stock consisted of commercial molybdenum rods from powder metallurgy processing and electron beam melted Mo-Re master alloy. The ingots were canned in Mo and hot extruded to rectangular sheet bar. The purpose is to investigate whether intermediate Re content could still result in good fracture toughness compared to diluted alloys and in improved radiation resistance compared to concentrated Mo-Re alloys at the same. The "Re-effect" was also studied on W-5Re and W-25Re alloys. Fracture toughness of these alloys are compared to pure W properties.

9:10 AM
Room Temperature Fracture Toughness of Mo-41%Re and Mo-47.5%Re Alloys: Dylan Liebl[1]; *Jennifer Gaies*[2]; Mark Opeka[2]; [1]University of Wisconsin-Madison; [2]NSWC Carderock Division

The room temperature fracture toughness of Mo-41%Re and Mo-47.5%Re was measured for alloys produced by three processes: hot isostatic pressing, swaging, and hot rolling. Fracture toughness testing and analysis was performed per the ASTM E1820 standard. The various fabrication processes yielded microstructures that differed in grain size, porosity, and texture, and the fracture toughness values are compared.

9:30 AM
Stress-Controlled Cyclic Deformation Response of Mo, Mo-Re and Mo-Si Solid Solutions: *Xiaojiao Yu*[1]; Sharvan Kumar[1]; [1]Brown University

The addition of solute atoms such as Rhenium and Silicon to Molybdenum appears to alter its response to cyclic loading significantly. In this study, stress-controlled cyclic deformation behavior has been evaluated as a function of temperature on two solid solution alloys, one which is a concentrated solid solution, Mo-41 wt.% Re and the other is a dilute solid solution, Mo-0.3 wt.% Si. Fatigue life and ratcheting strain evolution are compared to pure Mo to understand the effect of alloying. The resulting dislocation substructure evolution has been characterized by electron microscopy to understand differences in observed behavior. Further, the imposition of a dwell time during cyclic loading, both at the maximum and minimum stresses, enables the examination of the influence of creep on these parameters. The results of these experiments will be presented and their implications for the behavior of multiphase alloys will be discussed.

9:50 AM
Fabrication of Tungsten and Tungsten-Rhenium Alloys via Pulsed Electric Current Sintering: *Jonathan Webb*[1]; Cory Sparks[2]; Mary O'brien[1]; Indrajit Charit[1]; Darryl Butt[2]; Megan Frary[2]; Mark Carroll[3]; [1]University of Idaho; [2]Boise State University; [3]Idaho National Laboratory

This study describes some microstructural characteristics and macroscopic properties of highly dense tungsten and tungsten-rhenium specimens manufactured by the consolidation of submicron tungsten powder via Pulsed Electric Current Sintering (PECS). Tungsten powder batches with an average particle size of ~0.425 micrometer were consolidated at temperatures ranging from 1373 K to 1973 K and isothermal hold times from 2 to 30 minutes at applied stresses of 20 to 80 MPa via PECS. The relative densities of the consolidated specimens ranged from 80% to 97% (with respect to the theoretical density of tungsten). Alloyed powders of tungsten and rhenium were also sintered under similar conditions. The sintering mechanisms were studied by dynamic kinetics analysis based on the specimen time-temperature dependent displacement. Tensile properties of the fabricated samples were characterized using a micro-tensile testing apparatus. This research is supported by the NEUP contract # 42246-57.

10:10 AM Break

10:20 AM
Stress-Strain Behavior of Nb Single Crystal Tensile Specimens with Different Grain Orientations: *Di Kang*[1]; Derek Baars[1]; Aboozar Mapar[1]; Payam Darbandi[1]; Thomas Bieler[1]; Farhang Pourboghrat[1]; Chris Compton[2]; [1]Michigan State University; [2]Nat'l Superconducting Cyclotron Lab

Nine Nb single crystal tensile specimens with different grain orientations were extracted from a Ningxia ingot slice. All specimens were deformed to 40% engineering strain, and the stress-strain curves are presented. OIM scans were done at the center of the gauge length of each specimen before and after deformation to investigate the effect of strain on grain orientations. As a reference, OIM scans were also done on undeformed specimens that were cut adjacent to the deformed specimens. Some of the undeformed specimens show a noticeable orientation gradient along the gauge length. The effect of this gradient on the deformation behavior is examined. SEM images on the top and transverse surfaces of the deformed specimens were taken in order to identify slip systems. The results are compared with crystal plasticity finite element simulations of the same experiments to examine how well models can predict observed slip activity.

10:40 AM
Synthetic 3D Tantalum Microstructures: *Veronica Livescu*[1]; John Bingert[1]; Davis Tonks[1]; Joseph Tucker[2]; Gregory Rohrer[2]; [1]Los Alamos National Laboratory; [2]Carnegie Mellon University

Physics-based damage models must account for the microstructural complexity of materials to enable accurate prediction of ductile failure. Microstructural variables must be captured in a statistical framework to enable mean-field modeling of meaningful volumes. This work is concerned with the characterization in 3D of high-purity tantalum using planar Electron Backscatter Diffraction data, toward the development of statistical descriptions of real polycrystalline microstructures. Distributions of grain size and orientation were analyzed from the tantalum. Representative statistics were implemented into MBuilder, virtual microstructure-generating software developed at Carnegie Mellon University. Boundary segments extracted from EBSD data were used to describe the distribution of grain boundary misorientations and orientations of grain boundary planes. Observations are discussed in the context of understanding the contribution of microstructural features to damage nucleation under shock loading. Virtual microstructures offer a starting point for damage models to screen for microstructural instantiations of tantalum based on actual structural distributions.

11:00 AM
Coherent Precipitates in Cr Colid Solution: *Omer Dogan*[1]; Xueyan Song[2]; Michael Gao[3]; [1]DOE National Energy Technology Laboratory; [2]West Virginia University; [3]URS

Lack of structural materials that can be used in aggressive environments is a major barrier for development of more efficient fossil energy conversion technologies. Refractory metals present a potential for development of high-temperature materials due to their high melting point and good high-temperature strength. Solid solution refractory metal based alloys can mimic Ni-based superalloys in that they can precipitate phases coherent with the matrix and stable at high temperatures to give them superior creep strength. Ab initio calculations predicted Ni, Al, and Ti containing phases with a B2 crystal structure to be coherent with the bcc solid solution Cr. A series of Cr- Ni-Al-Ti alloys was produced by arc melting and solidification. Microstructural characterization was performed using XRD, SEM, and TEM. Along with major phases (Cr solid solution and Ni2AlTi), a fine distribution of TiNi precipitates with ordered B2 crystal structure was identified in the Cr solid solution phase.

11:20 AM
Strengthening Mechanisms of the Molybdenum-Base Alloy MHC: *Christopher Poehl*[1]; Juergen Schatte[2]; Harald Leitner[1]; [1]Montanuniversität Leoben; [2]Plansee SE

The particle strengthened molybdenum-base alloy MHC (molybdenum hafnium carbon) is known for its high temperature strength, which is caused by hafnium carbides. The strengthening mechanism of the carbides is known to be twofold, either by interacting direct with dislocations or indirect by stabilizing the substructure. The aim of the present work is to quantify the contribution of these two hardening mechanisms. For this reason molybdenum - hafnium and the molybdenum-base alloy MHC are compared. The alloys are produced via powder metallurgical route and after a thermomechanical treatment the alloys are recrystallized. To determine the mechanical properties, compressive tests and Vickers hardness are performed. The microstructure is characterized by scanning electron microscopy and transmission electron microscopy. Furthermore, the orientation relationship and the phase boundary conditions between matrix and carbides are investigated with high resolution transmission electron microscopy.

11:40 AM
Nature and Results of Dynamic Abnormal Grain Growth in Tantalum: *Nicholas Pedrazas*[1]; Elizabeth Holm[2]; Eric Taleff[1]; [1]The University of Texas at Austin; [2]Sandia National Labs

Dynamic abnormal grain growth (DAGG) is an abnormal grain growth phenomenon that is initiated and propagated by plastic straining at elevated temperature. Large single crystals have been produced in two different refractory metals, Mo and Ta, through DAGG, which occurs at much lower temperatures than typical of historically observed static abnormal grain growth phenomena. The largest abnormal grains produced in Ta through DAGG, approximately one centimeter in diameter, are smaller than those produced in Mo, which can be many centimeters in length. The factors which affect this difference in abnormal grain size will be discussed. These include microstructure stability and initial grain size. The character of abnormal grains produced in Ta through DAGG will be discussed. A simple model will be proposed to explain the mechanism of DAGG.

12:00 PM
Influence of the Heating Rate on the Recrystallization Behavior of Molybdenum: *Sophie Primig*[1]; Harald Leitner[1]; Wolfram Knabl[2]; Alexander Lorich[2]; Helmut Clemens[1]; Roland Stickler[3]; [1]Montanuniversität Leoben; [2]Plansee SE; [3]Universität Wien

Due to its high stacking fault energy, the recrystallization behavior of molybdenum is strongly dominated by concurrent recovery processes. Therefore, the extent of pre-recovery is believed to influence any subsequent recrystallization. In the present investigation, this influence was studied by isochronal heating experiments of cold compressed specimens with heating rates in the range of 1 to 1000 K/min to target temperatures in between 800 and 1300°C. The subsequent microstructural characterization was carried out by SEM, hardness tests and EBSD. This revealed that pre-recovery seemed to promote subsequent recrystallization at lower heating rates (1-100 K/min) which resulted in increased volume fractions of recrystallized grains with decreasing heating rate. In contrast to that, upon fast heating (1000 K/min), low temperature pre-recovery seemed not to occur. Consequently, there was enough stored energy for ultra-fast recrystallization at higher temperatures. The effects of the heating rate on the recrystallization behavior of molybdenum are discussed.

Solid-State Interfaces II: Toward an Atomistic-Scale Understanding of Structure, Properties, and Behavior through Theory and Experiment: Non-metallic Interfaces, Electronic Structures

Semiconductor Interfaces – Structure, Properties, and Dopant Segregation: *Wolfgang Windl*[1]; [1]Ohio State Univ.

The thin-film design of modern semiconductor devices causes their interfaces to have crucial influence on their properties. Important questions include the effect of interfaces on dopant distribution; intermixing vs. sharp interfaces; and polarization effects in heterostructures that offer additional design choices (2DEG). In this talk, we will discuss atomic-resolution investigations of Si/SiO2 and III-V heterostructure interfaces through a combination of density-functional theory and several experimental techniques with focus on electron microscopy. We will first discuss combined theoretical/experimental methods to resolve the atomic structure of interfaces, with focus on amorphous SiO2 on Si. Next, we will examine segregation of dopant atoms to this interface and the difficulties in resolving their detailed configuration, while concentrations can be determined with very high resolution. Finally, we will look at polar interfaces and discuss on the example of AlN/GaN heterostructures novel ways to determine fields and interface charges with very high precision.

9:00 AM Invited
A First Principles Thermodynamic Study of Si-HfO2 and Pt-HfO2 Interfaces: *Rampi Ramprasad*[1]; Hong Zhu[1]; [1]University of Connecticut

Si-HfO2 and Pt-HfO2 interfaces are found in the emerging technologically important "high-k" MOSFETs. The phase diagrams of these interfaces as a function of temperature and oxygen pressure have been determined using first principles thermodynamics (FPT), i.e., by combining density functional theory results with statistical thermodynamics. The vibrational and configurational entropic contributions to the free energies of the condensed phases are explicitly included. We demonstrate that the predictions of the FPT approach are in quantitative agreement with experiments. In particular, under UHV conditions, the correct Si-HfO2 silica-like interface and an interfacial oxygen coverage of 0.5-1.0 monolayer at the Pt-HfO2 interface are predicted. These results have important implications both for the applicability of FPT methods for the considered classes of interfaces as well as for high-k dielectrics-based electronic devices in which such interfaces are expected.

9:30 AM
Interfacial Reconstruction of Au/TiO_2 from ab Initio: Min Yu[1]; *Dallas Trinkle*[2]; [1]Lawrence Berkeley National Laboratory; [2]University of Illinois, Urbana-Champaign

We determine the stability and properties of interfaces of low-index Au surfaces adhered to TiO_2(110), using density functional theory energy density calculations. We consider Au(100) and Au(111) epitaxies on rutile TiO_2TiO_2(110) surface, as observed in experiments. For each epitaxy, we consider several different interfaces: Au(111)//TiO_2(110) and Au(100)//TiO_2(110), with and without bridging oxygen, Au(111) on 1×2 added-row TiO_2(110) reconstruction, and Au(111) on a new 1×2 TiO reconstruction. The density functional theory energy density method computes the energy changes on each of the atoms while forming the interface, and evaluates the work of adhesion to determine the equilibrium interfacial structure. The new results showcase an unusual change in chemistry that is possible in an interface: additional reduction of the TiO_2(110) surface combined with mixing in the layer.

9:50 AM
Structure and Properties of the Y2O3/Fe Interface from First Principles Calculations: *Samrat Choudhury*[1]; Christopher Stanek[1]; Blas Uberuaga[1]; [1]Los Alamos National Laboratory

Nanostructured ferritic alloys are considered excellent candidate materials for structural applications in nuclear reactors as they exhibit exceptionally high creep strength due to the presence of highly stable nanometer sized Y-Ti-O precipitates. It is believed that these properties result from the characteristics of the particle and ferritic matrix interface. Y2O3 has also been shown to form nanoprecipitates in Fe and is a simpler surrogate for the Y-Ti-O precipitates. In this work, we will present the behavior of the interface between the ferritic matrix and Y2O3 using density functional theory. In particular, the role of alloying elements and orientation relationship on the atomic structure of the particle-matrix interface, segregation energies of the alloying elements, electronic structure at the interface, and calculated interfacial energy will be discussed. These results form the basis of a phase-field model that will examine the nucleation and growth of Y2O3 precipitates in Fe.

10:10 AM Break

10:20 AM Invited
The Structure of Interfaces in GaSb/InAs Superlattices: *Emil Zolotoyabko*[1]; [1]Technion

Short-period superlattices, based on semiconductor or oxide layers, have wide range of applications from infrared imaging to giant magneto-resistance devices. Some applications require deposition of sub-layers with thicknesses below one monolayer. Under such constraints, the interface quality becomes crucial for device functioning. Most common imperfections are related to atomic intermixing during growth, which is difficult to characterize on this length scale. We use for this purpose a set of advanced techniques, which include high-resolution transmission electron microscopy (HR-TEM) for lattice imaging and, especially, high-angle annular dark field (HAADF) HR-STEM for Z-contrast imaging, scanning tunneling microscopy (STM) for direct defect counting, atom-probe tomography (APT) for chemical analysis with a nm-resolution, and high-resolution X-ray diffraction (HR-XRD) for spatial profiling of d-spacings. All this is applied in order to examine the atomic intermixing and interface roughness in GaSb/InSb/InAs/InSb superlattices. We discuss the suitability, limits, complementarity, and uniqueness of the above mentioned characterization techniques.

10:50 AM
In Situ TEM Investigations of Wetting-Dewetting Transitions of Ultra-Thin Nickel Films on (100) Silicon Substrates: Andrew Thron[1]; *Klaus van Benthem*[1]; [1]University of California, Davis

For solid/solid interfaces changes in temperature alter the wetting behavior of thin films on substrates by unbalancing the current equilibrium of surface and interface energies. This can lead to dispersion of the thin film, the so-called wetting-dewetting transition. For this study, thin nickel films were deposited at room temperature onto the (100) surface of silicon. Cross-sectional high-resolution transmission electron microscopy characterization of the as-deposited films revealed a complex interface structure consisting of up to four distinct layers with varying structure and composition. Electron energy-loss spectroscopy combined with aberration-corrected scanning transmission electron microscopy identified the formation of reaction layers with gradually changing nickel silicide composition, followed by a silicon oxide layer that acts as a diffusion barrier for the remaining ultrathin nickel film. In-situ annealing of the interface structure leads to a wetting-dewetting transition of the remaining nickel film and hence the formation of facetted, nanometric nickel islands.

11:10 AM
Hybrid Monte Carlo–Molecular Dynamics Simulations of Nanometer-Scale Y–Ti–O Precipitation in BCC Iron: *Karl Hammond*[1]; Lauren Marus[2]; Hyon-Jee Lee Voigt[2]; Brian Wirth[1]; [1]University of Tennessee, Knoxville; [2]University of California, Berkeley

Nanometer-scale clusters containing yttrium, titanium and oxygen have been observed experimentally to precipitate from supersaturated solid solutions of mechanically alloyed Fe–Cr–Ti–Y–O powders. Our simulation work to date has used on-lattice Monte Carlo simulations that aim to understand so-called "nanocluster" nucleation, growth, and stability. Such simulations require a rigid lattice, which imposes artificial stresses and strains on atoms in the clusters, particularly the large (relative to iron) titanium and yttrium atoms. Here, we report hybrid Monte Carlo–molecular dynamics simulation results to study off-lattice relaxations of yttria/titania clusters in BCC iron. These simulations use relatively simple, computationally inexpensive pairwise potential energy models that allow for off-lattice relaxation, which enables the preferred size and spatial arrangement of the nanoclusters to evolve naturally through strain partitioning processes. The hybrid approach provides insight into plausible pathways of titania/yttria cluster formation in ferritic alloys.

11:30 AM
Phase-Field Simulation of Segregation to Lamellar Interface in Refractory NbSi2/MoSi2 Duplex Silicide: Yuichiro Koizumi[1]; *Toshihiro Yamazaki*[1]; Akihiko Chiba[1]; Koji Hagihara[2]; Takayoshi Nakano[2]; Koretaka Yuge[3]; Haruyuki Inui[3]; [1]Tohoku University; [2]Osaka University; [3]Kyoto University

NbSi2/MoSi2 duplex silicide is one of the most promising candidates for ultra-high- temperature structural materials for a new high efficiency gas turbine power generation systems. Recently, a C40/C11b lamellar structure of (Nb,Mo)Si2 system was found to improve its high-temperature strength, and it was demonstrated that Cr-addition stabilize the lamellae by Cr-segregation [K. Hagihara, T. Nakano, S. Hata, O. Zhu, Y.Umakoshi, Scripta Mater . 2010;62:613.] Theoretical understanding is important for further improvement. In this study, a phase-filed model of segregation to C40/C11b lamellar boundary has been developed, and the segregation behavior was examined focusing on the effect of elastic strain energy. In the absence of elasticity, solute-distribution simply agreed with the equilibrium phase diagram; the concentrations monotonically varied. In the presence of elasticity, Nb-atoms are depleted at the C11b-side and segregated at the C40-side of the interface. Namely, the interfacial segregation occurred so as to reduce the interfacial misfit.

11:50 AM
Solute Segregation at Cu/Alumina Interface and Its Influence on Alumina Growth Kinetics in Alumina Dispersion-Strengthened Copper: Jian Wu[1]; Jianmin Huang[2]; Zhuohui Xu[2]; Xuanhui Qu[3]; *Shaojun Liu*[4]; [1]Graduate School at Shenzhen, Tsinghua University; [2]Shenzhen Zhongjin Lingnan Nonfemet Co., Ltd., Shenzhen; [3]University of Science and Technology Beijing; [4]Central South University

Alumina dispersion-strengthened copper (ADSC) that has been used commonly in automobile and electronics industry possesses high strength at elevated temperatures combined with high electrical and thermal conductivity. The effectiveness of the dispersion strengthening of alumina is closely related to the particle size, interparticle spacing, and bonding strength at alumina/Cu interface. In the present work, we focus on the silver segregation kinetics at alumina/Cu interface and alumina growth kinetics under various thermal and stress conditions in a silver-doped ADSC. Additionally, the influence of silver segregation at heterogeneous alumina/Cu interface on the structure and chemistry of the interface is investigated. These results show that the silver segregation kinetics and the alumina growth kinetics are interacted with each other. Based on the experimental results, a model is proposed to simulate these two interacted kinetics. This model can be an important progress in optimizing the processing and improving the properties of ADSC.

Statistics of Fracture: Weibull, Gumbel and Other Questions...: *Ashivni Shekhawat*[1]; Claudio Manzato[2]; Phani Nukala[3]; Mikko Alava[4]; Stefano Zapperi[5]; James Sethna[1]; [1]Cornell University; [2]Universita di Modena e Reggio Emilia; [3]Oak Ridge National Laboratory; [4]Aalto University; [5]CNR - Consiglio Nazionale delle Ricerche

A common problem in engineering studies of fracture is the lack of large experimental datasets of fracture strength distributions. Should the available data be fit to a Weibull distribution or a Gumbel distribution? How far should such fits be extrapolated? We address these questions by using a combination of critical droplet theory and extreme value statistics. We find that for a class of disordered brittle systems the Gumbel distribution is the correct form of fracture strength distribution, however, the convergence to the Gumbel form is extremely slow. We explore the question of extrapolating fracture data in to the 'low reliability tail' and find that while extrapolating the Gumbel distribution is perilous, the Weibull distribution can be extrapolated on a case-by-case basis. We present numerical results based on studies of disordered fuse network models.

9:00 AM
Development of a Novel Support Vector Machine (SVM) Model to Predict the Process-Structure-Property Relations in Materials Informatics: *Osama Abuomar*[1]; Hongjoo Rhee[2]; Roger King[1]; [1]Department of Electrical and Computer Engineering, Center for Advanced Vehicular Systems (CAVS), Mississippi State University, Mississippi State, MS 39762; [2]Center for Advanced Vehicular Systems (CAVS), Mississippi State University, Mississippi State, MS 39762

The main objective of this study is to develop a novel stochastic-based model to predict process-structure-property relations by analyzing intrinsic materials properties and output mechanical responses. Output mechanical properties of the laser-deposited material were modeled using Support Vector Machine (SVM) and other unsupervised learning methodologies after imposing different modes of straining onto the specimen. Three distinctive types of specimens with different porosity levels (e.g., solid state, isolated pores, and connected pores) were fabricated by laser engineered net shaping (LENS) process. Given the various material input data (e.g., morphology, density, total length, and the nearest neighbor distance of pores) and by applying loads to the specimen, the relationship between the intrinsic materials properties due to process parameters and the output mechanical properties such as strength, ductility, total elongation, etc. were achieved. The SVM was then optimized by proper regression, classification and other data mining techniques.

9:20 AM
Bootstrap Analysis of Experimental Uncertainties Affecting the Accuracy of a Flow Stress Model for Metal Forming: Thomas Henke[1]; *Markus Bambach*[1]; Gerhard Hirt[1]; [1]RWTH Aachen University

Numerical simulations are widely used in metal forming to design and optimize processes and products. The accuracy of process simulations in metal forming strongly depends on the prediction of flow stress, which is determined in mechanical tests. Due to scatter in material properties, variations in testing conditions and measurement errors, tests conducted multiple times under the same conditions do not show identical results. With few exceptions, the uncertainty that results from experimental scatter is not taken into account in metal forming simulations, although it affects the reliability of the model predictions. This paper investigates the potential of two Bootstrap resampling methods to statistically analyze and capture stochastic effects in flow stress modeling. Confidence intervals for the parameters and predictions of a microstructure-based flow stress model are derived and compared for both methods. It is shown that resampling the model residuals is a more efficient method than resampling individual flow curves.

Uncertainty Quantification Of Yield Stress Predictions In Nanocrystalline Nickel: *Lei Cao*[1]; Marisol Koslowski[1]; [1]Purdue University

Recent experimental and theoretical studies on nanocrystalline (nc) plasticity reveal that the mechanical behavior of nc materials cannot be characterized only by the average grain size, without considering the effect of the grain distribution. To quantify uncertainties in the prediction of the inelastic response, including yield and creep, we carry out dislocation dynamics simulations with a Phase Field Dislocation Dynamics model. The dependence of the yield stress on the grain size and initial dislocation density is characterized and compared to the Hall-Petch relation. The comparison between the predicted yield stress on uniform and non-uniform grained nc Nickel indicates that grain size distribution has a more significant influence on the yield stress for smaller grains. Finally, we show predictions of the yield stress distribution of the Nickel membranes in a RF-MEMS device.

10:20 AM
Continuum Theory of Dislocation Cellular Structures: Fractals, Scaling Ttheories, and X-Ray Diffraction: *Yong Chen*[1]; Woosong Choi[1]; Stefanos Papanikolaou[1]; James Sethna[1]; [1]Cornell University

We present a minimal continuum dislocation dynamics model[1] to explain the emergent mesoscale self-similar cellular dislocation structures observed in plastically-deformed crystals. In three dimensions, we evolve the geometrically necessary dislocations to minimize the elastic free energy in a single crystal within an isotropic approximation, starting from a smooth initial deformation. Whether or not climb is forbidden, GNDs always evolve into self-similar structures. This striking self-similar morphology is measured in terms of correlation functions of physical observables, like geometrically necessary dislocation density, plastic distortion, and crystalline orientation. We provide a generic scaling theory to show that all these correlation functions, exhibiting spatial power-law behaviors, share a single underlying universal critical exponent[2]. We also develop experimental observers (simulating X-ray diffraction experiments) to visualize the underlying dynamics of sub-grain cell structures under loadings. [1] Yong S. Chen et al. , *Phys. Rev. Lett.* 105,105501, 2010. [2] Yong S. Chen et al. , arXiv:1106.0195.

10:40 AM
Stochastic Modeling and Simulation of Fiber Evolution during Melt-Blowing Slag Fiberization: *Dimitrios Gerogiorgis*[1]; Dimitrios Panias[1]; Ioannis Paspaliaris[1]; [1]National Technical University of Athens (N.T.U.A.)

Red mud fiberization is a process with remarkable potential, alleviating environmental pressure by transforming an aluminum by-product into marketable products. A promising mineral wool process is molten slag fiberization via an free-falling vertical jet which meets an impinging air jet, inducing intensive droplet generation and subsequent fiber elongation. The fibers follow independent trajectories towards a collection chamber, often breaking up to form shots (off-spec product). Fiber as well as shot size and geometry distributions are pivotal in order to predict and ensure mineral wool product quality. This paper focuses on stochastic modeling and simulation of molten slag fiber generation and evolution: the model encompasses published, validated correlations of dimensionless numbers within the well-defined cone of fiber dispersion. Fiber elongation and breakup along trajectories are explicitly studied, considering temperature-dependent slag transport properties and explicit variability of both flight trajectory and operating conditions, towards achieving process optimization.

Thermal Conductivity Prediction of Nano Fluid Using ANN/GA - A Hybrid Approach for a Radiator Design: *Payodhar Padhi*[1]; France Behera[1]; Debashis paNDA[1]; [1]Konark Institute of Science & Technology

Thermal conductivities of nano fluid in a two-phase having different compositions of both base fluid as well as nano particles in a closed thermosyphon system that is thermally enhanced by a radiator has been predicted by a proposed hybrid model i.e. Artificial Neural Network (ANN) & Genetic Algorithm (GA) that predicts the thermo syphon behaviour correctly within the given range of the training data. In this study, a new approach for the radiator design of neural networks, based on a genetic algorithm, has been used to predict collection output of a closed thermo syphon system. Here the cooling fan is replaced by the use of nano fluid circulation under an ultrasonic field thus saving the energy and weight of radiator. The ultrasonic field strength, particle size, volume fraction of nano fluid in base fluid were used as input parameters and the thermal conductivity was used as output parameters.

11:30 AM
Effect of Discrete Particle Size Distribution of Iron Ore on the Porosity in Fluidization Process: *Guoliang Yin*[1]; Liangying Wen[1]; [1]Chongqing University

As for fluidized bed as pre-reduction reactor in iron-making process, cold test is used to study the change of bed porosity under the condition of different iron particle size distribution. Particles are divided according to Binomial and Poisson distribution in the process of experiment. There are three types of experiment: from fine particles to coarse ones, from coarse particles to fine ones, mixing up. Conclusion is to be drawn: when particles are put in the fluidized bed from fine to coarse, the bed porosity have nothing to do with particle size distribution; when particles are put in from coarse to fine, particles are fluidized layer by layer and the required flow of granule fluidization in each layer is changed with particle size distribution. When particles are mixed up thoroughly, the rate of bed porosity will increase with the increasing of Fa values.

11:50 AM
Research on Prediction of the Stability of Partially Stabilized Zirconia Prepared by Microwave Heating Using Levenberg Marquardt-Back Propagation Neural Network: Lijun Liu[1]; *Shenghui Guo*[1]; Dongbo Li[1]; Jinhui Peng[1]; Guo Chen[1]; Lei Xu[1]; [1]Faculty of Metallurgical and Energy Engineering, Kunming University of Science and Technology; Key Laboratory of Unconventional Metallurgy, Ministry of Education; Engineering Laboratory of Microwave Application and Equipment Technology, Yunnan Province

In the present study, Levenberg Marquardt-Back Propagation (LM-BP) neural network model was proposed for the prediction of the stability of partially stabilized zirconia (PSZ) prepared by microwave (MW) heating. The inputs of the LM-BP neural network model are the holding temperature, rising rate of temperature, holding time, decreasing rate of temperature and hardening temperature. And the stability of PSZ is the only output. Typical data collected from 58 experiments were used for training and testing. The predicted results agreed with the actual value within reasonable experimental error, which indicates that the model is reasonable. Besides, multiple influence factors can be comprehensively considered in the LM-BP neural network model. And a new highly effective method for predicting the stability of PSZ prepared by MW heating is provided for prospective application.

Fabrication Routes and the Effect of Microstructure on the Mechanical Behavior of Ni-Base Superalloy Thin Films and MEMS Structures: Devin Burns[1]; Yong Zhang[1]; Timothy Weihs[1]; *Kevin Hemker*[1]; [1]Johns Hopkins University

Commercial Ni-base superalloys possess remarkable elevated temperature properties owing primarily to their highly developed multi-phase microstructures. Macro-scale components of Ni-base superalloys are produced by casting, forging and machining, but these processes cannot be employed to fabricate and shape thin films or micro-scale structures. Here we report on the optimization of deposition parameters to sputter deposit relatively thick films of a first generation superalloy, Haynes 718. Following deposition as a solid solution subsequent heat treatments evoke unique kinetic pathways to nucleation of intermetallic phases and lead to novel, nanoscale microstructures. The resultant ultra-fine microstructures impart very beneficial strength and ductility and enjoy impressive high-temperature microstructural stability. Applications as thin film sensors and coatings and MEMS or NEMS devices are envisioned. This work supported by the NSF Materials World Network under grant No. 0806753.

Following Deformation Mechanisms in Nanocrystalline Ni Using In Situ Synchrotron Techniques and Orientation Imaging: *Patric Gruber*[1]; Jochen Lohmiller[1]; Oliver Kraft[1]; Christian Braun[2]; Manuel Grewer[2]; Rainer Birringer[2]; Aaron Weis[3]; Christian Kuebel[4]; Veijo Honkimäki[5]; [1]Karlsruhe Institute of Technology, Institute for Applied Materials, P.O. Box 3640, 76021 Karlsruhe, Germany; [2]Universität des Saarlandes, Lehrstuhl für Experimentalphysik, Campus D2 2, 66041 Saarbrücken, Germany; [3]Karlsruhe Institute of Technology, Institute of Nanotechnology, P.O. Box 3640, 76021 Karlsruhe, Germany; [4]Karlsruhe Institute of Technology, Institute of Nanotechnology, P.O. Box 3640, 76021 Karlsruhe, Germany and Karlsruhe Institute of Technology, Karlsruhe Nano Micro Facility, Herrmann-von-Helmholtz-Platz 1, 76344 Eggenstein-Leopoldshafen, Germany; [5]European Synchrotron Radiation Facility, Materials Science Group, BP 220, 38043 Grenoble Cedex, France

The contribution and activation of specific deformation mechanisms which have been proposed for nanocrystalline (nc) materials is still under heavy debate. In situ characterization is necessary in order to (i) detect reversible mechanisms and (ii) separate and ascribe the active mechanism to the respective strain regime. Therefore in situ compression tests are conducted on nc Ni specimens using high energy synchrotron X-ray diffraction (XRD). A fast area detector allows for continuous recording of complete Debye-Scherrer rings. Based on this unique setup the deformation behavior of nc Ni can be unraveled and is determined to be a distinct sequence of elastic grain interaction, grain boundary sliding, grain rotation, dislocation activity and grain growth. The succession of the different deformation mechanisms leads to a specific in-plane texture which could be determined for the first time and could also be verified by Orientation Imaging in a transmission electron microscope.

Studying the Micromechanical Behavior of fcc/bcc Metals by Quantitative In-Situ TEM and μ-Laue: *Daniel Kiener*[1]; Andreas Schneider[2]; Nobumichi Tamura[3]; Martin Kunz[3]; Andrew Minor[4]; Patric Gruber[5]; [1]University of Leoben; [2]INM - Leibnitz Institute for New Materials; [3]Lawrence Berkeley National Laboratory; [4]University of California; [5]KIT - Karlsruhe Institute of Technology

Mechanical properties of miniaturized single-crystals, being stronger when smaller, have drawn considerable attention. While in-situ studies yielded understanding of the deformation mechanisms in fcc metals, the situation is less clear for bcc materials. We investigated vanadium and copper samples prepared by FIB from melt-grown single-crystals. Sample testing was performed by in-situ TEM, allowing direct observation of plastic deformation. Additionally, μ-Laue investigations were performed before and after loading. Complementary to TEM, μ-Laue depicts the global strain field and its evolution in the cause of deformation. The different size-effect for bcc materials compared to fcc is not related to increased dislocation-dislocation interaction, but governed by activation of individual dislocation sources. The deformation behavior is similar to fcc, but the stress level is different due to the limited mobility of screw dislocations in bcc materials. Overall, combining in-situ TEM and μ-Laue allows a better understanding of the deformation of micron- and submicron-sized samples.

Understanding the Small-Scale Plasticity of Pillars in Compression and Fibers in Tension: *E. P. George*[1]; P. Sudharshan Phani[2]; K. E. Johanns[2]; G. M. Pharr[2]; [1]Oak Ridge National Laboratory; [2]University of Tennessee

We review here the small-scale plasticity of Mo-alloy pillars and fibers. A transition in strength from theoretical to bulk is observed as the specimen size and/or the dislocation density is increased. At intermediate sizes and densities, the strengths tend to be highly stochastic whereas at the two extremes (theoretical and bulk) the strengths show very little scatter. Transmission electron microscopy showed that the high (theoretical) strengths correspond to specimens containing no dislocations whereas the low (bulk) strengths correspond to specimens containing many dislocations. Stochastic strengths in the intermediate regime are observed when the dislocation distribution is itself stochastic. These observations are explained with the help of a statistical model and Monte Carlo simulations based on a random distribution and orientation of dislocations. In addition to predicting the average yield strengths, the model correctly predicts the scatter in the yield strengths and the different behaviors observed in compression and tension.

Deformation Mechanisms in Nanocrystalline Alloys: *Steven Van Petegem*[1]; Julien Zimmermann[1]; Helena Van Swygenhoven[1]; [1]Paul Scherrer Institute

It is well known that nanocrystalline metals exhibit increased hardness and strength compared to their coarse-grained counterparts. The mechanisms responsible for these enhanced properties are still under debate, especially for the smallest grain sizes. This is even more the case for nanocrystalline alloys due to the additional complexity of segregation, change of elastic constants, etc. Recently the presence of upper and lower yield points upon strain rate change was found for nanocrystalline Ni-Fe. In this work we study the temperature dependence of this phenomenon by in- and ex-situ mechanical testing during x-ray diffraction. The results are discussed in view of results obtained from transient testing and insights from molecular dynamics and quantized crystal plasticity simulations.

11:00 AM Invited

Two StrainHardening Mechanisms in Nanocrystalline Austenitic Fe-Cr-Ni-W Steel: Michael A. Weisser[1]; *Helena Van Swygenhoven*[1]; Patrick Schloth[1]; Steven Van Petegem[1]; V. Subramanya Sarma[2]; Martin Heilmaier[3]; [1]Paul Scherrer Institute; [2]Indian Institute of Technology Madras; [3]TU Darmstadt

The mechanical behaviour of nanostructured austenitic steels with nominal composition [wt%] of Fe-18Cr-8Ni-2W, one without and the other with 0.5% Y2O3 [wt%] particles were investigated using in-situ synchrotron diffraction during tensile deformation. The experiments were carried out at the MS beamline of the Swiss Light Source. The observations demonstrate the concurrent occurrence of two strain hardening mechanisms in both types of austenitic nc steel. The first one is predominantly connected to the austenite-martensite phase transformation, which saturates after 80% of the austenite is transformed. The second hardening mechanism can be related mainly to deformation twinning in the fragmented retained austenite. The kinetics of martensitic phase transformation is remarkably enhanced in the nanocrystalline structure compared to ultrafined and coarse grained metals. The effect of the ODS particles lies predominantly in the enhancement of the yield stress.

Deformation, Strengthening and Intermittency Behavior of Ni3Al Alloy Microcrystals: *Dennis Dimiduk*[1]; Michael Uchic[1]; Satish Rao[2]; Paul Shade[1]; Chris Woodward[1]; Ed Nadgorny[3]; [1]Air Force Research Laboratory; [2]UES, Inc.; [3]Michigan Technological University

Ni3Al alloys exhibit selected unique deformation characteristics at small scales when compared with other materials for similar loading conditions. The present work examines the microcrystal deformation of Ni3Al with respect to deformation phenomenology, strengthening and flow intermittency and, evaluates these responses relative to sample size or deformation conditions for this material. The findings are analyzed with respect to current understanding and models for each aspect of plastic response. This will include analysis of the relevance of flow-stress anomaly mechanisms, dislocation nucleation, the single-arm source model, exhaustion hardening, and the mean-field avalanche model for describing the response of Ni3Al alloy microcrystals. While aspects of the flow stress anomaly mechanisms and, a form of the single-arm source model work remarkably well, other limitations exist for understanding Ni3Al behavior from current data and models.

Titanium: Advances in Processing, Characterization and Properties: Fatigue of Titanium Alloys

Understanding Fatigue of Ti Alloys: *James Williams*[1]; [1]The Ohio State University

The phenomenology of the fatigue behavior of Ti alloys is reasonably well understood. However, the basic causes for some particular fatigue failures and the details of actual failure modes are less well understood. One consequence of this lack of understanding is the need to design very conservatively in many failure critical situations. Another is the potential for "misdiagnosing" the cause of a failure. A key example in failure analysis of alpha + beta Ti alloys is reaching an understanding of the formation of planar facets on the fracture surface and the implications these have for determining the root cause of failure. This talk will discuss several of these situations and suggest approaches to improve our understanding.

3D Observations of Short Fatigue Crack Interaction with Lamellar and Duplex Microstructures in a Two-Phase Titanium Alloy: *Soran Birosca*[1]; [1]University of Cambridge

EBSD and Synchrotron X-ray microtomography were used to investigate crack tip interaction with microstructure. Three samples with different microstructures were tested; lamellar, duplex and a heterogeneous microstructure. The three microstructures showed significantly different short crack propagation rates. It was found that a columnar lamellar microstructure creates a relatively smooth crack front while a basket weave type microstructure forces the crack tip to undulate at the lath width scale. Crack bridging of the fine lamellar region of the duplex microstructure was observed, which seems to hinder significant crack bifurcation to occur, but still provides improved crack growth resistance. In the third microstructure the crack tended to grow slightly asymmetrically due to the heterogeneous nature of the microstructure, which resulted in the intermediate growth rate. EBSD grain orientation and Schmid factor analysis revealed that the crack path is strongly influenced by the crystallographic orientation of the grains.

9:30 AM

Experimental Correlation Between a Microscopic Non-Local Strain Parameter and Macroscopic Fatigue Crack Growth in Beta-Annealed Ti-6Al-4V: *Pedro Peralta*[1]; Thomas Villarreal[1]; Ikshwaku Atodaria[1]; Aditi Chattopadhyay[1]; [1]Arizona State University

Correlations between crack tip strain, applied loads and fatigue crack growth kinetics are studied in beta-annealed Ti-6Al-4V. Tension-tension fatigue testing was performed using Compact-Tension specimens at R=0.1 and constant ΔK, (10 to 20 MPa.m^0.5). In-situ loading and Digital Image Correlation (DIC) were used to obtain the area integral of the opening strain field ahead of the crack tips over the cyclic plastic zone and found to be a power-law of ΔK, with an exponent approximately equal to the Paris exponent describing crack growth kinetics. Results are interpreted in terms of the dependence of strain fields on applied load and hardening exponent and a length scale parameter is deduced that predicts the measured Paris exponent for the material based on plasticity arguments. This length scale is shown to be proportional to the accumulated plastic displacement ahead of the crack tip, and discussed in terms of plastic blunting and cumulative damage models.

9:50 AM
Microstructural Crack Initiation and Growth during the High Cycle Fatigue Damage of a Ti-6Al-4V Alloy: *Edward Chen*[1]; [1]Transition45 Technologies, Inc.

The development of a methodology for predicting high cycle fatigue (HCF) lifetimes in titanium-base alloys will provide design engineers with a tool to more accurately predict failure in gas turbine engine components, optimize designs to fully utilize a material's mechanical properties, and extend the maintenance-free life of the engines. Potential payoffs include decreased failure rates, improved system safety, reduced maintenance and spare parts cost, and reduced system weight. This study looked at advancing a mechanistic understanding of fatigue crack initiation and early crack growth under HCF conditions in an $\alpha + \beta$ Ti alloy in an initially undamaged state. Effort focused on identifying the initiation and growth mechanisms of the critical cracks that govern the useful material life under HCF. An improved understanding of HCF crack initiation provides a foundation for developing physics-based mechanistic models necessary to predict HCF life of Ti-base materials under a wide range of operational/environmental conditions.

10:10 AM
Monitoring of Small Fatigue Crack Initiation and Evolution in Ti Alloys: *Stan Rokhlin*[1]; George Connolly[1]; Jia Li[1]; Bahman Zoofan[1]; [1]The Ohio State University

The development and integration of several nondestructive evaluation methods for monitoring and sizing microcracks in titanium fatigue samples are described. For in-situ monitoring of crack initiation and evolution ultrasonic Lamb wave is excited and acquired continuously during fatigue tests at different levels of fatigue load using a high-speed acquisition system. The data are collected for a range of applied fatigue and modulation load levels and for a range of spatial propagation positions with each fatigue cycle. These samples are characterized by strong microstructure-induced ultrasonic scattering. To enhance crack identification A post-processing subtraction technique is introduced to improve the signal-to-noise ratio. Microradiography and scanning ultrasonic techniques have been also performed to confirm the localization and sizing of the detected cracks with other ultrasonic NDE techniques. The fusion of data from different NDE techniques provides useful information on the initiation, location, shape, size and growth history of fatigue cracks.

Deformation and Facture in Titanium Alloys: Microscale Characterization: *M Brandes*[1]; [1]The Ohio State University

It is widely known that the creep, fatigue, and fracture properties of titanium alloys of alpha, near-alpha, and alpha/beta titanium alloys are greatly affected by material structure, particularly those related to the elastic and plastic anisotropies of the alpha-phase. Although macroscale properties are intimately linked to plastic behaviors at the microscale, understandings of these relationships have yet to be fully developed. Recent advancements in materials characterization technologies and techniques have provided new capabilities to investigate Ti alloys at length scales relevant to the factors that control their properties. This paper discusses the microscale phenomena that dictate the performance of titanium alloys, and the techniques that may be utilized to investigate them.

11:10 AM
Dislocation Level Mechanisms of Dwell Fatigue Crack Initiation and Propagation in Near-Alpha Titanium: Matt Brandes[1]; *Adam Pilchak*[2]; Robert Williams[1]; Michael Mills[1]; Hamish Fraser[1]; James Williams[1]; [1]The Ohio State University; [2]Air Force Research Laboratory

Facet formation during dwell fatigue loading has invariably been associated with marked decreases in lifetime. Despite their importance to explaining the dwell debit, the mechanisms of facet formation have not been thoroughly investigated. In this work, we have analyzed crack initiation and propagation sites in the near-alpha Ti-8Al-1Mo-1V alloy. The dislocation activity and degree of lattice rotation in cracked and uncracked grains of the same orientation were investigated by way of TEM and EBSD analysis, respectively, of site-specific foils extracted from the fracture surface and from bulk material. The results show that <c+a> slip bands intersect planar basal <a> slip bands to form extended pileup structures at grain and phase boundaries. These pileups, and the accompanying large lattice rotations, appear to play an important role in the crack initiation process. Crack propagation through hard-oriented grains, on the other hand, is accommodated by <c + a> slip that is extremely localized near the fracture surface to accommodate crack tip opening and the formation of sub-micron sized tear ridges on the facet surfaces.

11:30 AM
Micromechanisms of Fatigue in Ti-5Al-5Mo-5V-3Cr: Nicholas Jones[1]; *David Dye*[1]; Trevor Lindley[1]; [1]Imperial College London

High strength metastable beta titanium Ti-5Al-5Mo-5V-3Cr (Ti-5-5-5-3) is increasingly being used in large sections, such as aircraft landing gear truck beams. The wide two phase region enables a range of microstructures to be produced allowing property optimisation. A recently developed heat treatment schedule has produced a lower strength yet more damage tolerant microstructure, leading to interest in using this material in unconventional areas of the airframe. The high cycle fatigue performance of this material has been reported to be significantly better than that of Ti-6Al-4V, with a ~ 50% higher 1e7 cycle endurance stress. However, relatively little is known about the micromechanisms of fatigue crack initiation and propagation in these alloys, and the influence of microstructure. In the present study, the high cycle fatigue performance of different Ti-5-5-5-3 microstructures is considered. The micromechanisms of fatigue cracking will be discussed in terms of the influence of the underlying microstructural features.

Simulating the Blanking of Preg Robbers in Gold Ores by Treating Activated Carbon with Hard Paraffin Wax: *Gus Van Weert*[1]; John Jiang[2]; Olivia Wang[3]; Yeonuk Choi[2]; [1]ORETOME Limited; [2]Barrick Gold Corporation; [3]Process Research ORTECH

As part of a general review of processing double refractory ores through Barrick Gold's autoclaves / CIL facility at Goldstrike, NV, blanking the gold cyanide adsorbing native carbon in the ore with hard (m.p. >55 C) paraffin wax was proposed. To avoid interference from other ore constituents in the exploratory testwork, commercial activated carbon was substituted for native carbon to establish the best conditions for de-activation of carbon with molten wax.

8:50 AM

Dissolution of Platinum,Palladium and Rhodium in 250g/l NaCl Solution: *Kristian Lillkung*[1]; Jari Aromaa[1]; Olof Forsén[1]; [1]Aalto University, School of Chemical Technology

The dissolution rates of Pt, Pd and Rh in 250 g/l NaCl solution were calculated from the current densities determined by polarization curves and potentiostatic measurements measured with wire electrodes under atmospheric pressure. The results achieved with the two methods were similar. The dissolution rates at open corrosion potential were in the order of few nanometers per hour. The polarization curves indicated that to achieve dissolution rates required for economical operation in industrial scale, the samples need to be polarized to higher potentials. When polarized to higher potentials, the metal dissolution rates were in the order of micrometers per hour. As the Tafel slopes of the metal dissolution region are fairly steep, the potential affects the dissolution rate greatly. Based on the activation energies, the dissolution reactions were controlled by charge transfer step.

9:10 AM

Silver Recovery from Complex Concentrates- A Mineralogical Approach: *Joe Ferron*[1]; [1]Hydroproc

This paper presents results of non-conventional techniques to recover silver from complex concentrates. The Platsol process was developed to recover in one step base metals and precious metals from sulphide concentrates too low grade to enter the mainstream extraction processes. Due to solubility limits, silver is only partially recovered in solution. However, the silver minerals are transformed into silver chloride that can then be recovered from the Platsol residue using traditional techniques. Some South American silver concentrates contain impurities (mostly arsenic) such that the smelter penalties incurred significantly affect the process economics. Metallurgical results have shown that a low temperature calcinations pre-treatment transform the concentrate into a calcine well suited to traditional recovery processes. Metallurgical details are provided as well as the results of mineralogical studies that helped clarify the process mechanisms.

9:30 AM

Development of New Recycling Process of PGMs: *Toru Okabe*[1]; Jumpei Mitsui[1]; Katsuhiro Nose[1]; [1]The University of Tokyo

In order to develop a new process for recovering platinum group metals (PGMs) directly from scrap, fundamental studies on enrichment/extraction processes of platinum (Pt) metal and its compounds were conducted. Both chemical dissolution technique and physical separation technique are studied to enrich and extract the Pt. Various types of recycling processes that are presently under development, are introduced, and their features and differences are discussed. The advantages and disadvantages of the new recycling processes are evaluated, and the possibility of establishing new recycling processes in the future is discussed from a multilateral perspective.

9:50 AM

Molybdenum Recovery and Impurity Removal from Smelter Dusts: Troy Bednarski[1]; *Violina Cocalia*[1]; Tyler McCallum[1]; Matthew Soderstrom[1]; Alexis Soto[2]; [1]Cytec Industries Inc.,USA; [2]Cytec Chile Ltda

Solvent extraction (SX) is a well established separation technology that can be extremely selective toward a specific target metal. Smelter dusts have been identified to contain significant concentrations of molybdenum, which can be leached and economically recovered from the solution. Other impurities such as As, Bi, and Sb will also be leached and removed from the dust recycle, which can improve anode quality. This paper will describe a method of selectively recovering molybdenum from leach solutions using a phosphinic acid-based reagent developed by Cytec Ind. Molybdenum stripping is achieved by using ammonia/ammonium carbonate mixtures to achieve a high concentration of molybdenum in the rich liquor. Piloting results confirm the ability to purify and concentrate Mo from acidic solutions. Molybdenum is then precipitated to produce a mixture of Mo salts, which can be further purified into ammonium molydates.

10:10 AM Break

10:30 AM

Acid Separation for Impurity Control and Acid Recycle using Short Bed Ion Exchange: *Michael Sheedy*[1]; Paul Pajunen[1]; [1]Eco-Tec Inc.

Short bed ion exchange is now well established technology in copper refinery tankhouses. Liberator bleeds are treated by short-bed-systems to produce an acid free byproduct stream containing the bleed metals and valuable nickel. Removing acid eliminates the need for black acid evaporators and reduces the sodium carbonate required to selectively precipitate nickel. Recovered sulfuric acid can be recycled to the tankhouse. The technology also treats hydrochloric, nitric, and hydrofluoric acid. For hydrochloric the process can selectively separate Zn, Pb, and Cu chloro-anionic complexes, which are then eluted with water. The technology can be coupled with ion exchange processes to minimize regenerant acid consumption. Resin regeneration often requires an acid dosage multiple times the stoichiometric minimum. Coupling an acid recovery bed with the IX column allows recovery and recycle of the free acid in the spent regenerant, thus reducing the overall acid consumption to just slightly more than stoichiometric.

Various Arsenic Treatments in Non-Ferrous Metallurgy and Other Potential Applications: *Tetsuo Fujita*[1]; Shun Fujieda[2]; Kozo Shinoda[2]; Shigeru Suzuki[2]; [1]Dowa Metals & Mining company limited; [2]Tohoku University

Dowa Metals & Mining Co. Ltd. has developed and plant-practiced a unique scorodite synthesis technology (DMSP®) for arsenic immobilization by oxidizing Fe(II) ions in the presence of As(V) ions. Dowa has improved the DMSP® technology and has developed the process extensively for other applications. This paper focuses on the applicability of the DMSP® for various cases of copper smelting, and introduces other technologies for fixing arsenic and recycling gallium from GaAs, simultaneously processing (fixing) arsenic and thallium, and fixing and recovering arsenic from dilute arsenic solutions. The DMSP®was found to be applicable not only for various processes in nonferrous smelting, but also for other applications with a high potential for reducing environmental problems.

11:10 AM
New Vermiculite-Copper Nanoparticle Product with Antibacterial Properties: *Jaroslaw Drelich*[1]; Bowen Li[1]; Jiann-Yang Hwang[1]; [1]Michigan Technological University

Vermiculite covered with copper nanoparticles is a new antimicrobial material that was prepared in this study through ion-exchange process and hydrogen reduction. Copper ions were introduced to an interlayer structure of vermiculite from concentrated copper sulfate solutions and then reduced to a metallic copper at 400-600°C in hydrogen atmosphere. During the reduction process copper diffused to surfaces of vermiculite and formed copper nanoparticles. Strong adhesion of copper nanoparticles to the vermiculite carrier makes this hybrid material very stable and durable. The vermiculite-metallic copper hybrid shows strong antibacterial activity against Staphylococcus aureus at 37°C. Vermiculite is an inexpensive mineral that is very stable under a wide range of industrial and environmental conditions, and extensively used as filler in fireproof materials, plastics, paints and lightweight concrete. The addition of metallic copper as an antimicrobial agent opens new avenues for the application of vermiculite in consumer products and other areas.

11:30 AM
Scorodite Solubility and Storage Management Systems for Arsenic-Bearing Compounds: *Tetsuo Fujita*[1]; Shun Fujieda[2]; Kozo Shinoda[2]; Shigeru Suzuki[2]; [1]Dowa Metals & Mining Company Limited; [2]Tohoku University

Dowa's scorodite, synthesized by oxidation of Fe(II) ions in the presence of As(V) ions at atmospheric pressure, was characterized. The scorodite was well crystallized and had a very low solubility. To examine the conditions for stable storage of the scorodite for long periods, experiments with various synthesis and leaching conditions were done. The scorodite had a very low arsenic solubility in sea water. It was estimated in consecutive leaching tests that the arsenic concentration would eventually converge to zero. The prevention of arsenic leaching by adding goethite or ferrihydrite was limited in some cases. Very low toxicity was confirmed by toxicity tests. The investigation results suggest that disposal at a specifically designed well-controlled storage place is preferable for the scorodite whose toxicity had been made sufficiently low. Disposal to an isolated final disposal site with more stringent prevention for the outflow of toxic substances was thought another option.

Ultrafine Grained Materials VII: Advanced Analysis Methods

Neutron Scattering Studies on the Stability of Texture in Cu/Nb Nanolamellar Composites Fabricated via Accumulative Roll Bonding: *John Carpenter*[1]; Sven Vogel[1]; Irene Beyerlein[1]; Nathan Mara[1]; [1]Los Alamos National Laboratory

Current work has shown that the texture of Cu/Nb nanolamellar composites fabricated via physical vapor deposition remain stable under mechanical and irradiation extremes. In this work, the stability of texture in bimetallic composites fabricated via accumulative roll bonding (ARB) will be explored. Prior work on ARB Cu/Nb multilayers found an atypical rolling texture saturated at a layer thickness (h) of 128 nm and was stable with increasing plastic strain (e). Through the use of high temperature in-situ neutron diffraction, the stability of the saturated texture will be investigated. The hypothesis is that a texture that is stable at one extreme (e) will also be stable at another extreme (temperature). Also, neutron scattering will be used to investigate the effects of e and h on the saturation of texture in ARB Cu/Nb multilayers. The hypothesis is that texture saturates as a function of e rather than as a function of h.

8:50 AM
Homogeneity of SPD Processed UltrafineGrained Aluminium: *Malgorzata Lewandowska*[1]; Michal Przybysz[1]; Mariusz Kulczyk[2]; Waclaw Pachla[2]; [1]Warsaw University of Technology; [2]Institute of High Pressure Physics PAS

Homogeneity of technical purity aluminium (1050) produced by hydrostatic extrusion with a total true strain of ~3 or via the combination of equal channel angular pressing (ECAP) technique and hydrostatic extrusion – total true strain of ~11 has been investigated. Microstructure of the samples has been investigated by focus ion beam (FIB) and transmission electron microscopy. The scatter of the properties has been determined by microhardness mapping on the cross and longitudinal section and by tensile testing using microsamples. The results show that 1050 aluminium processed by SPD techniques are to some extend non-homogeneous. It exhibits hard and strong core surrounded with a softer surface regions. In addition, it has been found that samples obtained by the combination of ECAP and HE methods are more homogeneous than the ones produced by HE alone. The gradient of variability of mechanical properties observed on the cross section is related to microstructure inhomogeneity.

9:05 AM
In Situ Measurements of Deformation Strain and Strain-Rate in Equal Channel Angular Pressing: *Saradhi Koneru*[1]; Saurabh Basu[1]; M. Ravi Shankar[1]; [1]University of Pittsburgh

Equal Channel Angular Pressing (ECAP) offers a viable route for the manufacture of bulk nanostructured metals of large cross-sections. In ECAP, strain and strain-rate are central variables of plasticity that determine microstructural refinement and process outcomes. Here, we observed the deformation of soft metals in an optically transparent ECAP die using high-speed CCD cameras. From resulting time-sequence images of metal-flow in the deformation zone, we present results of digital image correlation algorithms that were used to measure the strain and strain-rate fields in ECAP as a function of the scale, deformation speed and die geometry. Implications of these observations for optimizing process parameters in ECAP to achieve desired thermomechanical conditions and controlled microstructural outcomes are presented.

9:20 AM Invited
Influence of Alloying on a Strain Induced Grain Growth in Nanocrystalline Pd: *Lilia Kurmanaeva*[1]; Yulia Ivanisenko[1]; [1]Institute of Nanotechnology, KIT

An investigation of nanocrystalline (nc) materials is one of the key topics of modern material science. These materials demonstrate superior hardness, strength and fatigue properties as compared with their coarse grained counterparts. One of the intriguing aspects in a deformation behavior nc materials is the deformation-induced grain growth, which has no analogy in coarse grained materials. Even in the absence of deformation, nanocrystalline materials can undergo significant grain growth at ambient conditions. Plastic deformation significantly accelerates the growth rate. Therefore the search for strategies to improve the stability of nc microstructure is an important issue for further developments in this area. Here, we present investigation of the microstructure evolution of nanocrystalline Pd and Pd-alloys at severe plastic deformation by high pressure torsion. The obtained results on microstructure development at HPT and related mechanical properties of Pd and Pd alloys are discussed.

9:40 AM
Nanostructural Evolution in Hierarchy-Strengthened Al-Mg Alloys: *Peter Liddicoat*[1]; Maxim Murashkin[2]; Xiaozhou Liao[1]; Ruslan Valiev[2]; Simon Ringer[1]; [1]The University of Sydney; [2]Ufa State Aviation Technical University

Reducing the average grain-size in a polycrystalline material necessarily increases the density of grain interfaces and heightens grain-boundary influence over material properties. The magnitude and mode of grain-boundary influence is not easily predicted by extensions of conventional boundary dispersion and misorientation relationships - nanostructured Al alloys, for example, possess yield strengths up to 1 GPa and contain a hierarchy of intergranular and intragranular solute structures. Beam convolutions, from multiple nanocrystalline grains within a specimen, make retrieval of the required 3D atomic-level chemical and spatial information complex or impossible using transmission-based microscopes (e.g., TEM, XRD, or SAXS). Using novel techniques in atom probe microscopy, a point-projection microscope, we will present the evolution of solute structuring, chemical-texture and nanotopology at progressive strain increments imparted by high-pressure torsion in Al-Mg alloys and discuss the intergranular relationships of misorientation and curvature to provide energetically favourable conditions for solute diffusion and partitioning.

9:55 AM
Validation and Analysis of a Model for Grain Refinement by Cold Severe Plastic Deformation: *Marco Starink*[1]; Xiaoguang Qiao[1]; Nong Gao[1]; [1]University of Southampton

We present a model to predict grain refinement and strength/hardness of Al alloys after very high levels of cold deformation through techniques including cold rolling, equal channel angular pressing (ECAP), high pressure torsion (HPT), accumulative rolling bonding (ARB) and embossing. At the beginning of deformation, the generated dislocations are stored in grains and contribute to overall strength. With increase in strain, excess dislocations form and/or move to new cell walls/grain boundaries and grains are refined. The model is tested against data on a range of SPD processed Al based alloys. It is shown that grain size and strength/hardness are correctly predicted to a good accuracy. It is also shown that general trends in strengthening in all fcc pure metals are consistent with the model.

Spatial Distribution of the Dislocation Density and the Strength of Nb and Ta Deformed by High-Pressure-Torsion Determined by X-Ray Peak Profile Analysis: Bertalan Jóni[1]; Erhard Schafler[2]; *Tamás Ungár*[1]; Michael Zehetbauer[2]; [1]Eötvös University Budapest, Hungary; [2]University of Vienna, Austria

Niobium and Tantalum are two bcc metals with very different elastic anisotropy. The Az=2×c44/(c11-c12) constants for Nb and Ta are 0.51 and 1.58, respectively. Submicron grain-size state of the two refractory metals is produced by the method of high-pressure-torsion (HPT) with different pressures 2 and 4 GPa, and two different deformations of 0.25 and 1.5 rotations, respectively. The grain size, the dislocation density and the screw or edge type of dislocation character are investigated by high resolution diffraction peak-profile analysis. The beam size on the specimen surface is 0.2×1 mm allowing to characterize the sub-structure along the radius of the specimen. The strength of the samples is determined by microhardness testing. The sub-structure parameters are correlated with the strength data. The deformation mechanisms of the two different metals are discussed in terms of the different deformation modes, the elastic anisotropy and the dislocation structure.

10:45 AM
Mapping Microstructures Resulting from Severe Simple Shear Deformation: Sepideh Abolghasem[1]; Saurabh Basu[1]; Shashank Shekhar[1]; Jiazhao Cai[1]; *M. Ravi Shankar*[1]; [1]University of Pittsburgh

Grain refinement from interactive effects of severe shear strains, strain-rates and temperatures often follow complex trajectories. Microstructure control under these conditions can be simplified by delineating a map-space for projecting characteristics of deformed microstructures when it is parameterized as functions of the variables of deformation, while remaining cognizant of the underlying mechanisms of refinement. Using Large Strain Machining (LSM) as a test of material response in simple-shear, quantitative microstructure analysis is performed across broad deformation conditions, while simultaneously measuring the thermomechanics of the process using high-speed digital image correlation and infrared thermography. The implications of the microstructure maps generated from the emerging data-sets for predicting and custom-designing grain-refined materials are presented.

11:00 AM
A Crystal Plasticity FEM Study about Influence of Crystal Orientation on the Texture Evolution and Heterogeneity of ECAPed Copper Single Crystals: *Guanyu Deng*[1]; Cheng Lu[1]; Lihong Su[1]; Kiet Tieu[1]; Xianghua Liu[2]; [1]University of Wollongong; [2]Northeastern University

Equal channel angular pressing (ECAP) has been widely used to produce ultra-fined grains (UFG) in bulk materials over the last two decades. The present work investigates texture evolution and deformation heterogeneity of copper single crystals subjected to one-pass ECAP at room temperature using a crystal plasticity finite element method (CPFEM) model. Two special orientations are designed to examine the effect of initial crystallographic orientation on texture evolution and heterogeneity. The first orientation (Crystal I) meets the macroscopic shear deformation of ECAP and the second orientation (Crystal II) is rotated around the transverse axis (TD) by 20° in a counter-clockwise direction from Crystal I. It has been found that the initial orientation has a great influence on the plastic deformation zone (PDZ) and texture developments during ECAP. The crystal rotation during deformation is quantitatively estimated. These simulation results agree well with the experimental observations.

11:15 AM Invited
Using Deformation Mechanism Map to Depict Flow Processes in Superplastic Ultrafine-Grained Materials: *Megumi Kawasaki*[1]; Terence Langdon[1]; [1]University of Southern California

The introduction of significant grain refinement is very attractive because small grains lead to excellent creep properties especially superplastic ductility at elevated temperatures. Since the strain rate in superplastic flow varies inversely with the grain size raised to a power of two, a reduction in grain size to the submicrometer level will bring about the occurrence of superplasticity at higher strain rates of > 10-2 s-1. In the present report, an analysis was conducted to examine the flow behavior of several different ultrafine-grained metals processed by severe plastic deformation process in equal-channel angular pressing and high-pressure torsion. The analysis shows the superplastic flow of the UFG materials may be represented using a flow mechanism developed earlier for coarse grains and the flow process of high strain rate superplasticity is depicted using deformation mechanism maps.

11:35 AM
Modeling Temperature-Dependent Mechanical Response of UFG Al-1100 at High Strain Rates: *Emily Huskins*[1]; K.T. Ramesh[1]; [1]Johns Hopkins University

Recent improvements in the strength of aluminum alloys have been obtained through the development of complex microstructures containing reduced grain sizes. Under dynamic compression, failure in these materials often initiates as localization of plastic deformation. Localized plastic work results in a local temperature rise, and thus softening of the material. To understand bulk failure it is necessary to understand the thermal softening of the material under these high strain rate and high temperature conditions. In this work, a modified Kocks-Mecking model is developed to predict the thermal softening observed for UFG commercially pure aluminum. This is a mechanism-based constitutive model which accounts for temperature, strain rate, and grain size effects through the evolution of dislocation density during deformation. The model predictions are compared to experimental results on UFG Al-1100 tested at high temperatures (298-573K) and high strain rates on a modified Kolsky bar system.

Stress-Induced Grain Growth in Ultra-Fine Grained 5083 Al during Hot Extrusion: Yaojun Lin[1]; Ying Li[1]; *Enrique Lavernia*[1]; [1]University of California, Davis

Due to the potential for high tonnage manufacturing, the approach to produce ultrafine grained (UFG) materials via mechanical milling has received particular attention. Minimization of grain growth during consolidation of mechanically milled powders, including primary consolidation, such as hot isostatic pressing (HIPing), and secondary consolidation, such as extrusion, rolling and forging, is critical for retention of UFG structure in the resultant materials. Stress-induced grain growth during secondary consolidation heretofore remains poorly understood. Consequently, this presentation reports on a study of the influence of second-phase particles and solute/impurity segregation at grain boundaries (GBs) on stress-induced grain growth during hot extrusion of 5083 Al consolidated by HIPing mechanically milled powders. Based on TEM and HRTEM observations, the contributions of GB migration and grain rotation to grain growth are analyzed and discussed. On the basis of the analysis, we propose that grain rotation is the predominant mechanism responsible for stress-induced grain growth.

8:50 AM
Large Scale Powder Processing of High Strength Copper Alloys: *Joseph Paras*[1]; Kris Darling[2]; Laszlo Kecskes[2]; Suveen Mathaudhu[3]; Deepak Kapoor[1]; [1]U.S. Army ARDEC; [2]U.S. Army Research Laboratory; [3]U.S. Army Research Office

Research is currently being conducted on the stabilization of grains in nanocrystalline materials. Recent progress has shown nanocrystalline alloys with high temperature stability because of the interfacial energy reduction associated with solute segregation. These materials are typically synthesized through powder processing in non equilibrium conditions, such as high energy milling, and carefully consolidated to preserve the engineered microstructure. The intent of this work was to scale up the processing of such nanocrystalline alloys beyond the laboratory scale. Previous work on the thermally stabilized nanocrystalline Cu-10at%Nb was applied to a Cu-10at%Ta system and the powders produced were initially consolidated into 40mm diameter discs with 5mm thickness via field assisted sintering and 25mm diameter billets via instrumented hot isostatic pressing. Preliminary results have shown 75% retention of the microhardness going from the powder to bulk form. This work will provide appropriate processing and consolidation parameters for large scale fabrication of these materials.

9:05 AM

Mechanical Properties of Nanocrystalline Cu-, Mg-, and Fe-Base Alloys from In-Situ and HPT Consolidated Ball-Milled Powders: *Khaled Youssef*[1]; Daria Setman[2]; Michael Zehetbauer[2]; Suhrit Mula[3]; Pengchao Kang[4]; Ronald Scattergood[1]; Carl Koch[1]; [1]North Carolina State University; [2]University of Vienna; [3]National Institute of Technology; [4]Harbin Institute of Technology

Since ultra-high strength nanocrystalline metals often suffer from poor ductility, it has been a challenge for researchers for years to improve it. Another challenge has been to produce nanocrystalline materials with a fine grain size in bulk form without processing artifacts. Recent progress in processing – e.g. in ball milling involving in-situ consolidation - allowed to come about both problems. While related works so far mostly concerned pure nanocrystalline metals, this work was devoted to ball milled nanocrystalline alloys including fcc (Cu-Zn-Al, Cu-Nb), hcp (Mg-Zn-Y), and bcc (Fe-Y, Fe-Zr) crystal structures, not at least due to their potential for enhancing the thermal stability. This is attributed to kinetic mechanisms impeding grain boundary migration, and/or thermodynamic mechanisms reducing the grain boundary energy, as a result of solute segregation. Experiments are reported which focused on the variation of processing parameters, also attempting High Pressure Torsion (HPT) for consolidation, and on tensile tests providing the mechanical properties.

9:20 AM Invited

Microstructure Features,Strengthening Mechanisms and Hot Deformation Behavior of Oxide-Dispersion Strengthened Al6063 Alloy with Ultrafine-Grained Structure: *A. Simchi*[1]; H. Asgharzadeh[1]; H.S. Kim[2]; [1]Sharif University of Technology; [2]Pohang University of Science and Technology

Ultrafine-grained (UFG) Al6063/Al2O3 (0.8 vol%, 25 nm) nanocomposite was prepared via powdr metallurgy route. The grain structure of the nanocomposite composed of nano-size grains (< 0.1 µm), ultrafine grains (0.1-1 µm) and micron-size grains (>1 µm) with random orientations. It was found that the yield strength of the UFG nanocomposite is mainly controlled by the Orowan mechanism rather than the grain boundaries. The deformation activation energy at temperature ranges of T <300 °C and 300 °C =T < 450 °C was determined to be 74 and 264 kJ mol-1, respectively. At the higher temperatures, significant deformation softening was observed due to dynamic recrystallization of non-equilibrium grain boundaries. A duplex microstructure consisting of large substructured grains and fine grains separated by high-angle grain boundaries was formed after hot deformation. The deformation behavior is described based on the formation of nonequilibrium grain boundaries with high internal stress and dislocation-based models.

9:40 AM

Microstructure and Mechanical Properties of Polycrystalline Nickel with Controlled Micro/Nano Grain Volume Fractions: Guy-Daniel Kollo[1]; *David Tingaud*[1]; Guy Dirras[1]; [1]Université Paris 13- Institut Galilée

Nickel powder blends were prepared by mixing nano and micron-sized powder . Bulk polycrystalline Ni samples with controlled volume fractions of 100%, 60%, 30% and 0% of micro-sized (mc) grains embedded in an ultrafine-grained matrix (ufg) were processed by spark plasma sintering. The relative mass density was higher than 96%, reaching 100% for the sample containing 60% of mc grains for which the number average grain sizes within the matrix and the mc inclusions were about 300nm and 1.60µm, respectively. EBSD investigations showed the presence of a high amount of high angle boundaries (>30%) in both the ufg matrix and the mc inclusions. Quasi-static compression tests performed at room temperature and at a strain rate of 10-3 s-1 indicates a decrease of the yield strength from 1450 to 500 MPa while the strain to failure starts to 6% and exceeds 40% for the fully ufg and mc samples, respectively.

9:55 AM

Nickel with Multimodal Grain Size Distribution Achieved by SPS: Microstructure and Mechanical Properties: Guy-Daniel Kollo[1]; *David Tingaud*[1]; Guy Dirras[1]; [1]Université Paris 13- Institut Galilée

Bulk nickel ultrafine-grained (ufg) Ni samples were processed by spark plasma sintering of high purity Ni nanopowders. Microstructural investigations showed that the powder was heterogeneous, comprising ultrafine (0.05-1µm) as well as coarse particles (1-5µm). Sintering resulted in bulk Ni samples having a relative mass density of ~97%. Thorough microstructural investigation was carried out by EBSD and revealed composite-like microstructure consisting of ~10 vol. % of large multi-crystalline agglomerates of 10µm in diameter embedded the ufg (200-300 nm) matrix. The mechanical behavior was investigated by compression tests conducted at room temperature at strain rates of 2x10-4 s-1 and 2x10-2 s-1. After the onset of yielding, a softening behavior was observed for the sample deformed at 2x10-4 s-1 while at 2x10-2 s-1 a large strain hardening behavior was observed. As a consequence the measured strain to failure was two times higher than the one measured for the lower strain rate.

10:10 AM

Quantifying Strengthening Mechanisms in Cryomilled Al Alloys and Their Composites: *Troy Topping*[1]; Zhihui Zhang[1]; Ying Li[1]; Enrique Lavernia[1]; [1]University of California, Davis

Aluminum alloys with nanocrystalline (NC) and ultra-fine grain (UFG) size are of interest because of their high strength – typically more than 30% stronger than conventionally processed alloys. By generating NC powders via cryomilling in liquid nitrogen, a thermally stable UFG microstructure evolves during thermomechanical processing (TMP). The constituents that stabilize the microstructure – dispersed oxides and nitrides – also contribute to the strength of the system. By examining microstructures and stress-strain data generated for cryomilled pure Al and Al-Mg alloys, with various milling times and media, the strengthening mechanisms can be dissected to improve understanding of cryomilled Al alloys. Hall-Petch, Orowan, solid solution and dislocation hardening mechanisms are quantified based on experimentally developed UFG Al alloys crossing multiple investigations. Additionally, the intentional addition of ceramic particulates, such as Al_2O_3 and B_4C, provides the basis for analyzing systems using basic composite models.

10:25 AM Break

10:40 AM

Mechanics of Powder Equal Channel Angular Pressing: *Hyoung Seop Kim*[1]; [1]POSTECH

Manufacturing bulk nanostructured materials with least grain growth from initial powders is challenging because of the bottle neck of bottom-up methods using the conventional powder metallurgy of compaction and sintering. In this study, bottom-up type powder metallurgy processing and top-down type SPD approaches were combined in order to achieve both real density and grain refinement of metallic powders. ECAP, one of the most promising processes in SPD, was used for the powder consolidation method. For understanding the ECAP process, investigating the powder density as well as internal stress, strain distribution is crucial. We investigated the consolidation and plastic deformation of the metallic powders during ECAP using the finite element simulations. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST) (No.2010-0026981).

10:55 AM

Microstructure Evolution and Mechanical Behavior of Ultrafine Grain Structured Al 7075 Developed by Cryomilling: *Kaka Ma*[1]; Troy Topping[1]; Enrique Lavernia[1]; Julie Schoenung[1]; [1]University of California, Davis

Al 7075 alloys are used extensively in aircraft and aerospace structures due to their high strength-to-density ratio as well as moderate toughness and corrosion resistance. It has been commonly accepted that a sequence of precipitation reactions occur in conventional Al 7075 with increasing temperature: solid solution --> Guinier-Preston (G-P) zones --> η' --> η. The formation and dissolution of the precipitates have a significant influence on the mechanical behavior of the materials. In this paper, gas atomized Al 7075 powder was modified by using the cryomilling technique to develop an ultrafine grain microstructure. The cryomilled material is compared to conventional material by investigating the morphology and microstructure of the powders, the precipitation reactions, and the mechanical behavior and microstructure evolution in bulk consolidated materials.

11:10 AM

Explosive Fabrication of Bulk Ultrafine Grained Al-Ni-Ti Composite Materials: Nikoloz Chikhradze[1]; Akaki Gigineishvili[1]; *Mikheil Chikhradze*[1]; [1]Mining Institute/Georgian Technical University

The properties of Al-Ni-Al composite materials significantly improved if they are prepared in nanostructured/ultrafine grained form. Same time the industrial fabrication of Al-Ni-Ti ultrafine grained bulk materials is reduced. The preparation of the precursors and compaction technique of Al-Ti-Ni- blend for obtaining bulk samples is discussed in the paper. For homogenization, mechanical alloying and transformation in amorphous and ultrafine grained structure of the Al-Ni-Ti blend the high energy planetary ball mill was used. The explosive generated shock wave compaction technique is selected and investigated for obtaining ultrafine grained bulk materials. Structural investigations and micro-hardness measurements were used to characterize the phase composition and mechanical properties of the materials. The results of analysis revealing the effects of the compacting conditions and precursor particles sizes, affecting the consolidation and the properties of this new ultra high performance alloys are discussed.

11:25 AM

Mechanical Properties of Nanostructured Al-Bi Alloys: *Koteswararao Rajulapati*[1]; Sreedevi Varam[1]; K Bhanu Sankara Rao[1]; [1]University of Hyderabad

The size and volume fraction of the second-phase particles greatly influence the mechanical properties of the matrix in composite materials. Al and Bi are mutually insoluble both in the liquid state as well as solid state. Nanostructured Al-Bi alloy powders were synthesized using high energy ball milling and are characterized using X-Ray Diffraction (XRD), Transmission Electron Microscopy (TEM) and Differential Scanning Calorimetry (DSC). XRD data of Al-Bi alloy samples milled for 50 hours showed both Al and Bi peaks with no considerable change in lattice parameter values of Al, indicating a two-phase structure. Further analysis of the synthesized powders is in progress. The mechanically alloyed powder samples will be Consolidated using uniaxial compression and/or Spark Plasma Sintering (SPS) and the mechanical properties of these bulk samples are evaluated by micro indentation and nanoindentation. The wear properties of the bulk samples are determined and correlated with the nanostructure.

11:40 AM

Effect of Grain Size Distribution and Zr Addition on Mechanical Properties and Oxidation Resistance of Fe-Cr-Ni Alloys: *Mahesh Venkataraman*[1]; Raman Singh[1]; Carl Koch[2]; [1]Monash University; [2]North Carolina State University

The effects of nanocrystalline and bimodal grain size distributions as well as alloying additions of Cr and Zr on the oxidation resistance of nanocrystalline (nc) Fe-based alloys has been investigated. Fe-Cr-Ni-Zr alloys having nc and bimodal grain size distributions were prepared using mechanical alloying followed by a novel multi-step hot-compaction route. The ductility of bimodal alloys, determined by shear punch test, was found to be significantly superior to the nc alloys owing to the presence of the microcrystalline grains in the matrix of the bimodal alloys. The oxidation resistance of these alloys, in a temperature range 500-700 °C, has been compared with conventional micro-crystalline stainless steel. The remarkably superior oxidation resistance of these alloys as compared to stainless steel is attributed to the enhanced diffusivity of Cr in nc and bimodal alloys, which results in the enrichment of Cr at the metal oxide interface even at lower bulk Cr contents.

11:55 AM

Comparison of Structure and Properties of Nanomaterials Processed by Ball Milling and High Pressure Torsion: *Jelena Horky*[1]; Daria Setman[1]; Michael Kerber[1]; Hamed Bahmanpour[2]; Carl Koch[2]; Ron Scattergood[2]; Michael Zehetbauer[1]; [1]University of Vienna; [2]North Carolina State University

Cu nanomaterials processed by Ball Milling (BM) and High Pressure Torsion (HPT) were investigated by microhardness, multiple whole X-ray profile analysis, and differential scanning calorimetry (DSC). The strength of BM samples and its dependence on milling time (equivalent to strain) is much higher than that of HPT samples, which can be related to the huge difference between coherent domain sizes (CSD) after BM and HPT, respectively. Therefore, very high values of fatigue strength in BM samples can be expected. The stored energy of BM samples derived from DSC again is much higher than those of HPT, but strongly decreases with increasing milling time finally reaching the level of HPT. Since neither dislocation density nor CSD can account for this behaviour, the extra high energy stored in BM samples is attributed to a very high concentration of deformation induced vacancy type defects which appear to gradually anneal with increasing milling time.

12:10 PM

Synthesis and Characterization of Binary Al-Mn Alloys for Structural Applications: *Lauren Armstrong*[1]; Rajendra Sadangi[1]; Kris Darling[2]; Chris Haines[1]; Deepak Kapoor[1]; [1]US Army, ARDEC; [2]US Army, ARL

Nanocrystalline and amorphous Al-Mn alloys, produced by electrodeposition, have demonstrated exceptionally high hardness (>5GPa)[1]. Powder metallurgy is being examined as a viable route to produce pilot scale quantities of Al-Mn alloys. Binary Al-15 wt. % Mn alloys were synthesized via high energy mechanical alloying (MA) of elemental, gas atomized, and rapidly solidified powders. These alloys were characterized with an array of techniques, including x-ray diffraction, electron microscopy, calorimetry, and mechanical indentation. Influence of synthesis route and processing parameters on structure and properties will be presented. Formation and thermal stability of the ultra-fine grained phases will also be discussed in reference to hot consolidation of the powders. 1. Ruan S, Schuh CA; "Electrodeposited Al-Mn alloys with microcrystalline, nanocrystalline, amorphous and nano-quasicrystalline structures"; *ACTA MATERIALIA* 57, 3810, 2009.

12:25 PM

Grain Size Dependence of Deformation Microstructure Formation in Compressed Aluminum: *Guomin Le*[1]; Andy Godfrey[1]; Xiaoxu Huang[2]; Niels Hansen[2]; Grethe Winther[2]; [1]Tsinghua University; [2]Risø National Laboratory for Sustainable Energy, Technical University of Denmark

The effects of grain size on the extent and patterning of the dislocation storage during plastic deformation has been examined in samples of aluminum with average grain sizes ranging from 30μm to 0.7μm deformed by compression. Initial fine grain samples were produced using spark plasma sintering to obtain fully recrystallized grains with a low dislocation density. In the coarsest grain samples the deformation microstructure follows the pattern previously reported during tensile deformation, with cells formed in grains with a compression axis near [100] and extended planar boundaries formed in other grains showing an orientation dependence in their crystallographic alignment. With decreasing average grain size the crystallographic alignment of the planar boundaries becomes less well defined and the fraction of grains showing cell structures increases. In the finest grains examined only loose dislocations are found. These observations are discussed with respect to the differences seen in the work-hardening of the samples.

Ultrasonic Fatigue of Advanced Materials and Systems: Ultrasonic Fatigue of Metals and Alloys I

Sponsored by: The Minerals, Metals and Materials Society, State Research Center for Mathematical and Computational Modelling, University of Kaiserslautern, Germany, State Research Focus "Advanced Materials Engineering", University of Kaiserslautern, Germany, TMS Light Metals Division, TMS Structural Materials Division, TMS: Advanced Characterization, Testing, and Simulation Committee, TMS/ASM: Computational Materials Science and Engineering Committee, TMS: Materials Characterization Committee, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Young Leaders Committee
Program Organizers: Frank Balle, University of Kaiserslautern; Dietmar Eifler, University of Kaiserslautern; Guntram Wagner, University of Kaiserslautern

Wednesday AM March 14, 2012 | Room: Europe 1 Location: Dolphin Resort

Session Chairs: Frank Balle, University of Kaiserslautern (Germany); Dietmar Eifler, University of Kaiserslautern (Germany); Guntram Wagner, University of Kaiserslautern (Germany)

8:30 AM Introductory Comments: Frank Balle, Symposium organizer-in-chief

8:35 AM
A Method for In Situ Capture of Cyclic Strain Accumulation during Ultrasonic Fatigue of Structural Alloys: *Jason Geathers*[1]; Samantha Daly[1]; J. Wayne Jones[1]; [1]University of Michigan

A novel experimental capability that combines ultrasonic fatigue instrumentation and Digital Image Correlation (DIC) to has been developed to enable the quantification of cyclic damage accumulation at the microstructural length scale during Very High Cycle Fatigue (VHCF). Both macro-DIC and micro-DIC, the latter using calibrated stereomicroscopes for image capture, are employed to examine the evolution of small-scale strain fields in local microstructural neighborhoods that favor crack initiation. Damage evolution and cyclic strain localization leading to crack formation is examined for a range of polycrystalline metals will be described, as will the characterization of small crack propagation in both bulk ultrasonic specimens and in thin foils ($t \sim 150$ µm) cycled at 20 kHz. The unique advantages of these combined techniques, as well as the experimental challenges encountered, will be discussed.

8:55 AM
Influence of Grain Size and Precipitates on the Fatigue Lives and Deformation Mechanisms in the VHCF-Regime: *Heinz Werner Höppel*[1]; [1]University Erlangen-Nürnberg

Research in the field of very high cycle fatigue (VHCF) strongly increased during the last decade. It is meanwhile established that when investigating the deformation mechanisms in the VHCF-regime it has to be separated between inclusion free type I materials and materials with inclusions (type II). Despite all the attempts made so far, a basic understanding on the dominating deformation mechanisms in the VHCF-regime is still missing. Hence, in this study the deformation mechanisms of the aluminium alloy AA6082 (type II material) were investigated. The material was investigated in the as-received condition and after different heat treatments. The heat treatment changes the deformation mechanism from internal crack initiation to initiation from the surface. In the as-received condition a non-defect crack initiation site was detected. Based on thorough investigations using EBSD, FIB-techniques and nanoindentation mechanisms for featureless crack initiation are discussed and compared to other datat in literture.

9:15 AM Invited
Ultrasonic Fatigue Testing at Different Load Ratios under Constant and Variable Amplitude: *Herwig Mayer*[1]; Michael Fitzka[1]; Reinhard Schuller[1]; Stefanie Stanzl-Tschegg[1]; [1]BOKU, Institute of Physics and Material Science, Vienna

Ultrasonic resonance fatigue testing is a powerful tool to investigate the High Cycle Fatigue (HCF) and Very High Cycle Fatigue (VHCF) properties of materials in short testing times. Closed lock loop control of load amplitude and resonance frequency to obtain high accuracy, and pulsed loading to prevent heating of specimens, for example, allow endurance and fatigue crack growth experiments with high precision. New technique performing ultrasonic tests with Variable Amplitude (VA) at constant load ratio R is presented and used to investigate 2024-T351 aluminium alloy. VA lifetimes at R=-1, R=0.1 and R=0.5, respectively, are presented and compared with Constant Amplitude (CA) tests. Non-propagating cracks are detected in specimens surviving more than 10exp10 CA cycles that formed at fractured iron-containing constituent particles. VA tests and damage accumulation calculations show that VHCF lifetimes can hardly be predicted from HCF data, which indicates the technical importance of the presented technique.

9:35 AM Break

10:05 AM Keynote
Damage Mechanisms in the VHCF Regime in Quasi Defect-Free Metals Regarding Different Levels of Microstructural Inhomogeneity: *Martina Zimmermann*[1]; Hans-Juergen Christ[1]; [1]Universitaet Siegen

Numerous experimental studies of metal failure in the very high cycle fatigue (VHCF) range have proven that fatigue life is dominated by the crack initiation phase rather than the crack growth period. Microstructural discontinuities play a major role in the VHCF behavior of quasi-defect free metals, acting as local stress raisers or decreasing the resistance to slip transmission across or along grain boundaries. The crack initiation sites are manifold, reaching from crack initiation at slip bands at the surface, triple junctions of Sigma3 twin boundaries, clusters of similarly oriented grains to second phases or large particles. An overview of the diversity of damage mechanisms will be given for a wide range of non-ferrous metals with focus on an increasing level of microstructural inhomogeneity. Results on the VHCF behavior of pure metals such as copper, aluminum and nickel and their alloys will be presented based on latest methods in metallography.

10:35 AM
Local Cyclic Plastic Deformation and Damage during Ultrasonic Fatigue: *Guocai Chai*[1]; [1]Sandvik Materials Technology

During ultrasonic or very high cycle fatigue (VHCF), the applied stresses or strains are sometime well below the bulk yield strength or in the elastic regime of the material. How can a cyclic plastic deformation or damage occur in such a case? Fatigue behaviors of three metals with respectively one phase, dual phase and multiphase have been studied by ultrasonic fatigue testing and then evaluated using SEM, EBSD and TEM. It was found that the strains in the specimens were highly localised where the local maximum strain can be eight times higher than the average strain value in the specimen. This can cause a local plasticity exhaustion that leads to fatigue damage and finally crack initation. The results in this study show that fatigue damage and crack initiation mechanisms in the VHCF regime can be different in different metals, but mainly due to local plasticity exhaustion.

10:55 AM
Comparison of Fatigue Property of Metallic Materials under Conventional and Ultrasonic Testing Methods: *Benjamin Guennec*[1]; Yuki Nakamura[2]; Tatsuo Sakai[1]; Akira Ueno[1]; Isamu Nonaka[3]; [1]Ritsumeikan University; [2]Toyota National College of Technology; [3]Tohoku University

Ultrasonic testing method, due to its very high frequency of stress solicitations, is a very convenient response of the new challenges of which fatigue researches have to cope with. To reach 10^9 or 10^{10} cycles is really faster with this type of machines, compared to conventional servo-hydraulic machines. In addition, for many researchers, it is possible to obtain S-N properties of materials by using ultrasonic devices even for high cycle fatigue domain, which is extended from 10^4 to 10^7 cycles. This paper deals with a comparison of results from conventional and ultrasonic tests, taken from literature, in the high cycle fatigue domain. A direct comparison and a statistical study have been carried out. Both indicate some divergences between these two methods.

11:15 AM
Basic Need of Standardization for Ultrasonic Fatigue Testing: *Claude Bathias*[1]; [1]University Paris Pouest

The ultrasonic fatigue testing is a new approach in perfect agreement with the real fatigue life of modern machines, structures, engines, according to the policy of sustainable economy. As the main international standards do not take account the very high cycle fatigue, it is of interest to sum up the research results published in the literature , concerning the gigacycle fatigue carried out at 20kHz, facing the conventional fatigue data, in push pull or rotating bending. The remaining questions are always the same:-what about the frequency effect-what about the size effect-influence of the shape of the specimen-temperature rising at 20kHz-influence of the pulse control-fatigue corrosion in ultrasonic fatigue-environmental effect at 20kHz.The topic of this paper is to give a tentative answer in order to prepare a scientific approach for standardization of ultrasonic fatigue.

2012 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: Structural Nanomaterials

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Nanomaterials Committee
Program Organizers: Jiyoung Kim, University of Texas; David Stollberg, Georgia Tech Research Institute; Seong Jin Koh, University of Texas at Arlington; Nitin Chopra, The University of Alabama; Terry Xu, UNC Charlotte

Wednesday PM — Room: Pelican 1
March 14, 2012 — Location: Swan Resort

Session Chair: Yonghao Zhao, Nanjing University of Science and Technology

2:00 PM Invited
Mechanical Properties and Deformation in Multi-scale Nanostructured Cu and Ti: *Yonghao Zhao*[1]; Y. Li[2]; T. Topping[2]; Y.T. Zhu[3]; R.Z. Valiev[4]; E.J. Lavernia[2]; [1]University of California Davis;Nanjing University of Science and Technology; [2]University of California Davis; [3]North Carolina State University; [4]Ufa State Aviation Technical University

Multi-scale nanostructured materials containing bi-/multi-modal grain size distributions can be engineered to display unusual balance of properties, such as strength and ductility. Despite well documented reports of enhanced ductility in multi-scale nanostructured materials, systematic identification of the quantitative relationship between mechanical properties and microstructures as well as underlying deformation mechanisms has not been accomplished. In this work, we selected high-purity Cu and commercial pure Ti as a model material system in an effort to elucidate the underlying mechanisms. The bi-/multi-modal Cu and Ti were prepared by equal-channel-angular pressing (ECAP) and subsequent annealing. Transmission electron microscopy (TEM) in combination with tensile testing are used to characterize the deformation mechanisms and mechanical behavior.

2:35 PM
Mechanical Behavior of Bulk Diamantane Stabilized Aluminum Matrix Nanocomposites: Khinlay Maung[1]; Colin Arnold[1]; Ali Yousefiani[2]; Farghalli Mohamed[1]; *James Earthman*[1]; [1]University of California, Irvine; [2]Boeing Research & Technology

A bulk aluminum matrix nanocomposite has been produced by cryomilling with the addition of 0.5 and 1 wt.% diamantane diamondoid molecules. The milled powders were consolidated to at least 99% density by hot isostatic pressing at 421°C and 521°C and subsequent extrusion at room temperature. The average grain diameter of each diamantane-stabilized nanocomposite sample was found to be consistently smaller (58 to 95 nm) than those achieved in previous studies of the commercially pure counterpart. Furthermore, the mechanical properties were assessed after full consolidation and after additional post-consolidation heat treatment at 575°C. As expected, Hall-Petch associated strengths were measured after cryomilling, and further strengthening was evident after post-consolidation heat treatment steps. Evidence of pore formation and Al-organic precipitation was also revealed following the 521°C HIP and post-consolidation heat treatment. Pore formation and precipitation were not observed in the samples that were consolidated at 421°C.

2:55 PM
Mechanical Characterization of Alumina In-Situ Aluminum Di-Borides Nano Composites: *Sudeep Ingole*[1]; Zulfiqar Khan[2]; Rajeshwari Paluri[1]; Fevzi Ozaydin[1]; [1]Texas A&M University; [2]Bournemouth University

High strength with in-situ lubricious phases can potentially enhance the service life of sliding interfaces. Nano composites are developed with in-situ lubricious phases using alumina and boron. The mechanical characterization of Al2O3 matrix nano composites using 2 wt. %B will be reported. The mechanical properties such as Vicker's hardness, fracture strength will be discussed. The effect of milling time and sintering temperature on mechanical properties will be evaluated. It is hypothesized that the reduced grain size will enhance the mechanical properties of composites. This will be a significant contribution towards specific industrial applications. Additionally, formation of borate (Al18B4O33) will also contribute to the enhancement of mechanical properties as well. The scanning electron micrographs showed the grain refinement as compared to as-received materials (i.e. alumina and boron).

3:15 PM
Phase Transformations during Mechanical Alloying of Ni-Al-Cr Powders Mixture to Produce Nanocrystalline Intermetallic Compounds: *M.H. Enayati*[1]; A. R. Shirani[2]; A Shokoohfar[3]; [1]Isfahan University of Technology; [2]Azad University; [3]Khaje Nasir Toosi Technical University

Phase transformation of the Ni50Al50, Ni25Cr25Al50 and Ni50Cr25Al25 system by mechanical alloying (MA) was investigated. The structural changes of powder particles during MA were studid by XRD, SEM and TEM. The results showed that for all three compositions a gradual interdiffusion of elements was occurred during MA leading to the development of different phases. The final product obtained by MA for Ni50Al50 and Ni25Cr25Al50 had nanocrystalline structure while MA of Ni50Cr25Al25 led to the formation of a partially amorphous structure. The details of structural evolution of powder during MA and after subsequent heat treatment are being investigated.

3:50 PM

Synthesis of Gold, Manganese and Nickle Alloy Films Possessing Nano and Various Microstructures: *Bassey Udofot*[1]; [1]Aerospace

Alloy films of Au, Ni, Fe-Mn, Fe-MnP, Ni, Fe-Ni nano or microcrystalline structures can be thermally or electrochemically deposited or joint from vacuum or solvent systems that are aqueous onto a conductor, semiconductors, insulators or glass substrate. The films produced by electrochemical means can be produced by thermal means but such process is expensive usually requiring the use of high temperature and high energy conditions.These films have nano, microstructures ranging from single ordered crystalline to polycrystalline disordered structures. The hysteresis loop of Fe-Mn, Fe-Ni alloy films characterized under a vibratory sample magnetometer and cyclic voltermmetry shows the films to have soft magnetic properties and codeposited at a single potential. Codeposition of Mn with Fe occurred at a potential nearer that of Mn resulting in less Mn deposition but in the Fe-Ni systems the deposition was nearer the potential of the Fe resulting in less Ni deposition, presenting anomalous condition.

4:10 PM

Formation of Aluminum Di-Borides in Alumina Matrix Through Mechanical Mixing for Tribological Applications: Sudeep Ingole[1]; *Fevzi Ozaydin*[1]; Rajeshwari Paluri[1]; [1]Texas A&M University

The synthesis and characterization of borides in an Al2O3 matrix using 2 wt. %B via mechanical alloying will be reported. These phases can be used as in-situ reinforcement to develop nano composite materials for reduced friction, and wear applications. The evolution of the reaction products with milling time and sintering temperature and the microstructure analysis is carried out using microprobe analysis and X-ray diffraction techniques. Preliminary results showed the reduced grain size as compared to as received powders used in this study. In addition to aluminum diboride (AlB2), other phases such aluminum borate (Al18B4O33) and boron oxide (B2O3) were formed as reaction products. The SEM analysis indicated a duplex or bimodal grain size distribution of the microstructure at low milling time however, as the milling time increased more uniform grain size distribution was observed.

4:30 PM

Fabrication and Characterization of Porous Zinc via Selective Dealloying of Al-Zn Alloys: *Elvin Estremera*[1]; Rafael Soler[1]; Amarilis Declet[1]; Ulises Barajas-Valdes[1]; O. Marcelo Suarez[1]; [1]University of Puerto Rico

Porous zinc was fabricated via chemical dealloying of various Al-Zn alloys. These alloys were quenched to promote finer microstructure. The alloy specimens were cut and polished prior to the selective corrosion to favor a uniform dealloying process. Sodium hydroxide solutions were used to selectively remove the aluminum atoms. Concentration and cooling rate were varied to observe their effect on the attained pore size. The microstructure of the resulting porous sponge was characterized using X-ray diffraction (XRD) and scanning electron microscopy (SEM). Nanoindentation measurements were used in the characterization of the materials mechanical properties. Our results revealed that porosity depends highly on the Zn concentration of the alloy, the cooling rate upon alloy fabrication while the mechanical properties were affected by that cooling rate and the corrosion levels.

4:45 PM

Refinement of Ligaments of Nanoporous Ag Ribbons by Controlling the Surface Diffusion of Ag: *Tingting Song*[1]; Yulai Gao[1]; Zhonghua Zhang[2]; Qijie Zhai[1]; [1]Shanghai University; [2]Shandong University

Nanoporous silver (NPS) with different nanoporosity was manufactured by chemical dealloying of rapid solidified Al-Ag ribbons consisting of two distinct phases of a-Al(Ag) and Ag2Al. The as-dealloyed samples were characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM), and energy dispersive X-ray (EDX) analysis. It has been found that the width of the average ligaments can be dramatically decreased and be more homogeneous when surfactants were added to the H2SO4 solution, which would definitely increase the specific area of NPS and is pretty desirable for certain applications, such as catalyst, absorption, etc. The finer ligaments were attributing to the hindered surface diffusion of Ag atoms by surfactants, and the surface diffusion coefficient (Ds) of Ag was decreased from the order of 10-14 to 10-16 m2/s as a result of surfactants. This simple method to reduce the ligament width of NPS is also anticipated to prepare the other related nanoporous metals.

5:00 PM

Synthesis and Morphology of Nanoporous Cu and Cu Oxide Foams: *I-Chung Cheng*[1]; Andrea Hodge[1]; [1]University of Southern California

Nanoporous copper foams (65-80% porous) were synthesized by dealloying different copper alloys, including Cu20Zn80, Cu35Zn65 and Cu30Al70. Ligament sizes, porosities, and oxide content of the nanoporous copper foams were examined to determine the structure and thermal stability of the foams. The pore and ligament size of nanoporous copper foam can be controlled by either the dealloying process or a subsequent heat treatment. Pore and ligament sizes of 35 to 220 nm were observed. Heat treated samples were analyzed using Raman spectroscopy and XRD. The data showed no copper oxide peaks for the as-prepared samples; however, copper oxide peaks appeared after any heat treatment above 200 °C. These foams were shown to retain their structural integrity even after oxidation. A novel method was thus determined for synthesizing nanoporous Cu oxide foams by heat treating nanoporous copper.

5:15 PM

Pulsed Laser Melting and Solidification of Metallic Nanoparticles: *Ritesh Sachan*[1]; S. Yadavali[1]; N. Shirato[1]; A. Gangopadhyay[2]; G. Duscher[1]; R. Kalyanaraman[1]; [1]University of Tennessee-Knoxville; [2]Washington University

Metallic nanoparticles subjected to thermal cycling, such as in medical therapeutic applications, can undergo changes to their nanostructure, which in turn influences their physical properties. Here, we present studies of nanosecond (ns) pulsed laser melting and the ensuing granular structure of Ag and Co metallic nanoparticles which have applications as plasmonic and ferromagnetic systems. Thermal modeling of the ns pulsed laser melting and solidification established that significant but transient temperature gradients exist in the nanoparticles. Transmission electron microscopy studies were performed to investigate the size and arrangement of the grains within these nanoparticles. By utilizing classical nucleation theory, we established that the thermal gradients play a critical role in controlling the nanostructure of the particles. Therefore, modifying the thermal behavior, such as by choice of laser and substrate parameters appears to be a potential route to manipulate the granular nature of nanoparticles.

2012 Symposium on Surfaces and Heterostructures at Nano- or Micro-Scale and Their Characterization, Properties, and Applications: I-Chemical Sensing and Devices II-Biomaterials and Applications

Nanometal-on-Semiconductor Substrates for Single-Molecule Spectroscopy: *Kaan Kalkan*[1]; [1]Oklahoma State University

The present work has developed a single-molecule surface-enhanced Raman scattering (SERS) technique, based upon monolayers of Ag nanoparticles chemically reduced on semiconductor thin films. The acquisition starts with spotting of an aqueous aliquot on the SERS substrate. Subsequently, SERS from the water-Ag interface is collected that captures temporal appearance of discernable Raman peaks over a weak background. On the average, these spectral jumps sustain about a second which are associated with single molecules diffusing in and out of SERS hotspots. Typically, ~50 spectra can be recorded during a 1-s-long jump that serve like the "molecule's logbook", which records the structural steps taken by the molecule in the "1-s-long visit". Over the past five years, the technique enabled capturing the light-driven conformational changes in various photoactive molecules at the single molecule level, such as photoactive yellow protein, green fluorescent protein, and azobenzene.

2:30 PM Invited

Plasmonics Based Harsh Environment Compatible Chemical Sensors: *Michael Carpenter*[1]; [1]University at Albany-SUNY

The surface plasmon resonance band of gold nanoparticles embedded in metal oxide heterostructure films is used as an optical beacon for the detection of emission gases, CO, NO2 and H2, at temperatures ranging between 500 and 800°C. A summary of previous experiments detailing the sensing characteristics will be provided. A challenge for the detection of emission gases is not only high levels of sensitivity but the selective detection of the gas of interest. Recent work will be detailed which shows the implementation of sensing arrays for the detection of emission gases. Multiple sensing elements within the array are probed simultaneously and principal components analysis (PCA) is used to characterize the selective detection characteristics of the array. Variations in gold particle size and shape as well as the chemistry of the metal oxide matrix are being varied to produce sensing arrays with enhanced selective sensing properties.

3:00 PM

2012 Shri Ram Arora Award: Novel Sensor Structure of SnO2 Thin Film Integrated with Catalytic Micro-Discs for the Detection of Trace Level NO2 Gas: *Anjali Sharma*[1]; Monika Tomar[1]; Vinay Gupta[1]; [1]University of Delhi

Rf sputtered SnO2 nano-thin film based sensor structures integrated with various metal oxide catalysts (WO3, TeO2, NiO and Al2O3) have been exploited for trace level detection of NO2 gas at lower operating temperature. Metal oxide catalysts were dispersed in the form of nano-thin micro-discs (8 nm thickness and 600 micrometer diameter) over SnO2 and gas sensing characteristics have been studied towards NO2 gas as a function of temperature. SnO2 sensor structure with WO3 micro-discs showed a drastic increase in sensor response (~5.4x10^4) as compared to other catalysts at a relatively low operating temperature (100 □C) with a fast response time of ~62 sec and recovery time of ~15 min towards 10 ppm of NO2 gas. Such an improvement in the sensing response, response time and recovery time could be attributed to the spill-over of sensing gas molecules over the uncovered surface of SnO2 thin films by WO3 micro-discs catalyst.

3:35 PM Invited

Sub-Nanometer Scale Nanostructures: Ultrathin Nanowires and Nanoclusters: *Yuping Bao*[1]; Yaolin Xu[1]; Soubantika Palchoudhury[1]; [1]The University of Alabama

The extremely small sizes of ultrathin nanowires (d, ~ 2 nm) and nanoclusters (tens of atoms) place them at the transition from super molecules to typical nanocrystals, resulting in new chemical and physical phenomena. These novel properties are highly promising for applications in emerging technologies such as gas sensing, photocatalysis, spintronics devices, batteries, and bioimaging. In this presentation, we will discuss the the importance of the surface to the synthesis of ultrathin nanowires, their structural characterization, and potential applications. Au/Ag nanoclusters (< 2 nm) consist of several to tens of atoms and exhibit size-dependent fluorescent emissions, similar to the semiconductor quantum dots, which are of great fundamental and technical importance. Here, using small capping molecules, we will discuss the synthesis and coupled behaviors of these nanoclusters. Finally, the integration of magnetic and fluorescent nanostructures has led interesting properties.

4:05 PM

Magnetic Particles Accumulated in Acidithiobacillus Ferrooxidans Cells under Static Magnetic Field Affection: *Hongxu Li*[1]; Chao Li[1]; Zhi Qian Zhang[1]; Lin Wang[1]; [1]University of Science and Technology

It has studied the rule of Acidithiobacillus ferrooxidans cell growth and magnetic particles accumulated under static magnetic. The processed results under 15, 20, 25, 30, 35, 40, 45, 50mT show that more intensify static magnetic field (>10mT) might restrain the cell density increasing, especially when magnetic field high than 25mT, it could led to severe leakage of nucleic acid from cell. SEM, TEM, VSM were used for characteristic analyzing of cell and nano particle. It observed that one part of nano-particles in the cell was compact spheroidal configuration,the size is about 50nm, the other parts were loose anomalous shape, and the smallest particle size was below 10nm with fixed and distributed around the cytoderm.

4:20 PM

Nanotechnology For Drug Formulation: Improving Solubility of Insoluble Drugs: *Aeriel Murphy*[1]; Dennis Leung[2]; [1]University of Alabama; [2]Merck Sharp & Dohme Corporation Inc.

Many of the marketed drugs we use today are practically insoluble. Nanomaterials science is being studied to improve the solubility of these drugs. Nanosize particles are ideal because they cover more surface area which improves exposure and bioavailability and they have faster dissolution rates in the body. Nanoparticle stability is a major issue because Van der Waals forces cause the particles to aggregate and clump together and Ostwald Ripening causes the particles to increase in size over time. Because of the stability issues polymer/surfactant stabilizers are being studied to help prevent aggregation and recrystalization. In this experiment, drug nanosuspenion formulations were created using three model compounds and five different stabilizers. Each drug/stabilizer combination was tested for particle size, zeta potential, solubility, and chemical stability. The purpose of this experiment is to understand why certain drug/stabilizer combinations are more efficient than others by analyzing what properties make each combination unique.

4:35 PM

Tunable and Functional Silica Cross-Linked Micellar Core-Shell Nanoparticles: *Fangli Chi*[1]; Bin Yang[1]; Qisheng Huo[2]; Jiuhua Chen[1]; [1]Florida International University; [2]Jilin University

Size-tunable silica cross-linked micellar core-shell nanoparticles (SCMCSNs) were successfully synthesized from a Pluronic nonionic surfactant (F127) template system with organic swelling agents such as 1,3,5-trimethylbenzene (TMB) and octanoic acid at room temperature. The size and morphology of SCMCSNs were directly evidenced by TEM imaging and DLS measurements (up to ~90 nm). Pyrene and coumarin 153 (C153) were used as fluorescent probe molecules to investigate the effect and location of swelling agent molecules. Papaverine as a model drug was used to measure the loading capacity and release property of nanoparticles. The swelling agents can enlarge the nanoparticle size and improve the drug loading capacity of nanoparticles. Moreover, the carboxylic acid group of fatty acid can adjust the release behavior of the nanoparticles.

4:50 PM

Vertically Aligned and Axially Heterostructured Metal Nanowires and Their Soft Composites: *Junchi Wu*[1]; Nitin Chopra[1]; [1]The University of Alabama

Here we report an efficient approach to fabricate vertically aligned and axially heterostructured metal nanowires by coupling template method and wet-chemical deposition process. In order to prepare a smart and multi-functional material utilizing these nanowires, they were incorporated into a smart polymer that could be stimulated by chemical and magnetic triggers. The hybrid materials showed strong potential for drug delivery devices. Also, the hybrid materials were processed further to result in a carbon shell/membrane on the metal surface. X-ray diffraction (XRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM), and Raman spectroscopy were used to completely characterize these axially heterostructured architectures.

5:05 PM

Superhydrophobic Properties of Polymethylmethacrylate (PMMA) Nano Modified: *Ariosvaldo Sobrinho*[1]; Marcos Baracho[2]; Edjânio Araújo[3]; Luiz Pontes[3]; Analigia Araujo[1]; Geilza Porto[1]; Daniel Campos[4]; [1]UAEMA / UFCG; [2]UAEC / UFCG; [3]DTM / UFPB; [4]UAEQ / UFCG

Recent works has shown that natural phenomena seen in some animals and plants through the well-known phenomenon called the "Lotus Effect" have served increasingly as a source of inspiration for the rise of new materials for coating various substrates (metals, polymers, ceramics and biomaterials). A relatively simple method of obtaining superhydrophobic surface was presented in this paper and can be used on metal surfaces, polymeric, ceramic and biomaterials interface. The aim of this work was to obtain polymethylmethacrylate(PMMA)nano modified with superhydrophobic properties in presence of SiO2, organophilic clays and trimethylsiloxysilicate.

5:20 PM

The Bioadsorption Behavior of Rhodococcus Opacus on the Surface of Calcium and Magnesium Minerals: *Hongxu Li*[1]; An Li[1]; Binbin Liu[1]; [1]University of Science and Technology

The paper focused on the Rhodococcus opacus adsorption behavior on surface of calcite, serpentine and dolomite by bio adhesive test, contact angle measurements, Zeta potential, FTIR spectra and TEM images. The results show that the cell of Rhodococcus opacus adsorption was dependent on the pH value and temperature. The minerals contact angle decreased after Rhodococcus opacus attached on the surface,Zeta potential measurements elucidated that the cell with charge was opposite to the minerals on the broad pH value scope. The TEM images revealed that R.opacus combined tightly with mineral, and a large number of small mineral particles gathered around the cell and FTIR spectra showed the active group of the cell wall gave a net charge on the surface.

5:35 PM

The Formation of an Eutectic Mixture for Predicting the Ideal Solubility of Thermally Stable and Unstable Compounds: *Rodolfo Pinal*[1]; Ryan McCain[1]; [1]Purdue University

The melting properties of organic compounds are critical to the solubility behavior of APIs (active pharmaceutical ingredients). Solubility of poorly water soluble APIs is one of the largest challenges in formulation development. Estimating solubility by means of the melting temperature and heat of fusion is a widely established practice. However, a common problem in drug development is that some APIs are thermolabile and undergo chemical decomposition before melting. This situation makes the essential melting parameters experimentally inaccessible. Eutectic microcrystalline mixtures offer the potential advantage of increased dissolution rates at lower temperatures without changing the selected crystalline form of the API. Eutectic mixtures also offer a means to overcome the hurdles imposed by thermal limitation. The purpose of this work was to develop and test a thermodynamic model for estimating the enthalpy of fusion of thermolabile compounds, based on the entropy of fusion, thus enabling further prediction of their ideal solubility.

5:50 PM Invited

Microstructure and Mechanical Properties of Multistructured Peacock Feathers: Neelima Mahato[1]; Debrupa Lahiri[2]; Arvind Agarwal[2]; *Kantesh Balani*[1]; [1]Indian Institute of Technology Kanpur; [2]Florida International University

Brilliant iridescence of a peacock's feather has been explored using electron and fluorescence microscopy. The morphology and anatomy of an Indian peacock reveals high level of complexity in the structural patterns of barbules. The complicated diffraction and interference patterns of colors and different levels of iridescence are attributed to the difference in the complex arrangement of structures on the barbules of differently colored regions of the peacock's feather. Such a response has been compared with that of white peacock's feather to isolate the coloration behavior. Further, the nanomechanical properties (elastic modulus and hardness) have also been correlated corresponding to the equivalent regions of a coloured and white peacock feather. Such a correlation of mechanical properties with coloration of peacock feather can allow engineering of artificial structures to show iridescence.

6:20 PM

Production of Various Silicates from Rice Hull Ash: *Ozgul Taspinar*[1]; Evre Sadic[1]; Onur Ozcan[1]; [1]Istanbul Technical Univ.

This study covers the laboratory scale production method of magnesium, calcium, barium, zinc and aluminum silicates from rice hull ash (RHA). Sodium silicate solution was obtained firstly by extraction of SiO2 content of RHA with boling 1 N NaOH solution. This solution was then treated with magnesium, calcium, barium, zinc and aluminum salts individually to precipitate the silicates of these reagents. Silicate products were then analyzed using TGA, X-ray and BET analysis techniques. Chemical compositions of the silicate products for calcium, magnesium and zinc were as 45-49% SiO2 and 13-14 % MO by weight. The compositions of barium and aluminum silicates however were different as 44.7% SiO2, 23.3% BaO for barium silicate and 30.3% SiO2, 7.0% Al for aluminum silicate. All the silicates have an amorphous structure. Surface areas of Mg, Al, Ca, Ba and Zn silicates were also obtained as 625, 309, 141, 84 and 60 m2/g, respectively.

3rd International Symposium on High Temperature Metallurgical Processing: Energy and Environment

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Energy Committee, TMS: Pyrometallurgy Committee
Program Organizers: Tao Jiang, Central South University; Jiann-Yang Hwang, Michigan Technological University; Patrick Masset, TU Freiberg; Onuralp Yucel, Istanbul Technical University; Rafael Padilla, University of Concepcion; Guifeng Zhou, Wuhan Iron and Steel

Wednesday PM Room: Southern II
March 14, 2012 Location: Dolphin Resort

Session Chairs: Mansoor Barati, University of Toronto; Hongmin Zhu, University of Science & Technology Beijing

2:00 PM
Current Status of Heat Recovery from Granulated Slag: *Shaghayegh Esfahani*[1]; Mansoor Barati[1]; [1]University of Toronto
The produced slag both in the ferrous and non-ferrous industry is a high potential heat source which if treated properly can contribute to recovery of a significant amount of energy and more importantly avoid the harm to the environment. The idea behind all the approaches is to granulate slag and use it as a material which is energy intensive to produce such as cement. In this article, the development, application and advantages of various granulation techniques currently in use and the subsequent energy recovery processes are described. The discussed heat recovery processes include thermal energy recovery and chemical heat recovery. Based on the discussed processes, possible solutions will be introduced and evaluated.

2:15 PM
Contribution to the Energy Optimization in the Pyrometallurgical Treatment of Greek Nickeliferous Laterites: Konstantinos Karalis[1]; Charalabos Zografidis[2]; *Anthimos Xenidis*[1]; Stelios Tabouris[2]; Eamonn Devlin[3]; [1]National Technical University of Athens; [2]General Mining and Metallurgical Company S.A. LARCO; [3]NCSR Demokritos
The main parameters that affect the energy consumption in smelting reduction of the Greek nickeliferous laterites in submerged arc electric furnaces (E/F) were investigated. Within this framework, operational data of the E/Fs, such as energy consumption indicators, electrode consumption indicators and chemical characteristics of Fe-Ni and slag, were correlated with the physicochemical characteristics of the calcine produced by the roasting reduction of laterite in rotary kilns (R/Ks), such as reduction degree, temperature, chemical composition and granulometry. The obtained results provide serious input for further research on the modelling of the roasting reduction – smelting reduction process, which is a critical tool for energy optimization.

2:30 PM
Strengthening Sintering of Refractory Iron Ore with Biomass Fuel: *Xiaohui Fan*[1]; Zhiyun Ji[1]; Min Gan[1]; Xuling Chen[1]; Wenqi Li[1]; [1]Central South University
Abstract: Specularite and vanadium-titanomagnetite are difficult to granulate, and with the increase of their proportions , the permeability of sintering bed is deteriorated, so is the combustion velocity of fuel for the shortage of air through the sintering bed, which can lower sintering speed and specific production capacity significantly. The biomass charcoal utilized in this research has a higher combustion velocity than coke breeze, therefore,the productivity of specularite and vanadium-titanomagnetite ore can be improved remarkably by replacing coke breeze partly with biomass charcoal. The results showed that the sintering speed and specific production capacity of 35% specularite were improved from 19.06mm/min, 1.33 t/(m2•h)to 21.45mm/min, 1.47 t/(m2•h)when the proportion of biomass fuel replacing coke is 40%,and that of 55% vanadium-titanomagnetite were improved from 17.23mm/min, 1.11 t/(m2•h)to 22.80mm/min, 1.44 t/(m2•h). As a conclusion, biomass fuel is effective to strengthen sintering of refractory iron ore.

2:45 PM
Combustion Behavior of Pulverized Coal Injection in Corex Melter Gasifier: *Zhang Shengfu*[1]; Zhu Feng[1]; Bai Chenguang[1]; Wen Liangying[1]; Qiu Guibao[1]; Hu Meilong[1]; Qin Yuelin[1]; [1]College of Materials Science & Engineering, Chongqing University
The COREX process is the first reduction ironmaking technology with coal and pure oxygen to get high quality hot metal, which consumes a lot of high quality lump coal and some coke. In order to increase the utilization of fine coal, reduce coke consumption and enhance the competitiveness of the technology, the combustion behavior of pulverized coal injection (PCI) in melter gasifier is studied experimentally. The results show that the combustion rate of PCI is increased with the increase of temperature. And the combustion rate is increased with the decrease of coal granularity. Compared bituminous coal with anthracite, the former's burning ratio is higher than the latter in the same granularity. The combustion effect is remarkable when the smaller sized mixed coal with bituminous coal and anthracite is pulverized in COREX process.

3:00 PM
Improved Short Coil Correction Factor for Induction Heating of Billets: *Mark Kennedy*[1]; Shahid Akhtar[2]; Jon Arne Bakken[2]; Raghild Aune[2]; [1]Norwegian University of Science and Technology; [2]Norwegian University of Science and Technology
To determine the heating rate of billets using 'short coils', an appropriate correction factor must be applied to the theoretical relationship. In 1945, Vaughan and Williamson published a semi-empirically modified Nagaoka coefficient applicable for moderate frequency induction heating processes (10 kHz). Recently it was demonstrated that the method of Vaughan and Williamson gives <10% error in the estimated power when heating aluminum billets at 50 Hz. In the present study, experiments have been conducted on aluminum billets in order to verify an empirical frequency corrected 'short coil' equation. Measurements of electrical conductivity (<± 0.5%), current (± 1%), heat (± 1-3%), and magnetic flux density (± 1-2%) have been performed. The results are compared with 1D analytical calculations, and 2D axial symmetric FEM modeling using COMSOL 4.2®. The frequency corrected equation has proven to provide accurate predictions of power (<4% error) within the frequency range 50 Hz to 500 kHz.

3:15 PM
Liberation of Metallic-Bearing Minerals from Host Rock Using Microwave Energy: *Matthew Andriese*[1]; Jiann-Yang Hwang[1]; Zhiwei Peng[1]; [1]Michigan Technological University
It has been demonstrated that metallic-bearing minerals are physically liberated from host rock when exposed to microwave (MW) energy. The metallic minerals are iron sulfides and spinel oxide minerals contained in peridotite rock. Experimental evidence has shown ore particles readily couple with MW energy at 2.45 GHz, 1000 W resulting in rapid heating. Thermal stresses are generated by highly absorbing metallic-bearing minerals resulting in cracking and embrittlement of ore particles that assists in crushing and grinding processes. The liberated metallic-bearing minerals are shown to report to coarser size fractions as a result of MW exposure.

3:40 PM
Effects of Binders Additives on Compressive Strength of Hematite Pellets in Firing Process: *Yanfang Huang*[1]; Guihong Han[1]; Tao Jiang[1]; Guanghui Li[1]; Yuanbo Zhang[1]; Dan Wang[1]; [1]Central South University
Hematite concentrates are characterized by bad high-temperature reactivity and poor balling index, which restrict their large-scale application in the production of oxidized pellets. An organic additive, namely MHA, was authorized and used as binder recently in China.

WEDNESDAY PM

Compared with bentonite, the effects of MHA on compressive strength of hematite pellets at various firing conditions were investigated in this study. Experimental results showed the compressive strengths of preheated pellets with different binders were increased with increasing the preheating temperature and time. The compressive strength of preheated pellets with MHA binder was lower than that of pellets with bentonite, which can be ascribed to the high porosity of pellets with MHA binder. However, the compressive strength of roasted pellets with MHA binder was higher than that of pellets with bentonite. The compressive strength of finished pellets balled with MHA binder 1.0 wt% could meet the operation requirements of grate-kiln process.

3:55 PM

Mechanisms of NO Formation during SiO Combustion: *Nils Eivind Kamfjord*[1]; Halvard Tveit[1]; Edin Myrhaug[2]; Mari Næss[1]; [1]NTNU; [2]ELKEM

As a part of the FUME research programme being done by the Norwegian Ferroalloy Research Association (FFF), the SINTEF Group and NTNU several measurements towards quantifying the gaseous and solid emissions from the draining of the silicon furnaces for metal have been carried out. Based on the measured size distribution of the formed fume particles and known particle growth theory an estimate of the growth time for the given particles has been calculated. The formation time for the measured NO amount has also been calculated based on the fume measurements and a thermodynamic model of the furnace gases combusting with air. The two “formation” times is in the same order of magnitude and they are therefore used as parameters in a CFD model, modelling that the formed fume particles heating up the surrounding air and thereby form NO according to the Zeldovich mechanism.

4:10 PM

New Technologies of Energy Saving and Low CO2 Emission for Iron Making: *Xiuwei An*[1]; Jingsong Wang[1]; Qingguo Xue[1]; [1]University of Science and Technology Beijing

Energy saving has drawn more and more attention of the world due to the pressure of the environment and society. Metallurgy is one of the biggest energy consumption industries, accounting for about 16% of the total industry, basically the same ratio as the emission of CO2 and other pollutants. About 70% of total energy for steel production is consumed in iron-making process with the same ratio of CO2 discharged, so it has a great significance to achieve energy saving and low CO2 emission in iron-making process. The new iron-making technologies with energy saving and low CO2 emission such as oxygen blast furnace, ITmk3, application of waste plastics and biomass in iron-making, were introduced in the present work. Particularly, the latest research progress, merit and demerit were compared, and the contribution of the different technologies to low CO2 emission and the energy saving were analyzed.

4:25 PM

Pilot Scale Measurements of NOx Emissions from the Silicon Process: *Nils Eivind Kamfjord*[1]; Ingeborg Solheim[2]; Halvard Tveit[1]; [1]NTNU; [2]SINTEF

The NOx emissions has an increased focus as an environmental problem. The production of high silicon alloys is carried out in open reduction furnaces that give NOx in the off-gas. Earlier and new industrial measurements towards FeSi- and Si-metal furnaces reveal substantial NOx-emission. The NOx is believed to be produced in the combustion zone above the furnace surface, mainly as thermal NOx. In order to expand the knowledge on NOx-formation in silicon metal production, a pilot scale experiment in a 440 kVA silicon furnace has been carried out. The experimental set-up was especially designed to investigate the formation mechanisms for NOx by controlling the flow of false air into the off-gas system. The resulting NOx-values showed significantly variation between the different air inlet geometries.

4:40 PM

The Effect of Thermal State of Raw Pellets on the Strength of Reduced Pellets: *Zhu-Cheng Huang*[1]; Daoguang Yang[1]; Ling-Yun Yi[1]; [1]Central South University

In the traditional gas-based direct reduction process, the burden of reduction furnace are roasted pellets which had experience cooling process.In this work, hotroastedpellets without cooling process used as the burden of the reduction furnace has been studied. The strength of reduced pellets could be increased by using hotroastedpellets in place of coldroastedpellets as the burden. Nucleation and growth mechanism of iron crystal grain in gas-based direct reduction process of hotroastedpellets were investigated by optical microscope.The iron crystal nucleus is formed firstly on the interface of grains and the edge of wustite , then gradually grow from surface layer to inner core as reduction carries on.Using the hotroastedpellets in gas-based reduction can promote the accumulation , transportation and growth rate of iron crystal grain eventually.

Aluminum Alloys: Fabrication, Characterization and Applications: Emerging Technologies

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Processing Committee

2:00 PM

Effect of Tool Rotational Speed on the Microstructures and Tensile Properties of 7075 Aluminum Alloy Via Friction Stir Process (FSP): *Ming-Hsiang Ku*[1]; Fei-Yi Hung[1]; Truan-Sheng Lui[1]; Li-Hui Chen[1]; [1]National Cheng Kung University

7075-T6 aluminum alloy plates were subject to FSP with various tool rotational speeds (1230, 1450 and 1670 rpm) followed by different heat treatments (natural aging and T4T6 treatments). The influences of tool rotational speeds and aging treatments on the microstructures and tensile properties were discussed. The experimental results showed that the tensile strength of FSPed specimens with various tool rotational speeds were close. After aging treatments, higher tool rotational speeds (1670 rpm) had an embrittlement phenomenon on the SZ due to the contribution of low element bands (LEBs) and precipitates. EPMA analysis showed that the LEBs are low element distributions, such as Zn, Mg, Cu. Decreasing the tool rotational speeds, the LEBs were not obvious and restrained the brittle behavior to improve the ductility. Compared with natural aging, after T4T6 treatments, the tensile strength of FSP specimens with all tool rotational speeds was improved obviously.

2:20 PM

Improving Microstructure of AISI H13 Extruding Dies Using Ion Nitriding: Francisco Montalvo[1]; *Eulogio Velasco*[2]; Adrian Canales[1]; [1]CUPRUM; [2]Texas State University

A varied range of aluminum profile shapes are produced by hot extrusion and the typically used die is steel AISI H13. The quality and dimensions of the extruded piece are determined by tribological and surface conditions of the die bearing surface. Dies for hot extrusion require good metallurgical characteristics and chemical stability against hot aluminum. Experiments were conducted to evaluate the performance of specimens treated with conventional nitriding, and the ion nitriding process. Microstructural characterization, X-ray diffraction profiles, and wearing tests were carried out on the surface of H13 specimens. The ion nitriding process showed advantages over the conventional nitriding process, including productivity and tooling life.

2:40 PM
Linear Friction Welding of a 2024 Al Alloy: Microstructural, Tensile and Fatigue Properties: Alessandro Morri[1]; Lorella Ceschini[1]; *Fabio Rotundo*[1]; [1]University of Bologna

The aim of this work was to evaluate the possibility of using linear friction welding (LFW) to produce high quality joints on a aerospace grade aluminium alloy (AA2024). In this solid state joining process the bonding of two flat edged components is achieved through frictional heating induced by their relative reciprocating motion, under an axial compressive force. The Al joints were subjected to microstructural and mechanical characterization, including hardness and tensile test at different welding conditions. S–N probability curves were also computed after axial fatigue tests. No post-weld heat treatment was performed. The microstructural analyses showed substantially defect-free joints, with a relevant plastic flow in the thermo-mechanically altered zone. Maximun hardness decrease in the in the joint zone was approximately 10% in respect to the base material. The joint efficiency was about 90%, although with a slight reduction in the elongation to failure. Good fatigue performances were detected.

3:00 PM
The Effect of Friction Stir Welding on the Microstructure and Tensile Properties of Al 2139-T8 Alloys: *Tomoko Sano*[1]; Jian Yu[1]; Chian-Fong Yen[1]; Kevin Doherty[1]; [1]US Army Research Laboratory

In this research, two plates of Al 2139-T8 alloys were welded together by friction stir welding (FSW). An evaluation of the crystallographic texture, grain size, and morphology of the grains in the FSW region, in comparison to those of the grains outside of the weld region, was made by scanning electron microscopy (SEM) and electron backscattered diffraction. In addition, the quasi-static tensile behavior of samples from the FSW region and those from outside of the FSW zone was characterized by in-situ tensile experiments in the SEM with digital image correlation. It was found that the ultimate tensile strength and elongation were greater in the samples from the FSW region except in the through thickness, parallel to the FSW direction. The full results of the effect of the FSW on the Al2139 microstructure and tensile behavior will be discussed.

3:35 PM
Friction Stir Welding of Al- Zn- Mg Alloy AA7039: Chaitanya Sharma[1]; *Dheerendra Dwivedi*[1]; Pradeep Kumar[1]; [1]Indian Institute of Technology Roorkee

In this present investigation Al-Zn-Mg alloy AA7039 was friction stir welded (FSW) successfully employing a rotary speed of 635 rpm and welding speed of 75 mm/min, in order to elucidate the effect of FSW on mechanical and corrosion properties. Three points face and root bend tests were conducted to reveal welding defects. The yield and ultimate tensile strength of the joint was found lower (33.75 and 14.41 %) than the base material while ductility was higher (41.45 %) than the base material. The joint efficiency of friction stir welded joint was 85.59 %. The microstructure and other unique features associated with different weld zones of FSW were studied by optical and scanning electron microscopy. Failure initiates from the breaking of secondary strengthening precipitates MgZn2. Immersion corrosion tests on friction stir welded joints are to be performed to investigate the effect of corrosive environment on the performance of welded joints.

3:55 PM
Fabrication and Particle Pushing of TiB2 Particle Reinforced Aluminum Composites: *Meng Wang*[1]; Qingyou Han[1]; [1]Purdue University

In this article TiB2p/Al composites with different particle sizes ranging from 0.5-20μm were fabricated by casting method with the aid of ultrasonic casting. The observation by optical and scanning electron microcopy (SEM) showed good interface bonding between matrix and particle. By controlling different casting temperatures, cooling rates and particle sizes, the particle distribution situation was observed and analysis with qualitative and quantitative methods and the results were compared with the ones got from the composites fabricated without ultrasonic vibration. It showed that with the aid of ultrasonic, particles were more prone to be distributed inside grains, while most of them stayed at grain boundary because of the effect of particle pushing during the solidification process. Higher casting temperature and cooling rates facilitated particle pushing, and smaller particles might be engulfed. The experimental results were compared with theoretical explanation, and the reason of discrepancy between them was analyzed.

4:15 PM
Post Weld Heat Treatment of Friction Stir Welded AA2017: *Mohamed Ahmed*[1]; Bradley Wynne[2]; [1]Suez Canal University; [2]The University of Sheffield

In this study a friction stir welded AA2017 is post weld heat treated at 500°C for 20, 40 and 60 min holding time and then quenched in water and naturally aged. The effect of post weld heat treatment on the microstructure and hardness is investigated across the transverse cross section of the weld. Experimental results show that the PWHT causes abnormal grain growth of the grain structure mainly near to the advancing side of the weld. The grain size increases with the increase of the holding time however the region near to the retreating side of the weld retained its fine grain structure. EBSD has been used to examine the microstructure and texture before and after PWHT. EBSD investigation showed that the grain growth is texture dependent as grain growth occurs in some grains of (B+C) texture components while in the adjacent grains of texture components B- does not occur.

2:00 PM
Cryoscopic Data for Hall-Héroult Bath Containing Magnesium Fluoride, Calcium Fluoride, Potassium Cryolite, and Sodium Chloride: *Asbjorn Solheim*[1]; Lisbet Stoen[1]; Jannicke Kvello[1]; [1]SINTEF

The well-known cryoscopy equation for a binary system was extended to the ternary system NaF-AlF3-B, where B is a substance present in small amounts. It was derived that the depression in the liquidus temperature for a given molar fraction of B depends on how B influences the activity of NaF, as well as on the NaF/AlF3 molar ratio. This implies that it is difficult to estimate the effect on the liquidus temperature of contaminants in the Hall-Héroult bath, and the three-component cryoscopy equation can be regarded as a theoretical justification of the cross-terms used in most empirical equations for calculating the liquidus temperature. New cryoscopic data are given for the system Na3AlF6-CaF2 as well as for some substances that are normally present in only small amounts, and empirical equations containing cross-terms between these substances and aluminium fluoride are suggested.

2:20 PM
Potentiometric Fluoride Analysis with Improved Analytical Performance: *Thor Anders Aarhaug*[1]; Kalman Nagy[1]; [1]SINTEF

Since the 1960s SINTEF has in collaboration with the Nordic aluminium smelters developed methods for sampling and analysis of fluoride. Unlike conventional potentiometric analysis, this methodology involves detection of fluoride in acidic media. At low pH, the electrode kinetics is improved, resulting in faster analysis. Reduced leak of fluoride from the ion-selective electrode improves the sensitivity of the method. Standard addition methodology is applied for improved analytical performance. The acidic media makes it possible to perform a direct analysis of fluoride in biological samples. In this way, fluoride is extraced from the biological matrix by the acid. The high sensitivity requires low sample masses to used and thus does not interfere with the fluoride detection at the ion-selective electrode. This is far more efficient than the conventional approach of ashing the sample at elevated temperatures. Acid extraction can also be applied to filter dust samples.

2:40 PM

Investigation of the Mechanism of Mass Transport between the Anode-Bath Interface and the Active Bubble Generating Sites in the Hall-Héroult Cells: Sandor Poncsak[1]; *Laszlo Kiss*[1]; [1]Univeristy of Quebec at Chicoutimi

During the last decades, lots of efforts were spent to investigate different aspects of the Hall-Héroult cells. However, many questions remain unanswered due to the complexity of the process and the hostile environment. For example, the mechanism of the transport of the carbon-oxide gas between the active electrolysis sites and the bubble evolving anode pores is still non-clarified. Generally, during electrolysis in aqueous systems, the generated gas is dissolved and transported through the electrolyte. However, the solubility of CO2 in the molten cryolite is poor and the anodes are highly porous. In this paper, different mechanisms of the carbon-oxide transport between the CO2 generating anode - bath interface and the bubble releasing sites are examined. The majority of the anode gas seems to be transported through a thin superficial layer of the porous anodes, while transport via the molten bath and gas adsorption by the anodes plays a secondary role.

3:00 PM

Depolarized Gas Anodes for Electrowinning of Aluminium from Cryolite-Alumina Melts in a Laboratory Cell: *Geir Martin Haarberg*[1]; Saijun Xiao[1]; Arne Petter Ratvik[1]; Tommy Mokkelbost[2]; [1]Norwegian University of Science and Technology; [2]SINTEF

Consumable carbon anodes are used in the electrowinning of aluminium by the Hall-Heroult process and in other proposed processes for electrowinning in molten salts. Emissions of CO_2 may be eliminated by introducing an inert oxygen evolving anode, which however will require a higher anode potential. By introducing natural gas or hydrogen to the anode the CO_2 emissions can be reduced and the anode potential can be lowered. Laboratory experiments were carried out in a modified Hall-Heroult electrolyte with excess AlF_3 at 850 ^oC. Porous anodes of platinum, tin oxide and graphite were tested during electrolysis at constant current, with the supply of argon, methane and hydrogen through the anodes. Laboratory studies showed that by introducing both hydrogen and methane separately through a SnO_2 anode in molten Na_3AlF_6-AlF_3-Al_2O_3 (4.5 wt%) at 850 ^oC the anode potential was lowered by several hundred millivolts for a limited time during electrolysis.

3:20 PM Break

3:40 PM

Reduction of the Operating Temperature of Aluminium Electrolysis: Low-Temperature Electrolyte: Alexey Apisarov[1]; Juan Barreiro[2]; *Alexander Dedyukhin*[1]; Leopoldo Galán[2]; Alexander Redkin[1]; Olga Tkacheva[1]; Yuri Zaikov[1]; [1]Institute of High Temperature Electrochemistry; [2]Aleastur

Aluminium Potassium Fluoride obtained as a byproduct in the production of Aluminium grain refiners and master alloys may be used as an additive to the existing aluminum reduction process. The component leads to a considerable reduction in the melting temperature, and maintains other important parameters such as conductivity and solubility of alumina. Both, laboratory tests and semi industrial trials in a 100A cell have been conducted in order to test the suitability of this new additive to the electrolytic process, with positive results. Aluminium Potassium Fluoride can be also used as a basic component of the low-temperature electrolyte for aluminum electrolysis.

4:00 PM

Specific Molecular Features of Potassium-Containing Cryolite Melts: Evgeny Antipov[1]; Dmitri Glukhov[2]; Alexander Gusev[3]; Veronika Laurinavichute[1]; Renat Nazmutdinov[2]; Dmitri Simakov[3]; Sergey Vassiliev[1]; Tamara Zinkicheva[2]; *Galina Tsirlina*[1]; [1]Moscow University; [2]Kazan State Technological University; [3]RUSAL ETC

Experimental in situ Raman spectra are presented for potassium, sodium and mixed fluoroaluminate melts. More acidic melts with cryolite ratio (CR) below 2 are accented. The cation-dependent ratio of integral band intensities is assigned to specific interactions of potassium cations with low coordinated fluoroaluminates. For alumina containing melts, the effect of potassium on the stoichiometry of predominating oxofluoroaluminate anion is observed indirectly. Density functional theory and classical molecular dynamics are employed to investigate behavior of different fluoroaluminates (including dimers) and their associates formed by alkali metal cations. The results are discussed in the context of CR-dependent thermodynamic data.

4:20 PM

Aluminum Flouride Purity Test by Different Techniques: *Hussain Al Halwachi*[1]; [1]Aluminium Bahrain (Alba)

The purity test is one of the key parameter for Aluminium fluoride material used in Aluminium smelting process. Aluminium Fluoride is added to the reduction cell to react with Alumina impurities such as Cao and Na2O and to generate more Alumina (Al2O3) and cryolite to the reduction cell. Good quality AlF3 usually having purity between 89 to 93%, purity has to be measured accurately, through quick and safe method. This study provides several solutions for measuring AlF3 Purity by instrumental methods such as NMR, XRF dilution, SEM and XRF standard less qualitative method as an alternative for the wet chemical methods known for this test. This approach is applicable also for Al2O3/AlF3 mixed sample, due to the close physical shape of both material, the differentiation between Al2O3 and AlF3 is required by reduction staff in case of any cell disturbance.

4:40 PM

Micro-Raman Spectra Research on NaF-AlF3-NaCl Melts: *Xianwei Hu*[1]; Jingjing Liu[1]; Huan Li[1]; Bingliang Gao[1]; Zhongning Shi[1]; Yaxin Yu[1]; Zhaowen Wang[1]; [1]Northeastern University

Raman spectra of NaF-AlF3-NaCl melts with the compositions in aluminum electrolysis practice are recorded by using the ultraviolet laser source. A kind of sealed sample cell was used to improve the measuring precision. Ionic structure of the melts with different cryolite ratio(molar ratio between NaF and AlF3) and NaCl contents was studied. The effect of the composition and temperature was analyzed. The results have shown that with the addition of the NaCl to the acid NaF-AlF3 melts, the relative amount of the Al-F entities have been changed, obviously. It is thought that the relative amount of the complex ions is also greatly influenced by the temperature.

GHG Measurement and Inventory for Aluminum Production: *Jerry Marks*[1]; Chris Bayliss[2]; [1]J Marks & Associates; [2]International Aluminium Institute

The primary aluminum industry has achieved good progress over the past decade in reducing GHG emissions associated with metal production. The reductions have been measured through well documented protocols for the measurement of GHGs associated with production processes as well as established inventory methodology vetted with stakeholders from within and outside the industry. These protocols and inventory methodologies are currently in the process of being updated to reflect new findings and changes in the industry over the past decade to further enhance the accuracy and robustness of GHG accounting for the aluminum industry. This paper discusses the revisions being considered and the factors driving the changes.

2:20 PM
Optimization and CFD Simulation in the Ventilation of AP60 Reduction Cell Buildings: Edmund Baltuch[1]; *Siegmar Baltuch*[1]; [1]Air-Therm Inc.

Ventilation of the reduction buildings of the state of the art Rio Tinto Alcan AP60 Technology is critical to proper process function. Correctly engineered systems evacuate the surplus of thermal energy from the process area and allow an optimized air change rate. Computational fluid dynamic simulations combined with 4 dimensional CAD modeling and 365 day, 24 hour environmental conditions were used tp demonstrate to sophisticated end users and assist engineers, coupled with traditional calculations and physical modeling as predictive tools that the optimal solution was being put forward for smelter ventilation. Due to the highly confidential nature of the technology and project, some empirical data will not be included in the report. Results from modeling and calculations are currently in place on Phase 1 and we continue to study, optimize and innovate as new tools become available to provide the best possible engineered solutions for particular applications.

2:40 PM
HEX Retrofit Enables Smelter Capacity Expansion: *Hussain Qassab*[1]; Sayed Salah Aqeel Ali Mohd[1]; Geir Wedde[2]; Anders Sorhuus[2]; [1]Aluminium Bahrain; [2]Alstom

Aluminium Bahrain is one of the largest producers of primary high quality aluminium in the world, and continues to consider further expansions such as the planned new line 6. In parallel the amperage on existing pot lines will be increased further. A bottleneck in the amperage creep projects is limitations on gas flow and temperature to the existing gas treatment centers (GTCs). Cooling can be provided by adding dilution air, or water injection, but in both cases additional scaling, HF emissions and operation costs are expected, as well as reduced lifetime of filter bags due to increased hydrolysis. Another option is to install heat exchangers integrated into each compartment in the existing GTCs (IHEXs) to cool the potgas. Stable heat transfer and pressure drop, and successful avoidance of scaling are demonstrated. The performance is compared to the HEX data collected for close to 3 years at Alcoa Mosjøen.

3:00 PM
Experimental and Theoretical Study on the Fluidization of Alumina Fluoride Used in the Aluminum Smelter Processes: *Paulo Douglas Vasconcelos*[1]; André Luiz Mesquita[2]; [1]Albras Alumínio Brasileiro S.A; [2]Federal University of Pará

Fluidization is an engineering unit operation that occurs when a fluid (liquid or gas) ascends through a bed of particles, and these particles get a velocity of minimum fluidization enough to stay in suspension, but without carrying them in the ascending flow. As from this moment the powder behaves as liquid at boiling point, therefore the term "fluidization". This operation is broadly used in the aluminum smelter processes, for gas dry scrubbing (mass transfer) and in the modern plant for continuous alumina pot feeding (particles' momentum transfer). The understanding of the alumina fluoride rheology is of capital importance in the design of fluidized beds for gas treatment and fluidized pipelines for pot feeding. This paper demonstrates the results of the experimental and theoretical values of the minimum and full fluidization velocities for the alumina fluoride used to project the state of the art round non-metallic air-fluidized conveyor of multiples outlets.

3:40 PM
A Method for Comparing the HF Formation Potential of Aluminas with Different Water Contents: *Camilla Sommerseth*[1]; Karen Osen[2]; Christian Rosenkilde[3]; Astrid Meyer[4]; Linda Kristiansen[3]; Thor Aarhaug[2]; [1]Norwegian University of Science and Technology, NTNU; [2]SINTEF; [3]Hydro Aluminium; [4]Norsk Hydro

In the aluminium industry today, smelters often have to rely on more than one alumina supplier. This creates diversity in the properties of smelter grade alumina (SGA). A method has been developed to compare the HF formation from aluminas containing different amounts of water. The water content of the different aluminas was determined by loss on ignition tests (LOI) and thermal gravimetric analysis (TGA). Further, the aluminas were added to a cryolitic melt kept in a gas tight furnace with a constant nitrogen flow rate. The HF concentration in the off gas during the alumina additions was measured in-situ using a tunable diode laser. A correlation between the quantity of water found from LOI characterisation and the amount of HF formed has been found. It was also found that in this laboratory setup, all types of water contribute to HF formation; structural hydroxyl, physisorbed and chemisorbed water.

4:00 PM
Visualising the Sources of Potroom Dust in Aluminium Smelters: *David Wong*[1]; Nursiani Tjahyono[1]; Margaret Hyland[1]; [1]University of Auckland

'Potroom dust' comprises one of the major sources of particulate emissions from a smelter to the environment. With regulatory emission limits for particulates continually tightening, there is a need for smelters to understand the sources and pathways by which dust is generated in a potroom. Only armed with this understanding can smelters develop targeted strategies to counter these emissions. Methodologies to sample and analyse the composition of potroom dust (both settled on surfaces and airborne) have been applied in four smelters. By taking samples across a range of potroom locations and elevations, an overall compositional picture of dust can be built and visualised for any potroom. In general, settled dust is dominated by cover material and alumina – the role of each, however, is influenced by the granulometry of cover and how alumina is delivered to the pot. In contrast, airborne dust in a potroom is typically dominated by bath-related compounds.

4:20 PM
Impurity Elements in Raw Gas Ultra-Fines from Aluminum Electrolysis Cells: *Heiko Gaertner*[1]; Arne Petter Ratvik[1]; Thor Anders Aarhaug[2]; [1]NTNU; [2]SINTEF

In the present work the effect of cell operation on the amount and composition of dust in raw gases was investigated. Particle size distribution of ultra-fines (Di < 10 µm) were measured in real time and the chemical composition of particle size groups were analyzed. Mass concentrations from cells under different operational condition are computed based on the density estimates calculated from measured number concentrations and fraction weights. EDS analysis and HD ICP-MS revealed a significant increase in contaminant level for particle with a Di >0,75 µm. The findings indicate that particles with Di<1,2 µm consist mainly of quenched bath fume basically NaAlF4, Na5Al3F14 partly hydrolyzed to Na3AlF6 and Al2O3 with a low level of contaminants, while particles with Di> 1,2 µm exhibit significant levels of contaminants presumably entrained particles from the combustion of anode carbon and alumina feed.

Atomistic Effects in Migrating Interphase Interfaces - Recent Progress and Future Study: Roles of Interface on Microstructure Development

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS/ASM: Phase Transformations Committee
Program Organizers: Tadashi Furuhara, Institute for Materials Research, Tohoku University; Sudarsanam Babu, Ohio State University; Hatem Zurob , McMaster University; Jian-Feng Nie, Monash University; Wen-Zheng Zhang, Tsinghua University; James Howe, University of Virginia

Wednesday PM Room: Europe 3
March 14, 2012 Location: Dolphin Resort

Session Chairs: Masato Enomoto, Ibaraki University; Annika Borgenstam, Royal Institute of Technology

2:00 PM Invited
Structural Transformations in Binary Alloys with Phase Field Crystals: Michael Greenwood[1]; Nana Ofori-Opoku[2]; Nikolas Provatas[2]; Joerg Rottler[1]; *Chad Sinclair*[1]; Mathias Millitzer[1]; [1]University of British Columbia; [2]McMaster University

The phase field crystal model for structural transformations is extended to include two-component alloys via two-particle correlation functions. These free energy kernels result in broad density modulations that can be treated with high numerical efficiency. A simplified binary alloy model is shown to describe the equilibrium properties of eutectic and peritectic binary alloys in two and three dimensions. Using the simplified binary model, the drag effects of composition on the interfacial motion under applied driving pressures is examined.

2:30 PM Invited
Application of the Diffusion-Multiple Approach in Alloy Development: *Ji-Cheng Zhao*[1]; [1]The Ohio State University

Diffusion multiples are assemblies of many diffusion couple and triples that are diffusion annealed at elevated temperatures for extended periods of time to promote interdiffusion between/among the elements. Local equilibrium at phase interfaces evaluated from microprobe analysis allow rapid establishment of phase diagrams that are essential input for CALPHAD modeling. Diffusion profiles obtained from the diffusion multiples allow extraction of diffusion coefficients for kinetic databases and kinetic simulations. Micron-scale resolution tools were recently developed to measure thermal conductivity, elastic modulus, and coefficients of thermal expansion (CTE). A combination of compositional gradients in diffusion multiples and localized property measurements/mapping allows fast establishment of composition-structure-property relationships and databases for accelerated materials development. Precipitation kinetics can also be very effectively evaluated from diffusion multiples for alloy development. This talk will show examples to demonstrate the effectiveness of the diffusion-multiple approach in alloy design.

3:00 PM
Modelling Growth and Dissolution Kinetics of Grain-Boundary Cementite in Cyclic Carburizing: *Kouji Tanaka*[1]; Hideaki Ikehata[1]; Hiroyuki Takamiya[1]; Hiroyuki Mizuno[2]; Takeyuki Shimada[2]; [1]Toyota Central R&D Labs., Inc.; [2]Aichi Steel corp.

Vacuum carburizing is a rapid and energy-saving industrial heat treatment. However, filmy cementite ($\theta_{g.b.}$) precipitates on γ grain boundary and short-time cyclic carburizing is followed by diffusion periods to eliminate it. In order for an accurate prediction of C profiles, kinetic models have been required for the growth and dissolution of $\theta_{g.b.}$ both of which highly depend on steel chemistry. Based on the analysis on AISI 5120 carburized steel, they have been formulated with the parabolic rate constants for partitioning process of a single element. And a multicomponent diffusion simulation have validated the constants as a function of fixed C activity. The kinetic models were incorporated in solving C diffusion in γ which was supersaturated while carburizing and undersaturated in later diffusion period. Calculations on C profiles and $\theta_{g.b.}$ fractions represented experimental observations quite well. We will discuss how the Si(Cr) diffusion in $\gamma(\theta)$ controls the growth (dissolution) rate.

Mechanisms for Negative Creep in Nickel Base Superalloys: *J. Tiley*[1]; S. Knox[2]; S Nag[3]; G. Viswanathan[1]; R. Banerjee[3]; H. Fraser[4]; [1]Air Force Research Laboratory; [2]Southwestern Ohio Council for Higher Education/ Air Force Research Laboratory; [3]Department of Materials Science, University of North Texas; [4]Department of Materials Science and Engineering,The Ohio State University

Advanced characterization techniques and atomistic models were used to investigate negative creep in Rene88DT. Specifically, researchers analyzed the site occupancy of alloying elements and their role in changing lattice parameters associated with the early stages of heat treatment. Samples were aged at 760 degree C and evaluated using advanced TEM, atom probe tomography, and diffraction using both neutron and x-ray approaches. Atomistic modeling of element interactions and their mechanisms were compared with high resolution EELS and APT techniques. Results indicate the major mechanisms associated with negative creep.

Transient High Temperature Oxidation of a Ni Base Superalloy: *Emmanuelle Marquis*[1]; Roger Reed[2]; [1]University of Michigan; [2]University of Birmingham

The empirical knowledge about oxidation behavior has often been sufficient for the development of current alloys. However, further development and efficient design of new alloys requires the detailed mechanistic understanding of the early stages of oxide formation and development. In particular, controlling the roles of solute and alloying elements in modifying the oxidation resistance of alloys can be complex. It is often speculated that interfacial segregation, preferential oxidation are responsible for the observed behaviors. In the case of a novel single crystal nickel-based superalloy of high Cr content, the addition of Si has been associated with superior oxidation resistance exhibited by this alloy as compared to those used currently for aeroengines. Atom probe tomography and electron microscopy observations of the oxide scale provides unique and new insights into the mass transport mechanisms occurring at the metal/oxide interface, oxide grain boundaries and into the exact role of alloying elements.

4:40 PM
Interphase Precipitation of Vanadium Carbide in Low Alloy Steels: *Tadashi Furuhara*[1]; Toshio Murakami[2]; Goro Miyamoto[1]; Naoya Kamikawa[1]; [1]Institute for Materials Research, Tohoku University; [2]Kobe Steel Ltd.

Recently, fine dispersion of alloy carbide formed by interphase precipitation during ferrite transformation attracts lots of attentions as a promising microstructure for high strength and high ductility. In this study, the microstructures obtained by interphase precipitation of vanadium carbide in low alloy steels are examined. 0.3mass% of vanadium was added to carbon steels containing 0.1 and 0.45mass% carbon. Specimens are isothermally transformed to ferrite after austenitization. TEM observation was made to analyze the carbide dispersion quantitatively. As transformation temperature is lowered, the carbide sheet spacing becomes narrower.Finer and denser particle distribution is obtained at lower ferrite transformation temperature. Interestingly, the carbide sheet spacing is decreased as approaching toward the growth front of ferrite in the 0.45C steel which suggests a slower growth rate results in more frequent nucleation of carbide. Some discussions will be made based upon a new interphase precipitation model taking a time-dependent segregation of vanadium into account.

5:00 PM
The Effect of Molybdenum on Niobium, Titanium Carbonitride Precipitate Stability and Grain Refinement in a High-Temperature Vacuum Carburizing Steel: *Charles Enloe*[1]; J.G. Speer[1]; K.O. Findley[1]; [1]Colorado School of Mines, Advanced Steel Processing and Products Research Center

Coarsening and compositional evolution of mixed Nb,Ti(C,N) carbonitride precipitates have been investigated in molybdenum-bearing microalloyed SAE 4120 steel. The effects of molybdenum on niobium-bearing carbonitride interfacial energy and niobium diffusion during reheat to carburizing temperatures were of special focus. Characterization of precipitate evolution is fundamental to process design for the retardation of abnormal grain growth at increasingly high processing temperatures. The experimental characterization techniques include analytical scanning transmission electron microscopy (STEM) and three dimensional atom probe tomography (APT). A reduction in the ripening rate of carbonitrides was observed in molybdenum-bearing alloys containing 0.05 wt pct and 0.10 wt pct niobium. Molybdenum incorporation was observed in spheroidal carbonitrides less than 30 nm in diameter, but APT and STEM investigations revealed no appreciable molybdenum segregation to the particle/matrix interface.

Bionic Hydrogel Sensors and Actuators: *Paul Calvert*[1]; [1]University of Massachusetts

There is a need for devices that can allow a dialog between electronics and soft, wet biocompatible sensors and actuators. We have used inkjet printing and extrusion methods to form gels based on epoxy-amine chemistry that can be coupled to electronic systems. These gels may be used to sense strain or biochemicals, they can be induced to contract under electrical stimulation and may be used to deliver small or large molecules to cells or the surrounding tissue. The mechanical, transport and response properties of these gels will be discussed in the context of forming a bionic devices with flexible electrodes embedded in an active gel.

2:30 PM
The Effect of Polyvinyl Alcohol (PVA) Weight Ratio on Apatite-PVA Composites: *Tugba Basargan*[1]; Gulhayat Nasun-Saygili[1]; [1]Istanbul Technical University

It is known that natural bone is an organic–inorganic composite in which inorganic apatite crystals are accumulated on organic collagen fibers. Thus, inorganic apatite-organic polymer composites have been gained interest for their possible usage in biomedical area. In this work, apatite-PVA composites were prepared in two steps. In the first step, apatite was produced using dipotassium hydrogen phosphate and colemanite (2CaO.3B2O3.5H2O). Wet method was used to obtain the apatite. In the second step, apatite and PVA were physically mixed with different weight ratios to investigate the effect of PVA content on the composite structure. During the experiments, apatite-PVA slurries were dried using a laboratory scale spray dryer. Samples in each step were structurally analyzed by XRD and FTIR. Also boron analysis was made volumetrically. It was showed that apatite-PVA composites were successfully synthesized. The intensity of characteristic peaks of PVA changed according to the PVA content of the composite.

2:50 PM
Silver Base Nano-Particle Preparation by Ion Bioadsorption of Bacillus Megaterium: *Hongxu Li*[1]; Yunchi Guo[1]; Chuanqi Jiao[1]; [1]University of Science and Technology

The paper aims at the silver base nano-particle prepared during Bacillus megaterium culture and growth. The biosorption properties of Ag+ and surface bioreduction reaction of [Ag(NH3)2]+ by Bacillus megaterium were evaluated and the particles were almost globular and the average particle size was 14.5nm.The influence factors experiments results show that the adsorption efficiency was affected greatly by initial biomass concentration and initial Ag+ concentration and the determined best adsorption pH value was 6. The surface machanism of silver biosorption by Bacillus megaterium included electrostatic adsorption and complexation. FTIR studies demonstrated that amino and carboxyl groups were confirmed to be the main active groups. The silver sol was well-distributed by the mean of TEM.

3:10 PM
A Comprehensive Study of Hydrogel Material Mechanical and Tribological Properties at Small Scales: *Bo Zhou*[1]; Nicholas Randall[1]; Drew Griffin[1]; Rahul Nair[1]; [1]CSM Instruments

The unique properties of soft hydrogels have caused them to be widely adopted in various fields, such as for biomedical applications and contact lenses. In this study, a series of up-to-date methodologies were employed to investigate hydrogel properties, such as stiffness, elastic recovery, viscoelasticity, adhesion, and friction properties. An Ultra Nanoindentation Tester was employed for mechanical measurements. Long load-holding tests were performed in order to accurately monitor the evolution of creep. Nanoindentation was also used for surface adhesion force evaluation. The dehydration effect on the gel stiffness was investigated by performing a series of indentations over a period of dehydration time. A Nano Scratch Tester was used to quantify the elastic/viscoelastic properties of hydrogels. Moreover, the surface coefficient of friction was evaluated with a Nano Tribometer. The tests yielded distinctive results compared to bulk data, which could play an important role in the fundamental study of small scale hydrogel materials.

3:30 PM
Biomechanics Studies at the Advanced Photon Source Using High-Energy X-rays: *Jonathan Almer*[1]; Stuart Stock[2]; [1]Argonne National Laboratory; [2]Northwestern University

The fracture propensity of bone and teeth has been linked to both fracture strength and loading spectra, so it is important to quantify mechanical input and identify "weak-link" microstructures or changes in global parameters characterizing microarchitecture. Here we present recent efforts to reveal this information with wide-and small-angle x-ray scattering under in situ loading. High-energy x-rays (E>60 keV) and a transmission geometry are used at the Advanced Photon Source to provide true bulk sampling across several mm2 cross-sections of animal tissue. Wide-angle scattering is used to quantify texture, particle size and internal strains in the apatite mineral phase. Small angle x-ray scattering reveals the average mineral platelet spacing, mediated by collagen, which is used to infer the load transfer between the constituent phases. The ability to create small (micron-level) x-ray beams reveals gradient information, as will be illustrated in the vicinity of the dento-enamel junction in teeth.

Adhesion of Shells: Applications in Bacteria Aggregation and Transportation in a Porous Medium: Jiayi Shi[1]; Sinan Muftu[1]; April Gu[1]; *Kai-Tak Wan*[1]; [1]Northeastern University

Spherical and cylindrical shells adhere to a rigid substrate in the presence of electrical double layers (EDL). The adhesion-detachment mechanics is governed by the DLVO surface potential with two energy minima. If a shell interacts weakly with the substrate and only the outer secondary energy minimum is involved, the JKR-type "pull-off" predicted conforming to the classical colloidal filtration theory (CFT) are predicted. Should the shell acquire sufficient energy to overcome the energy barrier and reach the deep priminary minimum, the adhesion mechanics and CFT must be substantially modified. The new model has significant impacts on bacteria adhesion-aggregation-transportation behavior in porous medium and is consistent with experimental measurments using conventional column test. We will also report new methods to characterize the mechanical and viscoelastic properties of convex shells of hydrogels and bacteria glycoprotein shells of single cells. These results have strong implications in waste water treatment and tranportation of pollutants.

4:30 PM
Nanoindentation: Potential Diagnostic Method for Cancerous Transformation of Melanocyte: Ana Paula Benaduce[1]; *Debrupa Lahiri*[1]; Lidia Kos[1]; Arvind Agarwal[1]; [1]Florida International University

Nanoindentation could be a valuable tool to analyze the differences in mechanical properties of normal and cancerous cells and act as a potential marker of cellular transformation. In this study, we evaluated the changes in nano-mechanical properties to distinguish between normal and transformed melanocytes. We adapted nanoindentation technique to compare the elastic modulus and membrane rupture load of human primary melanocytes and human melanoma cells in-vitro. We found that primary melanocytes are 2.5 times stiffer and 3.5 times harder than melanoma cells. This difference in elasticity may facilitate the migration and invasion of cancerous cells during metastasis. Previous studies have suggested the activation of Endothelin receptor b by Endothelin 3 (Edn3) may be involved in melanoma progression. Our results demonstrate that primary melanocytes and melanoma cells modulate their biomechanical properties differentially upon Edn3 exposure.

4:45 PM
Antimicrobial Efficacy and Degradation Route of Silver-Based Coated Endotracheal Tubes: *Minoo Arzpeima*[1]; Gunilla Björling[2]; Sigbritt Karlsson[1]; Ragnhild. E Aune[3]; [1]Royal Institute of Technology; [2]Karolinska Institute; [3]Norwegian University of Science and Technology (NTNU)

At present silver-based coatings are being increasingly developed. Several studies have questioned the antimicrobial efficacy of silver, which might be obscured due to inactivation of the coating by biological fluids. Poor adhesion between the coating and the substrate can, however, also inhibit long-term efficacy of the coating. In the present work, a novel silver-based coating applied to EndoTracheal Tubes (ETT) was studied. The efficacy of the coating in preventing bacterial colonisation was evaluated in-vitro, both before and after exposure to relevant Synthetic Biological Fluids (SBF) for 10 days. The surface properties of the coating and its degradation after exposure to SBF and bacteria were studied by Scanning Electron Microscopy (SEM), Atomic Force Microscopy (AFM) and X-ray Photoelectron Spectroscopy (XPS). According to the results obtained by Inductive Coupled Plasma Mass Spectrometry (ICP-MS) the release rate of silver was clearly more significant in the initiating hours of the exposure to SBF.

5:00 PM
Nano-Scale Mechanical Response of the Organic Constituent in Abalone Nacre: *Maria Lopez*[1]; Yu-Chen Chan[2]; Hsien-Wei Chen[2]; Pao-Sheng Chen[2]; Po-Yu Chen[2]; Jenq-Gong Duh[2]; Joanna McKittrick[1]; Marc Meyers[1]; [1]UCSD; [2]National Tsing Hua University

Abalone nacre is a natural multilayered composite structure that exhibits excellent mechanical properties due to the hierarchical organization of CaCO3 tiles and organic interlayers. In this study, the contribution of the organic interlayer on the overall mechanical properties of the abalone nacre is investigated. Nanoindentation and nanoscratch tests are employed on untreated and deproteinized abalone nacre. Contrast in the mechanical behavior of these materials demonstrates the impact of the organic matrix to the toughness of the entire structure. Nanoindentation and AFM experiments are performed on the organic interlayer. These results can quantitatively asses the relationship between the overall strain and expansion undergone by the organic membrane. Specimens are characterized by SEM to verify the toughening and deformation mechanisms. This approach generates a comprehensive picture of the mechanical response of the organic layer and its effect on the mechanical properties of the abalone nacre. EAPSI-Grant1108531; NSF-Grant1006931; Ford Foundation Fellowship.

5:15 PM
Cell Toxicity of Go/Rgo: Function of Size and Oxygenated Functional Group Density: *Soumen Das*[1]; Sanjay Singh[1]; Virendra Singh[1]; Daeha Joung[1]; Janet Dowding[1]; Rameech McCormack[1]; Lei Zhai[1]; Saiful I. Khondaker[1]; William Self[1]; Sudipta Seal[1]; [1]University of Central Florida

Herein, we report in-vitro toxicological effect of graphene oxide (GO). We have synthesized different size and differentially reduced GO, and characterized using atomic force microscopy (AFM) and x-ray photoelectron spectroscopy (XPS). GO and RGO were found to be toxic to cells, with smaller GO/RGO materials exhibiting more significant toxicity. We also observed GO is more toxic when compared to RGO using both MTT and LDH release to assess toxicity. To explore the cause of GO/RGO toxicity, we have quantified the heme oxygenase 1 and thioredoxin reductase mRNA expression levels, known to be expressed during oxidative stress. Significant decreases in both mRNA levels were observed with more reduced GO, and this supports the hypothesis that oxidative stress mediated cellular toxicity. Therefore, it can be concluded that though size of the GO sheet plays a role, the functional group density on the GO sheet is also a key component mediating cell cytotoxicity.

Bulk Metallic Glasses IX: Simulation and Modeling

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee

Packing, Cluster Formation and Their Roles in Physical and Mechanical Property of Metallic Glasses: *Mo Li*[1]; Qikai Li[2]; [1]Georgia Institute of Tech; [2]Tsinghua University

Ordered packing, either short- or medium-ranged, and the clusters formed by such ordered packing has been investigated as “structural unit” in metallic glasses. Their roles range from affecting crystal nucleation, diffusivity and viscosity in undercooled liquids, to mechanical properties. In this work, we re-examine the packing and cluster formation and their roles with the physical and mechanical properties. We show that the seemingly ordered structure has little bearing on being the structural unit in thermodynamic sense. Rather, we show that those local patterns exert large kinetic effect on liquid as well as solid behaviors.

2:20 PM Invited
First-Principles Tensile and Compression Experiments on a Model Metallic Glass: *Wai-Yim Ching*[1]; Yungfeng Shi[2]; Despina Louca[3]; Gongyao Wang[4]; Peter Liaw[4]; [1]University of Missouri-Kansas City; [2]Rensselaer Polytechnic Institute; [3]University of Virginia; [4]University of Tennessee

An Ab initio method has been applied to investigate the mechanical behavior of a metallic glass (MG). A periodic supercell model of a-Cu0.5Zr0.5 with 256 atoms is constructed using classical molecular dynamics and then fully relaxed using VASP to near zero stress. Tensile and compressive experiments are performed by successively applying tensile/compressive loads in small steps until the stress reaches a maximum and beyond. At each step, the structure is fully relaxed, and the r.m.s. value of |s| of the stress (sxx, syy, and szz) and the corresponding strain |e| in a given direction are extracted. The stress vs. strain data are compared with that of crystals. The calculated bulk, Shear, Young’s modulus and Poisson ratio for this MG model are 117, 24, 67 GPa and 0.40 respectively. The electronic structure and bonding of the BMG are also evaluated. On average, Zr loses 0.61 electrons to Cu per atom.

2:40 PM Invited
Simple Analytic Models for Plastic Deformation and Slip Avalanches: From Crystals to Amorphous Materials to Granular Materials: *Karin Dahmen*[1]; Yehuda Ben-Zion[2]; Jonathan Uhl[1]; Georgios Tsekenis[1]; [1]University of Illinois at Urbana Champaign; [2]University of Southern California

Slowly sheared crystalline materials are known to deform in an intermittent way with slip avalanches. In many materials power laws govern the statistics of the avalanches. A basic micromechanical model for deformation of solids with only one tuning parameter (weakening e) is introduced [1]. The model can reproduce observed stress-strain curves, acoustic emissions and related power spectra, statistics of slip avalanches, and geometrical properties of slip, with a continuous phase transition from brittle to ductile behavior. Exact universal predictions for the power law exponents and scaling functions are extracted using mean field theory and renormalization group tools. The results agree with recent experimental observations and simulations of dislocation dynamics, sheared amorphous materials, and granular materials [2].[1] K.A. Dahmen, Y. Ben-Zion, J.T. Uhl, Phys. Rev. Lett. 102, 175501 (2009)[2] K.A. Dahmen, Y. Ben-Zion, J.T. Uhl, Nature Physics 7, 554-557 (2011)

3:00 PM
Phase-Field Simulation Study of Nucleation and Propagation of Shear Bands in Bulk Metallic Glasses with Stress-Induced Precipitation of Martensitic Nanocrystals: *Alireza Zaheri*[1]; Fadi Abdeljawad[1]; Mikko Haataja[1]; [1]Princeton University

Bulk Metallic Glasses (BMGs) exhibit a unique combination of mechanical properties, such as high strength and large elasticity limit. On the other hand, plastic strain localization via the nucleation and propagation of shear bands limits the overall ductility of such systems. Recent experimental findings have demonstrated that BMG systems, in which stress-induced precipitation of martensitic shape memory alloy nanocrystals occurs, display enhanced mechanical properties. In this work, a continuum phase-field modeling framework is employed to investigate the nonlinear interaction between stress-induced precipitation of martensitic nanocrystals and shear band formation in two spatial dimensions. In agreement with experimental observations, simulation results show that the presence of martensitic nanocrystals enhances the overall ductility relative to monolithic BMGs. Finally, we quantify the roles of the area fraction of the martensitic particles and their intrinsic hardening behavior on the overall ductility of the system.

3:10 PM Invited
Correlations during Plastic Flow in Model Metallic Glasses: *Craig Maloney*[1]; [1]Carnegie Mellon University / Civil & Environmental Engineering

Computer simulations of sheared glasses exhibit profound spatio-temporal correlations in the local strain. These correlations directly impact the macroscopic viscoplastic response and may have important consequences for macroscopic shear localization. We will review recent developments in this area and discuss how observations from computer simulation relate to experimental studies such as those on the distribution of serration sizes in stress-strain curves during mechanical tests and acoustic emission measurements.

3:30 PM Invited
Computer Simulation of the Structure of Zr-Based Amorphous Alloys: *Mikhail Mendelev*[1]; [1]Ames Laboratory

A new interatomic potential for the Ni-Zr system will be presented. This potential was developed specifically to match with scattering data from Ni, Zr and NiZr2 liquids. This potential and similarly developed potential for the Cu-Zr alloys have the C11b being more stable than C16 in the CuZr2 alloy while C16 is the more stable than C11b in the NiZr2 alloy, consistent with experiments. It was found that in contrast to the crystalline alloys, the Ni-Ni, Cu-Cu and Zr-Zr separations are almost the same in both disordered alloys. On the other hand, Cu-Zr separations are considerably larger than the Ni-Zr separations. The differences in the structures of the disordered alloys will be discussed and it will be shown that most features can explained by the smaller Ni-Zr separation driven by the higher heat of mixing. Work at the Ames Laboratory was supported by DOE BES under Contract No. DE-AC02-07CH1135.

Simulating the Effect of Poisson Ratio on Metallic Glasses: *James Morris*[1]; [1]Oak Ridge National Laboratory

The Poisson ratio of a glass has been correlated with the fragility of the liquid phase and with the fracture energy of a glass. There has been little theoretical work supporting this, due to a lack of a direct method of incorporating this. We have developed an interatomic potential that allows the Poisson ratio to be tuned. Simulations of the liquid show that increasing the Poisson ratio stabilizes the liquid phase, and increases the liquid fragility. Structural and dynamic properties in the liquid phase all show changes on undercooling that indicate a change in the liquid behavior above the glass transition.

4:25 PM

Analysis of Glass-Forming Ability through Atomistic Modeling: *Logan Ward*[1]; Katharine Flores[1]; Wolfgang Windl[1]; [1]The Ohio State University

Recently-developed techniques for measuring glass-forming ability using molecular dynamics have enabled the validation of many structural and dynamic properties as traits of glass-forming ability. In this work, we will present a computational tool for identifying glass-forming alloys using molecular dynamics. This method approximates the kinetics and driving force for nucleation in a liquid by studying its fragility and the relative amount of energetically-favorable short-range order. With this technique complete, it was possible to investigate how other properties correspond with glass formation in several systems for which interatomic potentials are available. It was also possible to alter the nature of bonding between species to study their effects on those key properties and glass-forming. The combination of these efforts yields not only a useful tool for identifying candidates for amorphous alloys, but a means of improving existing intuition for what properties are contributing factors in the stability of bulk metallic glasses.

Bauschinger Effect in Metallic Glass Nanowires under Cyclic Loading: *Yunfeng Shi*[1]; Jian Luo[1]; Louca Despina[2]; Gongyao Wang[3]; Peter Liaw[3]; [1]Rensselaer Polytechnic Institute; [2]University of Virginia; [3]The University of Tennessee

We present a molecular dynamics simulations on fatigue behaviors of model metallic glass nanowires. We found asymmetric hardening in fatigued metallic glass nanowires, which is analogous to the Bauschinger effect commonly observed in metals and polymers. Here both compression-compression and tension-tension cyclic loading are imposed using strain-controlled loading scheme up to 100 cycles, with the maximum strain of 4 %. It was found that, upon compression-compression fatigue tests, the metallic-glass nanowire hardens in compression tests, while softens in tensile tests. However, upon tension-tension cyclic loading, it was found that the metallic-glass nanowire softens in compression tests, while hardens in tensile tests. The observed Bauschinger effect cannot be explained by population variations of preferred short-range orders such as icosahedral clusters, as it was shown to be almost a constant. Instead, such asymmetric hardening behavior is related to the anisotropic distribution of icosahedral pairs, which evolves during cyclic loading.

4:55 PM

Modeling the Intrinsic Shear Strength of Metallic Glass: *Yongqiang Cheng*[1]; Evan Ma[1]; [1]Johns Hopkins University

The intrinsic (ideal) strength has been extensively studied for crystalline alloys, but remains largely unsettled for metallic glasses. This study, by combining computer simulations and the cooperative shear model (CSM, Johnson and Samwer, Phys. Rev. Lett. 95, 195501, 2005), found that, at the athermal limit, the yield strain of metallic glass can be as high as ~10% in pure shear, and the corresponding ideal shear strength is ~G/10 (where G is the shear modulus), at which shear bands nucleate homogeneously in the metallic glass. The athermal extrapolation of the measured strength in conventional loading tests is much lower, owing to the unavoidable imperfections in realistic samples, where shear band nucleation is always heterogeneous and facilitated by stress concentrators. The two scenarios have different temperature dependence and merge at elevated temperatures, when the yielding mode eventually changes from strain localization to homogeneous flow.

Atomistic Anisotropy in Deformed Metallic Glasses Studied via Molecular Dynamics Simulations: *Yunche Wang*[1]; Chun-Yi Wu[1]; Peter Liaw[2]; [1]National Cheng Kung University; [2]University of Tennessee

Recent studies on the deformation mechanisms in metallic glasses led to the atomically anisotropic behavior of the materials under loading. It has been shown that if the anisotropy is not included in the data analysis, synchrotron experiments may overestimate the modulus values of the materials. In this study, two metallic glasses are adopted. The Cu-Zr-Al glasses and Zr70Ni16Cu6Al8 are studied. The simulated, as-deposited films were amorphous. After the deposition, the samples were subject to uniaxial loading/unloading MD simulations, and results were compared with experimental data from in-situ synchrotron experiments. Calculated elastic constants are in agreement with experimental data. Diffraction pattern calculations are performed to compare with experimental ones to disclose the anisotropic deformation, through change of coordination numbers, at atomic scales in metallic glasses under loading. The effects of the anisotropy alter the short range order of amorphous alloys, and hence need to be incorporated to correctly interpret experimental data.

Structures, Phase Transformations and Elastic Properties of High-Entropy AlxCoCrCuFeNi Alloys: Ab Initio Molecular Dynamics Simulation: *Michael Gao*[1]; Louis Santodonato[2]; Peter Liaw[2]; [1]National Energy Technology Lab; [2]University of Tennessee

The high-entropy AlxCoCrCuFeNi alloys are known for their high strength and good wear resistance at elevated temperatures. The mechanical properties critically depend on especially aluminum contents and annealing temperatures, both of which dictate the microstructures and subsequent phase transformations involving A1, A2, and B2 phases. In the present study, ab initio molecular dynamics simulations are performed to reveal the atomic structures as a function of Al contents and temperatures. A comprehensive analysis on the atomic pair correlation function, structure factors, electronic charge density distribution, and atomic diffusion constants are performed in the liquid, as-quenched state, and annealed state in comparison to the crystalline A1, A2, and B2 structures. Elemental partitions among these phases are predicted and compared with experiential findings. The elastic properties are also calculated using density function theory (DFT) methods and compared with experimental measurements.

5:45 PM

Quasi-Phase-Transition Model of Shear Bands in Metallic Glasses: *Zengqian Liu*[1]; Ran Li[1]; Gang Wang[2]; Sujun Wu[1]; Xuyang Lu[1]; Tao Zhang[1]; [1]Beihang University; [2]Shanghai University

A quasi-phase-transition model of shear bands in metallic glasses (MGs) is presented from the thermodynamic viewpoint. Energy changes of shear banding in the sample-machine system are analyzed following the fundamental energy theorems. Three characteristic parameters, i.e.

the critical initiation energy ΔGc, shear-band stability index k0, and the critical shear-band length lc, are derived for elucidating the initiation and propagation of shear bands. The criteria for good plasticity in MGs with predominant thermodynamic arrestment of shear bands are proposed as low •ΔGc, large k0, and small lc. The model combining with experimental results was used to analyze some controversial phenomena about deformation behaviors in MGs, like the size effect, the effect of testing machine stiffness and the relationship between elastic modulus and plasticity. This study has important implications for the fundamental understanding of shear banding as well as deformation mechanisms in MGs and provides theoretical basis for improving the ductility of MGs.

Cast Shop for Aluminum Production: Direct-Chill Casting and Microstructures

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee
Program Organizer: Trond Furu, Hydro

Improving Strip Surface Quality Using Different Casting Atmospheres for the Horizontal Single Belt Strip Casting (HSBC) Process
: *Donghui Li*[1]; Mihaiela Isac[1]; Roderick Guthrie[1]; [1]McGill Metals Processing Centre

The surface quality of as-cast strip is a key factor in the production of strips produced by Horizontal Single Belt Strip Casting process (HSBC). Aluminum alloys were cast on an HSBC simulator, using different casting atmospheres at meniscus region, including preheated air and pure oxygen. The strip's bottom surface was analyzed in order to evaluate the effect of casting atmosphere on strip surface quality. The preheated air or oxygen was injected into the hollowed backwall refractory and was released through the orifices on the bottom of the refractory, close to the back-wall meniscus region. The purpose was to flush out the ambient air entrained above the moving substrate. The possibility of eliminating surface defects caused by air pockets' on the strip's bottom surface and improving surface quality by controlling the casting atmosphere in the meniscus region were confirmed. The surface profiles of the sand-blasted substrates and those of the related strips were analyzed using 3D Profilometry. The interfacial heat fluxes through using an oxygen atmosphere at the upstream meniscus were also enhanced greatly, as compared to the casting process using a graphite coating on the substrate. A novel way for improving strip surface quality with high attendant interfacial heat fluxes is now proposed for the HSBC process.

2:20 PM
Influence of Casting Direct Chill Casting Process Variables on Surface Quality of Aluminum Alloy Sheet Ingots: *Mostafa El-Bealy*[1]; [1]Ain Shams University, (CC)

The effect of surface defects formation on surface quality of aluminum direct-chill cast ingots has been investigated by metallographic examinations and mathematical modeling. The influence of process variables such as alloy composition, casting speed and lubricant on the surface defects has been determined. The metallographic study for collected samples of plant trials involved visual surface, macro, microstructure examinations and macrosegregation analysis. A 2-D mathematical model has been developed to characterize the thermal, solidification, interdendritic strain and macro-segregation distributions. The model predictions were compared to measurements from collected samples to verify the model, where good agreements were obtained. The model predications illustrate that all the process variables tested in this study have observed effect on the surface quality by different levels. The mathematical analysis of thermal fields as well as metallographic study has been used to explain and discuss the effects of different process variables on the surface quality.

2:40 PM
Square Rolling Slabs from Start of Casting - the Elimination of Butt Swell: *Arild Hakonsen*[1]; Harald Næss[2]; Idar Steen[1]; Terje Iveland[3]; [1]Hycast AS; [2] Hydro Aluminium; [3]Hydro Aluminium

The thickening of the bottom part of DC cast rolling slabs, butt-swell, is a well known problem in the aluminium business. The slabs are scalped, normally in the rolling plant, prior to rolling to a absolute rectangular shape. The rolling mill therefore prefers rolling slabs with geometry close to rectangular from the casthouse. Due to geometry specifications from the rolling mills the supplier casthouse has to cut off the bottom part of the slab before shipping. The bottom cut length is typically 0.3-0.6m (1-2') depending on the thickness and casting speed. This paper describes the basic principles behind the development of the flexible mould technology, and the operational experience so far from close to 15 years of operation. For 600mm thick ingots flexible moulds typically reduce the total scrap rate in the casthouse with more than 5% compared to conventional moulds with fixed geometry.

3:00 PM
Residual Stresses in As-Cast Billets: Neutron Diffraction Measurement and Thermomechanical Modeling: *Jean-Marie Drezet*[1]; Thilo Pirling[2]; Christophe Jaquerod[3]; [1]Ecole Polytechnique Federale Lausanne; [2]Institut Laue Langevin; [3]Constellium Valais SA

Stress relief treatment is often required prior to sawing aluminium DC cast products in order to prevent crack formation and significant safety concerns due to the presence of high residual stresses generated during casting. Numerical models have been developed to compute these residual stresses and yet have only been validated against measured surface distortions. In the present contribution, the variation in residual strains and stresses have been measured using neutron diffraction in two AA6063 grain-refined cylindrical billet sections cast at two casting speeds. The measured residual stresses compare favorably with the numerical model, in particular the depth at which the axial and hoop stresses change sign. Such results provide insight into the development of residual stresses within castings and show that the stored elastic energy varies linearly with the casting speed, at least within the range of speeds that correspond to production conditions.

The Deepwater Horizon Explosion and Correlations to the Aluminium Casthouse: *Alex Lowery*[1]; Terry Bateman[2]; Joe Roberts[3]; [1]Wise Chem LLC; [2]Pyrotek Pyt Ltd.; [3]Pyrotek Inc

On April 20, 2010, an explosion rocked the Deepwater Horizon in the Gulf of Mexico. Resulting the 11 deaths. Tens of thousands of documents were released during the investigation for the root cause of the explosion. "What emerges is stark and singular fact: crew members died, suffered terrible injuries because every one of the Horizon's defenses failed on April 20. Some were deployed but did not work. Some were activated too late, after they had almost certainly been damaged by fire or explosions. Some were never deployed at all. Parallels with the aluminium industry standout when comparing the Deepwater Horizon disaster (violent explosions, damaged equipment, worker deaths,worker injuries). Aluminium plants, just as deepwater oil rigs, value training and safety measures to prevent accidents from occurring. On April 20, 2010 every safety measure employed failed, could safety measures employed in a casthouse to prevent a molten metal steam explosion fail too?

4:00 PM
Deformation Behaviors of Pure Al and Al-4.5 Mass%Cu Alloy in Semi Solid State: *Nobuhito Sakaguchi*[1]; [1]Sumitomo Light Metal Industries,LTD.

To clarity the hot tearing mechanism in DC casting ingot, the mechanical properties and the deformation behaviors of pure Al and Al-4.5mass%Cu alloy in semi solid state were investigated by the new tensile test method. In Al-4.5mass%Cu alloy, the tensile strength and the elongation decreased remarkably above the solidus. The healing phenomenon the liquid flowed into the crack was observed at high temperature range in semi solid state by in situ observation. Pure Al had a very high ductility until near the liquidus. The deformation behaviors of both alloys in semi solid state were classified into four stages according to these mechanical properties, fracture surface morphologies and in situ observations of the tensile tests. The brittle temperature range in which the hot tearing occurs was determined in both alloys. These data obtained by the tensile test in semi solid state were able to apply to several simulations.

4:20 PM
Chemical Additions to Reduce Hot Tearing in the Cast House: Lisa Sweet[1]; John Taylor[1]; *Mark Easton*[1]; Malcolm Couper[2]; Nick Parson[3]; [1]CAST Co-operative Research Centre; [2]ARC Centre of Excellence of Design in Light Metals; [3]Rio Tinto Alcan

Hot tear susceptibility in VDC casting is strongly affected by the chemical additions of alloys, hardeners and grain refiners. This paper assesses a few different approaches to reducing hot tearing in the casthouse. Grain refinement is commonly used in the casthouse, including dosing at cast start. Another approach is to control the alloy content, through the additions of Si, Mg, Mn or Fe which can influence the type and amount of intermetallics present during the final stages of solidification when hot tearing occurs. This paper summarizes experimental findings which assess the influence of additions on the hot tear rating in 6xxx series alloys. Strategies which could be used in the cast house are discussed. While changes to the bulk metal can have consequences for alloy specification and quality control, additions at cast start could be used to reduce scrap from hot tearing without changing the composition of the saleable product.

2:00 PM Keynote
Modeling Magnetically Excited and Magnetically Damped Liquid Metal Flow: *Valdis Bojarevics*[1]; Koulis Pericleous[1]; [1]University of Greenwich

A number of different methods have been developed for noncontact electromagnetic treatment of liquid metal and to investigate the melting/solidification processes. Applying AC magnetic field in terrestrial conditions, along with the buoyancy and thermo-capillary forces, results in turbulent flow. The use of a homogenous DC magnetic field allows damping both of the turbulence and the large scale flow at different rates leading to surprising results at some stages. The dynamic interaction of the turbulent flow with the oscillating interface needs to be accounted if it is required to levitate liquid metal of up to few kilograms without the contact to container walls. At the high values of magnetic field some oscillation modes are damped quickly, while others are modified with a considerable shift of the oscillating droplet frequencies and the damping constants from the non-magnetic case. Even a purely DC magnetic levitation can be used for advanced material research.

Numerical Simulation of Liquid Metal Flows under the Influence of Magnetic Fields: *Andre Thess*[1]; Thomas Boeck[1]; Christian Karcher[1]; Joerg Schumacher[1]; Dmitry Krasnov[1]; Gautam Pulugundla[1]; Saskia Tympel[1]; Vitaly Minchenya[1]; Shuai Dong[1]; [1]TU Ilmenau

We report a wide range of high-resolution numerical simulations of liquid metal flows interacting with DC magnetic fields ranging from fundamental studies of magnetohydrodynamic turbulence to applications like simulation of electromagnetic flow measurement devices for metallurgical applications.

2:55 PM Invited
Numerical Analysis of the Influence of Melting and Application of Electromagnetic Stirring Prior to Solidification on Macrosegregation Formation during Casting of a Binary Alloy: *Knut Omdal Tveito*[1]; Mohammed M'Hamdi[2]; Hervé Combeau[3]; Miha Založnik[4]; Xiaodong Wang[5]; Bachir Saadi[5]; Yves Fautrelle[5]; [1]Norwegian University of Science and Technology; [2]SINTEF Materials and Chemistry; [3]Institut Jean Lamour, Departement SI2M, CNRS – Nancy-Université – UPV-Metz, Ecole des Mines de Nancy; [4]Institut Jean Lamour, Departement SI2M, CNRS – Nancy-Université – UPV-Metz, Ecole des Mines de Nancy; [5]SIMAP – CNRS – INPG - Université Joseph Fourier

Numerical simulations of macrosegregation formation during horizontal solidification of a hypoeutectic Sn-Pb alloy in a rectangular cavity is presented and compared to experimental results. The experiment involves a melting phase, a holding stage at constant temperature with or without application of electromagnetic stirring, and finally solidification. We simulate all stages of the experiment and study the segregation of Pb throughout the experiment. A two-phase volume-averaged model is used for the numerical simulations, accounting for thermo-solutal convection and assuming perfect microscopic mixing (lever rule). The influence of the melting phase and of the electromagnetic stirring is studied with different cases to illustrate the consequences on the flow pattern and on Pb segregation during melting and during solidification. The numerical simulations are compared to the experimental data and the impact of chemical inhomogeneities prior to solidification on macrosegregation formation is discussed.

3:20 PM Invited
Multiscale Modeling of Ingot Solidification Structure Controlled by Electromagnetic and Ultrasonic Stirring Technologies: *Laurentiu Nastac*[1]; [1]The University of Alabama

Two advanced control solidification technologies were studied in this article to improve the quality of the cast ingots as well as to control the solidification structure evolution during the plasma arc melting [PAM] processing of Ti-6-4 ingots: (i) electromagnetic stirring (EMS, and (ii) ultrasonic treatment (UST). The developed EMS modeling approach is based on the numerical solution of Maxwell's equations, fluid flow, and heat transfer equations, and mesoscopic modeling of the grain structure. The UST analysis tool is capable to model acoustic streaming and cavitation. Predictions of the macrostructure, CET formation and primary dendrite arm spacing for PAM Ti-6-4 ingots processed with and without EMS or UST were discussed.

4:05 PM
Evolution of the Velocity Field during Solidification in an Electromagnetically Stirred Melt: Gregory Poole[1]; *Nagy El-Kaddah*[1]; [1]The University of Alabama

This paper describes the evolution of electromagnetically driven flows during unidirectional solidification in a bottom chill mould. The electromagnetic field in the metal and chill blocks was computed using the mutual inductance technique, while the temperature and flow field equations were solved using the control volume method. The k-e model was used to determine the turbulent viscosity in the melt. The computed results showed that the flow field at the beginning of solidification is characterized by four recirculating loops typically found for stationary magnetic fields and changes to two loops at the end of solidification. The velocity was also found to vary along the solid-liquid interface. The magnitude of the velocity was not found to be constant, but increases as solidification progresses. The significance of these findings on grain refinement in electromagnetically-stirred melts will be discussed.

4:30 PM
Modeling the Case Hardening of Crankshafts: *Tiruttani Kamal*[1]; Suresh Sundarraj[1]; [1]General Motors

A 3-D numerical model of the induction hardening process of steel cranks has been developed and the predicted results of temperature, stresses, and phase distribution during this solid state phase transformation process are verified with experimental data from the literature. This heat treatment process involves heating the crank to the austenitic temperature range using an induction coil followed by rapid quenching in water to harden the surface of the crank. The model has been developed using ABAQUS, a commercial FEA software. The formation of martensite, pearlite, and retained austenite phases are modeled and implemented through a user defined function in ABAQUS. A sensitivity study on the various process parameters affecting the amount of phase distribution has been carried out. Based on this study, some recommendations are arrived at in selecting optimum crank rotation speed and quenching temperature and time during the induction hardening process.

4:50 PM
Study of De-Agglomerations Ceramic Nano Particles in the Aluminium Melt under Cavitation Phenomenon for Processing of Metal Matrix Nanocomposites: *Payodhar Padhi*[1]; Pragyan Mohanty[2]; [1]Konark Institute of Science & Technology; [2]ITER

The present study models the dispersion of ceramic nano particles in the liquid aluminum melt during the cavitation process. Cavitation produces when high-intensity ultrasound wave passes in the liquid which is used for de-agglomeration, dispersing and mixing of the fine particles in the liquids. When sound wave propagates into the liquid alternating high pressure (compression) and low-pressure (rarefaction) cycles depending upon frequencies are generated. When the bubble reaches a critical size at which it can no longer absorb energy, they collapse violently during high-pressure cycle. During the collapse of bubbles, high-pressure shock waves are generated and propagate through the liquid at velocities above the speed of sound, which creates high velocity collisions among solid particles suspended in such liquids. Here we have applied eulerian granular flow model using ANSYS R12 to study the particle de-agglomeration and dispersion during cavitation process which helps to process nanocomposites

5:10 PM
Fundamental Study on Behavior of Inclusion in Electromagnetic Swirling Flow in Immersion Nozzle in Continuous Casting Process: *Su Zhijian*[1]; Li Dewei[1]; Yang Ying[2]; Nakajima Keiji[2]; Jönsson Pär[2]; Marukawa Katsukiyo[3]; He Jicheng[1]; [1]Northeastern University; [2]Royal Institute of Technology (KTH); [3]Sumitomo Metal Industries, Ltd.

Swirling flow in an immersion nozzle is effective on improving quality of casting block and casting speed in continuous casting process of steel. A refractory swirl blade installed in the nozzle is liable to cause clogging, which limit the application of the process. A new process of electromagnetic swirling flow in immersion nozzle has been developed by EPM lab, China. That is a rotating electromagnetic field is set up around an immersion nozzle to induce swirling flow in it. The magnetic, flow and temperature field have researched. However the behavior of inclusion in this process is essential for the product quality. In this study, the inclusion trajectory in the immersion nozzle and square mold in the process is given, together with the magnetic, flow and temperature field. Results show that the swirling flow can achieve the same effects generated by the swirling blade process without the clogging in the nozzle.

Characterization of Minerals, Metals, and Materials: Characterization of Energy, Electronic and Optical Materials

2:00 PM
Influence of La2O3 Additive Content on the Phase Stability, Sintering and Microstructure of 8 MOL% Y2O3 Stabilized Zirconia (8YSZ) Ceramic Used for Solid Oxide Fuel Cell Applications: *Suleyman Tekeli*[1]; Bulent Aktas[2]; Serdar Salman[3]; [1]Gazi University; [2]Harran University; [3]Marmara University

The effect of La2O3 content up to 15 wt% on phase stability, sintering and microstructure of cubic zirconia (8YSZ) was investigated. XRD results showed that specimens containing up to 15 wt% La2O3 were composed of only cubic structure. Also, the specimens doped up to 5 wt% La2O3 revealed no La2O3 peaks, indicating that La2O3 was completely solubilised in cubic structure. However, when > 5 wt% La2O3 was added, the peak of La2Zr2O7 compound emerged, showing that overdoped La2O3 was not solubilized in the 8YSZ matrix. The lattice parameter of 8YSZ slightly decreased with increasing La2O3 content up to 1 wt% but further increase in La2O3 amount resulted in an increased lattice parameter. The comparison of grain size of 8YSZ specimens with various La2O3 content showed that grain size slightly increased with increasing La2O3 content up to 1 wt% but further increase in La2O3 amount resulted in a decreased grain size.

2:15 PM
Development and Characterization of Carbonaceous Materials Incorporated with Metal (Ti, V and Zn)-Organic Compounds for Hydrogen Storage: *Mala Nath*[1]; Asheesh Kumar[1]; Arjit Mallick[1]; [1]Indian Institute of Technology Roorkee

Activated charcoal incorporated either with titanium n-butoxide, titanium diisopropoxide bis(2,4-pentanedionate), vanadium bis(2,4-pentanedionate) or zinc bis(2,4-pentanedionate) having 2–8 wt% of the metal were prepared using ethanol as solvent at 40–50 °C followed by calcinations at 100, 150 and 200°C, except the samples with titanium diisopropoxide bis(2,4-pentanedionate) calcinated at 80 °C. AAS and FESEM revealed that the maximum incorporation of metals (Zn, V and Ti) in activated charcoal was observed with 4 wt% of zinc bis(2,4-pentanedionate) calcinated at 150 °C, 4 wt% of vanadium bis(2,4-

pentanedionate) at 100 °C, 2 wt% of titanium n-butoxide at 100 °C and 2 wt% of titanium diisopropoxide bis(2,4-pentanedionate) at 80 °C, using equilibration time of 20-24 h. Hydrogen sorption behavior at 77.4 K and 1 bar indicated that the highest hydrogen uptake was obtained 1.45 wt% (164.5 cm3 (STP)/g at P/P0 = 1.0) for activated charcoal incorporated with 4 wt% of zinc 2,4-pentanedionate calcinated at150 °C.

2:30 PM
Characterization of Nickel Oxide Nanoparticles for Hydrogen Adsorption with External Electric Field: *Zheng Zhang*[1]; Xiang Sun[1]; Zhiwei Peng[1]; Jiann-Yang Hwang[1]; [1]MTU

Nickel oxide nanoparticles were synthesized using sodium dodecyl sulfate as the surfactant and urea as the hydrolyzing agent and different calcination temperatures and time were selected for preparation. Nitrogen adsorption (BET), X-ray diffraction (XRD) and scanning electron microscope (SEM) were subsequently used to characterize the prepared samples. The effect of an external electric field on hydrogen adsorption over a prepared nickel oxide was carried out. The electric filed was introduced by a piezoelectric element, which is capable of autogenously generating charges under hydrogen pressure. Increased hydrogen adsorption was obtained from this study, which indicated a stronger interaction between the adsorbent surface and hydrogen.

2:45 PM
Ag /Diamond Composite Shims for High-Performance Thermal Management: *Jason Nadler*[1]; Lee Bannister[1]; [1]GTRI

A silver-diamond (Ag-Di) composite thermal shim has been developed in efforts to meet the thermal management challenges and dimensional constraints of next generation high-power wide-bandgap semiconductor devices. Some of these devices can generate heat fluxes exceeding 8kW/cm2 at temperatures over 225°C, and consistently dissipating this heat requires thermal expansion (CTE) matched, high thermal conductivity, small form factor shims. Composite shims consisting of a high volume fraction of diamond (50-75%) serving as both a high-conductivity phase and CTE-modifier distributed in a silver matrix integrate and tailor these key requirements. Shim microstructures are designed to have multi-modal diamond particle size and spatial distributions based on a primary diamond monolayer. Initial performance has been characterized through thermal expansion and effective thermal resistance measurements up to 250°C as well as quantitative microstructural analyses to evaluate suitability for high power device integration.

3:00 PM
Nanocrystalline CdS Thin Films Prepared by Vacuum Evaporation: *Shadia Ikhmayies*[1]; [1]Al Isra University

Nanocrystalline CdS thin films were prepared by vacuum evaporation on glass substrates at ambient temperature. The films were characterized by recording and analyzing their transmittance, X-ray diffraction (XRD) patterns, scanning electron microscope (SEM) images and Energy dispersive X-ray spectra. X-ray diffractograms revealed that the material is nanocrystalline with cubic crystal structure and preferential orientation along (111) plane. SEM micrographs confirmed the nanostructure of the material and showed uniform and well covered surfaces. EDX reports revealed that the films are cadmium rich and contain oxygen. The first derivative of the absorbance was used to estimate the effective bandgap energies of the nanocrystallites and the hyperbolic band model was used to estimate their radii. The results were compared with those obtained by XRD and SEM measurements.

3:15 PM
Structure–Property Correlation of $Pb(Ni_{0.33}Nb_{0.67})O_3$–(1-x) $Pb(Zr_{0.31}Ti_{0.69})O_3$ Based Relaxor-Ferroelectric Ceramics Synthesized Via Columbite Precursor Method: Bandi Mallesham[1]; T. V. Jayaraman[2]; A. R. James[3]; *Dibakar Das*[1]; [1]University of Hyderabad; [2]University of Nebraska; [3]Defence Metallurgical Research Laboratory

Lead based relaxor-ferroelectric material, with nominal compositions $xPb(Ni_{0.3}Nb_{0.67})O_3$-(1-x)$Pb(Zr_{0.31}Ti_{0.69})O_3$(PNN-PZT) ($0.2 \le x \le 0.6$), have been synthesized by columbite precursor method. Homogeneous mixture of the oxide powders was calcined at 850°C for 4 h to obtain phase pure perovskite followed by sintering of the pellets of PNN-PZT at 1100°C for 4 h. The presence of phase pure perovskite structure was confirmed by the X-ray diffraction (XRD) analysis; it also revealed structural transitions from rhombohedral to tetragonal phase with increasing PZT content. A morphotrophic phase boundary (MPB) is observed at x = 0.5. Electrical polarization measurements showed high remnant polarization (19.12 μ C/cm^2) and low coercive field (6.89 kV/cm) at MPB as compared to other compositions. The electromechanical planar coupling coefficient (k_p) was estimated to be ~33% at MPB. A high piezoelectric strain coefficient (d_{33} = 398 pC/N) was obtained at the MPB.

3:30 PM
Evolution of High-Energy Electron Beam Irradiation Effects on Zeolite Supported Catalyst: Metal Nanoprecipitation: *Kai Song*[1]; Jinsong Wu[1]; Dana Sauter[1]; Vinayak Dravid[1]; Peter Stair[1]; [1]Northwestern Univeristy

The high-energy electron irradiation effects on Fe-loaded, zeolite-supported catalyst were examined by transmission electron microscopy. Metal nanoparticles were found to precipitate quickly under beam illumination with electron dose of 2.4×10^7 nm^{-2} or above at room temperature. Since electron microscopy was widely applied in characterization of all sorts of catalyst supported on zeolites, the current observations could be treated as a model system to distinguish the metal nanoparticles existing in original catalyst from those precipitated by electron beam irradiation. It was the electron radiation, other than temperature, that played an important role in the formation and growth of metal precipitates. In the current system, the induced nanoprecipitations were identified as pure Fe metal with a FCC structure by electron energy loss spectroscopy (EELS), high-resolution transmission electron microscopy (HRTEM) and electron diffraction.

3:45 PM
The Characteristics of Optical Recording Media Affected by The Accelerating Aging Test: *Der-Ray Huang*[1]; [1]NDHU

In this paper, some DVD-R discs have been selected for long time light exposure test and high temperature and humidity test. Generally, recordable media under long time light exposure maybe be defected seriously. If we use Jitter value 8% as a reference to determine the life time of DVD-R samples, some discs defect after 5 hours of light exposure while some discs can endure over 25 hours. Also if we use reflectivity 45% to determine the life time, some discs defect after 20 hours light exposure while some discs can endure over 50 hours. From our results, the good samples show good characteristics of PI error. The absorption spectrum of recordable media is a good reference to justify the quality of dye media. These results can be used to estimate the life time of recordable discs. Also, these data provide good references for the research of long lifetime recordable media.

4:00 PM
A Comparison between the Properties of Spray-Pyrolyzed SnO2:F/CdS:In Structures Prepared by Using NH4F and HF as a Source of Fluorine: *Shadia Ikhmayies*[1]; Riyad Ahmad-Bitar[2]; [1]Al Isra University; [2]University of Jordan

SnO2:F/CdS:In structures were prepared by the spray pyrolysis technique on glass substrates at a substrate temperature Ts = 450 °C. NH4F and HF were both tried as the sources of fluorine in the precursor solution of SnO2:F. A comparison between the properties of structures obtained by using the two doping compounds was performed. X-ray diffraction (XRD), scanning electron microscopy (SEM) and transmittance measurements were used to characterize the films. The structures prepared by using HF as a fluorine source were found to have more ordered crystal growth, larger grain size and sharper absorption edge. From the inspection of the first derivative of the absorbance it is expected that more interdiffusion on the SnO2:F/CdS:In interface takes place in the structures made by using HF. These results confirm that these films are better as forecontacts for CdS/CdTe solar cells.

4:15 PM
Transmission Electron Microscopy Study on Interfaces in Cu/CuZr Multi-layer Thin Films: *Ying Li*[1]; Robert Dickerson[1]; Amit Misra[1]; [1]Los Alamos National Laboratory

Cu/CuZr multi-layer thin films with different layer thickness were synthesized by magnetron sputtering. The interface structures in these films were investigated by transmission electron microscopy (TEM), scanning TEM (STEM), high resolution TEM (HRTEM), energy dispersive X-ray spectroscopy (EDX), electron energy loss spectroscopy (EELS) and energy filtered TEM (EFTEM) method. The bonding between the two phases, atomic structure around the interface, the crystallization phenomena of CuZr phase at the interface and other microstructural features were studied in detail. Based on the comparison of microstructure characterization in the Cu/CuZr multi-layer thin films with different thickness, the microstructure evolution at the interfaces induced by layer thickness was also investigated.

4:30 PM
Characterization and Preparation of Anti-Reflection Coatings in the RANGE of 3-5 µm for Si Optical Window: *Khurram Iqbal*[1]; Asghari Maqsood[1]; [1]National University of Sciences and Technology

It is suitable for application in the infrared array camera (IRAC)

4:45 PM
Investigation of Room Temperature Dislocation Mobility in Metal Diborides (ZrB2) Using Nano and Micro Indentation: *Ghatu Subhash*[1]; Dipankar Ghosh[1]; [1]University of Florida

Unlike structural ceramics that exhibit brittle behavior, transitional metal diborides (ZrB2 and HfB2) which are potential candidates for ultra high temperature applications, exhibit ductile deformation features and high electrical conductivity similar to metals. To further investigate this behavior, we have conducted nano- and micro-indentations and noted extensive slip-line patterns akin to those observed in metals. TEM analysis revealed multiple sets of dislocations and dominance of pyramidal slip. Nano indentation experiments on individual grains before and after macroindentation-induced deformation revealed that these slip regions are harder than the virgin material. The dislocation plasticity and hardening behaviors are argued on the basis of its chemical bonding and non-localized dislocation core structure.

Cluster Expansion Methods - Progress and Outlook: *Axel van de Walle*[1]; [1]Brown University

Although ab initio methods excel at calculating physical properties for any given atomic arrangements, proper modeling of the thermodynamic properties of solid-state alloys demands the exploration of the large number of states visited in thermal equilibrium, a task that is computationally intractable via a brute-force approach. This talk will overview the field research devoted to overcoming this problem, through a combination of computational techniques that are able to efficiently model electronic excitations, lattice vibrations and configurational disorder within a unified framework. This framework is the so-called cluster expansion formalism in conjunction with a suitable coarse-graining of the partition function. Various approaches that have been proposed to construct an optimal cluster expansion will be contrasted and examples of application will help illustrate the methods discussed and their capabilities.

2:25 PM
Kinetic Monte Carlo Simulations of Diffusion-Limited Nucleation: *Yang Hao Lau*[1]; Ramanarayan Hariharaputran[1]; David Wu[1]; [1]Institute of High Performance Computing

Nucleation, the stochastic formation of clusters of a stable phase from a metastable phase, is the first step in many phase transformations. Due to its simplicity, classical nucleation theory (CNT) is often used to estimate nucleation rates, but since its derivation depends on the growth rate's being collision (or interface) limited, Kelton has recently modified CNT for diffusion-limited growth, which involves long-range diffusion and applies, e.g., to oxygen precipitation in silicon and, more generally, to crystallization in alloys [Kelton, K. F., Acta mater., 2000, 48, 1967]. Unfortunately, critical tests of either CNT or Kelton's theory have been prevented by the lack of key input parameters, which are notoriously difficult to obtain experimentally. We therefore perform kinetic Monte Carlo simulations of diffusion-limited crystallization in 2D to obtain theoretical input parameters, nucleation rates, and size distributions of clusters. The predictions of CNT and Kelton's theory are compared to simulation results.

2:40 PM

Kinetics of Tellurium Precipitation in CdTe-Based Materials: *Vincenzo Lordi*[1]; [1]Lawrence Livermore National Lab

CdTe and related alloys, such as CdZnTe, are important materials for solar photovoltaic application as well as for high-resolution room-temperature gamma radiation detectors. However, the performance of devices, particularly in high-energy applications, is limited by various material defects. Among the most important defects are Te precipitates caused by non-stoichiometric growth conditions. In this work, we study the kinetics of Te aggregation and precipitation at the atomic scale, using a multi-scale modeling approach informed by first-principles calculations. Density functional theory is used to compute the energetics, migration rates, and binding energies of point defects involved in Te aggregation, which include various interstitials, vacancies, and anti-site defects. Kinetic Monte Carlo is then used to simulate the aggregation process leading to precipitation nuclei. The mechanism and kinetics of formation, and the resultant structures, of these Te-rich regions are compared for various conditions of stoichiometry and temperature. Prepared by LLNL under Contract DE-AC52-07NA27344.

2:55 PM

Influence of Misfit Stresses on Sputter-Induced Patterns on Alloy Thin Films: *Bharathi Srinivasan*[1]; Ramanarayan Hariharaputran[2]; Yong-Wei Zhang[1]; [1]Institute of High Performance Computing, Singapore; [2]Institute of High Performance Computing

Understanding self assembly of nanoscale patterns like quantum dots, ripples and nanowires have gained significant importance recently for their role in devices for optoelectronic applications. Sputtering using low energy ion beams is one of the emerging techniques to grow these self-organized nanostructures. In single phase materials, these patterns are formed as a result of competition between sputtering and surface diffusion. In alloys, the component dependent diffusivity results in coupling between composition and surface modulation patterns. In alloy films epitaxially grown on substrate, the mismatch strains enrich these patterns by additional path of morphological evolution due to Asaro-Tiller instability. We present the results of kinetic Monte Carlo simulations of the formation and evolution of patterns on binary alloy surfaces under the influence of the non-uniform misfit stresses. Our talk would focus on the influence of parameters such as sputter yield, composition and misfit stress on the composition and height patterns.

3:10 PM Break

3:40 PM

Continuous Displacement Cluster Variation Method and Its Applications: *Tetsuo Mohri*[1]; [1]Hokkaido University

Continuous Displacement Cluster Variation Method (CDCVM) is a revised version of conventional Cluster Variation Method and local lattice distortion effects are efficiently incorporated into the free energy formula. By emplyoing CDCVM, the calculations of a phase diagram and diffuse intensity spectra originating from the local distortion are attempted for fcc based alloys. As compared with the transition temperature obtained by conventional CVM for an ordering system, the result of the CDCVM yields lower transition temperature, indicating the stabilization of a disordered phase. Diffuse intensity spectra are obtained in a systematic way in terms of concentration and temperature. The intensity distribution in the k-space is discussed in view of the atomic potentials of a given system.

3:55 PM

Positive Vibrational Entropy of Chemical Ordering in FeV and Its Electronic Origin: *Brent Fultz*[1]; Jorge Munoz[1]; Lisa Mauger[1]; Chen Li[1]; Matthew Lucas[2]; Olivier Delaire[3]; Douglas Abernathy[3]; Matthew Stone[3]; [1]California Institute of Technology; [2]Wright-Patterson AFB; [3]Oak Ridge National Laboratory

Inelastic neutron scattering and nuclear resonant inelastic x-ray scattering were used to measure phonon spectra of FeV as a B2 ordered compound and as a bcc solid solution. The two data sets were combined to give an accurate phonon density of states, and the phonon partial densities of states for V and Fe atoms. Contrary to the behavior of ordering alloys studied to date, the phonons in the B2 ordered phase are softer than in the solid solution. Ordering increases the vibrational entropy by +0.22 \177 0.03 k_B/atom, stabilizing the B2 ordered phase to higher temperatures. First-principles calculations showed that the electronic generalized susceptibility was isotropic and well behaved, and the number of electronic states at the Fermi level increased upon ordering. During ordering, the increased screening between ions reduced the interatomic force constants. The effect of screening was larger at the V atoms than at Fe atoms.

4:10 PM

***Ab Initio* Study of Advanced Metallic Nuclear Fuels for Fast Breeder Reactors**: *Alexander Landa*[1]; Per Söderlind[1]; Patrice Turchi[1]; Andrei Ruban[2]; Levente Vitos[2]; [1]Lawrence Livermore National Laboratory; [2]Royal Institute of Technology

The U-Zr and U-Mo alloys proved to be very promising fuels for fast breeder reactors. In this work we perform *ab initio* study of the ground state properties of bcc U-Zr and U-Mo alloys and compare their heats of formation with CALPHAD assessments. We discuss how the heat of formation in both alloys correlates with the charge transfer between the alloy components, and how the specific behavior of the density of states in the vicinity of the Fermi level promotes stabilization of the U_2Mo compound. Our calculations suggest that bcc U-Mo alloys should have much lower constituent redistribution than U-Zr alloys. We also explore the idea of stabilization of the UZr_2 compound against the α-Zr due to increase of Zr d-band occupancy by the addition of U to Zr. This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

4:25 PM

Ordering of Oxygen and Vacancies in Hexagonal Closest Packed Zr and Hf: ZrO_X; and HfO_X ($0 \leq X \leq 1/2$): *Benjamin Burton*[1]; Axel van de Walle[2]; [1]NIST; [2]California Institute of Technology

First principles phase diagram (FPPD) calculations were performed for the hcp-based systems: ZrO_X; and HfO_X ($0 \leq X \leq 1/2$). The Vienna Ab Initio Simulation Package (VASP) was used to calculate formation energies which became input for Alloy Theoretic Automated Toolkit (ATAT) fits of cluster-expansion (CE) Hamiltonians, and these were used in Monte-Carlo phase diagram calculations. Very similar CE-Hamiltonians were obtained for both systems, but significantly different phase diagrams were calculated. In both CEs nearest-neighbor (nn) interactions parallel- and perpendicular to c_{Hex} were strongly repulsive for O-O nn-pairs, but farther nn pair-terms were significantly larger in HfO_X. In ZrO_X, Long Period Superstructures (LPSS) were reported in samples with bulk compositions near Zr_3O, but they were not reproduced by the FPPD calculation. In HfO_X, no such phases have been observed experimentally, but Devil's Staircases of ordered phases were predicted in (metastable) Hf_3O and Hf_2O.

4:40 PM

DFT Study of Initial Oxidation State on TiN Step Surfaces: *Minki Hong*[1]; Simon Phillpot[1]; Susan Sinnott[1]; [1]University of Florida

Titanium nitride (TiN) film has extreme hardness, high chemical reactivity and high electrical conductivity and thus is widely used for wear and corrosion resistant coatings as well as diffusion barriers and gate electrodes in microelectronic devices. They are thus routinely subjected to extreme conditions such as high pressure and temperature, corrosive environments, and consequently undergo oxidation. Here, density functional theory calculations are used to determine the mechanisms associated with step-related oxidation process and the formation of nitrogen exit channels induced by Ti surface diffusion. The energy barrier associated with Ti diffusion on (210) step surface is ~3 eV while the energy barrier for oxygen dissociation is almost zero.

4:55 PM
Generalized Cluster Expansion of III-V Semiconductor Alloys: *Gregory Pomrehn*[1]; Axel van de Walle[2]; [1]California Institute of Technology; [2]Brown University

The III-V system of semiconducting alloys (Al, Ga, In cations and N, P, As anions) is investigated through the use of a generalized cluster expansion. This method provides a general expression relating the state of atomic order of an alloy to various tensor-valued properties, such as static strain, elastic constants, carrier masses and dielectric properties. The unknown coefficients in this general expansion are determined via first-principles calculations. The resulting structure-property relationships can provide helpful guidance in the design of optoelectronic devices.

Defects and Properties of Cast Metals: Novel Processes and Applications

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Solidification Committee
Program Organizers: Mark Jolly, University of Birmingham; Brian Thomas, University of Illinois at Urbana-Champaign; Carl Reilly, University of British Columbia

Wednesday PM — Room: Oceanic 4

Session Chairs: Peter Lee, University of Manchester; Mark Jolly, University of Birmingham

2:00 PM
Flux Entrapment Defects in Electroslag Remelting of High Ti, Low Al Nickel Based Superalloys: *Jonathan Busch*[1]; Jack deBarbadillo[2]; Matthew Krane[1]; [1]Purdue University; [2]Special Metals Corporation

High Ti, low Al nickel based alloys, such as INCOLOY alloy 800 and 825, are particularly prone to macroscale slag inclusions and microscale cleanliness issues. These issues can result in significant yield losses (~10%) due to surface grinding. Slag inclusion samples from near the outer radius of the toe end of alloy 800 and 825 ingots were found to have a multiphase microstructure consisting of CaF2, CaTiO3, Ca12Al14O33, MgAl2O4 and MgO. These inclusions were often surrounded by a field of smaller TiN cuboidal particles 1 to 10 microns in size. Several process changes have been enacted at the Special Metals facility in Burnaugh, KY to reduce the exposure of liquid metal to atmospheric nitrogen in an attempt to mitigate these issues. However, the slag inclusion and microscale cleanliness problems persist and the exact mechanism by which they form is still under investigation.

2:25 PM
Defect Control on Al Castings for Excellent Quality and Improved Performances through Novel Rheocasting Processes: *Mario Rosso*[1]; Ildiko Peter[1]; [1]Politecnico di Torino

Commonly, components of complex shapes are prepared by casting or by forging processes, the choice is based on economical, as well as performance basis. Casting technologies versus forging are decidedly more competitive from the economical point of view, while forging is able to guarantee the best performances, thanks to the highest soundness. Castings can be affected by defects like voids or cavities, inclusions and oxides. Semi-solid processes are able to better control the defect level and can reduce the existing gap between casting and forging.In this paper the attention will be focused on some very promising rheocasting processes, which have been recently developed. Particular emphasis will be devoted to the study and discussion of the possible causes of defects, of their origins and mechanisms, in order to realize their full control and to attain the production of high performance and reliable complex shape components at competitive costs.

2:50 PM
Defect Elimination in Cast Al Components via Friction Stir Processing: *Ning Sun*[1]; Diran Apelian[1]; [1]Worcester Polytechnic Institute

Friction stir processing (FSP) is an outgrowth of Friction stir welding (FSW) that locally manipulates the microstructure by imparting a high level of energy in the solid state resulting in improved mechanical properties. Our work to date has shown that FSP can be implemented as a post-casting method to locally eliminate casting defects, such as porosity due to gas evolution during casting. Coarse second phase are broken into fine nearly equiaxed particles and distributed uniformly in the matrix; grain refinement is also attained by dynamic recrystallization during FSP. This results in improved tensile properties and fatigue behavior of the cast Al A206 alloy. Such improvements have important implications for manufactured components for a variety of automotive and other industrial applications. The convenience of FSP as a post-processing step that can easily be adapted during machining operation makes it quite attractive for adoption. These results will be reviewed and discussed.

3:15 PM Break

3:40 PM
Quality Improvement of Aluminium Alloy Castings by application of a New Casting Facility instead of a Conventional Investment Casting Process: *Xiaojun Dai*[1]; Mark Jolly[1]; Binxu Zeng[1]; [1]University of Birmingham

The production of aluminium alloy castings in traditional investment casting process usually uses chunky runner system and top filling method. The large runner system has a low yield and generates lots of wastes. The top filling method (gravity filling method) makes the liquid flow in the runner system in turbulent behaviour. In this way the oxide films on the liquid metal will fold, break up and trap into the liquid. When the liquid metal is solidified, the trapped oxide films will form the porosities and cracks which will damage the mechanical properties of the castings. By using a new facility, called CRIMSON, the weight of the runner system and defects are drastically reduced. The experimental outcomes can validate the simulation results. It was verified that the castings produced by the new facility have better mechanical properties in comparison with the castings produced by traditional method.

4:05 PM
Ribbon-Substrate Adhesion and Catastrophic Sticking in the Planar-Flow Melt Spinning of Metals: *Anthony Altieri*[1]; Eric Theisen[2]; Paul Steen[1]; [1]Cornell University; [2]Metglas, Inc

In the planar-flow melt spinning process, liquid metal is brought into contact with a cold, rotating wheel and a thin, solid ribbon is spun off. The ribbon adheres to the wheel until it detaches naturally or is mechanically removed. In the absence of a mechanical removal system, the natural detachment mechanism is thermo-elastic contraction of the solidified ribbon as it cools. Under certain conditions, the ribbon does not contract sufficiently to detach in the time of a wheel revolution. This event is called catastrophic sticking. In this situation, the ribbon reenters the liquid-wheel contact region which typically ruins the integrity of the ribbon and can damage the casting equipment. The transition between successful detachment and catastrophic sticking happens rapidly and depends primarily on the wheel surface-temperature. A model of ribbon cooling which successfully predicts the point of ribbon detachment and the sudden transition to catastrophic sticking will be presented.

4:30 PM Concluding Comments

Deformation, Damage, and Fracture of Light Metals and Alloys: Session V

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Light Metals Division, TMS/ASM: Mechanical Behavior of Materials Committee
Program Organizers: Qizhen Li, University of Nevada, Reno; Fuqian Yang, Univ. of Kentucky; Ke An, Oak Ridge National Laboratory

Wednesday PM — Room: Northern A2
March 14, 2012 — Location: Dolphin Resort

Session Chairs: Qizhen Li, University of Nevada, Reno; Wen-Ming Chien, University of Nevada, Reno

2:00 PM Invited
Study of the High-Performance Super-Light Mg-Li Alloys and Heat-Resistant Mg-RE Alloys: *Milin Zhang*[1]; Ruizhi Wu[1]; Jinghuai Zhang[1]; Fengchun Jiang[1]; [1]Harbin Engineering University

The research results about Mg-Li alloys and heat-resistant Mg alloys in Harbin Engineering University are summarized. As for the super-light Mg-Li alloys, we mainly investigated the alloying effect, the ageing reaction and the superplasticity. As for the high strength and heat-resistant Mg-RE alloy, we investigated a new Mg-Gd-Dy-Zn alloy. The results showed that the as-cast sample with 14H long period stacking ordered (LPSO) structure exhibits acceptable strength and high ductility, and the peak-aged sample with basal plane stacking faults (SF) shows high strength and adequate elongation.

2:30 PM
Effect of Stacking Fault Energy and Solute Size on the Rare Earth Texture Evolution and Deformation Behavior of Magnesium Alloys: *Zachary Bryan*[1]; Ryan Hooper[1]; Michele Manuel[1]; [1]University of Florida

It has recently been shown that rare earth solutes in magnesium modify the conventional basal-dominated texture during recrystallization and lead to increased formability. It is thought that the unique texture component arises from shear band nucleation and solute drag effects due to the solute's large atomic radius. The effect of variable stacking fault energy, which is important in deformation and thus annealing, has not been studied concurrently with atomic size. This study systematically varied solute misfit strain and stacking fault energy through alloy selection to determine their individual and combined effects on the mechanical properties and annealed texture. Mechanical tests were performed at temperatures from 25 to 300°C and strain rates from 10^{-4} to 10^{-1} s^{-1} to elucidate the effect of dynamic strain aging on texture evolution. This work is supported by the National Science Foundation (Award#: DMR-0845868) and the Department of Energy Office of Science Graduate Fellowship (Contract#: DE-AC05-06OR23100).

2:45 PM
Strengthening Mechanisms in Solution-Annealed Ni-rich NiTi Alloys: *Billy Hornbuckle*[1]; Taisuke Sasaki[2]; Ron Noebe[3]; Glen Bigelow[3]; Mark Weaver[1]; Greg Thompson[1]; [1]The University of Alabama; [2]National Institute for Materials Science; [3]NASA Glenn Research Center

The two properties generally associated with NiTi alloys are shape memory and superelasticity. As such, most NiTi research has concentrated on near equiatomic compositions. In the present study, we have investigated the Ni-rich 60NiTi (Ni55Ti45 at.%) composition. This composition still possesses superelasticity, but also exhibits elevated Vickers micro-hardness values. In the hot-rolled condition, the alloy contained the NiTi (B2), Ni4Ti3, and Ni3Ti phases with a Vickers micro-hardness value of 375 Hv. This alloy was then solution annealed at 1050 deg. C for 10 hours and water quenched. This resulted in a significant increase in Vicker's microhardness to 645 Hv. Similar solution aging for a 57NiTi (Ni52Ti48 at.%) alloy only resulted in a Vicker's microhardness of 450 Hv. The retained phases, post-solution annealing, for both compositions was B2 and Ni4Ti3. Through TEM and Atom Probe analysis, the increase in hardness is discussed in terms of nanoscale precipitates and local chemical modulations.

3:20 PM
Twinning Mechanisms in Hexagonal Close-Packed Metals: *Bin Li*[1]; Xiyan Zhang[2]; [1]Center for Advanced Vehicular Systems; [2]Chongqing University

We present atomistic simulations on configurations of twinning dislocations and transmission electron microscopy observations on interfacial structures of twin boundaries of major twinning modes in HCP metals (Mg, Ti, Zr, Co etc.), i.e., {10-11}<10-1-2>, {10-12}<10-1-1>, {11-21}<11-2-6> and {11-22}<11-2-3>. Our results show excellent agreement with the classical theory in terms of the magnitudes of the Burgers vectors of the twinning dislocations, but the structure of the twinning dislocation differs drastically from one mode to another because of the diversity in shear and shuffle. The most commonly observed {10-12}<10-1-1> twinning is an extreme case in which shear is negligible and shuffle is dominant. The {11-21}<11-2-6> twinning is an extreme case in which no shuffle is involved and shear dominant. The {10-11}<10-1-2> twinning is shear dominant with minor off-plane shuffles; and the {11-22}<11-2-3> twinning is in the middle where shear and shuffle are nearly equal but the shuffles are in-plane.

3:35 PM
Alloy Development and High Temperature Deformation of TiAlNbCrMo Alloys: *Glenn Bean*[1]; Michele Manuel[1]; [1]University of Florida

Titanium aluminides have been of great interest due to their high specific strength and good mechanical properties below 700°C. Limited research has been conducted towards increasing strength and operating temperatures of these alloys, by developing a γ(TiAl)+σ(Nb_2Al) microstructure. Alloys with over 50% σ-phase have shown excellent high temperature properties up to 1000°C, but are brittle at room temperature. Recently, alloys with less than 30% σ-phase have been investigated with regards to alloy development, characterization, and deformation behavior at elevated temperature, while exploring relationships between chemistry and microstructure, and the resulting mechanical properties. Alloys in the TiAlNb(Cr,Mo) system with varying Nb content have been produced and characterized at high temperature (≥700°C) under compression at strain rates ranging from 10^{-2} to 10^{-5} s^{-1}. Microstructural analysis was conducted to determine the deformation and damage characteristics of the alloys. This work has been supported by the National Science Foundation under award number DMR-0856622.

3:50 PM
Role of Substitution Elements on Twinning Nucleation Mechanism in Magnesium: *Mehul Bhatia*[1]; Kiran Solanki[1]; Amitava Moitra[2]; Mark Tschopp[3]; [1]SEMTE; [2]Department of Chemical Engineering and Materials Science and Engineering; [3]CAVS - Center for Advanced Vehicular System

Within hcp materials, plastic deformation along the <c> axis, is primarily accommodated through twinning due to the limited number of slip modes imposed by c/a ratio. Moreover deformation twining is greatly influenced by the alloying contents. In this work, we investigate the role of substituting elements (Al) on homogenous nucleation of twins and its profound effect in the strain hardening behavior of defect-free pure magnesium using molecular dynamics. Simulation results reveal multiple $\{10\bar{1}2\}$ $\langle 10\bar{1}1\rangle$ twin nucleation under uniaxial tensile loading along [0001] direction. With an increase in Al content, the deformation mechanism changes and the twin nucleation was no longer observed with Al substitution contents greater than 8%. Consistent with the advanced fracture theory of Sleeswyk (1969), nanovoids nucleated in pure Mg due to twin-twin interactions. Finally, these results reveal complex mechanisms associated with solute-twin and twin-twin interactions and also provide a basis for new alloy design.

4:05 PM
Effect of Aging Treatment on Fatigue Behavior of an Al-Cu-Mg-Ag Alloy: *Micheal Burba*[1]; Michael Caton[2]; Sushant Jha[3]; Christopher Szczepanski[2]; [1]University of Dayton; [2]US Air Force Research Laboratory; [3]Universal Technology Corporation

An investigation of the fatigue properties of an Al-Cu-Mg-Ag alloy with two different heat treatments, underaged and peak-aged, was conducted. Particular focus was on the effect of these treatments on the lifetime distribution and the role played by crack initiation versus the small-crack growth regime. Tests were performed to characterize the distribution in fatigue lifetimes at a given stress level and the small-crack growth behavior under the two aging treatments. Results showed that there was almost no difference in mean lifetimes for either heat treatment but a significant difference in the minimum lifetimes, where the peak-aged condition had a higher propensity for life-limiting failure mechanisms. Further, the small-crack growth rates at room temperature were largely unaffected by the aging treatments. Based on this study, it is suggested that the under-aging treatment primarily influences the crack-initiation regime in terms of reducing the likelihood of developing a life-limiting deformation condition.

Spent Potlining: an Update: *Rudolf Pawlek*[1]; [1]TS+C

This paper continues a review given in 1999 and resumes practices to treat the waste of worn cathodes of the primary aluminium industry. The waste cathode lining consists of a carbon part and a refractory part. Spent potlining contains water-soluble fluorides and small amounts of leachable cyanides, and is therefore classified as hazardous.Besides inertization such as treatment at high temperatures, by vitrification, or by leaching and flotation the refractory component can also be used for instance in the manufacture of cement, concrete and brick, or as a road pavement additive, or as a potline electrolyte additive for the production of Al-Si pre-alloys.The carbon component can be used as a fuel additive in cement kilns but also as an additive in the pig iron and steel industry. Various ways to treat and use spent potlining have been published in the meantime and will be reviewed.

2:25 PM
Analysis of Porous Structures of Graphitic Cathode Materials and the Correlation to Penetrated Sodium: *Xiang Li*[1]; Jilai Xue[1]; Jun Zhu[1]; Qingcheng Zhang[1]; [1]Unversity of Science and Technology Beijing

Cathode materials used in aluminum reduction cell today are of porous structure. This work is aimed to have better control of the cathode quality through quantitatively analyzing the pore structure and its correlation to the penetrated sodium (metallic Na and NaF). The cathode samples were made of graphite aggregate and pitch, and formed with various pressures (12 - 36Mp). Image analysis was applied to characterize their porous structures. XRD and SEM-EDS were used to analyze the penetrated sodium. When the forming pressure was at 20Mp, the cathode density got to its maximum value (1.58 g/cm3) with the minimum total porosity (21.96%) and the least pore number (549). When the pore connectivity was from 9.81% up to 37.95%, the depth of sodium penetration was from 11mm to 39mm. The other porous structure parameters, such as total porosity, pore number and shape factor, showed little correlation to penetrated sodium.

2:50 PM
Characterization of Carbon Cathode Materials by X-Ray Microtomography: *Martin Brassard*[1]; Martin Lebeuf[1]; Alexandre Blais[2]; Loig Rivoaland[2]; Martin Désilets[1]; Gervais Soucy[1]; [1]Université de Sherbrooke; [2]Rio Tinto Alcan

The carbon cathode is the main component of the aluminium reduction cell. As it is the container for molten electrolytic bath and aluminum, it provides the electrical contact that is essential for electrolysis. Its properties are thus crucial. X-ray microtomography was used to compare different virgin cathode materials, as well as cathode materials that had been used in laboratory-scale aluminium reduction cells. Results demonstrated significant differences in terms of bath penetration, pore distribution and metallic inclusions. X-ray microtomography was shown to be a powerful tool for 3-D characterization of cathode materials.

3:15 PM
New Observations in Creep Behavior of Ramming Paste in Aluminium Electrolysis Cell: *Sakineh Orangi*[1]; Donald Picard[1]; Houshang Alamdari[1]; Donald Ziegler[2]; Mario Fafard[1]; [1]NSERC/Alcoa Industrial Research Chair MACE3 and Aluminium Research Centre-REGAL, Laval University; [2]Alcoa Canada

Creep of ramming paste was studied from ambient to operational temperature in order to characterize its mechanical behavior as used in the peripheral joint of aluminium electrolysis cells. Two types of uniaxial creep test over a specified stress level were performed on two inch samples: tests at room temperature for samples baked at different temperatures and test at temperatures close to the sample baking temperature. It is concluded that at certain baking temperatures and given stress level, three types of creep, called primary, secondary and tertiary, take place successively. In addition, at lower baking temperatures (200 °C), the creep level is larger in comparison with creep at higher baking temperatures. Also, for specified baking temperature, creep strain obtained by high temperature testing is larger than creep strain obtained by room temperature testing. These results give new insights on the ramming paste behaviour in aluminium electrolysis cell.

3:55 PM
Wetting of KF-AlF3-Based Melts on Graphite Cathode Materials for Aluminum Electrolysis: *Yanan Zhang*[1]; Jilai Xue[1]; Jun Zhu[1]; Xiang Li[1]; [1]University of Science and Technology Beijing

Graphite cathode materials are nowadays used in aluminum reduction process where KF-AlF3-based melts may serve as an alternative electrolyte. In this work, wetting angles of KF-AlF3-based melts on graphite cathode materials were measured using a modified sessile drop method. A fresh drop of the melt was injected through a BN tube on to the samples surface, and then the wetting angles were photographed against time elapsed. It was found that the wetting angles on the full graphitic and graphitized cathode samples were larger than those on the semi-graphitic at 750 oC, and their values changed with alumina content (3 – 5 wt%), cryolite ratio (1.2 – 1.5) and time elapsed (0 - 20 min). The melt penetration profiles on the cross-sections of the melt-graphite interface after wetting tests were also inspected using SEM-EDS technique. The results obtained can be useful for optimizing the properties and compositions of graphite cathode materials.

4:20 PM
Fundamentals of Aluminum Carbide Formation: *Bronislav Novak*[1]; Kati Tschöpe[1]; Arne Petter Ratvik[1]; Tor Grande[1]; [1]Norwegian University of Science and Technology

The fundamentals of formation of aluminum carbide were studied by aluminum-carbon diffusion couple experiment. The diffusion couples consisted of pure liquid aluminum and graphitized carbon, and the diffusion couple experiments were performed at temperatures 1000-

1200°C in stagnant argon atmosphere. In some experiments the diffusion couple interface was coated with small amount of cryolite. The formation of aluminum carbide layer at the solid-liquid interface was confirmed by X-ray diffraction and electron and optical microscopy. The kinetics of the formation of the carbide layer was investigated in detail and the influence of molten cryolite and possible gas phase transport will be discussed.

4:45 PM

Investigation of the Cathode Wear Mechanism in a Laboratory Test Cell: *Kati Tschöpe*[1]; Anne Støre[2]; Stein Rørvik[2]; Egil Skybakmoen[2]; Tor Grande[1]; Arne Ratvik[1]; [1]NTNU; [2]SINTEF Materials and Chemistry

Cathode wear has become one of the major challenges for the life time of high amperage aluminium reduction cells due to the use of graphitized cathodes. The fundamentals of the cathode wear are still a matter of debate, and a laboratory procedure for testing of cathode materials is desired. Here, we present a laboratory electrolysis cell designed to investigate the cathode wear of industrial cathode materials. The formation and transport of aluminum carbide is considered to be an important factor for the cathode wear, and the laboratory test cell is designed in such a way that the cathode is exposed directly against the electrolyte, and aluminum carbide formed at the cathode can then be more easily dissolved in the electrolyte. Here we present a study of cathode wear of selected cathode materials where the influence of the cathode surface morphology, diffusion and hydrodynamics in the electrolyte have been in focus.

5:10 PM

Study on Graphitization of Cathode Carbon Blocks for Aluminum Electrolysis: *Gao Feng*[1]; [1] Northeastern University

High quality graphite cathode carbon blocks require low resistivity, strong resistant erosion to melt salt and liquid aluminum in the aluminum electrolytic cells. It not only can decrease cathode voltage drop and reduce the powder consumption, and but also can improve service life of the cell. Applying hot mould technology under 40 MPa pressure, different amount petroleum coke in anthracite mixtures is graphitized in graphitized furnace. By the X-ray diffraction parameters, density, compressive strength and resistivity drop measured, the experimental results show that compressive strength and volume density of graphited containing 30% of petroleum coke block respectively are 1.366 g/cm3 and 4.8 MPa, resistivity drop from 114μO • m to 13μO • m, most confirms to the production requirements.

Ab-Initio Thermal Conductivity for Thermoelectric Nanostructured Materials: *Derek Stewart*[1]; Anupam Kundu[2]; Natalio Mingo[2]; Alistair Ward[3]; David Broido[3]; [1]Cornell University; [2]CEA-Grenoble; [3]Boston College

Manipulating the thermal properties of materials by embedding nanoparticles is a successful route to improve thermoelectric materials. The development of a first principles approach to predict thermal transport can help this effort by identifying potential material candidates and providing insight into nanoscale heat transfer. We present a new ab-initio approach for predicting thermal conductivity in bulk and nanoscale materials. Harmonic and anharmonic interatomic force constants are calculated from density functional perturbation theory and used to solve the phonon Boltzmann transport equation exactly. We find excellent agreement with experiments for technological materials (Si, Ge, and diamond). We can also examine thermal transport in materials with nanoinclusions, such as nanoparticle embedded in alloy thermoelectrics (NEAT) materials. I will discuss how nanoparticle composition and size can significantly affect thermal conductivity in SiGe alloys. Linking these force constants with a Green's function approach, we can also manipulate thermal transport in nanotubes and graphene.

2:25 PM

Characterization of Nanostructured Thermoelectric Materials Using Electron Backscattered Diffraction: *Matt Nowell*[1]; [1]EDAX-TSL

Recent trends in thermoelectric materials development are directed towards using nanostructural engineering to reduce thermal conductivity and improve material performance. Understanding how to optimize this engineering requires structural characterization on a nanometer scale. In this work, Electron Backscatter Diffraction (EBSD) has been used to characterize nanostructured Bi2Te3 precursor powders and consolidated bulk samples. A variety of consolidation processes have been used and the resulting structures characterized and compared. The effects of the spatial resolution limits of EBSD as a function of both sample and analytical data acquisition conditions will also be addressed. For this work, grains as small as 20nm have been resolved. Comparisons with other characterization techniques will also be discussed.

2:50 PM

Study to Bi2Te3-Based Thermoelectric Nanocomposite Added Silver Nanoparticles by Metal-Organic Decomposition: *Hsin-Hsien Yeh*[1]; Chiung-Hsiung Chen[2]; Hong-Ching Lin[2]; Ming-Wei Lai[2]; Chien-Neng Liao[1]; [1]National Tsing Hua University; [2]ITRI

Bulk nanostructure is one of methods to enhance the figure of merit of thermoelectric materials. In this study, nano-silver particles were dispersed well at the grain boundary by metal organic decomposition (MOD) to improve the characteristics of bulk nanocomposite of bismuth telluride. The Bi_2Te_3 powders were milled with the solution of silver salts and dehydrated alcohol by the planetary miller then formed the bulk by spark plasma sintering (SPS) process. The bulk materials were cut into rectangular bars (3x2x6 mm^3) for measuring electrical conductivity and Seebeck coefficient by commercial equipment of ULVAC model ZEM-3. The microstructure of the modified powders and the bulk materials were examined using field emission scanning electron microscopy and high-resolution transmission electron microscopy. The compositions were analyzed by energy-dispersive x-ray spectroscopy.

3:15 PM

Enhanced Performances of Micro-Thermoelectric Devices Integrating Layered A2Te3 (A= Sb, Bi) Films: *Tanming Tan*[1]; [1]Beihang University

Herein, an approach for the fabrication of devices integrating the layered Sb2Te3 and Bi2Te3 thin films with ordered structures was reported by radio-frequency (RF) magnetron sputtering method. The composition and microstructure of the films were studied by X-ray diffraction (XRD), scanning electron microscopy (SEM), and energy dispersive X-ray spectrum (EDS), presenting a well preferential crystal growth along the planes perpendicular to the c-axis. The thermoelectric properties of the layered thin films were characterized. The power generation and the cooling of the two types of micro devices with n and p elements in series or parallel circuit, respectively, have been tested. The results have proved that high-performance micro devices could be realized by introducing the layered Sb2Te3 and Bi2Te3 thin films with ordered structure.

Thermal Transport in Nanomaterials for Energy Applications: *Xinwei Wang*[1]; [1]Iowa State University

Nanomaterials have attracted significant attention for their great applications related to energies. Examples include nanostructured thermoelectric materials for significant efficiency improvement, and nanofibers/wires for photo-voltaic applications. Thermal transport capability of nanomaterials plays a critical role for energy conversion efficiency and sustained device functionality. In this talk, I will give a review on the experimental and theoretical work we have done/are doing about the thermal transport in nanoscale/structured energy materials. For experimental investigations, our research focuses on development of advanced technologies to characterize thermophysical properties of nanomaterials. Examples will be given about the study on anatase TiO2 nanofibers and their secondary porosity, thermal contact resistance between TiO2 nanotubes, and the thermal transport in carbon related nanomaterials. The theoretical work will be focused on the structure and localized thermal transport in coherent thermoelectric materials, ballistic and non-Fourier thermal transport in graphene nano-ribbon, and coherent phonon dynamics in materials.

4:30 PM
Effects of Surface Faceting and Twinning on Thermal Transport Characteristics of Silicon Nanowires: *Frederic Sansoz*[1]; [1]University of Vermont

Precise control over phonon transport in nanowires is critical to the development of next-generation thermoelectric devices in semiconductors. This talk particularly examines the impact of surface morphology and twinning on thermal conductivity in crystalline Si nanowires, with particular emphasis on circular, hexagonal and sawtooth-faceted shapes, by using non-equilibrium molecular dynamics simulations. From this study, 47% reduction of thermal conductivity is found in sawtooth-faceted {111}/{100} Si nanowires compared to nanowires of equivalent diameter with smooth sidewalls. This effect is shown to result from a strong dispersion of surface phonons in {100}-type facets. However, the simulations reveal that phonon dispersion is less pronounced with {113}-type facets and absent with {111}-type facets, which suggests a new means to control phonon dynamics at the nanoscale. Also I show that some anomalous thermal transport characteristics exist in periodically-twinned Si nanowires due to this unique faceting dependence on phonon modes.

4:55 PM
Mechanical and Thermal Energy Transport in Biological and Biologically Inspired Nanostructures: *Markus Buehler*[1]; [1]Massachusetts Institute of Technology

We present molecular-based computational studies of mechanical and thermal energy transport in biological and biologically inspired nanostructures. A series of studies will be presented, including energy transport in carbon nanotubes and interfaces of graphite, graphene and carbon nanotubes with other materials (e.g. metals), protein materials (e.g. beta-sheet nanocrystals and amyloids), as well as polymers. The concept of thermomutability will be introduced, a mechanism by which the energy transport of materials is controlled by external cues such as mechanical strain. We present a case study that demonstrates how hierarchical structures of carbon nanotubes, based on biological designs of mass and energy transport in cells and tissues, can be used to achieve a superior level of material performance for applications in thermal management and energy harvesting.

Energy Technologies and Carbon Dioxide Management: CO2 Management and Utilization

2:00 PM Introductory Comments

2:05 PM Keynote
Meeting the Materials Challenges to Enable Clean Coal Technologies: *Bryan Morreale*[1]; Cynthia Powell[1]; [1]US DOE National Energy Technology Laboratory

Realization that the environmental impact of energy production must be reduced on a global scale, combined with an increased national desire to reduce dependence on foreign energy, is driving significant change in the energy outlook of the United States. While renewable energy resources will continue to grow in importance, environmentally responsible fossil energy production will be necessary to provide a bridge to the next energy revolution. This drive to increase process efficiencies and reduce the environmental impact in fossil-based energy production will require processes with increased operating temperatures and pressures, and increasingly aggressive operating environments. The practical result is a requirement for affordable and reliable high-performance materials and materials systems to enable these next-generation fossil energy systems. This talk will focus on the research being performed within the National Energy Technology Laboratory's Office of Research & Development to meet this requirement for high performance yet affordable materials.

2:25 PM Keynote
Liquid Fuels from CO2, Water, and Solar Energy: *Aldo Steinfeld*[1]; [1]ETH Zurich

Solar thermochemical processes for the production of synthetic liquid fuels make use of concentrated solar radiation as the energy source of high-temperature process heat. Considered are H2O/CO2-splitting thermochemical cycles via metal oxide redox reactions, encompassing two steps: 1st step)a solar-driven endothermic reduction of the metal oxide into a metal or reduced-valence metal oxide and O2 evolution, and; 2nd step) an exothermic reaction of the reduced metal/metal oxide with H2O/CO2 which yields H2/CO, together with the initial form of the metal oxide; the latter is recycled to the first step. The syngas mixture H2/CO can be further processed via Fischer-Tropsch and other catalytic processes to liquid hydrocarbon fuels. ZnO and CeO2 based redox pairs have emerged as highly attractive because of their rapid fuel production kinetics, cyclability, and high selectivity. The solar tower technology is presented.

2:45 PM
Solar Activated Photocatalytic Conversion of CO2 and Water to Fuels by TiO2-Based Nanocomposites: Qianyi Zhang[1]; Lianjun Liu[1]; *Ying Li*[1]; [1]University of Wisconsin-Milwaukee

Photocatalytic conversion of CO2 and water to value-added products (CO, methane, and/or methanol) by sunlight is potentially a promising sustainable energy technology that not only reduces greenhouse gas emissions but also produces renewable fuels. However, the low CO2-to-fuel conversion efficiency has impeded the development of this technology. TiO2 has been widely used as a photocatalyst due to its low cost, high stability, and environmental benignness. In this work, material innovations have been made to TiO2 nanostructures to improve the CO2 conversion efficiency by increasing the surface area, inhibiting photoinduced electron-hole recombination, and enhancing visible light utilization. The catalysts are well characterized by UV-vis, XRD, SEM, TEM, XPS, and BET analysis. The experiments of photocatalytic CO2 reduction with water vapor are conducted under visible light, UV-visible, and simulated sunlight, respectively. The product yield and selectivity are correlated with the nanostructures and the reaction mechanisms are proposed.

3:00 PM

Photocatalytic Efficacy of 1-Dimensional Nanocomposite Electrode: *Bo Ding*[1]; Jung-Kun Lee[1]; [1]University of Pittsburgh

The photocatalytic splitting of water into H2 and O2 by oxide nanoparticles has received much attention. However, the full potential of photo-catalysts for efficient hydrogen generation out of water has not been fully realized yet due to unresolved limitations including the low electrical conductivity and ineffective carrier extraction. In this presentation, we report composite oxide materials consisting of 1-dimensional (1-D) transparent conducting oxide (TCO) core and TiO2 shell. The TCO core is first synthesized by vapor-liquid-solid growth technique and the TiO2 layer is subsequently deposited through atomic layer deposition. The photoelectrodes consisting of these 1-D nanocomposites have increased carrier mobility due to the TCO core, while the TiO2 shell provides the photocatalytic functionalities. In addition, the built-in-potential at the interface between TCO core and the TiO2 shell improves the collection of charge carriers from TiO2 to TCO. These factors altogether contribute to increasing the photocurrent of the device under light.

3:15 PM

Electro-Catalytic Conversion of Carbon Dioxide into Hydrocarbon Fuels: A Theoretical Study of Selectivity and Efficiency of Copper Catalysis: *Tao Liang*[1]; Yu-Ting Cheng[1]; Simon Phillpot[1]; Susan Sinnott[1]; [1]University of Florida

Electrocatalytic reduction of carbon dioxide into fuels would provide an ideal storage medium for intermittent renewable energy sources. Copper electrocatalysts have been found to be capable of producing significant quantities of hydrocarbons such as methane and ethylene from CO2. Despite extensive studies on electro-reduction of CO2 at metal electrodes, the mechanisms associated with catalytic reactions on Cu electrodes have remained elusive. Here, we use third-generation charge optimized many body (COMB3) potentials to determine the reaction free energy and atomic scale mechanisms associated with electrocatalytic reactions on Cu surfaces and clusters supported on metal oxide surfaces. The influence of system conditions on the results is quantified.

3:35 PM

Reduction of Energy Consumption and GHGs Emission in Investment Casting Process by Application of a New Casting Method: *Xiaojun Dai*[1]; Mark Jolly[1]; Binxu Zeng[1]; [1]University of Birmingham

In traditional investment casting process of aluminium alloys for the application of the aerospace industry, to assure the quality of the final casting, usually the foundry uses bulky runner system which results in low yield, high energy consumption and high GHGs emission. In one case of this investigation, the yield is between 5 ~ 10% which means that the current casting process wastes large amount of energy and generates lots of scraps. By applying a new casting method, the bulky runner system and the melting/holding time are greatly reduced, the quality of the casting is improved, and in the meantime the related energy consumption and emission of CO2 are significantly decreased. In the investigation, the energy efficiencies and emission of CO2 of between the current and traditional processes are calculated and compared.

3:50 PM

Bauxite Residue Neutralization and Carbon Sequestration from Flue Gas: *Luis Venancio*[1]; Emanuel Macedo[2]; José Antonio Souza[2]; Fernando Botelho[2]; Otacílio Dias[2]; [1]Federal University of Para ; [2]Federal University of Para

The production of alumina from bauxite using the Bayer process generates 0.7 to 2.0 ton of the residue known as red mud and about 800 kg of CO2 per ton of alumina. The direct use of exhaust gases to react and neutralize the bauxite residue may allow a double gain: open a wide range of new applications for bauxite residue reducing its reactivity and sequester from 38 to 107 kg of CO2 per ton of alumina. This paper shows a pilot scale reaction of a suspension of bauxite residue-water with flue gas produced from direct burning oil, similar to the exhaust gases of a refinery. Two different types of reactors are used, a spray tower and a packed column. The inlet and exhaust gases are analyzed using electrochemical cells and non-dispersive infrared sensors. The pH of the suspension is monitored during the reaction and after to evaluate the buffer effect.

4:05 PM

50% Reduction of Energy and CO2 Emission in Metallurgical Furnaces by Burners: *Michael Potesser*[1]; Davor Spoljaric[1]; Burkhardt Holleis[1]; Martin Demuth[1]; [1]Messer Group

The efficiency of industrial combustion processes can be raised in two ways, either by preheating the fuel and combustion air or by oxyfuel. The most important issue of the usage of oxygen burners is the substantially increasing melting rate by lowering the specific production costs because of the higher combustion efficiency. The flameless combustion (internal offgas recirculation) and the external offgas recirculation solves the problem with the high flame temperature and leads to cold combustion and lower dross formation or alloying elements combustion. The Oxipyr®-Air combines the technology of diluted combustion during air and oxygen usage decreasing the emission of pollutants. Constitutive of the Oxipyr®-Air development a fuel-oxygen-burner, Oxipyr®-Flex, was designed for a maximum of flexibility for the customer. The Oxipyr®-Air and Oxipyr®-Flex have been developed for the specific needs of melting and recycling companies for all non ferrous metals. The paper shows the theory, practical installations and economical outlook

4:20 PM

CO2 Removal from Industrial Off-Gas Streams by Fluidized Bed Carbonation: *Koulis Pericleous*[1]; Mazaher Molaei[2]; Mayur Patel[2]; [1]University of Greenwich; [2]University of Greenwich

The future trading of carbon credits and increased financial cost necessitates substantial cuts in incidental CO2 emissions in the production of metals (iron, steel, aluminum, zinc, lead). Although greener methods of production are being developed, in the short term the use of point-source CO2 extraction using existing technology remains attractive. Accelerated natural carbonation, in a fluidized bed is a feasible technological route investigated in this research. CFD modelling has been used to study the efficiency of CO2 capture in a fluidized bed reactor containing a CaO solid sorbent. A Lagrangian/Eulerian scheme describes describe CaO particle trajectories and exchange of mass, momentum and energy with the carrier gas, with a typical off-gas composition. Different reactor geometries are considered (with uniform, stepped and gradually expanding cross-section), to maximize conversion for a given particle loading and size distribution (100-200 microns). Removal efficiencies of up to 80% are demonstrated, making this a viable process.

4:35 PM

A Hydro-Mechanical Model and Analytical Solutions for Geomechanical Modeling of Carbon Dioxide Geological Sequestration: *Zhijie Xu*[1]; Yilin Fang[1]; Timothy Scheibe[1]; Alain Bonneville[1]; [1]Pacific Northwest National Laboratory (PNNL)

We present a hydro-mechanical model and deformation analysis for geological sequestration of carbon dioxide. The model considers the poroelastic effects by taking into account the two-way coupling between the geomechanical response and the fluid flow process in greater detail.

In order for analytical solutions, the simplified hydro-mechanical model includes the geomechanical part that relies on the theory of linear elasticity, while the fluid flow is based on the single-phase Darcy's law. The model was derived through coupling the two parts using the standard linear poroelasticity theory. Analytical solutions for fluid pressure field were obtained for a typical geological sequestration scenario and the solutions for ground deformation were obtained using the method of Green's function. Solutions predict the temporal and spatial variation of fluid pressure, the effect of permeability and elastic modulus on the fluid pressure, the ground surface uplift, and the radial deformation during the entire injection period.

Fatigue and Corrosion Damage in Metallic Materials: Fundamentals, Modeling and Prevention: Materials Corrosion and Prevention

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee

Program Organizers: Tongguang Zhai, University of Kentucky; Zhengdong Long, Kaiser Aluminum; Peter Liaw, University of Tennessee

Characterization of Constituent Particles in 7075-T6 Aluminum Alloy: *D Gary Harlow*[1]; [1]Lehigh University

Corrosion in aluminum alloys results from local galvanic coupling between constituent particles and the metal matrix. Since pitting is caused by particles, proper statistical characterization of the geometrical aspects of the particles is critical to the modeling. One of the more important statistics is the particle size distribution. Extensive optical microscopic observations on common 7075-T6 aluminum alloy have resulted in rather large sets of data for particle geometry. Thus, accurate statistical modeling is possible. Furthermore, similar data have also been collected from teardown specimens taken from seven different outer wing panels constructed from 7075-T6 aluminum alloy. The purpose of this effort is to use advanced multimodal statistical modeling methods to appropriately characterize the geometrical properties of constituent particles in these specimens. Comparisons between the teardown specimens and the common alloy are made. Suggestions for use in corrosion modeling are also presented.

2:20 PM Invited
Effect of Hydrogen on the Localized Corrosion of Stainless Steels: *Lijie Qiao*[1]; [1]University of Science and Technology Beijing

Hydrogen enhances nucleation of micro-cracks, increases propagation rates of stress-corrosion cracks, and reduces the threshold stress in stainless steel. Hydrogen decreases corrosion and pitting potentials, and increases passivation current of 2507 duplex stainless steels in 0.5mol/LH2SO4+3%NaCl solution. Both hydrogen and Cl- decrease linearly corrosion and pitting potentials, and increase the passivation current of carbon steel in boric acid buffer solution. Study of Scanning Kelvin probe force microscopy shows that many lower potential regions appear in the ferrite and the interface of ferrite and austenite after hydrogen charging. The region means the hydrogen clusters pitting location.

2:40 PM Invited
Water-Induced Damage of Subsurface Layer in AA 2037 Al Alloy Probed by a Slow Positron Beam: *Yichu Wu*[1]; Peihai Li[1]; Tongguang Zhai[2]; Paul Coleman[3]; [1]Wuhan University; [2]University of Kentucky; [3]University of Bath

Water-induced damage in AA2037 Al-Cu alloys processed by two different thermomechanical conditions was measured with positron beam-based Doppler broadening spectroscopy, in combination with XRD, AFM and TEM. Defect profiles in depth in the alloys were analyzed by measuring the S parameter as a function of incident positron energy up to 30 keV. It was found that, when the samples with more T (Al20Cu2Mn3) phases were immersed in the deionized water up to 20 days, a small decrease in the S parameter near the surface was observed, which did not change with immersion time. However, a significant decrease in S parameter,depending on immersion time, was observed in the samples with less T phase. This indicated that the AA2037 Al alloy with more T phase presented more stable surface oxide film and better resistance to water damage than the alloy with less T phase.

3:00 PM
Investigation on Corrosion Behavior of Ni-Based Alloys in Molten Fluoride Salt Using Synchrotron Radiation Technique: *Min Liu*[1]; Yanling Lu[1]; Yanyan Jia[1]; Junyi Zheng[1]; Zhijun Li[1]; Yang Zou[1]; Xiaohan Yu[1]; Xingtai Zhou[1]; [1]Shanghai Institute of Applied Physics, Chinese Academy of Sciences

Due to perfect corrosion resistance and excellent mechanical properties, Ni-based high temperature alloys are widely used in nuclear reactor. In this paper, corrosion processes of Ni-based superalloys including Inconel 600, Hastelloy X and Hastelloy C-276 were investigated in molten fluoride salts (LiNaKF) at 750°C. Then the samples were analyzed using scanning electron microscope (SEM), X-ray fluorescence analysis (μ-XRF) and X-ray diffraction (XRD). μ-XRF results have shown that the Ni-based alloy corrosion behavior in molten fluoride salt is mainly due to the erosion of element Cr. XRD results indicate that the alloying element Mo of Hastelloy c-276 have formed the Mo2C structure, which can enhance anti-corrosive performance of Ni-based alloy in molten fluoride salt. Among the three Ni-based alloys mentioned in this paper, Hastelloy C-276 has the best corrosion resistance in molten fluoride salts at 750°C.

3:20 PM
Electrochemical Measurement Methods for Evaluation of the Effects of Hydrogen on the Mechanical Properties of Metals: *Richard Ricker*[1]; [1]NIST

Electrochemistry makes available to investigators a number of promising tools and measurement methods for investigating the influence of hydrogen on the mechanical properties of metals and alloys. Experiments ranging from simple cathodic charging experiments to the measurement of the response to transients, periodic waveforms, and noise can be used to investigate the interactions that can lead to the absorption, diffusion, and embrittlement of metals and alloys. Experiments can be designed to answer fundamental questions about the effects of cyclic loading and metallurgical variables. This paper will review work at NIST investigating and comparing different electrochemical techniques for investigating hydrogen embrittlement including electrochemical permeation, absorption, repassivation transients, and optimization of cathodic charging conditions.

3:40 PM Break

3:45 PM
Evaluation of Residual Stresses by Sen ^{2} ø Method and Its Relationship with the Corrosion Resistance of ER NiCrMo-4 Weld Overlays on C-Mn Steel Pipelines: Raphael Henrique de Melo[1]; *Theophilo Maciel*[1]; Marcos da Silva[1]; Valmir Batista[1]; Marcos Antonio dos Santos[1]; [1]Federal University of Campina Grande)

The aim of this study was to evaluate the influence of nozzle-to-plate distance (stickout) on the dilution and geometric characteristics (penetration, reinforcement, and width) of the overlays, as well to verify the influence of the Fe content and level of residual stresses by X- ray diffraction, on its corrosion resistance. The increase of the stickout promoted a reduction of approximately 9% in the dilution of the overlays, thus reducing the Fe content in the surface. The residual stresses presented predominantly compressive and It had been noted that for same levels of residual stress the corrosion resistance is directly influenced by the Fe content, however, when the level of residual stresses becomes sufficiently dissimilar, the Fe content starts to be less meaningful. In addition, it was found that the less the level of the compressive residual stresses, lower will be the corrosion resistance.

4:05 PM
Influence of Non-Metallic Inclusions on Pitting Corrosion Resistance of Cr-Ni-Mn Austenitic Stainless Steel: Alexander Ramirez[1]; *Adriana Murcia Santanilla*[1]; Neusa Alonso-Falleiros[1]; [1]University of São Paulo

The aim of this work is to evaluate the influence of non-metallic inclusions on the pitting corrosion resistance of the Cr-Ni-Mn austenitic stainless steel in presence of chloride and bromide ions. The pitting potential (Ep) was determined by potenciodynamic polarization method in electrolytes containing 0.6M NaCl, 0.45M NaCl+0.15M NaBr, 0.3M NaCl+0.3M NaBr and 0.6M NaBr. The results showed that when this steel was tested using the 0.6M NaBr and 0.3M NaCl+0.3M NaBr, the pitting potential was almost constant, but, when it was tested in the electrolytes containing, 0.45M NaCl+0.15M NaBr and 0.6M NaCl the pitting potential decreased with increasing of chloride content into electrolyte. In this work was evaluated the influence of non-metallic inclusions as pit nucleation sites. There were found some non-metallic inclusions attacked by aggressive ions, such as: aluminum oxide and both silicon and aluminum oxide.

4:25 PM
A Study on the Effect of Applied Potentials on Tress Corrosion Cracking of X70 Pipeline Steel in High pH CarbonateBicarbonate by EIS: *Ayda Shahriari*[1]; Taghi Shahrabi[1]; Aliakbar Oskuie[1]; [1]Tarbiat Modares University

Stress corrosion cracking (SCC) behavior of X70 pipeline steel in high pH carbonatebicarbonate solution at different applied potentials was investigated using slow strain rate testing (SSRT). Electrochemical impedance spectroscopy (EIS) has been used to detect stress corrosion cracking in X70 pipeline steel sample exposed to high pH carbonatebicarbonate solution at different applied potentials. Morphology of X70 pipeline steel fracture surfaces at different applied potentials were also observed by scanning electron microscope (SEM). The results suggest that X70 pipeline steel is susceptible to SCC in a narrow window of potential. EIS measurements showed that a phase shift of impedance at particular frequencies is related to the length of a stress corrosion crack.

4:45 PM
Comparative Study of the Influence of Welding Parameters on the Characteristics of Stainless Steel Weld Overlays Applied by FCAW and SAW Process: Raphael Henrique de Melo[1]; *Theophilo Maciel*[1]; [1]Federal University of Campina Grande)

Welding is the main manufacturing process used not only in the assembly and repair of pipes, but for application of coatings for corrosion protection. The geometric shape of the weld overlays is directly affected by the process parameters being an indicative of the quality of the coatings. In this paper the modeling, analysis and optimization of the characteristics of stainless steel weld overlays deposited by SAW and FCAW welding processes were made. The experiments were conducted based on the technique of design of experiments with three factors at two levels of control and mathematical models were developed through multiple regression. Response parameters and the influence of welding parameters was discussed, the models provide parameters to optimize economically the process through the optimal geometry and deposition efficiency. The results showed that less voltage values and greater feed rate less will be the dilution with significative reflection on corrosion resistance

5:05 PM
Effect of Conversion Coatings on SCC Behavior of Pipeline Steels: *Aliakbar Oskuie*[1]; Taghi Shahrabi[1]; [1]Tarbiat Modares University

In this study the effect of application of conversion coatings on SCC behavior of API X70 pipeline steels in high pH carbonate-bicarbonate solution was investigated. Zinc phosphating and chromating were two conversion coatings were used to modify the surface of pipeline steels. The mechanical properties of the samples coated by these two methods were determined by slow strain rate tests (SSRT). These results were compared with mechanical properties of the sample tested in air. Tensile tests were conducted at 50oC. To monitor crack growth, electrochemical impedance tests were carried out at fixed durations along the tests. Stereo and scanning electron microscopy were used for fractography as well.

Federal Funding Workshop: Panel Discussion

2:05 PM Keynote
Fracture Mechanics by 3D Crack-Tip Microscopy: *Philip Withers*[1]; [1]University of Manchester

Prof. Ritchie has made a major contribution clarifying the crack-tip driving force in terms of intrinsic damage occurring ahead of a growing crack, and the extrinsic shielding mechanisms behind it. Increasingly, materials are designed at the microscale, or even the nanoscale, for improved resistance to sub-critical crack growth. Traditional global macroscopic approaches are insufficient. To progress, we need a means of extracting quantitative information about the local crack-tip environment. This paper will describe the concept of a 3D 'crack-tip x-ray microscope', by combining diffraction and imaging modes, as in an electron microscope. Critically, unlike an electron microscope we can follow the crack-tip deep in engineering samples under realistic conditions. Synchrotron x-ray diffraction is used to map crack-tip stresses, hence the operative stress shielding micromechanisms that slow cracks and 3D x-ray tomography to image the damage accumulation that contribute to crack growth and crack closure and deflection that impede it.

2:45 PM
Fracture Behavior of Tungsten: *Bernd Gludovatz*[1]; Stefan Wurster[2]; Andreas Hoffmann[3]; Reinhard Pippan[2]; [1]Lawrence Berkeley National Laboratory; [2]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences; [3]Plansee SE

Tungsten shows the typical change in fracture behavior from brittle at low temperature to ductile at high temperatures, however, the brittle fracture behavior of the material is not well understood yet. Crack propagation occurs either intergranularly or transgranularly and parameters like grain size and shape as well as texture, chemical composition and grain boundary impurities are amongst the main influences controlling the crack path. In order to analyze some of these parameters different microstructures were produced by high pressure torsion (HPT) and analyzed using techniques like Auger electron spectroscopy (AES) or electron backscatter diffraction (EBSD). AES revealed a limited influence of impurities on the crack path below a certain impurity concentration. Investigations on the crack propagation resistance showed an increasing fracture resistance with crack extension, so-called R-curve behavior. EBSD analyses revealed that this is mainly caused by crack bridging and increasing plasticity around the propagating crack with increasing temperature.

3:00 PM
Grain Boundary Cracking in Sn-Rich Pb-free Solders: *J. Shang*[1]; [1]University of Illinois

Health and environmental concerns over Pb have prompted the recent transition from Pb-bearing to Pb-free solders in microelectronic industry. Among many Pb-free solder alloys, the Sn-rich alloys have emerged as the primary replacement alloys. Our recent work has shown that Sn and Sn-rich alloys are very susceptible to grain boundary cracking under mechanical and electrical loading. While the classical grain boundary fracture mechanisms prevailed under mechanical loading, the divergence of vacancy concentration at the grain boundary induced grain tilting, rotation, sliding, and finally grain boundary cracking. Under cyclic loading, an intergranular cracking model was developed for cycle-dependent softening of Pb-free solders. The model was applied to explain the dependence of cyclic response to grain size, strain amplitude, and temperature in Sn-rich solder alloys.

3:15 PM
Tensile Deformation of Quenched and Partitioned Steel - A Third Generation High Strength Steel: Jason Coryell[1]; *Josh Campbell*[2]; Vesna Savic[1]; John Bradley[2]; Sushil Mishra[1]; Shashank Tiwari[1]; Louis Hector Jr[2]; [1]General Motors; [2]GM R&D Center

Quenching and partitioning (Q&P) is a steel heat treatment process that promotes carbon enrichment of retained austenite thereby enhancing ductility without substantially compromising strength. Deformation and fracture of Q&P steel, a new third generation advanced high strength steel, was investigated in quasi-static tensile tests ranging from -100 °C to 200°C. Strain fields of specimens tested at 25°C were measured with digital image correlation (DIC) using a stereo system, while standard tests with an extensometer were conducted at the other temperatures. The data were used to determine how the measured strength and ductility of Q&P steel compare with other advanced high strength steels such as TRIP (transformation induced plasticity) and TWIP (twinning induced plasticity). The temperature effect on the yield stress, ultimate tensile strength, and strain at uniform elongation was explored in detail. This provided insight into the austenite to martensite phase transformation at higher temperatures.

The Influence of Microstructure and Texture on Strain Localization in Thin Stainless Steel Sheet: Eric Buchovecky[1]; *Louis Hector Jr*[2]; Siguang Xu[2]; John Bradley[2]; Sushil Mishra[2]; Allan Bower[1]; [1]Brown University; [2]General Motors

Crystal plasticity finite element (CPFE) simulations are used to identify controllable material properties (e.g. distributions of grain size, grain shape, crystal orientation) that inhibit or enhance thinning instabilities in 75-90 μm thick ferritic stainless steel sheet. The CPFE material model is calibrated against a suite of oriented uniaxial tensile tests. Statistical measures of grain morphology and orientation from electron backscattered diffraction (EBSD) analyses are used to generate multiple FE meshes with grain morphologies and crystal textures that are statistically-equivalent to those of the actual material. Necking and failure in CPFE simulations of uniaxial tension and a simple plane strain forming process are correlated with statistical measures of texture and microstructure from EBSD.

Microscale Testing of Fracture Toughness in Graded Pt-Ni-Al Bond Coats on Superalloys: Jaya Nagamani[1]; *Vikram Jayaram*[1]; Sanjay Biswas[1]; [1]Indian Institute of Science

Diffusion bond coats that confer oxidation resistance to superalloys in aeroengines are typically produced by pack aluminising. The failure of the resultant graded microstructure is driven by a combination of stresses from thermal gradients, oxidation, centrifugal loading and particle impact. In order to understand failure modes and to develop design criteria, it is critical to understand the fracture process in different regions of the coating. We use FIB to machine beams from different positions across the coating and subjecting them to fracture in a depth sensing indenter. Because the ends of the beam are not free to move as in conventional 3-point bending, finite element analysis is used to validate the experimentally observed load-displacement response . The toughness, averaged from several beams at each of four locations reveals variations from as low as 5 to 20 MPa root m which can be correlated to microchemistry from SEM-EDS.

4:15 PM

Deformation Response of Cold-Drawn and Annealed MP35N Wire: *M.J.N.V. Prasad*[1]; Sharvan Kumar[1]; [1]Brown University

The alloy, MP35N (35%Co-35%Ni-20%Cr-10%Mo) is used in implants, especially as lead wires in pacemakers, because of its ultra-high strength and excellent corrosion resistance. In this study, low-Ti, MP35N alloy wire, 100 μm in diameter, was characterized both in the as-drawn and annealed conditions. In the as-drawn condition, numerous cold-drawing-induced nanotwins were observed; when deformed in this condition in uniaxial tension at room temperature, high strengths up to 2 GPa, limited ductility of 3 percent and strain rate sensitivity were noted. In contrast, the recrystallized wire (annealed) displayed improved ductility (~30%) and reduced strength (~0.6 GPa). The deformed microstructure is being characterized by bright field and dark field transmission electron microscopy as well as HRTEM. In the as-drawn condition, plastic deformation is enabled by both slip and twinning/de-twinning. Characterization of the annealed material is in progress. These results will be presented and the underlying deformation mechanisms will be discussed.

4:30 PM

Mechanical Behavior of Copper Single Crystal in the Presence of Point Defects: *Iman Salehinia*[1]; David Bahr[1]; [1]WSU

Structural defects affect both the nucleation and propagation of dislocations. Atomistic simulations of nanoindentation tests were used to explore the stochastic response of dislocation nucleation in copper in the presence of vacancies, solute atoms and self-interstitial atoms. Because of non-uniform and highly concentrated stress filed under the indenter, a spatial variation in defects varies the mechanical response even in a small simulation box, allowing stochastic behavior to be examined. The simulations exhibited maximum yield stress reductions of 8% and 20% in the presence of a vacancy and a self-interstitial atom, respectively. The distribution of Al solute atoms was used to demonstrate both concentration and distribution play role on altering the measured yield stress during nanoindentation. Since the shear stresses around a crack tip and an indenter are similarly high, the effect of these defects when positioned near a crack tip was also explored using tensile tests.

4:45 PM

Effect of Grain Boundary Character on Strain Localization and Grain Boundary Sliding during Creep Deformation of Nickel-Bases Superalloys: *Jennifer Carter*[1]; Michael Uchic[2]; Michael Mills[1]; [1]The Ohio State University; [2]Air Force Research Laboratory, Materials & Manufacturing Directorate

This work details how deformation localizes at grain boundaries in nickel-based superalloys using a novel in-situ digital image correlation technique to create full-field deformation maps. In-situ experiments at 700°C were conducted while periodically acquiring SEM images. Full-field deformation maps of localized behavior (including grain boundary sliding events) are correlated with microstructural features, such as grain boundary character and grain orientation as determined from EBSD mapping. Subsequent analysis of the displacement fields from image correlation with the EBSD maps allows for assessment of the direct relationship between strain localization and microstructural features. Site specific extraction of TEM foils and serial sections using the FIB are conducted at grain boundaries exhibiting large strain localization due to accumulation or grain boundary sliding. This allows for additional correlations between micro-scale 2-D strain data with underlying dislocation activity and 3-D nano-scale microstructural features, such as boundary topology; including nano-scale serrations and grain boundary borides.

5:00 PM

Comparison of Deformation Mechanisms for Constant Strain Rate and Creep Testing of a Ni-Based Superalloy: *Hallee Deutchman*[1]; Michael Mills[1]; [1]The Ohio State University

The effect of strain rate on deformation mechanisms was investigated under creep and constant strain rate conditions on an advanced, polycrystalline Ni-based disk superalloy. A detailed microstructure characterization aimed at measuring the gamma-prime precipitate size, morphology, and distribution was performed prior to mechanical testing experiments so that the effects of microstructure can be correlated with the deformation response. Constant load creep tests and constant strain rate tests were performed at the same temperature so that the influence of strain rate on deformation substructure can be assessed. Following mechanical testing, a thorough TEM characterization study was done to determine the operative deformation mechanisms. Significant differences have been observed with dislocation-mediated mechanisms at higher strain rates and microtwinning and faulting of precipitates at low strain rates. Funding for this work has been provided by AFRL through the Metals Affordability Initiative (MAI) program.

International Smelting Technology Symposium (Incorporating the 6th Advances in Sulfide Smelting Symposium): Pyrometallurgical Process Modeling, Control & Instrumentation

Sponsored by: The Minerals, Metals and Materials Society, The Metallurgy and Materials Society of CIM, TMS Extraction and Processing Division, TMS: Pyrometallurgy Committee
Program Organizers: Jerome Downey, Montana Tech of the Univ of Montana; Thomas Battle, Midrex Technologies, Inc.; Jesse White, Elkem Solar Research

2:00 PM

Comparison of Classical Tools and Modern Finite Element Modeling in the Electrical Design of Slag Resistance Furnaces: *Mark Kennedy*[1]; Melina Garcia[2]; Finn Olesen[3]; [1]Norwegian University of Science and Technology; [2]Elkem AS; [3]Elkem Bjølvefossen AS

Furnace resistance is a function of the complex interrelationship between many factors including: operating practice, slag conductivity, temperature, power intensity, and geometry (electrode shape, diameter, spacing, immersion, slag depth, etc.).Accurate prediction of resistance is critical for success of the overall furnace design. The sizing of electrodes, columns, bus-bars, and transformers are all impacted. Estimation of minimum and maximum resistance or maximum operational current, as well as the maximum operating voltage are of fundamental importance. Various mathematical tools have been developed to assist designers with the selection of furnace dimensions and the prediction of resistance. Elkem found the methods of Downing et al. 1965 and Westly 1975 to be particularly useful. In the current paper, comparisons are drawn between data from spent aluminium pot lining (SPL) demonstration testing at Elkem Bjølvefossen and predictions based on these classical tools and 3D finite element modeling (FEM) with COMSOL®.

2:25 PM

CFD Modelling of Combustion Behaviour in Slag Fuming Furnaces: Md Huda[1]; Jamal Naser[1]; *Geoffrey Brooks*[1]; M. Reuter[2]; Robert Matusewicz[2]; [1]Swinburne University of Technology; [2]Outotec Limited

A thin slice CFD model of a conventional tuyere blown slag fuming furnace has been developed in Eulerian multiphase flow approach. The model was developed by coupling CFD with kinetics equations developed by Richards et al. for a zinc fuming furnace. The model integrates submerged coal combustion and chemical reactions with the heat, mass and momentum interfacial interaction between the phases in the system. The model predicts the velocity, temperature field of the molten slag bath, generated turbulence, vortex and coal utilization behaviour from the slag bath. Highest coal penetration distance was found to be at l/L = 0.2, where l distance from the tuyere tip and L is the total length (2.44m) of the modelled furnace. The model also predicts that 10% of the injected coal bypasses the tuyere gas stream un-combusted and carried to the free surface, which contributes to ZnO reduction near the free surface.

2:50 PM
Modeling as a Tool for Scale-Up of an Iron Smelt-Reduction Process: *Mark Schwarz*[1]; Mark Davis[2]; [1]CSIRO; [2]Hismelt Corp

The HIsmelt Process is a smelt-reduction process involving the injection of iron ore and coal into a molten iron bath, and post-combustion of CO and H2 above the bath by means of a top jet of air to increase energy efficiency. Substantial fluid dynamic related challenges are involved in developing such a process: these include ensuring that the solids are injected down into the metal bath and that post-combustion heat is effectively transferred back to the bath while minimising oxidation back reaction. Reactive multi-phase Computational Fluid Dynamics (CFD) modelling can be used in conjunction with experimental modelling and plant trials to achieve reliable scale-up. The application of these modelling tools will be described.

3:15 PM
Validating Temperature Measurements in Pyrometallurgical Applications – A Case Study: *Håvard Mølnås*[1]; Joalet Steenkamp[2]; Merete Tangstad[1]; [1]NTNU; [2]University of Pretoria

Temperature affects several aspects of pyrometallurgical systems, including thermodynamics and reaction kinetics. Reliability of temperature measurements in laboratory and plant applications is thus important from process, safety and financial perspectives. This case study briefly introduces different techniques used for temperature validation, and demonstrates temperature validation on laboratory scale utilizing the wire-bridge method. Pt/Pt13Rh thermocouple hot junctions were constructed by mechanically connecting thermocouple wires through a pure metal bridge consisting of copper, gold, nickel or palladium wire. When heating the wire-bridge thermocouple alongside a regular Pt/Pt13Rh thermocouple, temperature offsets were quantified as the wire-bridge thermocouple short-circuited at the melting points of the pure metals. At the melting points of gold (1064°C) and palladium (1555°C), average measured temperature offsets were -2.1°C ± 2.3°C and 0.2°C ± 0.4°C, respectively. Results from the copper and nickel wire-bridges were inconclusive. The paper concludes with a discussion on the potential industrial applications of the technique.

4:00 PM
Electric Slag Furnace Dimensioning: *Mark Kennedy*[1]; [1]Norwegian University of Science and Technology

Electric furnaces containing high quantities of slag are applied in many areas of pyrometallurgy, often for smelting or slag cleaning. A variety of ratios or rules of thumb have been employed in the industry for the dimensioning of these vessels, in most cases with no clear technical basis. In this paper, several design guidelines are presented (electrode size, spacing, vessel dimensions, energy intensity, etc.) as an attempt to provide some technical basis for optimal dimensioning.Furnace heat generation is related to side wall copper cooler heat losses, in an attempt to establish a methodical design strategy particularly for minimum electrode to wall spacing for modern furnaces with cooled linings. Issues regarding the true nature of heat production in a slag furnace are discussed with regards to the possible impact on accurate modeling and design.

4:25 PM
Physical Modeling Study on Mixing Phenomena in a C-H2 Smelting Reduction Furnace Bath with Asymmetric Side Blowing Process: *Jinyin Xie*[1]; Jieyu Zhang[1]; Kongfang Feng[1]; Jixu Wang[1]; Fei Ruan[1]; Zhiyu Liu[1]; Shaobo Zheng[1]; Xin Hong[1]; [1]Shanghai University

The mixing phenomena in smelting reduction furnace with asymmetric side blowing process was studied in this paper. Mixing phenomena in smelting reduction furnace was represented as the mixing time by electrical conductivity measurements. Experiment was performed in a water modeling under various operating conditions to determine the effects of the upper/lower side nozzle horizontal angle, radial angle, inserting depth, flow rate and the included angle between the upper-side nozzle and the lower side nozzle on mixing phenomena in smelting reduction furnace. Comparing mixing time and mixing phenomena, the optimal conditions obtained through asymmetric side blowing process were listed as follow: the upper side nozzle horizontal angle at -15°, radial angle at 15°, inserting depth at 100mm, flow rate at 1.5m3/h; the lower side nozzle horizontal angle at 40°, radial angle at 15°, inserting depth at 0mm, flow rate at 1.5m3/h; the included angle between the upper-side nozzle and the lower-side nozzle at 60°.

4:50 PM
Successful Application of Model Based Predictive Control for Production and Thermal Efficiency Optimization of High Temperature Melters: Erik Muijsenberg[1]; [1]Elkem Technology

In the past decade, advanced multiple input/multiple output (MIMO) process control systems have found their way into the high temperature melting processes. Today a growing number of high temperature melters have been equipped with a supervisory control system. Daily regulation of fossil fuel firing and electric energy supply to stabilize temperatures is no longer in the hands of the operator, but fully taken over automatically by the ES IIITM MPC controller, which provides consistent process control, 24 hours per day, focused to operate the entire glass production process in the most efficient way. The presentation will show practical results and benefits achieved in the high temperature glass and cement industry.

Magnesium Technology 2012: Corrosion and Coating

2:00 PM
"Electroless" E-Coating for Mg Alloys: *Guang-Ling Song*[1]; [1]GM Global Research &Development

By utilizing the unique electrochemistry of Mg, a thin organic film can rapidly be deposited on the surface of a Mg alloy through simply dipping the Mg alloy in an E-coating bath solution without applying a current or potential. This "electroless" E-coating pre-film can offer sufficient corrosion protection for Mg alloys in a chloride-containing environment. The stability of the film can be further significantly improved after curing. The coating performance is influenced by the substrate Mg alloy and the surface treatment process. Several differently pre-treated Mg alloy surfaces by means of dry-polishing, wet-polishing and chemical etching are compared for their suitability for the "electroless" E-coating on process. It is found that a pretreatment including a wet process and a heat-treatment of the substrate could be a cost-effective surface preparation/ treatment process for the "electroless" E-coating. The dipping coating can also act as a base for further powder-coating or E-coating.

2:20 PM
The Influence of Galvanic Current on Cerium-Based Conversion Coatings on Mg, Al, and Galvanized Steel Couples: *Surender Maddela*[1]; Matthew O'Keefe[1]; Yar-Ming Wang[2]; [1]Missouri University of Science and Technology; [2]GM Research and Development

The influence of galvanic current on cerium-based conversion coatings (CeCCs) for magnesium (AZ91, AZ31), aluminum (6016), and electro-galvanized steel (EGS) couples has been studied using zero resistance ammeter (ZRA) measurements in prohesion solution. The galvanic current measured between magnesium-aluminum, magnesium-galvanized steel, and aluminum-galvanized steel couples correlated with significant changes in coating morphology and deposition rate. The ZRA galvanic currents (mA) were 0.02 for 6016-EGS, 0.38 for AZ91-EGS, 0.72 for AZ91-6016, 1.08 for AZ31-EGS, and 1.08 for AZ31-6016 couples. The corrosion performance of the coated couples was evaluated by ASTM B117 neutral salt spray testing and electrochemical polarization measurements. Cerium conversion coated couples performed better in salt spray testing compared to uncoated couples. The correlation of galvanic current, cerium deposition, and corrosion performance will be discussed.

2:40 PM
Effect of Sn^{4+} Additives on the Microstructure and Corrosion Resistance of Anodic Coating Formed on AZ31 Magnesium Alloy in Alkaline Solution: *S. Salman*[1]; K. Kuroda[2]; N. Saito[2]; M. Okido[2]; [1]Graduate School of Engineering, Al-Azhar University, Nasr City, Cairo 11371, Egypt; [2]Nagoya University

Magnesium is the lightest structural metal with high specific strength and good mechanical properties. However, poor corrosion resistance limits its widespread use in many applications.Magnesium is usually treated with chromate conversion coatings. However, due to changing environmental regulations and pollution prevention requirements, a significant push exists to find new, alternative for poisonous Cr^{6+}. Therefore, we aim to improve corrosion resistance of anodic coatings on AZ31 alloys using low cost non-chromate electrolyte. Anodizing was carried out in alkaline solutions with tin additives. The effect of tin additives on the coating film was characterized by SEM and XRD. The corrosion resistance was evaluated using anodic and cathodic polarizations and electrochemical impedance spectroscopy (EIS). Corrosion resistance property was improved with tin additives and the best anti-corrosion property was obtained with addition of 0.03 M Na_2SnO_3. $3H_2O$ to anodizing solution.

3:00 PM
Effect of Thickness on the Morphology and Corrosion Behavior of Cerium-Based Conversion Coatings on AZ31B Magnesium Alloy: *Carlos Castano*[1]; Surender Maddela[1]; Matthew O'Keefe[1]; Yar-Ming Wang[2]; [1]Missouri University of Science and Technology; [2]GM R&D Center

Cerium-based conversion coatings (CeCC) were deposited onto AZ31B magnesium alloy substrates using a spontaneous reaction of $CeCl_3$, H_2O_2 and gelatin in a water-based solution. The coating thickness was adjusted by controlling the immersion time in the deposition solution. Prior to deposition, the surface of the AZ31B substrates were treated using an acid pickling in nitric acid and then an alkaline cleaning in sodium metasilicate pentahydrate. After deposition, the coated samples were immersed in a phosphate bath that converted cerium oxide/hydroxide into cerium phosphate. Electrochemical impedance spectroscopy, potentiodynamic polarization, and neutral salt spray testing studies indicated that ~100 nm thick CeCC had better corrosion performance than ~400 nm coatings. The morphology of cerium-based conversion coatings was characterized by transmission electron microscopy (TEM) which revealed a structure consisting of three layers with different compositions.

3:20 PM
Mechanical and Corrosion Properties of As-Cast and Extruded MG10GD Alloy for Biomedical Application: *Petra Maier*[1]; Sören Müller[2]; Hajo Dieringa[3]; Norbert Hort[3]; [1]University of Applied Sciences Stralsund; [2]Extrusion Research and Development Center TU Berlin; [3]Helmholtz-Zentrum Geesthacht

Due to the good specific strength and the moderate corrosion rate Mg-RE alloys have found growing interest for medical applications as implant material. In this study extruded Mg10Gd has been investigated, once by voltametric measurements and again under cyclic load. Corrosion exposure is known to reduce the fatigue strength strongly. The data are compared to Mg10Gd cast alloys and show an increase in fatigue properties and similar corrosive behaviour. The form of corrosion and the influence of the temperature during voltametric tests are discussed. A temperature increase from room to body temperature accelerates the corrosion processes. Due to stress peaks under load pitting corrosion is not preferred. The influence of the microstructure on the corrosion form is discussed. Casted Mg10Gd reveals large dendrites, which change into a globular microstructure during extrusion resulting in improved mechanical properties, mostly the elongation to fracture up to 20%.

3:40 PM Break

4:00 PM
Corrosion Behavior of Various Steels by AZ31 Magnesium Melt: *Cheuk Kin Tang*[1]; Marie-Aline Van Ende[1]; In-Ho Jung[1]; [1]McGill University

During the production of Mg and its alloys, the melt is in contact with steel at various stages of the process. Steel can be eroded and corroded through chemical reactions with molten Mg and the protective gases such as SF6 or SO2. The dissolution rate and corrosion mechanism of steels in molten Mg were investigated by the rotating cylinder method. The effects of temperature (650 to 700 °C) and rotation time (1 to 10 h) on the rate of dissolution of four steel grades, i.e. high carbon and low carbon steel, stainless steel 316 and 400, were examined for AZ31 melt under N2-SF6 gas atmosphere. The corrosion rates were found to be different depending on steel grades. It is found that the corrosion mechanism of steels in Mg melts involves a two-stage process consisting of oxidation of Fe and its reduction by Mg melt.

4:20 PM
Corrosion of Ultrasonic Spot Welded Joints of Magnesium to Steel: *Tsung-Yu Pan*[1]; Michael Santella[1]; [1]Oak Ridge National Laboratory

Mixed-metal joining, especially between magnesium and steel, is one of the critical technologies in achieving light-weighting vehicle body construction. However, galvanic corrosion between mixed metal joints is inevitable but not well quantified. In this study, 1.6 mm thick Mg AZ31B-H24 is joined to 0.8 mm thick galvanized mild steel by ultrasonic spot welding in lap-shear configuration. Corrosion test is conducted with Ford Arizona Proving Ground Equivalent Corrosion Cycle (APGE) test procedure which includes cycles of dipping in the salt bath, air drying, then subject to constant humidity environment. Lap shear tensile strength, X-ray diffraction, cross-section micrographs, and fractographs are obtained and are presented in the paper.

4:40 PM
Effects of Orientation on Corrosion Behavior of Magnesium Single Crystals: Nguyen Dang Nam[1]; Ming Zhe Bian[1]; Kwang Seon Shin[1]; *Hwa Chul Jung*; [1]Magnesium Technology Innovation Center, Seoul National University

Magnesium alloys have distinct advantages such as low density and high specific strength, but limited corrosion resistance restricts their widespread use in industrial applications. Therefore, it is important to examine the critical factors that could affect the corrosion behavior of magnesium alloys in order to develop new corrosion resistant alloys. It has been reported that the corrosion resistance of magnesium alloys could be influenced by texture. However, there has been little study on the effects of the surface orientation on the corrosion behavior of magnesium single crystals. In this study, magnesium single crystals with various crystallographic orientations were prepared for corrosion tests in order to identify the effects of surface orientation on the corrosion behavior in a systematic manner. Corrosion tests were carried out using electrochemical techniques such as potentiodynamic polarization and electrochemical impedance spectroscopy in a 3.5 wt.% NaCl solution. The specimen surfaces were analyzed using SEM and XRD.

5:00 PM

Effect of Some Microstructural Parameters on the Corrosion Resistance of Magnesium Alloys: Yaning Hu[1]; Joseph Kish[1]; *Joseph McDermid*[1]; Wenyue Zheng[2]; [1]McMaster University; [2]CANMET-MTL

The influence of the β-$Mg_{17}Al_{12}$ phase and the solute composition of the a-Mg matrix on Mg-alloy passive film stability were investigated by cyclic polarization and anodic potentiostatic polarization tests on AM60B, AM30 and AZ31B Mg alloys in a mildly aggressive neutral environment. Results showed that the alloys corroded in a passive state at the corrosion potential in this environment. It was also determined that the alloys studied showed similar breakdown and repassivation potentials. This indicates that the solute matrix composition and ß-phase distribution did not thermodynamically affect the alloy passivation and repassivation behavior. It was further determined that a semi-continuous grain boundary network of \946-phase improved the overall AM60 alloy corrosion resistance and that the presence of β phase did not have a significant effect on the α-Mg matrix dissolution rate. This paper presents the results of this investigation and discusses implications for use of these alloys in automotive structures.

5:20 PM

Influence of Aluminum Content on Corrosion Resistance of Mg-Al Alloys Containing Copper and Zinc: *Hiroyuki Kawabata*[1]; Naohisa Nishino[1]; Yoshikazu Genma[2]; Tsuyoshi Seguchi[2]; [1]Toyota Central R&D labs., inc.; [2]Toyota Motor Corporation

Corrosion resistance of Mg-Al alloys gets worse significantly with increasing copper content, because copper-based intermetallic compounds are formed in alloys. Therefore, the tolerance limit of copper is commonly fixed at less than 300ppm for keeping the corrosion resistance. It is necessary to expand the tolerance limit for reduction of the cost of magnesium alloys and products. So, it is very important to prevent the corrosion resistance from getting worse by copper containing.In this study, the corrosion resistance of Mg-Al alloys containing copper and zinc was investigated. We revealed the optimum content of zinc and aluminum for high corrosion resistance.

2:00 PM

Effect of Rolling Temperature on the AZ31B Magnesium Alloy Microstructure: *Litzy Lina Catorceno*[1]; Angelo Fernando Padilha[1]; [1]USP

The influence of rolling temperature and the effect of strain rate on the microstructure of AZ31B Mg alloy were determined in order to improve its formability. A plate of AZ31 alloy was found to be sensitive to strain rate at high temperature and anisotropy was adversely impacted in cold rolling sheets. Thus, AZ31B has better workability within the temperature range of 200 to 250 oC, due to the grain refinement, caused by the dynamic recovery and dynamic recrystallization. The effect of rolling temperature was studied on recrystallized sheets (2 mm in thickness) which were deformed by rolling at different temperatures (25, 100, 200 and 250 oC) and the effect of strain rates was evaluated on two different rolling speed (10 and 20 rpm). The microstructural characterization was achieved using several complementary techniques of microstructural analysis, such as optical microscopy, scanning electron microscopy, X-ray analysis by energy dispersive, X-ray diffraction and microhardness.

2:20 PM

Hot Formability Curves for Four Mg AZ31B Sheets Obtained by the Pneumatic Stretching Test: *Fadi Abu-Farha*[1]; Ravi Verma[2]; Louis Hector[2]; [1]Penn State Erie; [2]General Motors

The formability of four Mg AZ31B sheets produced by either direct chill or twin roll casting, and having different initial grain sizes, was investigated at 400 C and 5x10-3 s-1 using pneumatic stretching. Blanks were pneumatically bulged through four elliptical die inserts, with aspect ratios ranging between 1.0 and 0.4, producing ellipsoidal domes with different biaxial strain combinations. The major strains were aligned either along or across the rolling direction of the material. Strain combinations were measured in the deformed material and mapped onto a formability diagram. Three zones were distinguished in constructing the formability curves for each of the four sheets: safe (no necking), marginal (some necking), and failure (extreme necking and/or rupture). Formability comparisons as a function of sheet rolling direction were quantified with "composite FLDs." Results obtained for the four sheets are indicative of differences in grain structure and material inhomogeneities.

2:40 PM

Texture Evolution during Hot Deformation Processing of Mg-3Sn-2Ca-0.4Al Alloy: Dharmendra Chalasani[1]; *Pitcheswara Kamineni*[1]; Y.V.R.K. Prasad[2]; Norbert Hort[3]; Karl Kainer[3]; [1]City University of Hong Kong; [2]Independent Consultant; [3]Helmoltz-Zentrum Geesthacht

An experimental investigation of texture evolution during high temperature compression of Mg-3Sn-2Ca (TX32) alloy containing 0.4%Al using electron backscatter diffraction (EBSD) technique is reported. Isothermal uniaxial compression tests were performed at different combinations of temperatures and strain rates in the ranges 300-500 °C and 0.0003-10 s^{-1} to examine the influence of processing conditions on the dynamic recrystallization (DRX) behavior and texture evolution. The onset of DRX during compression at low temperatures (300 and 350 °C) and low strain rates (0.003 and 0.001 s^{-1}) gave rise to a fine, partially recrystallized and necklaced grain microstructure, with the basal planes aligned at about 15-30° to the compressive direction although they were split. Certain deformation conditions at high temperatures resulted in a fully recrystallized microstructure and an almost random crystallographic texture. It is clear from Schmid factor analysis that the contribution of pyramidal slip system is significant for deformation at temperatures above 400 °C.

3:00 PM

The Effects of Strain and Stress State in Hot Forming of Mg AZ31 Sheet: *Alex Carpenter*[1]; Paul Sherek[2]; Louis Hector[3]; Paul Krajewski[3]; Jon Carter[3]; Eric Taleff[1]; [1]The University of Texas at Austin; [2]Mercer; [3]General Motors

Wrought magnesium alloys, such as AZ31 sheet, are of considerable interest for light-weighting of vehicle structural components. The poor room-temperature ductility of AZ31 sheet has been a hindrance to forming the complex part shapes necessary for practical applications. However, the outstanding formability of AZ31 sheet at elevated temperature provides an opportunity to overcome that problem. Complex demonstration components have already been produced at 450°C using gas-pressure forming. Accurate simulations of such hot, gas-pressure forming will be required for the design and optimization exercises necessary if this technology is to be implemented commercially. We report on experiments and simulations used to construct the accurate material constitutive models necessary for finite-element-method simulations. In particular, the effects of strain and stress state on plastic deformation of AZ31 sheet at 450°C are considered in material constitutive model development. Material models are validated against data from simple forming experiments.

3:20 PM

Effect of Strain Rate on Dynamic Recrystallization in Magnesium under Compression at High Temperature: *Q. Ma*[1]; B. Li[1]; A.L. Oppedal[1]; W. Whittington[1]; S.J. Horstemeyer[1]; E.B. Marin[1]; H. El Kadiri[1]; P.T. Wang[1]; M.F. Horstemeyer[1]; [1]Mississippi State University

Interrupted uniaxial compression tests were performed on an extruded Mg-Al-Mn magnesium alloy (AM30) at 450°C and various strain rates of 0.001 s-1, 0.1 s-1, 0.5 s-1 and 0.8 s-1. Texture and microstructure evolution were examined using the electron back-scatter diffraction (EBSD) and the X-ray diffraction (XRD) techniques. The results show that the microstructure strongly depends on the strain rate, with twinning activated at high strain rates. The extension twinning and the non-basal slips play crucial roles in dynamic recrystallization of the magnesium alloy. The Schmid factors of the slip modes and the twinning mode were calculated, and slip trace analysis was conducted to clarify the dynamic recrystallization (DRX) mechanisms.

3:40 PM Break

4:00 PM

Effect of Strain Rate on the Kinetics of Hot Deformation of AZ31 with Different Initial Texture: *Mehdi Sanjari*[1]; Amir Farzadfar[2]; Atefeh Nabavi[2]; Elhachmi Essadiqi[3]; In-Ho Jung[2]; steve yue[2]; [1]McGill ; [2]McGill; [3]CANMET

In this work, the effects of strain rate and initial texture on the flow behaviour and microstructure evolution on AZ31 Mg alloy were studied by compression tests. Cast plates were, homogenized and hot rolled and then compression tests were performed on samples with longitudinal axes either parallel to the rolling direction (RD) or the normal direction (ND). Compression tests were performed to various strains and samples were quenched to investigate the effect of dynamic recrystallization on the texture and microstructural evolution. Results show that for the samples machined in both rolling and normal direction, the rate of texture evolution is increased by increasing strain rate. The deformation mechanism was changed by increasing the strain rate for ND samples and at strain rate of 1s-1 from slip dominated flow to twin dominated flow. By using EBSD, the deformation mechanism and twinning types were investigated and double and tension twins were detected.

4:20 PM

Precipitation Behaviour of Micro-Alloyed Mg-Al-Ca Alloys during Heat Treatment and Hot Compression: *Jing Su*[1]; Shirin Kaboli[1]; Abu Syed Humaun Kabir[1]; Phuong Vo[1]; In-Ho Jung[1]; Steve Yue[1]; [1]McGill

Based on thermodynamic calculations, two micro-alloyed Mg-Al-Ca alloys, Mg-0.3Al-0.2Ca and Mg-0.1Al-0.5Ca, were selected in terms of the equilibrium precipitation temperatures of Al_2Ca and Mg_2Ca, respectively. The basic idea is to form precipitates during hot compression to examine their effect on hot deformation. Both alloys, cast by copper mould, were solution treated at 500°C for 8 hours to dissolve eutectic precipitates which formed in the as-cast microstructure, and then isothermally heat treated at 350°C for different times. SEM analysis of the heat treated alloys generally agreed with thermodynamic calculations. Hot compression tests were also conducted on solution treated alloys at 350°C with a strain rate of 0.01 s-1 and different strains (from 10% to 90%). The precipitation behaviour and microstructural evolution which was characterized by optical microscopy and SEM with EDS and EBSD of two alloys during isothermal heat treatment and hot compression were compared.

4:40 PM

Diffusion Couple Investigation of the Mg-Zn System: *Sarah Brennan*[1]; Katrina Bermudez[1]; Nagraj Kulkarni[2]; Yongho Sohn[1]; [1]University of Central Florida; [2]Oak Ridge National Laboratory

Phase layer growth and interdiffusion in the binary Mg-Zn system was investigated utilizing solid-to-solid diffusion couples annealed at 295°, 315° and 325°C for 21, 7 and 5 days, respectively. The diffusion microstructure was examined by scanning electron microscopy and concentration profiles were determined using X-ray energy dispersive spectroscopy and electron microprobe analysis. The Mg solid solution, Mg2Zn11, MgZn2 and Mg2Zn3 in all three couples were observed in addition to the high temperature, Mg51Zn20 phase at 325°C. The MgZn2 phase was observed to grow the thickest layer, followed by the Mg2Zn3 and the Mg2Zn11 phases. Activation energies for the parabolic growth were calculated to be 105 kJ/mol and 207 kJ/mol for the Mg2Zn3 and MgZn2, respectively. Relevant interdiffusion coefficients were calculated for the phases present by analyses of concentration profiles. This study was sponsored by the US Department of Energy, Office of Energy Efficiency and Renewable Energy, Vehicle Technologies Program (DE-AC05-00OR22725).

5:00 PM

Biaxial Deformation Behavior of AZ31Magnesium Alloy at High Temperature: *Yamashita Daisuke*[1]; Masafumi Noda[1]; Kunio Funami[1]; [1]Chiba Institute of Technology

Plastic deformation of metals is typically characterised with the uniaxial tensile test. However, multiaxial loading in sheet metal plastic forming requires more complex tests, such as the controlled biaxial test with cruciform specimens. Then, AZ31 magnesium alloy investigated relation between biaxial deformation behavior and microstracture for initial strain rate of 3.0×10-3 s-1 and 2.8×10-4 s-1 at 573 K and 623 K by cruciform specimens. As a result, the flow stress increased with decrease the sheet thickness and tensile twin is formed of during biaxial tensile deformation at 623 K for 2.8×10-4 s-1 in cross section. It's deformation behavior and evolution of microstructure peculiar to biaxial tensile test, and this deformation behavior was not recognized in uniaxial tensile test. In other words transition point of microstructure is biaxial tensile tested condition at 623 K for 2.8×10-4 s-1.

Cluster Dynamics and Kinetic Monte Carlo Simulations of Atomistic to Nanoscale Defect Dynamics in In-Situ TEM Irradiation on Thin Molybdenum Foils: *Donghua Xu*[1]; Brian Wirth[1]; Meimei Li[2]; Mark Kirk[2]; [1]University of Tennessee-Knoxville; [2]Argonne National Laboratory

In-situ TEM experiments and computer simulations are closely combined to investigate the detailed defect dynamics during irradiation of Molybdenum thin foils with 1 MeV Kr+. Specifically, the number density and size distribution of interstitial and/or vacancy clusters are obtained as a function of dose (time), dose rate, foil thickness and irradiation temperature. A spatially-dependent cluster dynamics (CD) model has been designed and parameterized to directly compare with the experiments. The CD model incorporates 1D spatial dependence to account for free surface sinks. A kinetic Monte Carlo model is used to directly capture the full 3D spatial dependence of the defect evolution. The effects of interstitial/vacancy cluster mobility and intra-cascade cluster production are examined, in addition to other material and irradiation parameters. Detailed comparisons provide the opportunity to validate understanding of defect diffusion and interaction kinetics, including key mechanisms controlling defect cluster evolution, and the assumptions of the cluster dynamics model.

2:20 PM
Kinetic Monte Carlo Simulation of He Bubble Nucleation at Different Types of Grain Boundaries in Mo: *Liangzhe Zhang*[1]; Paul Millett[1]; Michael Tonks[1]; Yongfeng Zhang[1]; Bulent Biner[1]; [1]Idaho National Laboratory

The kinetic Monte Carlo (KMC) algorithm, which offers a relatively long time description of microstructural evolution at atomistic level, is adopted to investigate the Helium bubble nucleation process at grain boundaries (GBs) in Mo. To make KMC simulations robust, corresponding molecular dynamics simulations are consulted, which provide the nucleation mechanisms in detail within various settings. In the current work, the He bubble nucleation process at three types (twin, tilt and twist) of GBs is studied with randomly distributed He atoms as the initial condition. It is found that He bubbles nucleate at GBs with different rates and more He bubbles appear at tilt and twist boundaries. This is because the He binding energy of tilt and twist GBs is superior over the counterpart of twin GBs. Furthermore, inhomogeneous nucleation occurs with the impact of dislocations.

2:40 PM
He Bubble Nucleation at Grain Boundaries (GBs) in BCC Mo: Molecular Dynamics Simulations: *Yongfeng Zhang*[1]; Paul Millett[1]; Michael Tonks[1]; Liangzhe Zhang[1]; Bulent Biner[1]; [1]Idaho National Lab

The He bubble nucleation at three different GBs, the (100) twist S29, the <110> symmetrical tilt (10.1°), and the twin, are simulated at 2000K. The results are quantified in terms of He binding energy, effective He diffusivity, and GB structure. He interstitials of 1000 appm are inserted into the grain interior initially, and the microstructural evolution is monitored for 2 ns. The He binding energy is about 0.5, 2.5 and 2.9 eV for the twin, the tilt, and the twist GBs respectively. Correspondingly, He atoms diffuse 3D and much faster in the cell with twins, 2D in the twist GBs, and 1D in the tilt GBs along the dislocation cores. As a result, less He bubbles form at twins than at the other two GBs, with a larger average size. The He clusters forms randomly in the twins and twist GBs, and along the dislocation cores in the tilt GBs.

3:00 PM
Strip-Yield Modeling of Creep Crack Incubation and Growth in Cr-Mo Steels for Nuclear Reactor Applications: *Gabriel Potirniche*[1]; Mehdi Basirat[1]; [1]University of Idaho

Cr-Mo heat-resistant steels are considered as possible materials of choice for reactor pressure vessels and reactor internals for nuclear power plants, thus modeling the creep damage in these materials becomes essential. In this work, a numerical strip-yield model was developed to simulate creep crack incubation and growth in Cr-Mo steels. Simulations of crack incubation and growth, evolution of the crack-tip plastic zone and damage evolution in the near crack-tip regions are performed. The strip-yield model is coupled with a dislocation-based model of creep deformation to compute the extent of each creep stage (primary, secondary and tertiary) in the near crack-tip region and calculate crack advance rates. The model assumes a pre-existing crack in a specimen, and models the behavior of the material prior to the onset and during the crack advance stage. Comparison with experimental data is performed, and good correlation is obtained.

3:20 PM
Peculiarities of Creep Temperature Dependence in Irradiated Materials: *Pavlo Selyshchev*[1]; Volodimir Sugakov[2]; [1]University of Pretoria; [2]Institute for Nuclear Research

In the framework of a dislocation climb-glide model a theoretical approach is developed to explain the appearance of a break (local minimum and maximum) on a curve of creep rate dependence on temperature in irradiated materials. The peculiarities of creep temperature dependence were explained by competition of radiation and thermal defect fluxes. At some temperature the both radiation and thermal fluxes become equal and compensate each other, which causes the creep to decrease. It was shown that the presence of sinks with different preference coefficients is important for explanation of appearance of the break. Theoretical and experimental results are in good agreement.

3:40 PM Break

3:50 PM
Ab Initio Study of Radiation Induced Amorphization in ZrC: *Ming-Jie Zheng*[1]; Dane Morgan[1]; Izabela Szlufarska[1]; [1]University of Wisconsin - Madison

ZrC is of interest for application in nuclear reactors due to its high melting temperature and possible effectiveness as a barrier layer to fission products. However, the response of ZrC to irradiation is poorly understood. We study the radiation induced amorphization in ZrC by using an ab initio based rate theory framework. The kinetics of the dominating Frenkel pairs in ZrC is investigated through the density functional theory calculation. It is demonstrated that the dose to amorphization vs. temperature curve and the critical temperature to amorphization Tc are sensitive to both migration barriers and recombination barriers. By using an approximate amorphization energy for ZrC, Tc is found to be much lower than the room temperature. This result may explain why it is hard to observe amorphization in experiments on ZrC conducted at room temperature or higher temperatures, even under high dose of radiation.

4:10 PM
Phase-Field Simulation and Experimental Studies of Oxidation of Zirconium: *Mohsen Asle Zaeem*[1]; Haitham El Kadiri[1]; Mark Horstemeyer[1]; [1]Mississippi State University

We study the oxidation kinetics of zirconium by both simulations and experiments. A phase-field model is presented for oxidation of pure metals in which the diffusion-controlled phase transformation is the mode of oxide growth. The metal is zirconium which produces zirconia in the oxidation process. A conserved phase-field variable is considered which represents the oxygen concentration and another non-conserved phase-field variable is used as the marker of different phases. The governing evolution equations of phase-field variables are coupled to mechanical equilibrium equations to investigate the evolution of stresses in the oxide and the zirconium substrate. The governing equations are solved using a finite element model. This model captures the composition depth profile of the oxygen in the oxide layer and in the metallic substrate and stresses induced by compositional changes close to the metal-oxide and oxide-fluid interfaces. The oxidation kinetics of zirconium achieved by phase-field simulations is validated by experiments.

4:30 PM
Characterization and Modeling of Creep Mechanisms in Zircaloy-4: *Benjamin Morrow*[1]; Robert Kozar[2]; Ken Anderson[2]; Michael Mills[1]; [1]The Ohio State University; [2]Bechtel Marine Propulsion Corp.

Zirconium alloys are used primarily as a structural material in nuclear reactors. Accurately predicting creep deformation throughout their lifecycle depends on reliable deformation models. The Modified Jogged-Screw (MJS) model asserts that the motion of tall jogs on screw dislocations act as the rate-controlling mechanism during creep in certain stress-temperature regimes. Previous studies have demonstrated the applicability of the MJS model to the thermal creep behavior of hcp metals, but many aspects of the model have never been fully explored. TEM was used to directly observe and characterize the dislocation substructure of creep-tested Zircaloy-4 over a range of conditions, and quantify pertinent model parameters. Effects of accumulated strain were examined through interrupted testing. Thorough characterization can provide a better understanding of material behavior in both primary and secondary creep regimes, resulting in more robust creep deformation predictions. Results of substructural observations and improvements to the MJS model are discussed.

4:50 PM

High-Temperature Creep and Superplasticity in Zirconium Alloys: Applications to LOCA Conditions: *Ali Massih*[1]; [1]Quantum Technologies

Understanding the high-temperature deformation property of zirconium alloys used as fuel cladding tubes is essential for analysis of fuel rod behavior during a postulated loss-of-coolant accident (LOCA) in water cooled reactors. Here, the high-temperature (900-1400 K) steady-state creep test data on as-received zirconium alloys, Zr-1wt%Nb and Zircaloy-4, are evaluated by employing two sets of models. In one modeling approach, the constitutive relations for the two single phase regions (alpha and beta) are combined through a phase transition model and a phase mixing rule; in another, a superplasticty model is used to calculate the creep deformation rate as a function of stress and temperature in the (alpha+beta)-domain. The results show that the former approach is inadequate in capturing the experimental data, while the latter provides a fair agreement with experiments. The two models are also used and compared in a computer code to assess fuel cladding rupture under LOCA conditions.

5:10 PM

Charge Optimized Many Body (COMB) Potential for the Zr-ZrO2 system: *Mark Noordhoek*[1]; Tao Liang[1]; Tzu-Ray Shan[1]; Susan Sinnott[1]; Simon Phillpot[1]; [1]University of Florida

Fuel clad for Light Water Reactors is made from zircaloy, a zirconium alloy. Oxidation and hydridation of zircaloy are important degradation processes. Here, a Charge Optimized Many Body (COMB) potential for the Zr-ZrO2 system is developed and fitted to the structure and properties of Zr and ZrO2, obtained from experiment and from density functional theory calculations. The hcp structure of Zr is found to be the most stable, with a non-ideal c/a ratio in good agreement with experiment. For Zr, satisfactory values are obtained for the stacking fault, surface and defect formation energies. Corresponding analyses are performed for ZrO2. This work was funded by the Consortium for Advanced Simulation of Light Water Reactors (www.casl.gov), an Energy Innovation Hub (http://www.energy.gov/hubs) for Modeling and Simulation of Nuclear Reactors under U.S. Department of Energy Contract No. DE-AC05-00OR22725.

Long-Term High-Temperature Microstructure Stability and Mechanical Properties of Advanced Ferritic-Martensitic Steels: *Lizhen Tan*[1]; Jeremy Busby[1]; [1]Oak Ridge National Laboratory

Ferritic-martensitic (FM) steels, e.g., 9-12 wt.%Cr, are important structural materials for use in advanced nuclear reactors due to their greater void-swelling resistant, higher thermal conductivity, and lower thermal expansion compared to austenitic stainless steels. Their high-temperature performance stability during long-term services is critical for reactor safety and design. High-strength FM steels are being developed at ORNL by means of optimizing alloy composition and thermomechanical treatment. Long-term thermal annealing at 650°C for times up to 10000 hours are being performed on the samples of the steels. Microhardness measurement and tensile testing showed that the mechanical properties are deteriorated by the long-term high-temperature annealing. Transmission electron microscopy characterization, together with electron backscatter diffraction, indicates that the annealing-induced microstructural evolution, including subgrains, dislocations, and precipitates, can reasonably explain the degraded mechanical properties. The understanding of the degradation mechanism is essential for further development of advanced FM steels with superior high-temperature performance.

2:20 PM

Characterization of Surface Modifications of 316L Stainless Steel: Giovanni Facco[1]; Andreas Kulovits[1]; *Jorg Wiezorek*[1]; [1]University of Pittsburgh

Linear raking, a novel severe surface plastic deformation process, and heat treatments are used to surface modify 316L stainless steel. This processing combination holds promise for grain boundary engineering of surface and near-surface regions to improve the degradation resistance of machined components utilized in pressurized water reactor. The influence of the rake angle on deformation processing related microstructural responses and the heat treatment related evolution of grain boundary character, grain orientation distribution and grain size have been studied quantitatively using transmission and scanning electron microscopy (TEM and SEM) and X-ray diffraction. TEM based orientation imaging microscopy enabled nanoscale measurements for even heavily deformed and grain refined states. Grain size and grain boundary character changes were effectively monitored. Stored strain and orientation-spread evolution were determined by conventional TEM diffraction. Dramatic differences in the rake-angle dependent responses of the 316L microstructure have been identified.

2:40 PM
Investigation of Effect of Zr Allotropic Transformation on Interdiffusion between Mo and Zr: *Ashley Ewh*[1]; Judith Dickson[1]; Yongho Sohn[1]; [1]University of Central Florida

Interdiffusion between molybdenum and zirconium was studied via solid-to-solid diffusion couples. The couples were assembled with disks of 99.95% pure Mo and 99.2 % pure Zr and were isothermally annealed at temperatures between 700 and 950°C for various times. Based on the binary phase diagram, Zr undergoes an allotropic phase transformation from a-(hcp) to ß-(bcc)Zr at approximately 860°C and only one intermetallic phase (Mo2Zr) exists. Microstructural observations were made via scanning electron microscopy and phase constituents were identified using a combination of energy dispersive spectroscopy and x-ray diffraction. Concentration profiles were determined by electron probe microanalysis and were used to determine effective interdiffusion coefficients. The effect of the allotropic transformation on both the rate of diffusion and the absence of the Mo2Zr intermetallic phase will be presented and discussed.

3:00 PM
Characterization of Oxide Dispersion-Strengthened (ODS) Alloy Powders Processed by Mechano Chemical Bonding (MCB) and Ball Milling: *Longzhou Ma*[1]; Bruce Kang[2]; C.C Huang[3]; [1]University of Nevada Las Vegas; [2]West Virginia University; [3]Hosokawa Micron Powder Systems

Oxide dispersion-strengthened (ODS) nickel-based alloying powders were processed by two approaches, MCB (mechano chemical bonding) and MCB plus conventional ball milling. The processed powders were characterized using XRD,SEM, and TEM to examine the microstructure of alloying powders. The results showed that compared to the commercial ODS MA 956 alloying powders subjected to ball milling for 72 hours, MCB plus ball-milling process allowed the alloying powders to receive remarkable deformation and to be mixed homogeneously, forming the dispersion effects similar to MA 956 powders. Powders subjected to only high speed MCB processing could form the composite structure consisting of Ni or Cr as hosting particles and deformed other starting particles including nano-sized yttria. Two approaches, MCB plus ball milling and MCB, are expected to act as alternatives to prepare the ODS alloying powders to fabricate ODS alloy with reduction of milling time.

3:20 PM
Laser Welding of Alloy 690 for Nuclear Power Systems: *Julie Tucker*[1]; Terry Nolan[1]; George Young[1]; [1]Knolls Atomic Power Laboratory

Advances in laser welding technology are increasing the applicability of this joining technique to nuclear power systems. Advantages of laser welding include fiber optic delivery, high power density, small heat affected zones, minimal distortion, and limited susceptibility to cracking. These advantages are of special interest to next generation nuclear power systems where new alloys and dissimilar metal welds are likely. This work focuses on nuclear structural material Alloy 690 to illustrate the effects of shield gas, travel speed and beam focus on the defect density in autogenous welds. Alloy 690 welds are shown to be especially prone to porosity and these defects have been characterized by light optical microscopy and x-ray computed tomography to quantify their number, size and distribution. This work provides a process map that describes the trade off between weld penetration and defect density.

3:40 PM Break

3:50 PM
Pulsed Magnetic Welding for Advanced Core and Cladding Steels: *Yong Yang*[1]; Sindo Kou[2]; Todd Allen[2]; [1]University of Florida; [2]University of Wisconsin-Madison

Advanced alloys including NF616, ODS Steel variants, and High Temperature-Ultra-fine Precipitate Strengthened Steel (HT-UPS) with specially tailored microstructures, have improved high temperature strength and exceptional radiation resistance, and they are being considered for the next generation of reactor. A potential issue that directly affects the application of them is the change in properties associated with welding. Since the superior properties depend on the uniform tempered martensitic microstructure or the evenly distributed nano-sized dispersed oxides and ultrafine precipitates for ODS steels and HT-UPS, respectively, any changes induced by conventional fusion formed welding may be deleterious. A solid-state joining method, pulsed magnetic welding, for welding the advanced core and cladding steels was studied in this paper. The flat coupon lap joints and pin/tube welding were tried, and the strength of welding was examined using a tensile shear test. The microstructures of welding were studied using electron back-scatter diffraction and transmission electron microscopy.

4:10 PM
Effects of Laser Shock Peening on Residual Stress, Microstructure and Corrosion Behavior of Alloy 600: *Abhishek Telang*[1]; Amrinder Gill[1]; James Guenes[1]; S Mannava[1]; Dong Qian[1]; Vijay Vasudevan[1]; [1]University of Cincinnati

Nuclear steam generator tubing materials like austenitic stainless steels, Ni-based alloys like alloy 600 and their weldments are susceptible to stress corrosion cracking (SCC) in different environments. The present work was undertaken to evaluate the effects of laser shock peening (LSP) on the SCC resistance of alloy 600. As-received and heat-treated coupons of alloy 600 were LSP-treated and residual stresses, near-surface microstructure were characterized. Single loop and double loop Electrochemical Potentiokinetic Reactivation (EPR) tests were used to quantify the degree of sensitization (DOS) and characterize the effect of LSP on the corrosion resistance and hence on the susceptibility of Alloy 600 to Intergranular SCC. Modified Huey tests and bend tests in thiosulfate environment were used to investigate the effect of LSP on SCC behaviour. Results show that LSP introduces deep compressive residual stresses and EPR tests indicate lower DOS, decreased extent and width of grain boundary attack after LSP.

4:30 PM
Nanoindentation and the Micromechanics of Zry-4: *Christabel Evans*[1]; Trevor Lindley[1]; David Dye[1]; [1]Imperial College London

Zircaloy-4 is widely used to contain fuel in light water reactors. During service at around 330C, corrosion occurs at the cladding/water interface producing hydrogen, which diffuses into the zirconium alloy. As hydrogen content increases beyond the room temperature solubility, hydrides precipitate on cooling leading to brittleness in the material. In addition, if a stressed crack is present hydrogen can migrate to the crack tip, promoting crack propagation. This delayed hydride cracking phenomenon is of concern for dry storage of present generation irradiated fuel. Little is known about the micromechanics of hydrides at the individual plate level and therefore in the present study nanoindentation is used to characterise the mechanical properties of individual hydride plates in a sheaf and how they interact with the surrounding matrix. Post-indentation TEM has been used to investigate dislocation arrays across the hydride and at each indent.

4:50 PM
Characterization of Zirconium Excel Alloy for Generation IV CANDU SCW Reactors: *Mohammad Sattari*[1]; Richard Holt[1]; Mark Daymond[1]; [1]Queen's University

Zirconium Excel alloy (Zr-3.5 Sn-0.8Nb-0.8 Mo) is the candidate material for pressure tube in Generation-IV CANDU® Super Critical Water-cooled Reactor (SCWR) design. It is a dual phase material, hcp alpha-Zr and bcc beta-Zr; and it has better creep resistance compared to the current pressure tube material, Zr-2.5Nb, mainly due to solid solution strengthening effect of Sn as well as potential age hardening. In order to understand the metallurgy of this alloy and improve its mechanical properties, it is important to know the transformation temperatures, i.e. a□a+ß and a+ß□ß. Metallography techniques as well as Differential Scanning Calorimetry (DSC) and resistivity measurement has been employed to study the transformation temperatures.Thorough

WEDNESDAY PM

microstructural characterization has been done using optical and electron microscopy techniques. Different heat treatment has been developed to study the aging response of this alloy and to improve its mechanical properties, particularly creep resistance which is investigated using accelerated stress-rupture experiments.

5:10 PM
Order-Disorder Transformation in a Ni-Cr-Mo Alloy: Amit Verma[1]; *Jung Singh*[1]; M Sundararaman[2]; Nelia Wanderka[3]; [1]Bhabha Atomic Research Centre; [2]University of Hyderabad; [3]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH

Ni–Cr–Mo alloys are potential candidates for structural materials application for high temperature reactors. These alloys form a long-range order (LRO) Ni2(Cr,Mo) (Pt2Mo type structure) phase, in the intermediate temperature range. Evolution of this phase has been studied using resistivity and transmission electron microscopy (TEM). The relative change in resistance as a function of temperature could be divided into 5 regimes, which could be attributed to different microstructural states. TEM investigations revealed the presence of a {1 ½ 0} type of short-range order (SRO) and subunit cells of Pt2Mo structure in solution treated and quenched state. Formation of the LRO could be identify to initiate at {1 ½ 0} SRO state. The progress of the SRO and LRO states has been correlated to the resistance change profile during continuous heating. The SRO state has also been found to have a strong influence on the kinetics of the transformation.

Alloy Design of 9% Cr Steel for High Efficiency Ultra-Supercritical Power Plants: *Fujio Abe*[1]; [1]National Institute for Materials Science

Boundary and sub-boundary hardening is shown to be the most important strengthening mechanism in creep of tempered martensitic 9% Cr steel base metal and welded joints at 650°C. The addition of boron reduces the coarsening rate of M23C6 carbides along boundaries near prior austenite grain boundaries during creep, enhancing the boundary and sub-boundary hardening at long times. Excess addition of nitrogen to the 9Cr-boron steel promotes the formation of boron nitrides during normalizing heat treatment, which consumes most of soluble boron and degrades the creep strength. Newly alloy-designed 9Cr steel with 100-150 ppm boron and 70-85 ppm nitrogen exhibits much higher creep strength of base metal than conventional steel P92 and also no degradation in welded joints at 650°C. The protective Cr2O3-rich scale forms on the surface of 9Cr steel by pre-oxidation treatment in Ar gas, which significantly improves the oxidation resistance in steam at 650°C.

2:30 PM Invited
Advanced Heat Resistant Austenitic Stainless Steel for A-USC Power Plant: *Guocai Chai*[1]; [1]Sandvik Materials Technology

Energy requirement, security and environmental concerns have promoted a worldwide develop in clean coal fired power technologies. Austenitic stainless steel grade UNS S31035 or Sanicro 25 has been developed for this purpose and will be used in the next generation of A-USC power plant at material temperatures up to 700°C. This new grade shows very good resistance to steam oxidation and hot corrosion, and higher creep rupture strength than other austenitic stainless steels available today. This presentation will provide a review on the development and application of this material. The structural stability, creep strength and resistances to oxidation and hot corrosion and the relations between microstructure and properties will be focused. The creep and fracture mechanisms at different conditions studied using TEM and SEM will be discussed. In order to predict the long term creep properties, different models have been used to evaluate the long-term creep behavior of the grade.

3:00 PM Invited
In Situ Inclusion Behavior in Ultra-High Strength Steels: Jon Groh[1]; Mark Rhoads[1]; [1]General Electric Company

The mechanical properties, especially low cycle fatigue behavior (LCF), of ultra-high strength steel materials are significantly impacted by the existence of non-metallic inclusions.To better understand the behavior of precipitates and inclusions on the behavior of Marage 250 and GE1014, specially designed SEM in-situ tensile and fatigue tests were conducted. The entire process of crack initiation and propagation to fracture in these ultra-high strength steels was accomplished at room temperature. Micro-mechanical behavior, such as crack initiation and propagation at tensile and fatigue tests, of inclusions in ultra-high strength steels GE1014 were investigated in detail.

Development of High-Performance Structural Alloys for Nuclear Energy Systems: *Steven Zinkle*[1]; Michael Brady[1]; Yuki Yamamoto[1]; Michael Santella[1]; Phillip Maziasz[1]; David Hoelzer[1]; Jeremy Busby[1]; Lizhen Tan[1]; Govindarajan Muralidharan[1]; [1]Oak Ridge National Laboratory

Numerous structural materials are required for the operation of fission and proposed fusion energy systems. A series of high performance pressure vessel steels, austenitic alloys, and tempered ferritic/martensitic steels have recently been designed and fabricated for aggressive operating environments such as fossil and nuclear energy systems. The alloy design utilized a variety of tools such as computational thermodynamics to rapidly converge on an optimized alloy composition. Several examples of these high-performance alloys that are tailored for specific extreme operating environments will be given, based on traditional ingot-based steel metallurgy methods and alternative techniques such as powder metallurgy production of oxide dispersion strengthened steels. Recent work to design a series of creep-resistant steels that form a self-healing alumina surface film at high temperatures will be summarized.

4:20 PM Invited
Design Approaches and Performance of Novel Austenitic Heat Resistant Steels Strengthened by TCP/GCP Intermetallics for A-USC Power Plants: *Masao Takeyama*[1]; Imanuel Tarigan[2]; [1]Tokyo Institute of Technology, Consotium of the Japan Research and Development Center for Materials (JRCM); [2]Tokyo Institute of Technology

For sustainable and reliable energy supply sources, advanced thermal power plants (A-USC) is receiving more attention since shutdown of nuclear power plants by an unprecedented devastating earthquake in Japan. For A-USC in reality, new materials with superior long-term creep rupture strength longer than 10^5 hours under 100 MPa at 973 K are desired. Besides some Ni base alloys, none of the conventional austenitic heat resistant steels meet this requirement. Why? This is due to microstructure instability of major strengthening spices/metallic carbides during high temperature exposure. We have developed novel austenitic steels strengthened by two intermetallic phases of GCP (geometrically close-packed) and TCP (topologically close-packed), and revealed excellent creep performance. In this talk, the design approaches based on phase diagram calculation and new strengthening mechanism called "Grain-boundary precipitation strengthening" by TCP Laves phase is presented. Part of this study was carried under the research activities of the Consortium, financially supported by NEDO.

4:50 PM
Effect of Grain Boundary Laves Phase on Mechanical Properties of Fe-20Cr-30Ni-2Nb Steels: *Naoya Kanno*[1]; Naoki Takata[2]; Masao Takeyama[2]; [1]Tokyo Institute of Technology; [2]Tokyo Institute of Technology, Consortium of the Japan Research and Development Center for Materials (JRCM)

We have developed novel austenitic heat resistant steels Fe-20Cr-30Ni-2Nb (at.%) strengthened by Fe_2Nb-Laves phase for A-USC power plant. The steels show superior long-term creep strength due to "*grain boundary precipitation strengthening*" by Laves phase. Question is whether the grain boundary Laves phase embrittles the steels. In this study, thus, we intentionally prepared the steels with the area fraction of Laves phase (ρ) in the range of 0 to 90 %, and examined the tensile and Charpy impact properties at room temperature. The tensile elongation reduces from 50 % to 30 % with increasing the ρ from 0 to 80 %. The impact absorption energy decreases from 200 J/cm^2 to 30 J/cm^2 with increase in the ρ from 0 to 90 %. In any samples, however, there is no indication of intergranular fracture, indicating that grain boundary Laves phase is not a factor to deteriorate the properties.

5:10 PM
Microstructural Studies on Thermomechanically Processed Plain Carbon Dual Phase Steel: Abhishek Singh[1]; G Chaudhari[1]; Mukesh Bharadawaj[1]; *S Nath*[1]; [1]I. I. T. Roorkee

Dual phase steel, whose microstructure consists of primarily ferrite plus martensite, is categorized under advanced high strength steel (AHSS). This is due to its high UTS, adequate ductility, high work hardening rate and absence of yield point phenomenon. A lot of effort is being put to improve its strength along with its ductility. This steel is primarily aimed for automotive industries. In the present work, plain low carbon steel is thermomechanically worked in the intercritical temperature range by using thermomechanical simulator Gleeble 3800. Intercritical temperature, strain and strain rate have been varied to process the dual phase steel. It has been found that the steel thermomechanically worked in the intercritical region shows decrease in ferrite grain size, increase in volume fraction of ferrite and refinement of martensite island size as compared to dual phase steel with no thermomechanical treatment

Materials Research in Microgravity: Session VI

2:00 PM Invited
Coarsening of Two-Phase Mixtures: Experiments on the International Space Station: J. Thompson[1]; E. Gulsoy[1]; *Peter Voorhees*[1]; [1]Northwestern University

In any two-phase mixture that contains particles of different sizes, the large particles tend to grow while the small particles shrink. Solid-liquid mixtures are ideal systems to study this coarsening process and compare the results to theory. Using the microgravity environment of the International Space Station it is possible to study the coarsening process in solid-liquid mixtures with reduced interference from the sedimentation that occurs on Earth. Specifically we have studied the coarsening process in systems consisting of particles of tin suspended in a liquid tin-lead alloy. A series of experiments were performed in the Microgravity Glove Box. The analysis of the experiments employs three-dimensional reconstructions of the microstructures. We have analyzed samples with a range of volume fraction of solid, and have compared the coarsening rates, particle size distributions, and interparticle spatial correlation functions with those predicted by theory. The implications of this test of theory will be discussed.

2:35 PM Invited
Multi-Scale Modeling on Liquid Phase Sintering Affected by Gravity: Preliminary Analysis: *Eugene Olevsky*[1]; Randall M. German[1]; [1]San Diego State University

Results of the multi-scale simulations of the gravitational role on liquid phase sintering are reported in terms of densification, distortion, and microstructure development. The gravity influence is taken into account at both the micro- and macro-scales. At the micro-scale, the diffusion mass-transport is directionally modified in the framework of kinetic Monte-Carlo simulations to include the impact of gravity. The micro-scale simulations provide the values of the constitutive parameters for macroscopic sintering simulations. At the macro-scale, we are attempting to embed a continuum model of sintering into a finite-element framework that includes the gravity forces and substrate friction. If successful, the finite elements analysis will enable predictions relevant to space-based processing, including size and shape and property predictions. Model experiments are underway to support the models via extraction of viscosity moduli versus composition, particle size, heating rate, temperature, time and these reflect bonding, dihedral angle, and liquid and solid phases.

3:10 PM
Self-assembly of Ni-nanoparticles in Aerosols Produced Thermally On-ground and under Microgravity Conditions: *Stefan Lösch*[1]; Bernd Günther[1]; Daniela Nolle[2]; Eberhard Göring[2]; [1]Fraunhofer; [2]Max-Planck-Institut

The self-assembly behavior in Ni-aerosols was studied on-ground and under microgravity conditions by using the European sounding rocket MAXUS 8 and the parabolic flight aircraft A300 Zero-G. In microgravity, convection within the thermally produced aerosols could be effectively suppressed. It is shown that due to magnetic dipole interaction the Ni-particles agglomerate in a chain-like morphology both on-ground and in parabolic flights. It is shown that the chain length increases with increasing agglomeration time. This time scale could be extended in the range of minutes by using the sounding rocket microgravity platform. In general,. under microgravity condition the intrachain size distribution of the Ni-particles is narrower than gets narrower. This is reduced to the ideal flow condition in microgravity. Surprisingly the sounding rocket platform did not result in chain-like Ni-agglomerates. Instead irregular morphology of fluffy agglomerates resulted similar to those observed for non-magnetic nanoparticles. These results are explained by considering the thermal history during particle synthesis in this process.

Crystallographic Stability of Metastable Phase Formed by Containerless Processing in REFeO3 (RE: Rare-Earth Element): *Kazuhiko Kuribayashi*[1]; M.S. Vijaya Kumar[2]; [1]Shibaura Institute of Technology; [2]Institute of Space and Astronautical Science, JAXA

Undercooling a melt often facilitates a metastable phase to preferentially nucleate. In case of REFeO3 (RE:Rare-earth element), although the equilibrium phase is perovskite, the space group of which is Pbnm, metastable hexagonal phases of P63cm or P63/mmc are formed from the deeply undercooled melt. The stability of perovskite structure can be well described by the tolerance factor TF. That is, TF=1: ideal, $0.8<TF<$

1: stable, and TF<0.8: unstable. For the metastable hexagonal phase of REFeO3, however, there has been no criterion for the crystallographic stability. In the present investigation, based on the geometrical consideration on the ionic radii of constituent ions, RE3+, Fe3+ and O2, the criterion for metastable hexagonal phase to be formed is also expressed by tolerance factor, as TF=0.87:ideal. TF<0.87:stable, and TF>0.87:unstable, respectively. Experimental result using aerodynamic levitator (ADL) well agreed with this prediction under reduced oxygen partial pressure, Po2, as well as in ambient one.

4:30 PM
On-Line Real Time Diagnostics of a Single Fluid Atomization System: *Pooya Delshad Khatibi*[1]; Arash Ilbagi[1]; Hani Henein[1]; [1]University of Alberta

A drop tube-impulse atomization technique was used to produce copper powders. In this method, by a plunger movement, energy is transferred to a liquid resulting in spherical droplets emanating from orifices. A mathematical model of the evolution of droplet velocity and temperature at various heights for different sized droplets was developed. To measure the velocity (Shadowgrah) and radiant energy (DPV-2000), a 3-D translation stage was designed, constructed and installed in the drop tube. Using experimental and model results, it was found that the falling droplets do not reach their terminal velocity at their melting point, and the acceleration of falling droplets is close to gravitational acceleration. The results of in-situ measurements showed that at each height, radiant energy of larger droplets is larger than that of the smaller ones. Correlation between experimentally measured radiant energy and predicted temperature of falling droplets at different heights will be discussed in this paper.

4:55 PM
Electrodeposition of Metals in Microgravity Conditions: Yasuhiro Fukunaka[1]; [1]JAXA/Waseda University

Metal electrodeposition may introduce various morphological variations depending on the electrolytic conditions including cell configurations. For liquid electrolytes, a precise study of these deposits may be complicated by convective motion due to buoyancy. Zero-gravity (0-G) condition provided by drop shaft or parabolic flight gives a straightforward mean to avoid this effect: we present here 0-G electrodeposition experiments, which we compare to ground experiments (1-G). Two electrochemical systems were studied by laser interferometry, allowing to measure the concentration variations in the electrolyte: copper deposition from copper sulfate aqueous solution and lithium deposition from an ionic liquid containing LiTFSI. For copper, concentration variations were in good agreement with theory. For lithium, an apparent induction time was observed for the concentration evolution at 1-G: due to this induction time and to the low diffusion coefficient in ionic liquid, the concentration variations were hardly measurable in the parabolic flight 0-G periods of 20 seconds.

5:20 PM
Propagation Regime of Iron Dust Flames: *Francois Tang*[1]; Samuel Goroshin[2]; Andrew Higgins[2]; [1]European Space Agency; [2]McGill

A flame propagating through an iron-dust mixture can propagate in two asymptotic regimes. When the characteristic time of heat transfer between particles is much smaller than the characteristic time of combustion, the flame propagates in the continuum regime where the heat release by reacting particles can be modelled as a space-averaged function. In contrast, when the characteristic time of heat transfer is much larger than the combustion time, the flame can no longer be treated as a continuum due to dominating effects associated with the discrete nature of the particle reaction. The discrete regime is characterized by a weaker dependence of the flame speed on the oxygen concentration compared to the continuum regime. The discrete regime is observed in flames propagating in a mixture of iron dust in a gas mixture containing xenon, while the continuum regime is obtained when xenon is substituted with helium.

Mechanical Behavior at Nanoscale I: Nanomechanical Experiment and Modeling

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Nanomechanical Materials Behavior Committee, TMS/ASM: Mechanical Behavior of Materials Committee

Program Organizers: Scott Mao, University of Pittsburgh; Julia R Greer, California Institute of Technology ; Jianyu Huang , Center for Integrated Nanotechnologies; Marc Legros, CEMES-CNRS; Ting Zhu, Georgia Institute of Technology

2:00 PM Invited
Effect of Electric Current on Nanoindentation of Copper: *Fuqian Yang*[1]; [1]University of Kentucky

The electromechanical behavior of electronic interconnects plays an important role in determining the reliability and lifetime of microelectromechanical devices and structures. Using the nanoindentation technique, the effect of electric current on the indentation deformation of copper wires was studied under the indentation load of 0.05 mN to 1 mN at room temperature. During the indentation, a constant direct electric current of the current density in a range of 6.4 to 31.8 kA/cm2 was passed through the copper wires, which introduced electromechanical interaction. The indentation results showed that the apparent contact modulus decreased with increasing electric current density and the apparent indentation hardness increased slightly with increasing electric current density. The decrease of the apparent contact modulus with increasing electric current density was likely due to the momentum exchange among high-speed electrons and atoms.

2:20 PM
Structure Effects on the Bending Strength of Si Nanowires: *Gheorghe Stan*[1]; Sergiy Krylyuk[1]; Albert Davydov[1]; Igor Levin[1]; Robert Cook[1]; [1]National Institute of Standards and Technology

Nanoscale mechanical tests for elasticity, plastic deformation, fracture, toughness, creep, and fatigue provide key information in selecting materials and structures for reliable and high performance functionality of emerging nanoscale devices. In this work, a new and direct method for testing the fracture strength of substrate-supported nanowires is introduced. The ultimate fracture strengths of Si nanowires with radii in the 20 nm to 60 nm range were measured through a sequential atomic force microscopy manipulation-scanning protocol. Using crystallographic structure analysis provided by transmission electron microscopy, the fracture strength of the measured Si nanowires was assessed in terms of microstructure and surface effects. On one hand, the internal twin-structure of the nanowires can account to some extent for the large average values of the measured fracture strengths. On the other hand, the radius dependence of the fracture strength can be rationalized as a surface effect determining the number of stress-concentrating surface flaws.

2:40 PM
Extended Structure of Point Defects in Graphene: *Mark Jhon*[1]; David Srolovitz[1]; [1]Institute of High Performance Computing

Nanoscale materials are often flexible, and can bend easily relative to bulk systems. If a flexible nanostructure has internal stresses due to, for instance, crystallographic defects, it can bend to accommodate them. The mechanical deformations associated with point defects can potentially cause large changes to the shape of the nanostructure. Considering graphene flakes as a model flexible nanostructure, we analyze the extended shape of point defects using continuum elasticity. We find conditions under which graphene will buckle due to a point inclusion.

The continuum analysis is validated by comparison to molecular statics calculations using empirical potentials.

3:00 PM
Estimation of Dislocation Nucleation Stresses from Nanoindentation by Combined Modeling and Experiment: *Li Ma*[1]; Dylan Morris[2]; Stefhanni Jennerjohn[3]; David Bahr[3]; Lyle Levine[1]; [1]NIST; [2]Michelin North America; [3]Washington State University

The dislocation nucleation stress of crystalline materials is frequently estimated from the maximum shear stress assuming Hertzian contact up to the first "pop-in" event, which is a sudden displacement burst during load-controlled nanoindentation. However, real Berkovich indenter tips may have irregular shapes. Here, we assess possible errors and pitfalls of the Hertzian estimation of initial plastic yield at the nanoscale. The near-apex shape of two Berkovich indenters, one sharp and one worn, were measured by atomic force microscopy and directly input into finite element approach (FEA) models for "virtual" nanoindentation experiments on single-crystal tungsten. Experiments were also carried out with those indenters. Excellent agreement is found between experimental and FEA force-displacement relationships, but the discrepancies between Hertzian and FEA estimates of the shear stresses are over 30%. This indicates that small irregularities in the shape of indenter tips may cause significant deviations from the Hertzian estimation of dislocation nucleation stress.

3:20 PM
Interaction of the Microstructure and Test Geometry on the Size Dependence of Plasticity: *Andy Bushby*[1]; David Dunstan[1]; [1]Queen Mary, University of London

Nanoscale plasticity is often studied within single crystals of material, for instance in nanoindentation, micro-pillar compression and micro-tensile experiments, and the size effects considered separately from those associated with microstructure. Theoretical models of size dependant plasticity also do not consider the mutual effect of microstructure. Here we present experimental data that explore the combined influence of different size effects in the flexure of thin foils, the torsion and tension of thin wires and nanoindentation, in which the grain size is varied in relation to the structure or stressed volume. This approach allows for cross-correlation between structure size and grain size. By carefully choosing different test geometries and grain sizes, the destination of dislocations can be manipulated and the interaction of the different length scales studied. The results are used to rigorously test the ability of theoretical models to describe the yield and flow in metals at the nanoscale.

3:40 PM
Quantifying Polysilicon Strength Size Effects Using an In-Situ on-Chip Tensile Test Platform: Mohamed Saleh[1]; Siddharth Hazra[1]; *Jack Beuth*[1]; Maarten de Boer[1]; [1]Carnegie Mellon University

Freestanding polycrystalline silicon (polysilicon) is a brittle material, necessitating a statistical representation of strength data supported by a large number of tests. In this research, size effects in the strength of polysilicon are studied using a compact micro/nanoscale testing platform using an on-chip thermal actuator to apply stresses to a self-aligned tensile specimen. The testing platform allows the testing of hundreds or more specimens on the same wafer, and results are presented for test trials of 200-300 specimens. Size effects in polysilicon strength are caused by a distribution of crack-like flaws that form at grain boundaries during processing. With results from large testing trials, Weibull statistics are used to predict the size-dependent strength of unnotched and notched tensile specimens over the full range of practical component sizes. Experimental results are presented yielding insights into the accuracy of such predictions and how they can be used effectively in designing MEMS devices.

4:00 PM Break

4:10 PM
Humidified Nanoindentation: Grant Klafehn[1]; *Corinne Packard*[1]; [1]Colorado School of Mines

The relative humidity of the testing atmosphere can have a marked influence on mechanical behavior— from fracture in ceramics to creep in hydrated polymers and biomaterials. The fundamentals of deformation in processes like these can be elucidated using the high-resolution measurement capabilities of nanoindentation. However, testing in humidified environments presents several challenges, including atmospheric control and monitoring, condensation management, sensitivities of equipment to corrosion, and mitigation of thermal drift for elevated temperature experiments. Historically, approaches to humidified indentation have ranged from the placement of saturated salt solutions close to the sample to custom apparatuses and commercial systems. In this talk, previous applications of indentation in humidified environments are reviewed and the development of a recently designed custom system for performing nanoindentation in a humidified environment with temperature control is presented. System design features and performance are described in detail and compared to the existing state of the art.

4:30 PM
A Nanoscale Investigation on Effect of Hydrogen in Confined Volumes: *Ilaksh Adlakha*[1]; Kiran Solanki[1]; Amitava Moitra[2]; Mark Tschopp[3]; [1]SEMTE; [2]Pennsylvania State University; [3]Mississippi State University

The detrimental effects of hydrogen on mechanical behavior of metals are well known. There are several proposed mechanisms to explain this behavior, but no general consensus has been reached. In this work, we use molecular dynamic simulations to gain a better understanding of the effect of hydrogen in confined volumes. Single crystal nanowires of different diameters are doped with various hydrogen percentages. Doping hydrogen severely decreases the yield strength across the studied size spectrum. It is hypothesized that studying the hydrogen diffusivity under changing stress state can shed light on its effect on mechanical properties. As hydrogen concentration is increased, the yield asymmetry increases; these findings are correlated with the diffusivity of hydrogen. These results help us gain a better understanding of the effect of hydrogen at nanoscale.

4:50 PM
Automated Analysis of Crystal Defects in Large-Scale Atomistic Computer Simulations: *Alexander Stukowski*[1]; Tom Arsenlis[1]; [1]Lawrence Livermore National Laboratory

Large-scale atomistic simulation methods such as molecular dynamics (MD) are routinely used to study the deformation of crystalline materials at the atomic scale. We present a set of sophisticated computational analysis methods to extract and characterize structural defects in such simulations in a fully automated way. The newly developed techniques cover defects such as stacking faults, grain boundaries, interfaces, dislocations, point defects, and defect clusters in a wide range of crystal lattices. To exemplify the range of applications of our approach, we discuss the identification of grain boundary dislocations in MD simulations, allowing us to directly visualize their interaction and/or reaction with lattice dislocations. We also show how atomic trajectories obtained from MD can be used to calculate the strain tensor field, and how it can be decomposed into elastic and plastic components to quantify the contribution of dislocations to total strain.

5:10 PM
Nanoindentation of Nanoporous Polycrystalline Platinum: Ran Liu[1]; Yuan Li[1]; *Antonia Antoniou*[1]; [1]Georgia Institute of Technology

Nanoporous Pt (np-Pt) is synthesized by electrochemical dealloying of co-sputtered Ptx¬Si1-x amorphous films. The initial alloy deposition conditions and dealloying conditions were varied and their effect on the assembled NP Pt was examined. We find that the spatial arrangement of nano-sized ligaments can be tailored. Nanoindentation tests reveal that the hardness of isotropic NP Pt is ~1GPa but it can increase by as much as 3-4 times due to the geometrical arrangement of NP metal ligaments.

5:30 PM
Deformation Mechanism of Nanocrystalline Copper during Relaxation Test: *Junya Inoue*[1]; Saethavuth Krasienapibal[1]; Toshihiko Koseki[1]; [1]The University of Tokyo

Void and twin formations in nanocrystalline Cu during relaxation experiments were quantitatively studied to clarify the effect of grain size distribution on the deformation behavior in nanocrystalline Cu at room temperature. Cu films with various thicknesses were deposited on Si/SiO2/TaN and polyimide substrates by magnetron sputtering deposition method. On the top and bottom surfaces of the Cu layer, Ta layers were deposited to suppress the surface diffusion of Cu during the relaxation test. The Cu films were annealed after the deposition to stabilize grain structure in a vacuum. Microstructural evolution as well as void formation was studied after relaxation experiment. Voids were found at the grain boundary triple points in the films subjected to the relaxation experiment. A clear grain-size dependencies of the number of void and the twin density was demonstrated. The competition between the accommodation processes will be further discussed.

Mechanical Behavior Related to Interface Physics: Deformation Mechanisms in Nanoscale Materials

2:00 PM Keynote
Deformation Mechanisms in Single Boundary-Containing Metallic Nano-Pillars: Grain, Phase, and Crystal Boundaries: *Julia Greer*[1]; Robert Maass[1]; Xun Gu[1]; Qiang Guo[1]; Siddartha Pathak[1]; [1]California Institute of Technology

When microstructural (intrinsic) or external material dimensions of materials are reduced to nano-scale, they exhibit size-dependent strengths. To date, most studies on "size effects" have focused on single crystalline metals. While these studies provide powerful foundation for fundamental deformation processes at small scale, they are a far reach from representing real materials, whose microstructure is often complex. To elucidate specific role a particular boundary plays on material deformation and mechanical properties, we fabricate nanopillars containing a single known boundary with diameters from 50nm to 1micron by E-beam lithography/electroplating and via FIB. Their mechanical response in uniaxial compression and tension is subsequently measured in in-situ mechanical deformation instrument, SEMentor. We present nano-mechanical behavior in four distinct metallic systems containing single well-characterized boundary: bi-crystalline Al, Cu/Fe (fcc/bcc), Cu/Ni (fcc/fcc), and Ni3Al precipitates in Ni-rich matrix. We discuss their deformation in context of dislocation activity when free surfaces and interfaces are present concurrently.

2:30 PM Keynote
Lithiation Induced Stress and Failure of Anode Materials in Lithium Ion Batteries: *Jianyu Huang*[1]; [1]Sandia National Laboratories

Lithiation induced stress and failure in anode materials were observed by in-situ electron microscopy. The stress and failure were strongly materials, size, and orientation dependent. Upon charging of SnO2 nanowires, we observed high density of dislocations in the reaction front, while in charging of ZnO nanowires, we observed discrete cracks in the reaction front. In charging Si nanowires, we found the volume expansion was highly anisotropic, resulting in a dumbbell-shaped cross-section and cracking, eventually splitting the single nanowire into sub-wires. Carbon coating not only increases rate performance but also alters the lithiation-induced strain of SnO2 nanowires. The radial expansion of the coated nanowires was completely suppressed. The lithiation process of individual Si nanoparticles was strongly size-dependent, i.e., there exists a critical particle size with a diameter of ~ 150 nm, below which the particles neither cracked nor fractured upon lithiation, above which the particles first formed cracks and then fractured.

3:00 PM
Effect of Contact Interface on the Mechanical Behavior of Submicro Sized Au Particles: Zhangjie Wang[1]; *Zhiwei Shan*[1]; Ju Li[2]; Jun Sun[1]; Evan Ma[3]; [1]Center for Advancing Materials Performance from the Nanoscale (CAMP-Nano) & Hysitron Applied Research Center in China (HARCC), State Key Laboratory for Mechanical Behavior of Materials, Xi'an Jiaotong University; [2]Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, Massachusetts Institute of Technology; [3]Department of Materials Science and Engineering, Johns Hopkins University

Pristine single crystalline gold particles with sizes ranging from 300~700 nm have been fabricated through high-temperature (1150°C) liquid de-wetting of gold thin films, and fixed atop a specially designed SiO2/Si substrate for in situ TEM testing. Quantitative compression tests indicated that these particles display structural collapse upon high stresses (over 1GPa) in the early stage. The initial structural collapse results in a nearly pristine postmortem microstructure. When the contact interface diameter d is small enough, spatially and temporally correlated load shedding is proposed to explain the pristine to pristine structural collapse. Upon further compression, once the d increases above a critical value (~250 nm), continuous plastic deformation begins to set in under relatively low flow stress with the postmortem microstructure containing a high density of tangled dislocations, indicating a critical d for dislocation interaction volume for multiple slip is needed for the dislocation storage and normal dislocation plasticity.

3:15 PM
Exhaustion Hardening in Mo-alloy Nanofibers: *Claire Chisholm*[1]; Hongbin Bei[2]; Matthew Lowry[1]; Jason Oh[3]; S.A. Syed Asif[3]; Oden Warren[3]; Zhiwei Shan[4]; Easo George[5]; Andrew Minor[1]; [1]University of California, Berkeley and National Center for Electron Microscopy; [2]Materials Science and Technology Division, Oak Ridge National Laboratory; [3]Hysitron Incorporated; [4]Center for Advancing Materials Performance from the Nanoscale (CAMP-Nano), State Key Laboratory for Mechanical Behavior of Materials, Xi'an University and Hysitron Incorporated; [5]Materials Science and Technology Division, Oak Ridge National Laboratory and Department of Materials Science and Engineering, University of Tennessee, Knoxville

The evolution of defects in Mo alloy nanofibers with dislocation densities ranging from 0 to ~1 x 10^14 m-2 were studied using an in situ "push-to-pull" (PTP) device in conjunction with a quantitative nano-indenter in a transmission electron microscope (TEM). By augmenting the in situ testing method with Digital Image Correlation (DIC), we can determine the true stress and strain in local areas of deformation. With no initial dislocations, the Mo-alloy nanofibers suffered sudden catastrophic elongation and softening at ultrahigh stresses. On the other extreme, fibers with a high dislocation density operated with sustained homogeneous deformation, but failed at lower stresses. Between these two extremes nanofibers with intermediate dislocation densities demonstrated clear exhaustion hardening behavior, where the progressive exhaustion of dislocations increases the stress required to drive plasticity.

3:30 PM
Fracture Toughness of Nanocrystalline Cu and Cu-Cr pillars Thin Film Composites: *Sharvan Kumar*[1]; Seong-Woong Kim[2]; Jin-Woo Yi[1]; Hyun-Gyu Kim[3]; Kyung-Suk Kim[1]; [1]Brown University; [2]Korea Institute of Materials Science; [3]Seoul National University of Technology

A hybrid method of experiments and finite element analyses is developed to measure in-plane elastic modulus and fracture toughness of free-standing, uniform-thickness, electron-transparent nanocrystalline thin films and thin film composites. Electron beam evaporation coupled with lithography and patterning is used to produce these films of nanocrystalline Cu and Cu-Cr "pillar" composites with uniform diameter and spacing of Cr pillars. The in-plane modulus of such films is measured non-destructively by using a modified bead-tip AFM in conjunction with a newly developed diamagnetic normal force calibrator capable of measuring forces from 0.1 nN to 1.0 μN with three digit accuracy. The films are then in-situ tested by loading in the TEM to advance a crack tip; the crack opening profile is used to obtain the fracture toughness employing an iterative finite element inverse analysis; the crack kinking angle at the Cu-Cr interface is then used to evaluate the interface fracture toughness.

3:45 PM Break

3:55 PM Keynote
Friction and Mechanics of Lamellar and Nanostructured MoS_2: Eric Bucholz[1]; Simon Phillpot[1]; *Susan Sinnott*[1]; [1]University of Florida

Classical molecular dynamics (MD) simulations are used to investigate the influence of structural changes on tribological and mechanical properties of MoS_2 with lamellar, fullerene-like, and nanotubes structures. The simulations probe the effect of edges on the friction behavior of the lamellar strutures by considering two-dimensional periodic sheets, one-dimensional periodic ribbons, and non-periodic flakes across a range of temperatures as a function of applied load. In the case of fullerene-like nanoparticles, two specific configurations with three nested layers each are considered: a curved, ellipsoidal particle and a faceted nanooctahedron. This allows for the characterization of the role of curved and faceted morphologies as well as grain boundaries on the rolling and sliding behavior as well as any lamellar exfoliation of individual nanoparticles. In the case of nanotubes, the simulations investigate compression, tension, torsion, and bending to explore the effect of aspect ratio on their mechanical properties.

4:25 PM Keynote
Dislocation-Twin Interactions in Nanocrystalline fcc Metals: *Yuntian Zhu*[1]; [1]North Carolina State University

Dislocation interaction with and accumulation at twin boundaries have been reported to significantly improve the strength and ductility of nanostructured face-centered cubic (fcc) metals and alloys. Here I describe plausible dislocation interactions at twin boundaries. Depending on the characteristics of the dislocations and the driving stress, possible dislocation reactions at twin boundaries include cross-slip into the twinning plane to cause twin growth or detwinning, formation of a sessile stair-rod dislocation at the twin boundary, and transmission across the twin boundary.

4:55 PM
Investigating the Role of Grain Boundaries during the Plastic Deformation of Bicrystalline Nanowires Using Molecular Dynamics: *Garritt Tucker*[1]; Zachary Aitken[2]; Julia Greer[2]; Christopher Weinberger[1]; [1]Sandia National Laboratories; [2]California Institute of Technology

The competition between free surfaces and grain boundaries to act as preferred sites for dislocation nucleation in aluminum nanowires is investigated using molecular dynamics simulations at room temperature. A number of bicrystalline nanowires containing various minimum energy boundaries are studied under uniaxial compression, providing a broad, inclusive look on the competition between the two types of sources. The simulation results provide insight into recent micro-compression experiments on bicrystals, suggesting the role of the vertical grain boundaries as sinks rather than sources for dislocations. Furthermore, this work compares the behavior of nanowires containing both low and high-angle symmetric tilt boundaries with those containing random high-angle boundaries.

5:10 PM
Interpreting Hardness Data in Multilayer Thin Films: *Michael Gram*[1]; John Carpenter[2]; George Pharr[3]; Peter Anderson[1]; [1]Ohio State University; [2]Los Alamos National Laboratory; [3]University of Tennessee

Metallic multilayer thin films are often characterized by hardness obtained from nanoindentation and more recently by compressing micron-scale pillars. However, the Tabor factor relating hardness and flow strength is unexplored for such high strength, nanoscale composite systems. Here, we show that the hardness to flow strength ratio can dip below 2, substantially less than ~3 used for conventional metals. This is demonstrated through finite element simulations of Cu/Ni multilayer thin films employing a variety of bilayer periods, Cu:Ni volume fraction ratio, and residual stress states. The largest reductions in the Tabor factor occur when there is a large disparity in flow strength between Cu and Ni layers and/or a large residual tension on the film. Nanoscale films are particularly sensitive to these effects because the flow strength is extraordinarily large, often reaching several percent of the composite elastic modulus. These findings are applied to experimental data for the Cu/Ni system.

5:25 PM
Interaction between Lattice Dislocation and Weak Interface in Anisotropic Bi-Crystal Composites: *Haijian Chu*[1]; Jian Wang[2]; Caizhi Zhou[2]; Irene Beyerlein[2]; [1]Yangzhou University; Los Alamos National Laboratory; [2]Los Alamos National Laboratory

"Weak interface strengthening mechanisms" have been proposed based on atomistic simulations and demonstrated by experiments on nanolayered composites. Related theoretical models in meso/macro scales remain, however, absent. We studied the interaction between lattice dislocations and weak interfaces in anisotropic bi-layer composites by using the Green's function method. The influence of interface strength on dislocation transmission is investigated. Also, the nucleation and growth of interface dislocations are considered as a lattice dislocation approaches the interface. The core collapse of interface dislocations that accompanies the emission of lattice dislocation from interfaces is taken into account. The numerical results show that 1) in contrast to elastic isotropy, elastic anisotropy has a strong influence on both the image force on the dislocations and stress distribution along the interface plane; 2) dislocation transmission across the interface is much easier for a strong interface (no interface dislocations are activated) than weak one.

Mechanical Performance of Materials for Current and Advanced Nuclear Reactors: Irradiation Performance of Advanced and Model Alloys

Effect of Irradiation on the Tensile and Impact Properties of Structural and Cladding Materials: *Jean Henry*[1]; Xavier Averty[1]; Philippe Dubuisson[1]; [1]CEA

The performance of structural and cladding materials is a key issue for the safe and reliable operation of nuclear reactors. In this presentation, we will illustrate the effect of irradiation up to high doses on the mechanical behaviour of structural and cladding materials, such as austenitic stainless steels and 9-12Cr ferritic-martensitic steels, with emphasis on tensile and impact properties. Microstructural evolution and the related degradation of mechanical properties depend strongly on the irradiation temperature but also on the radiation environment. For instance, high quantities of helium produced by transmutation in a fusion environment may induce drastic embrittlement of ferritic-martensitic steels. Advanced materials, such as nanodispersed ODS alloys are being developed in the hope that they will provide, in addition to good high temperature strength, excellent resistance to radiation and helium embrittlement . As a conclusion, we will discuss the irradiation behaviour of ODS alloys, based on fission and spallation data.

2:30 PM
Rate Sensitivity in Irradiated HT-9 for Reactor Applications: *Stuart Maloy*[1]; Tarik Saleh[1]; Tobias Romero[1]; Sara Perez-Bergquist[1]; Mychailo Toloczko[1]; [1]Los Alamos National Laboratory

The Fuel Cycle Research and Development program is investigating methods of burning minor actinides in a transmutation fuel through various fuel cycle options. To achieve this goal, the fast reactor core materials (cladding and duct) must be able to withstand very high doses (>200 dpa) while in contact with the coolant and the fuel. In order to develop physics-based models of cladding materials for fast reactor applications, more specific testing is required in addition to typical tensile testing. Analysis of a duct made of HT-9 after irradiation to a total dose of 155 dpa at temperatures from 370 to 510°C is almost complete including tensile, charpy impact and fracture toughness testing. Specific rate jump tests are underway to investigate rate sensitivity before and after irradiation. Detailed microstructural analysis has also been performed with TEM. A summary of rate sensitivity will be presented in connection with detailed analysis of controlling defects.

2:50 PM
High Temperature Mechanical Properties of Nanostructured Ferritic Alloys and Advanced Ferritic-Martensitic Steels: *Thak Sang Byun*[1]; David Hoelzer[1]; Lizhen Tan[1]; Stuart Maloy[2]; [1]Oak Ridge National Laboratory; [2]Los Alamos National Laboratory

Both the nanostructured ferritic alloys (NFAs) and the advanced ferritic-martensitic (FM) steels have been developed as primary candidate materials for the fission and fusion applications. High temperature tensile and fracture tests have been performed at RT-700°C for various NFAs and FM steels including 14YWT, PM2000, Fe-9Cr NFAs, NF616, and advanced 9Cr steels. The discussion aims at comparing the mechanical behaviors to elucidate strengths and weaknesses of these advanced materials in high temperature applications. The newly produced data as well as published data are integrated and compared in terms of the temperature dependences of their strength, ductility, plastic instability stress, fracture toughness, etc. Although the ductility and fracture toughness of NFAs are significantly lower than those of the advanced 9Cr FM steels, their high temperature strengths are generally higher. Comparing the strain hardening parameters, however, it is shown that the characteristic difference between NFAs and FM steels is not significant.

3:10 PM
Radiation Damage in ODS Ferritic Steel under Multi-Ion-Beam Irradiation: *Luke Hsiung*[1]; Michael Fluss[1]; Scott Tumey[1]; Bill Choi[1]; [1]Lawrence Livermore National Laboratory

A major challenge in designing fusion reactors is to develop high performance materials for first wall and breeding-blanket components that will be exposed to high fluxes of high-energy neutrons and helium and hydrogen gases. Although ferritic and martensitic steels and ODS steels are promising candidate materials, it remains to be understood the role of helium and hydrogen in the dimensional stability of the steels under fusion environment. One technique used to study the damage structure utilizes TEM examinations of specimens simultaneously bombarded by heavy ions and helium and/or hydrogen ions through "multi-beam" experiments. The heavy ions generate atomic displacements; the gas ions generate helium and hydrogen gases. HRTEM studies were conducted to compare radiation damage in Fe-14Cr alloy and Fe-16Cr ODS steel through (He + Fe) dual-beam and (H + He + Fe) triple-beam experiments. Results are presented to reveal the role of nanoparticles/clusters in the suppression of void swelling.

3:30 PM
Radiation Tolerant Metallic Multilayers: *Xinghang Zhang*[1]; L. Shao[1]; H. Wang[1]; E.G. Fu[2]; Nan Li[2]; A. Misra[2]; Y-Q Wang[2]; [1]Texas A&M University; [2]Los Alamos National Laboratory

Metallic materials in nuclear reactors are subjected to harsh radiation environment. Severe damage such as void swelling and embrittlement accompanied by hardening is frequently observed in structural steels. Strategies that can alleviate radiation damage may assist the design of radiation tolerant materials. We will summarize our recent studies on radiation damage in sputtered metallic multilayers with individual layer thickness of 1 - 200 nm, subjected to Helium ion irradiations up to 18 displacements-per-atom at room temperature. Swelling, Helium bubble density, lattice expansion and radiation hardening all decrease significantly with decreasing layer thickness. Pressurized He bubbles appear to play an important role on lattice distortion and radiation hardening. The study demonstrates that certain type of interfaces can significantly reduce radiation induced defect density, and consequently leads to radiation tolerant metallic nanocomposites.

3:50 PM Break

4:10 PM
Irradiation Response of Nanostructured Austenitic Model Alloy: *Yong Yang*[1]; Cheng Sun[2]; Xinghang Zhang[2]; Todd Allen[3]; [1]University of Florida; [2]Texas A&M University; [3]University of Wisconsin-Madison

A model austenitic alloy was processed using the equal channel angular pressing (ECAP) method to obtain the average grain size of 360 and 250 nm at two different processing temperatures, respectively. The irradiation response regarding to different grain size and grain boundary character was examined on the specimens after Fe++ and H+ irradiations. The irradiation effect on the grain size and grain boundary character distribution was evaluated using NanoMEGAS, an advanced electron diffraction tool in a transmission electron microscopy (TEM). And the irradiated microstructures included defect cluster and dislocations were examined using TEM at systematically tilted diffraction conditions, and irradiation induced hardening was studied using a nano-indenter.

4:30 PM
Microstructure and Mechanical Properties of Proton Irradiated Titanium Aluminides: *Ming Tang*[1]; Yong-won Kim[2]; Yongqiang Wang[1]; Stuart Maloy[1]; [1]Los Alamos National Laboratory; [2]UES-Materials & Processes

Titanium aluminide is being considered as innovative structural materials for its potential application in advanced nuclear energy system. Ensuring adequate mechanical properties and dimensional stability under radiation is a key part in practical application. However, there is very limited radiation response data for titanium aluminides available. In the present study, we report on microstructure and mechanical properties of titanium aluminides, following irradiation with 1.3 MeV proton at room temperature to a dose of 1.5 dpa. The materials of interest in this presentation are Ti-48Al-2Nb-2Cr and Ti-43.5Al-4Nb-3Mn, both of them in the duplex and fully lamellar microstructures. The radiation induced damage microstructure is examined using transmission electron microscopy (TEM). The mechanical properties (Young's modulus and hardness) of these irradiated samples are determined by cross-sectional nano-indentation measurements as a function of ion penetration depth. Related to their different microstructure and composition, the different radiation response of these materials will also be discussed.

4:50 PM
Mechanical Properties and Radiation Response of Ultrafine Grained Fe-Cr-Ni Alloy: *C. Sun*[1]; J. Ma[1]; K.Y. Yu[1]; K. T Hartwig[1]; L. Shao[1]; S.A. Maloy[2]; X Zhang[1]; [1]Texas A&M University; [2]Los Alamos National Lab

Austenitic stainless steels are widely used as structural materials in nuclear industry. However, their further application is hindered by the relatively low mechanical strength, limited resistance to significant void swelling, radiation hardening and embrittlement. In this study, we present detailed investigations of mechanical properties and radiation response of ultrafine grained Fe-Cr-Ni alloy, which was synthesized by equal channel angular pressing. The deformation mechanisms, including strain hardening and strain rate sensitivity of the alloy, were investigated through a combination of uniaxial tensile tests and various microscopy experiments. Helium ion irradiation was performed to probe its radiation tolerance. Radiation-induced defects and hardening mechanisms will be discussed.

5:10 PM
In Situ Study of Radiation Damage in Pure Zr and Zircaloy-2: *Yasir Idrees*[1]; Zhongwen Yao[1]; Mark Daymond[1]; [1]Queens University

In situ real-time dynamic observations of the radiation damage evolution in pure Zr and Zircaloy-2 under heavy-ion irradiation have been carried out using Intermediate Voltage Electron Microscopy (IVEM)-Tandem facility at Argonne National Lab. Thin foils were irradiated with 1 MeV Kr+2 ions. Materials have been irradiated to different damage levels ranging from 0.01 dpa to 3.3 dpa and different temperatures ranging from 573 K to 773 K. Direct formation of nano defects from individual displacement cascades at the early stages of damage development at very low dose (0.01 dpa) has been observed by TEM. In situ observations of growth and evolution of these small defects into complex defect structures at high dose (3.3 dpa) have been recorded. Furthermore, irradiation of materials at different temperatures provided an opportunity to investigate the temperature dependence of defect accumulation,damage structures, defect densities, and their dynamic growth.

Minerals, Metals and Materials under Pressure: Damage and Microstructure

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS Structural Materials Division, TMS: Chemistry and Physics of Materials Committee, TMS/ASM: Phase Transformations Committee

2:00 PM Invited
Isolating the Influence of Kinetic and Spatial Effects on Dynamic Damage Evolution in OFHC Cu: *Darcie Dennis-Koller*[1]; Pablo Escobedo-Diaz[1]; Ellen Cerreta[1]; [1]Los Alamos National Laboratory

The need to control material performance in extreme environments is the motivation for this study to examine the separate effects of kinetics (in the form of high strain rate dynamic loading rate) from that of spatial effects (in the form of microstructural defect distributions). Plate impact experiments are design and executed to produce a state of insipient spall in OFHC Cu samples of well-characterized microstructures. Post experiment soft recovery and metallurgical analysis correlates loading conditions, microstructure, and resultant damage effects. This provides a link between in situ mesoscale effects and continuum level measurements for process aware material models. Experimental results will be presented as well as a description of length scale and kinetic processes as a function of loading condition.

2:30 PM
Effect of Release Rate on the Dynamic Tensile Response of Polycrystalline Copper: *Juan Escobedo*[1]; Ellen Cerreta[1]; Darcie Dennis-Koller[1]; Carl Trujillo[1]; Curt Bronkhorst[1]; [1]Los Alamos National Laboratory

Plate-impact experiments were conducted to examine the effect of release or de-compression rate on the dynamic tensile response of high purity copper samples. Samples with similar grain size and other microstructural features were subjected to a variety of shock-loading conditions. The compressive stresses were in the 1.5 – 2.5 GPa range and the release rates were modified by using copper, z-quartz and aluminum impactors. The free-surface velocity histories showed increasing values of strength with increasing release rate. Accordingly, the volume fraction of damage (voids) was observed to decrease as the release rates were increase. In addition, an accompanying large plastic dissipation, in the form of grain misorientation measured by means of electron backscatter diffraction, was present in the samples deformed at higher release rates, suggesting a time dependent behavior of the process that converts plastic dissipation into void growth.

2:50 PM
Continuum Scale Material Modeling under Large Strain, Strain Rates and Pressure Incorporating Microstructure Effect: *Nicola Bonora*[1]; Andrew Ruggiero[1]; Gianluca Iannitti[2]; Simone Dichiaro[1]; [1]University of Cassino; [2]Techdyn Engineering

Microstructure effect on the macroscopic material response becomes more evident under high strain rate deformation. Continuum scale constitutive models requires appropriate modification for representing microstructural features. In this paper two experimental tests, the dynamic extrusion test (DTE, high strain rate) and ECAP (low strain rate), in which the material is subjected to severe plastic deformation and pressure, have been investigated using an advanced constitutive modeling. The average grain size and normalized dislocation density are used as microstructure evolution descriptors and two levels of coupling accounts for the microstructure evolution on the material strength. Numerical simulations have been validated with experimental data for high purity copper with different grain size

3:10 PM
Mechanical Properties and Constitutive Modeling of Metals under Shock Deformation: *Shuh Rong Chen*[1]; Geroge Gray[1]; [1]Los Alamos National Laboratory

Metals under shock loading conditions exhibit enhanced hardening in some cases, no apparent enhanced hardening in others, and with softening for those undergo phase transformation. In this talk examples will be presented to illustrate the shock effect on mechanical properties. Advanced constitutive model will be modified to include the shock effect. *Work support by the US Department of Energy

3:30 PM
3-D Modeling of Incipient Spall Damage in Shocked FCC Multicrystals Using Crystal Plasticity: *Kapil Krishnan*[1]; Leda Wayne[1]; Andrew Brown[1]; Pedro Peralta[1]; Shengnian Luo[2]; Darrin Byler[2]; Aaron Koskelo[2]; [1]Arizona State University; [2]Los Alamos National Laboratory

3-D finite element (FE) simulations were used to study effects of microstructure, e.g., grain boundaries (GBs), on spall damage in copper multicrystals. Laser-driven plate impact experiments were conducted at low pressures (2-6 GPa) to induce incipient spall damage. The 3-D model was created using serial sectioning and analysis was performed with ABAQUS/EXPLICIT. Post-impact characterization revealed a need to distinguish damage due to either interfacial strength or stress concentrations at the interfaces. Crystal plasticity was used to account for material anisotropy, whereas damage evolution was modeled using two approaches – (1) Damage mechanics via a modified Gurson-Tvergaard-Needleman (GTN) model and (2) a cohesive zone model for GBs. The GTN model predicts the global damage characteristics relatively well whereas the cohesive zone model helps in predicting damage relative to the GB characteristics. The FE simulations show how local microstructure plays a role in void nucleation and growth, particularly in its incipient stage.

Low Temperature Twinning in Tantalum: *Mukul Kumar*[1]; [1]Lawrence Livermore National Laboratory

Twinning is considered an alternative to slip as a deformation mechanism under high strain rate or synonymously low temperature loading. This holds true particularly for BCC and HCP metals. The extent of twinning under such conditions will be explored for the case of polycrystalline Ta, which has been deformed in compression at liquid nitrogen temperatures under strain rates ranging from quasi-static rates (10^{-4} /s) to dynamic conditions without pressure (10^4 /s). Samples have also been tested at high rates (up to 10^8 /s) using laser-based shock compression drives. Post-mortem analysis using ESBD and TEM has revealed the influence of the prior deformation substructure on the onset of twinning. The implication of these observations on a critical stress based criterion for the onset of twinning will be examined. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

4:30 PM
Review of Pressure Effects on Flow and Fracture of Materials: *John Lewandowski*[1]; [1]Case Western Reserve Univ

The presentation will review the effects of pressure on flow and fracture of polycrystalline metals using a recent review article (1) as background. The effects of superimposed pressure on the flow stress will be reviewed, followed by effects on fracture. While the flow stress of most cubic crystalline metals are not very pressure dependent, some exceptions from the literature will be reviewed. The pressure dependence of the ductility and fracture behavior is very dependent on the mechanism(s) of failure. The presentation will conclude with more recent work on novel materials such as composites, bulk metallic glasses, and nano-composite materials. (1) International Materials Reviews, 43(4), pp. 145-188 (1998)

4:50 PM
The Effects of Microstructural Evolution on the Spall Response of 1100 Aluminum: *Cyril Williams*[1]; Changqiang Chen[2]; Kaliat Ramesh[2]; Datta Dandekar[1]; [1]U.S. Army Research Laboratory; [2]The Johns Hopkins University

As received 1100-O aluminum was cold rolled (CR) to 30 and 70 percent reduction respectively to study the effects of microstructural evolution on the spall response using plate impact experiments. The results show a sharp increase in pullback velocity for 1100-O aluminum with increase in peak shock stress between 4.0 and 8.5 GPa, followed by a decrease for peak shock stresses up to 11.5 GPa. This maximum was not observed for the 30% CR, which showed only an increase in pullback velocity over the shock stress range of 4 - 12 GPa. As the rolling increased with the 70% CR, no change was observed in the pullback velocity over the range tested. EBSD and TEM were used to probe the deformation mechanisms in all cases to validate the hypotheses that shock hardening and recovery can explain these macroscopic observations.

5:10 PM
The Role of Crystallite Orientation & Grain Boundary Character on the Uniaxial Dynamic Tensile Response in Commercially Pure 1050 Aluminum: *Nathaniel Sanchez*[1]; Darcie Dennis-Koller[2]; David Field[3]; [1]Los Alamos National Laboratory/Washington State University; [2]Los Alamos National Laboratory; [3]Washington State University

A series of plate impact experiments were performed on well characterized samples of commercially pure 1050 aluminum with grain sizes of 28µm, 43µm, 55µm, and 200µm. These experiments were designed to soft capture incipient spall damage in shock loaded samples which could be correlated to microstructural features through metallographic analysis with electron back scatter diffraction (EBSD). An optical velocimetry (VISAR) trace from the free surface was utilized to correlate the effects of damage growth rate observed through EBSD to changes in free surface velocity pull back rate. The influence of defect distribution (spatial effects) was isolated by varying the grain size while controlling shock loading conditions, which controls the total grain boundary area loaded in dynamic tension during the experiment. The shock wave shape and pulse duration were held constant. The role of crystallite orientation and grain boundary character on the nucleation and growth of voids will be discussed.

Thermoelectric Nanocomposites:
Effect of Nanostructures on Lattice Thermal Conductivity
: *Terry Tritt*[1]; Wenjie Xie[2]; Xinfeng Tang[2]; [1]Clemson University; [2]Wuhan University of Technology

This talk will give a brief introduction to thermoelectric phenomena and challenges that these materials present to the researcher along with an overview of several former and current applications. Recently there has been an ever-increasing research effort on thermoelectric nanocomposite material; a mixture of bulk thermoelectric materials with nanoparticles incorporated within the bulk matrix in some manner. However, we have found that the growth of "in-situ nanodots" exhibit a significant impact on the lattice thermal conductivity. The ability to decouple the electron and phonon scattering mechanisms is very important in the development of higher efficiency thermoelectric (TE) materials, wherein the figure of merit, ZT, can be greater than unity. The role of phonons in these nanocomposites may be one of the most important parameters to understand in these novel materials. A discussion of recent results in nanocomposite TE materials from several research groups, including my own, will be presented.

2:40 PM
Stabilization of Graphene-Polyaniline Based Nanocomposite Electrodes Using Barium Strontium Titanate for Supercapacitor Application: *Supriya Ketkar*[1]; Manoj Ram[1]; Ashok Kumar[1]; Thomas Weller[1]; Andrew Hoff[1]; [1]University of South Florida

Supercapacitors provide the high power and long durability needed for several new energy devices in electric vehicles, backup sources for various electrical devices and uninterrupted power supplies. Graphene (G)-polyaniline (PANI) has successfully incorporated graphene's and aniline monomer's superior properties to produce highly conductive nanocomposite material. A leakage current due to Faradic reactions at electrode-surface hinders the application of supercapacitors in many low power battery-like electronic applications. Coating the surface of the electrodes with a thin film of a dielectric material generates a potential barrier which reduces the reaction rate, with a slight drop in specific capacitance but increases the relative dielectric constant by increasing the capacitance of the supercapacitor. For this report we have deposited nm –thickness of high dielectric constant, Barium Strontium Titanate (BST), material on GPANI using electrophoretic technique. This will enhance the energy storage capability of the capacitor making it desirable for application in hybrid vehicle batteries.

3:00 PM Invited
Thermoelectric Study of InGaN-Based Materials for Thermal Energy Harvesting: Liqing Su[1]; Bahadir Kucukgok[1]; Elisa Hurwitz[1]; Ian Ferguson; *Na Lu*[2]; [1]University of North Carolina at Charlotte; [2]University of North Carolina at Charlotte

InGaN-based materials have recently been demonstrated to have promising thermoelectric (TE) properties, providing a potential solution to the thermal energy harvesting of nitride-based high power devices. In addition, these materials have outstanding features that are environmentally friendly for TE applications include the ability for high power and high temperature operation, high mechanical strength and stability, and radiation hardness. However, the experimental data available on InGaN with respect to the indium concentration is very limited and does not clearly reflect the expected theoretical trends. In this work, the Seebeck coefficient and the electrical conductivity of MOCVD grown InGaN alloys at various indium concentrations are investigated, and the power factors are calculated. The results reveal that InGaN-based materials could be potentially applied in thermal energy harvesting.

3:40 PM
Nanocomposites for Electrochemical Energy Storage: *Yuanbing Mao*[1]; Elizabeth Martinez[1]; [1]University of Texas-Pan American

Nanocomposite materials have great potentials for applications in the field of energy store. To achieve high energy densities at high rate capabilities, it is necessary to use innovative electrode materials with architecturally tailored nanostructures for these devices, such as batteries and supercapacitors. Heterogeneous nanostructured materials with multi-components can be tailored to address different demands for these types of novel electrodes, which are expected to exhibit synergic properties. In this presentation, the design and synthesis of hierarchical carbon material/conductive polymer/metal oxide ternary nanocomposites for high performance electrochemical energy storage will be reported. The performance, i.e. specific capacitance, of the fabricated supercapacitors will be shown based on cyclic voltammetry and charge-discharge measurements and compared with literature results.

Thick and Thin Film Polymer – Carbon Nanotube Composites for Thermoelectric Energy Conversion and Transparent Electrodes: *Jaime Grunlan*[1]; Yeon Seok Kim[1]; Choongho Yu[1]; Yong Tae Park[1]; Gregory Moriarty[1]; [1]Texas A&M University

Segregated network (latex-based) composites containing carbon nanotubes were used to produce electricity from a thermal gradient. Thermoelectric materials harvest electricity from waste heat or any temperature gradient in the environment. The present work demonstrates that nanotube-filled polymer composites can be viable for energy conversion. By combining double-walled carbon nanotubes (DWNT), stabilized with poly(3,4-ethylenedioxythiophene): poly(styrene sulfonate) in water, an electrical conductivity (μ) near 2000 S/cm is achieved in a poly(vinyl acetate) latex-based matrix. When combined with a Seebeck coefficient (S) above 40 μV/K, a power factor ($S^2\sigma$) above 370 $\mu W/m \bullet K^2$ is achieved at room temperature. Additionally, highly transparent and electrically conductive thin films as a potential indium tin oxide (ITO) replacement using layer-by-layer assembly of DWNT. A 23 nm film has ~ 100 Ω/sq sheet resistance following nitric acid doping. These unique thin films are potentially useful as flexible transparent electrodes for a variety of applications (e.g., touch screens).

5:00 PM
Epoxy Resin Nanocomposites Reinforced with Conductive Polyaniline Nanostructures: *Xi Zhang*[1]; Jiahua Zhu[1]; Suying Wei[1]; John Zhanhu Guo[1]; [1]Lamar University

Epoxy resin nanocomposites prepared by two different polyaniline nanoparticles (NP) are studied and compared. The effect of the structure on the properties was investigated. Polyaniline nanoparticles in spherical shape offers better thermal stability, however, epoxy nanocomposites prepared with polyaniline nanofibers have higher conductivity and better rheological behaviors. The rheology result shows that compare with pure epoxy, viscosity of epoxy nanocomposites prepared with both kinds of PANI nanostructures decreases with the addition of NP at 1 wt%, however, when reach certain loading amount, the viscosity of nanocompostites becomes higher than that of pure epoxy, and the transition loading of fiber shape NPs is higher than that of the spherical shape ones. DMA is also run for these nanocomposites. Liquid sample test indicates the percolation threshold is also associated with NP's structure, the threshold occurs at lower loading percent of fiber shape NPs than spherical shape one.

5:20 PM
Synthesis, Characterization & Applications of Nanodiamond – Conductive Polymer Nanocomposites Films: *Humberto Gomez*[1]; Manoj Ram[2]; Ashok Kumar[2]; [1]Universdad del Norte; [2]University of South Florida

Nanocomposites of nanodiamond particles (NDs) with conductive polymers (i.e. polyaniline (PANI) and regioregular polyhexylthiophene (RRPHTh)) displayed novel properties resulting from the molecular interaction level of diamond with polymer molecules. We have synthesized the NDs-Polymer nanocomposites by oxidative polymerization under controlled conditions. The ND-Polymer nanocomposite films were characterized by UV-Vis, FTIR, electrochemistry, impedance, Scanning Electron Microscope (SEM), Transmission Electron Microscope (TEM) and electrical conductivity techniques, respectively. The electrochemical investigation on ND-PANI revealed the wider potential values with independent redox characteristics of polyaniline and nanodiamond. The ND-PANI film shows excellent corrosion inhibitor characteristics for metals (steel and aluminum) due to its chain conformation and electronic properties, as demonstrated in this work. The photoelectrochemical study has revealed photoinduced electron transfer in nanohybrid regioregular polyhexylthiophene (RRPHTh) with donor and ND as acceptor providing a molecular approach to high-efficiency photoelectrochemical conversion properties. The ND-RRPHTh has shown promising morphological and photoelectrochemical properties than RRPHTh films.

5:40 PM
Evaluation of Electrochemical Performance of a graphene–poly (o-toluidine) Nanocomposite for Supercapacitor Applications: *Punya Basnayaka*[1]; Farah Alvi[1]; Manoj Ram[1]; Ashok Kumar[1]; [1]University of South Florida

Supercapacitors are unique energy storage devices, where the selection of electrode material is one of the most vital factors in developing high energy density and longer cycle life devices. A novel graphene (G) – poly (o – toluidine) (POT) nanocomposite material has been synthesized using oxidative polymerization method. The physical characterization of the electrode material was performed by scanning electron microscopy (SEM), transmission electron microscope (TEM), UV-vis spectroscopy, Raman spectroscopy and x-ray diffraction spectroscopy (XRD) techniques. The observed change in the morphology and electrical conductivity of G-POT are due to the incorporation of graphene in polymer matrix. The electrochemical and capacitive properties of supercapacitor were studied using cyclic voltammetry (CV), impedance spectroscopy and charging-discharging measurement methods. The G-POT nanocomposite based supercapacitor showed enhanced capacitive property with highest specific capacitance of 424 F/g in 2M H_2SO_4 acidic electrolytic solution, revealing that G-POT could be a promising material for the supercapacitor applications.

2:00 PM Keynote
Next Generation 3DXRD: *Henning Poulsen*[1]; Søren Schmidt[1]; Erik Lauridsen[1]; Andrew King[2]; Gavin Vaughan[2]; Jonathan Wright[2]; Wolfgang Ludwig[2]; Jette Oddershede[1]; Xiaoxu Huang[1]; Wolfgang Pantleon[1]; Dorte Juul Jensen[1]; [1]Risoe DTU; [2]ESRF

3DXRD has become a mature methodology for generation of 3D maps of the morphology, orientation and type-II stress of poly-crystals with a thousand grains and with a spatial resolution of order 1 μm.We present exploratory work on generalising the concept in several directions: 1) Improved spatial resolution: Work on microscopy approaches for achieving 100 nm resolution is outlined. The connection to recent work on 3D orientation mapping with 1 nm resolution using TEM is discussed. 2) Orientation Imaging Microscopy: A non-destructive and 3D equivalent of the familiar EBSD technique has been established. 3) Mapping of phases: Work on the coupling of 3D imaging and multigrain crystallography is outlined. 4)Plastic strain tomography: The strain field of an Al alloy was mapped in 3D to 10% strain and compared to the 3D grain structure and local rotations. Finally, the coupling to 3D materials simulations will be discussed.

2:25 PM Invited
X-Ray Topography Studies of Synthetic Diamonds for Use as Optical Elements at Synchrotron X-Ray Sources: *Albert Macrander*[1]; Xianrong Huang[1]; Ali Khounsary[1]; Josef Maj[1]; Lahsen Assoufid[1]; [1]Argonne National Laboratory

Diamonds have a number of uses on beamlines such as monochromator crystals, phase plates to manipulate the x-ray polarization, and beam splitters, among others. Strain due to mounting as well as fabrication induced surface strain can severely degrade the performance of these crystals. In addition, grown-in lattice defects such as stacking faults are also deleterious to the performance. Studies involving both measurements and simulations that have been made over the last several years will be summarized, and more recent white beam topography results for bonded samples will be presented. This work supported by U.S. Dept. of Energy, Office of Science. Office of Basic energy Sciences under contracts DE-AC02-06CH11357.

2:45 PM Invited
Microstructure inside Nanocrystals Using Laue X-Ray Micro/Nanodiffraction: *John Budai*[1]; Jonathan Tischler[1]; Zhengwei Pan[2]; Alexander Tselev[1]; Andrei Kolmakov[3]; [1]Oak Ridge National Laboratory; [2]University of Georgia; [3]Southern Illinois University

High-brightness x-ray sources and focusing optics have enabled the transformation of white-spectrum Laue diffraction from a single-crystal tool to a spatially-resolved microscopy technique for imaging microstructures inside polycrystals. At the APS, we have developed a polychromatic, scanning microbeam facility currently with ~300 nm spatial resolution. In this talk, I will emphasize the ability to investigate microstructures in individual nanostructures using two examples. First, we have studied the lattice structures of strongly-photoluminescent EuAlO nanorods with different chemical compositions, different optical emission spectra, and with crystal structures not reported for bulk materials. In a second example, I will describe in-situ studies of local phase separation and microstrains observed inside individual microcrystals of vanadium dioxide as it cycles through a metal-insulator phase transition. Finally, I will discuss planned extensions of diffraction techniques to include x-ray beams focused to diameters below ~100 nm. Research supported by Materials Sciences and Engineering Division, U.S. DOE-BES.

3:05 PM Invited
In-Situ Micro-Beam X-Ray Diffraction Studies on Advanced High-Strength Steels: *Niels van Dijk*[1]; [1]Delft University of Technology

In novel high-strength steels deformation often leads a significant strengthening of the complex multiphase microstructure. In Transformation Induced Plasticity (TRIP) steels the combined high strength and good formability originates from a martensitic transformation of the metastable austenite phase, while for TWinning Induced Plasticity (TWIP) steels it is achieved by twin formation. Recent advances at synchrotron sources make it possible to perform in-situ X-ray diffraction experiments using micro-beams of high-energy X-rays. The combination of a high penetrating power and a good spatial resolution allows us to quantify the local structure evolution within the multiphase material at the level of single grains during tensile deformation at variable temperatures. By simultaneously monitoring the thermo-mechanical behavior of a collection of individual grains in combination with a powder analysis of the overall phase response new insight is obtained in the mechanism responsible for the improved mechanical behavior of high strength steels.

3:25 PM
3D Visualization and Modeling of Deformation in Pb-Free Solders Using X-Ray Tomography: *Eric Padilla*[1]; Vaidehi Jakkali[1]; Mario Pacheco[2]; Nikhilesh Chawla[1]; [1]Arizona State University; [2]Intel Corporation

3D X-Ray Tomography was used to visualize and reconstruct the pore microstructure of Sn-3.9Ag-0.7Cu/Cu solder joints. The incremental changes to the joint microstructure caused by progressive straining were imaged in 3D using X-Ray Tomography. The evolution of individual pore deformation and strain localization in the joint was tracked using the shape parameters of the pores as a function of strain. The experimental results were compared to a Finite Element Model, which incorporated the reconstruction of the as-processed joint and used the Ductile Damage Model to simulate shear deformation and eventual failure of the joint. The Finite Element Model correctly predicted the location of crack nucleation and broad features of deformation. The effectiveness of this technique in understanding the effect of size, shape, and distribution of pores on local and global plasticity of solder joints will be discussed.

3:35 PM
Nondestructive Determination of Residual Stress Using Strain Pole Figure Measurements and a Multiscale Workpiece Discretization: *Jun-Sang Park*[1]; Matthew Miller[1]; Eralp Demir[1]; Paul Dawson[1]; Ulrich Lienert[2]; [1]Cornell University; [2]Argonne National Laboratory

Quantifying the internal residual stress field in a processed polycrystalline component is important for predicting its mechanical properties and its behavior. In this work, a new method for measuring residual stresses is described. We focus on the experimental setup that combines monochromatic high energy synchrotron x-rays and a set of conical slits that allow the non-destructive measurement of strain pole figures (SPFs) for diffraction volumes located inside a polycrystalline aggregate. We also describe a novel optimization method that proposes a residual stress field that is consistent with the SPF measurements at the microscopic scale and enforces the macroscopic boundary conditions and equilibrium. To demonstrate the new method, a polycrystalline shrink-fit sample with a 3D stress gradient was manufactured from a low solvus high refractory (LSHR) Ni-based superalloy. The internal stress field determined using the new method compares favorably with an analytic approximation of the stresses within the shrink-fit sample.

3:50 PM
Annealing Study of Grain Boundary Engineered Copper Using High Energy X-Ray Diffraction Microscopy.: *S. F. Li*[1]; R. Suter[1]; C. Hefferan[1]; J. Lind[1]; U. Lienert[2]; J. Bernier[3]; M Kumar[3]; B. Reed[3]; [1]Carnegie Mellon University; [2]Argonne National Lab; [3]Lawrence Livermore National Lab

High Energy X-ray Diffraction Microscopy (HEDM) is a non-destructive orientation imaging technique housed at the high energy and brilliance x-ray source at the Advanced Photon Source. HEDM is applicable to bulk polycrystalline material characterization because of its robustness against grain size distribution and orientation moasicity. Recent advances in reconstruction and data collection methods have led to availability of volumetric orientation maps with sub-degree and micron angular and spatial resolutions for millimeter sized samples. The result is an unprecedented nondestructive access into the microstructure and grain boundary networks under the influence of external stimuli. Using HEDM, microstructural evolution of grain boundary engineered (GBE) copper was observed before and after annealing. The resulting grain boundary character distribution (GBCD) was compared against that of a high purity copper specimen without GBE processing; three-dimensional grain boundary networks were also examined. GBCD evolution suggests that special boundaries (CSL) play an interesting role in Copper annealing.

Study of Geometrically Necessary Dislocations by Depth-Resolved 3D X-Ray Microdiffraction and Crystal Plasticity Modeling: *Leyun Wang*[1]; Hongmei Li[2]; Rozaliya Barabash[3]; Martin Crimp[2]; Carl Boehlert[2]; Philip Eisenlohr[4]; Thomas Bieler[2]; Wenjun Liu[1]; [1]Argonne National Laboratory; [2]Michigan State University; [3]Oak Ridge National Laboratory; [4]Max-Planck-Institut für Eisenforschung

In polycrystalline metals, gradients in slip of individual grains is often observed, which gives rise to geometrically necessary dislocations (GNDs). An effective method to characterize GNDs is by analyzing streaked diffraction patterns from depth-resolved 3D X-ray microdiffraction experiment. Using polycrystalline alpha-Ti and a near-alpha Ti alloy as sample materials, it has been found that GNDs tend to pile up near grain boundaries and twin boundaries, especially when the slip transfer to the neighboring grain is difficult. Accumulation of GNDs eventually leads to the development of ledges or cracks at grain boundaries and twin boundaries. A crystal plasticity finite element model (CPFEM) was also used to simulate slip gradient in the same regions, and the simulations were compared with the experimental results. This work was supported by grants from DOE/BES and NSF/DMR.

4:35 PM
The Plastic Behavior of Micron Sized Single Crystals under Compression and Tension Analyzed by X-Ray µLaue dDffraction: *Christoph Kirchlechner*[1]; Marlene Kapp[2]; Wolfgang Grosinger[1]; Peter Imrich[2]; Christian Motz[2]; Jozef Keckes[1]; Jean-Sebastien Micha[3]; Olivier Ulrich[3]; Gerhard Dehm[1]; [1]University of Leoben; [2]Austrian Academy of Sciences; [3]ESRF

The influence of the samplesize on different aspects of plastic deformation is of paramount concern for the development and use of MEMS-devices. However, the plastic behavior at the micron scale is still under debate. For a thorough understanding of the mechanisms governing plastic deformation it is essential to characterize the initial and evolving defect-structure in these dimensions. We have performed in situ µLaue tensile and compression tests on micron sized, single crystalline copper specimens at BM32 at ESRF. Microstructural changes where analyzed using position and shape of Laue spots as described by Ice and Barabash. Besides the expected activation of the primary slip system the tensile experiments show – in some cases – an early activation of a lower-ranked slip system. Dislocations on these slip systems are stored at low strains, but continuously escape at the sample surface at higher strains leading to a sample-center free of geometrical necessary dislocations.

4:50 PM
Plasticity Evolution in the NanoscalE Cu/Nb Multilayers as Revealed by Synchrotron X-Ray Microdiffraction: *Arief Budiman*[1]; N. Li[1]; L. A. Berla[2]; N. Tamura[3]; M. Kunz[3]; W. D. Nix[2]; J. Wang[1]; A. Misra[1]; [1]Los Alamos National Laboratory (LANL); [2]Stanford University; [3]Advanced Light Source (ALS), Berkeley Lab

There is much interest in the recent years in the nanoscale metallic multilayered materials due to their unusual mechanical properties such as very high flow strength and stable plastic flow to large strains. In an effort to shed light on these topics, successive uniaxial compression experiments (total strains = 1%, 2%, 10% and 20%) on nanoscale Cu/Nb multilayer pillars using ex situ synchrotron-based X-ray microdiffraction technique were conducted. We found significant X-ray peak broadening in both Cu and Nb layers initially (up to strains of about 4%) which was then followed by the saturation of the X-ray ring width broadening (up to large strains of 20%). This observation indicates that the interfaces in the nanolayered Cu/Nb are very stable and effective in trapping and annihilating dislocation content during mechanical deformation, and explains why the Cu/Nb nanolayers can be deformed to large plastic strains without any onset of plastic instabilities.

5:05 PM
Grain Growth of High Purity Nickel with High Energy X-Ray Diffraction Microscopy (HEDM): *C.M. Hefferan*[1]; S.F. Li[2]; J. Lind[1]; U. Lienert[3]; A.D. Rollett[1]; R.M. Suter[1]; [1]Carnegie Mellon University; [2]Lawrence Livermore National Laboratory; [3]Argonne National Laboratory

The ability to non-destructively interrogate polycrystalline systems has been aided by the emergence of synchrotron based, high energy x-ray diffraction (HEDM). Specifically, an enhanced capability in monitoring the evolution of microstructures as they respond to thermo-mechanical stimuli has been realized. We present results from a high purity nickel specimen subject to incremental anneals resulting in differential grain growth. Repetitive probing of the same 0.25 cubic millimeter volume of microstructure, containing on the order of 2500 grains yields an experimental picture of the grain growth process. The progression of the microstructure is interpreted in the context of the five parameter grain boundary character distribution, with emphasis on special grain boundary types. This work is supported by the NSF Metals and Nanostructures program under grant DMR-0805100; SFL and JL are supported by DOE/BES contract number DESC0002001. Use of the Advanced Photon Source is supported by DOE/BES under Contract No. DE-AC02-06CH11357.

5:20 PM Invited
X-Ray Laue Diffraction 3D Microscopy - Upgrade and New Opportunities: *Wenjun Liu*[1]; Ruqing Xu[1]; Paul Zschack[1]; John Budai[2]; Jon Tischler[2]; [1]Argonne National Laboratory; [2]Oak Ridge National Laboratory

Significant progress has been made at the Advanced Photon Source over the past ten years in developing and applying focused x-ray diffraction techniques in spatially-resolved structural studies for material science. Laue diffraction 3D microscopy is applicable to a wide range of exciting problems in many diverse fields, including materials engineering, condensed matter physics, high-pressure geophysics, mineralogy, and environmental science. In this report, we will present the upgrade plan of pushing microdiffraction techniques with significant improvements in smaller beam sizes, beam and sample stability, detector performance, scanning speeds, and increased beamtime availability. This will enable new scientific progress towards a fundamental, predictive understanding of materials processing. A few examples will be highlighted.

5:40 PM
Investigation of Twin Inception and Growth in Three Dimensions: Hamid Abdolvand[1]; *Marta Majkut*[1]; Jette Oddershede[2]; Ulrich Lienert[3]; Bradley Diak[1]; Mark Daymond[1]; [1]Department of Mechanical and Materials Engineering, Queen's University; [2]Risø National Laboratory for Sustainable Energy, Technical University of Denmark; [3]Advanced Photon Source, Argonne National Laboratory

Tensile samples cut from rolled Mg-AZ31B were used to study twin inception and growth. In-situ three-dimensional synchrotron X-ray diffraction was used to determine the center of mass and volume of each grain, as well as elastic strain and stress inside each grain during straining along the plate normal direction. The tensile sample was strained up to a plastic strain 1.6 % by which many of the grains were twinned. Using Laguerre tessellation from the measurement center of mass and volume of each grain, grains were mapped into a crystal plasticity finite element code. Experiment and model were compared in terms of twin inception and propagation. Results demonstrate that newly formed twins are generally found at stresses different from those of the parent grain. The simulation results demonstrate that the CPFE code is able to predict inception sites very well on a statistical basis but not perfectly at a local level.

5:50 PM
X-Ray Micro-Diffraction Study of Crystallographic Orientation and Strain Distribution inside Microscopic Shear Bands Consisting of Martensite Plates: *Nan Li*[1]; Yandong Wang[1]; Wenjun Liu[2]; Dongping Wang[1]; Guilin Wu[1]; Peter Liaw[3]; [1]Beijing Institute of Technology; [2]Argonne National Laboratory; [3]The University of Tennessee

The traditional phenomenological crystallographic theory (PCT) of martensitic transformation can only explain the shape deformation and crystallography of a martensite plate in a single crystal. While matensitic transformation occurs in polycrystals, the microscopic shear bands (MSBs) are usually formed due to the fact that a martensite plate is blocked by grain boundaries. However, the stress evaluation to trigger the formation of deformation-induced martensite plates cannot be predicted by PCT. Here we used the synchrotron X-ray micro-diffraction technique to trace in-situ local strain/orientation distribution inside individual martensite plates and their parent grains in a polycrystalline 304 stainless steel during uniaxial tensile loading. It was found that there is a large gradient in strain of martensite plates inside MSBs. The crystallographic orientation of martensite plates strongly depends on orientation of the parent grains. Based on the above experimental findings, a modified PCT suitable for a polycrystal will be proposed in this presentation.

Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Whisker Growth in Tin and Related Solder Alloys

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Electronic Packaging and Interconnection Materials Committee
Program Organizers: Iver Anderson, Ames Laboratory; Sung Kang, IBM; Albert Wu, National Central Univ ; Laura Turbini, Research in Motion; Tae-Kyu Lee, Cisco Systems; Govindarajan Muralidharan, Oak Ridge National Lab; John Elmer, Lawrence Livermore National Lab; Yan Li, Intel

Effects of Grain Misorientation & Strain Distribution on Whisker Formation on Electroplated Sn-Cu films: *Carol Handwerker*[1]; Pylin Sarobol[1]; Wei-Hsun Chen[1]; Peng Su[2]; John Blendell[1]; [1]Purdue University; [2]Cisco

Tin whiskers spontaneously grow from electrodeposited Sn-containing films and can form short circuits in microelectronics. In order to better understand the nucleation and growth mechanisms, the local properties—grain misorientations and strain distribution—around whiskers and hillocks on electroplated SnCu films were examined via synchrotron x-ray micro-diffraction. High misorientation angles are observed between whisker/hillock grains and their surrounding grains, whereas low misorientation angles are associated with other grains in the film away from the defects. Out-of-plane strain distributions in regions around whiskers and hillocks from OOF2 simulation and micro-diffraction measurements were compared. Due to local grain misorientations, high strain is predicted by simulation at whisker/hillock locations. After growth, the strain is relaxed and is measured to be near zero. We are planning to use these results to construct a whisker growth model to predict whisker propensity and nucleation sites for Sn films with specific textures.

2:30 PM Invited
Probing Mechanisms for Sn Whisker Growth by In Situ Nanoindentation in a Scanning Electron Microscope: Nicholas Chapman[1]; Jason Williams[1]; *Nikhilesh Chawla*[1]; [1]Arizona State University

The presence of a protective oxide has been postulated to control the formation of Sn whiskers from Sn thin films. . In this investigation, the effects of oxygen on the degree of whisker formation was studied. Sn films were fabricated by electrodeposition. Nanoindentation was used to introduce local compressive stresses to drive whisker growth on the surface of the Sn thin film. The experiments were conducted under ultra-high vacuum, inert atmosphere, and air, and observed in situ in a scanning electron microscope. The propensity, location of the whiskers relative to the indentation, and the morphology of the whiskers were controlled by environment and indentation stress. The relationship between stress, oxide on the surface, and whiskering mechanisms will be discussed.

3:00 PM
Understanding the Variation in Mechanical Properties of Sn Films with Alloying and Modification of Microstructure: *Nitin Jadhav*[1]; Maureen Williams[2]; Fei Pei[1]; Gery Stafford[2]; Eric Chason[1]; [1]Brown University; [2]National Institute of Standards and Technology

Though it is well understood that compressive-stress due to IMC formation is the main driving force for whisker formation in SnCu System, the underlying mechanisms that control the stress-distribution and cause whiskering are not clear. In order to understand the propensity of whiskering in Sn-films it is essential to study their response to stress buildup. To avoid the complexity in the SnCu-system, we studied the evolution of stress due to the difference in thermal-expansion between Sn and the Si-substrate. We present the results of studies done to understand how modification of the Sn-layer (alloying and microstructure) affects its response to stress buildup. We found that alloying with Pb changes Sn's microstructure from columnar to equiaxial-grains and greatly enhances its stress-relaxation. An equiaxial-microstructure was also fabricated by pulse-plating Sn-Bi alloy, which do not relax stress as much as alloying with Pb does but nonetheless having equiaxial-grains significantly does enhance Sn-films relaxation.

3:20 PM
Mitigation and Verification Method of Sn Whisker Growth for Pb-free Automotive Electronics: *Won Sik Hong*[1]; Cul Min Oh[1]; Do Seop Kim[2]; [1]Korea Electronics Technology Institutue(KETI); [2]Hyundai Motor Company

Mitigation method of Sn whisker growth in Pb-free car electronics is a key issue. The verification of whiskering failure is essentially demanded because of long service life of automotives. Though JEDEC, IPC, iNEMI and industries have already recommended whisker evaluation method, but those have a disadvantage to take very long time for evaluating whisker formation and growth. Also, effective and economical verification method for use environment of automotives is demanded. Therefore, this research suggested the optimized test conditions based on conducting high temperature and high humidity test, thermal cycling test and ambient test and then analyzed whisker growth mechanism. To find out efficient mitigation effects of whisker growth, we have verified a validity of annealing, surface finish and conformal coating. Surface finish of component was Ni/Sn and Ni/Pd. Finally, mitigation effects of acryl, silicone and rubber coating were compared with non-coating components under various whisker test conditions.

3:50 PM
Crystallographic Characterization of an Electroplated Zinc Coating
: *Philippe Pareige*[1]; Auriane Etienne[1]; Agnès LINA[2]; Laurent Crétinon[2]; [1]Rouen University; [2]EDF

Whiskers grow spontaneously from cadmium, zinc or tin coatings at room temperature. Although whiskers have been studied for several decades, mechanisms of whisker growth are still not well understood. While a large number of studies have been focused on tin whiskers and the minimization of their formation, only a limited numbers of researches were interested on zinc whiskers. The risk of electronic failures caused by Zn whiskers in automotive, aerospatial or energy industry but also in computer data centre is significant. In order to avoid failures, whisker formation needs to be mitigated and so, mechanisms of whisker growth need to be clarified. At first, the understanding of whisker growth mechanism needs microstructural characterization of Zn whiskers and their coatings. In the present work, Zn coating has been investigated using SEM/FIB, EBSD and EDS. The observed samples were prepared and extracted from the root of the whisker.

4:10 PM
Real-Time Study of Whisker Formation in Tin/Copper Systems by EBSD Characterization: *Fei Pei*[1]; Nitin Jadhav[1]; Eric Chason[1]; [1]Brown University

We performed a systematic real-time study of whisker formation using electron back-scattering (EBSD) to simultaneously monitor surface morphology and grain orientation changes. A unique procedure for making samples with smooth surfaces was developed to enable the EBSD to index a large fraction of the grains over repeated scans. According to the experiment results, most whiskers or hillocks initiated from grains that had already been formed during sample preparation. The orientation of these grains did not change much after the surface morphology changed, suggesting whiskers can grow without undergoing recrystallization or nucleation of new grains. After the real-time study, the tin films were chemically stripped to expose the IMC (intermetallic compound) growing at the Sn-Cu interface. The IMC at the interface was measured over the same region as the surface morphology to correlate the surface evolution with the interface. No apparent accumulation of IMC was observed underneath the whisker sites.

4:30 PM
Tin Whisker and Hillock Formation on Thermally Cycled, Large Grained Pb-Free Solder Alloy Films: *John Koppes*[1]; Pylin Sarobol[1]; Wei-Hsun Chen[1]; Peng Su[2]; John Blendell[1]; Carol Handwerker[1]; [1]Purdue University; [2]Cisco Systems

Tin whiskers can grow long enough to contact adjacent leads and cause short circuits in electronic devices. For many years, Sn whiskers were only a concern on fine grained electroplated films. Furthermore, it was believed that if the film was melted and solidified (reflowed), the Pb-free Sn-film would be immune to whisker formation. Recently, surface defects (whiskers and hillocks) have been observed forming on large grain (~ 2 mm) Pb-free solder alloy films formed by solidification. The large grain size of the solidified solder alloys allowed for surface defects (whiskers and hillocks) to be readily studied relative to the local microstructure. It is observed that the formation of the surface defects occurs primarily along grain boundaries; and the linear defect density, along the grain boundary, is related to the local orientations of the adjacent grains and the corresponding anisotropic physical properties, including thermal expansion coefficient.

4:50 PM
Precipitation of Large Ag3Sn Intermetallic Compounds in SnAg2.5 Microbumps after Multiple Reflows in 3D-IC Packaging: *Ming-Yung Guo*[1]; Wei-Chi Sung[1]; Chih Chen[1]; [1]National Chiao Tung University

Microbumps have been adopted as interconnects between Si chips in 3D integrated-circuit packaging. The solder volume of a microbump decreases dramatically due to fine-pitch requirement and it is approximately two orders smaller in magnitude than that of a traditional flip-chip solder joint. The metallurgical reactions in the microbumps may behave quite differently to those in flip-ship bumps. Liquid-state metallurgical reactions were examined in SnAg2.5 microbumps with Ni metallization. The results indicate that large particles of Ag3Sn intermetallic compounds (IMCs) precipitate after a 1-min reflow on microbumps with 2.0-µm-thick solder, which does not occur with flip-chip solder bumps. It is proposed that the Ag concentration in the remaining solder may increase as Sn reacts with Ni. The increase in the Ag concentration is mainly responsible for the occurrence of the large Ag3Sn precipitates. The formation of these Ag3Sn IMCs would be detrimental to the mechanical properties of the microbumps.

Processing to Control Morphology and Texture in Magnetic Materials: Thin Films and Applications

NanostructureOptimization of FePt Thin Films for Magnetic Recording: *Kazuhiro Hono*[1]; Yukiko K Takahashi[1]; [1]National Institute for Materials Science

The L10 ordered FePt granular thin film is considered as the most promising candidate for next generation ultrahigh density magnetic recording media, because of the high magnetocrystalline anisotropy. For the application of FePt films as recording media, the c-axis of magnetically isolated L10-FePt particles of less than 5 nm must be strongly [001] textured. We recently reported well separated perpendicular anisotropic granular films with a narrow size distribution by cosputtering FePt and C on MgO interlayer. Polycrystalline MgO layer grows with a strong (001) texture on amrphous substrates, which works as effective seedlayer for the epitaxial growth of (001) FePt particles. Ag addition to FePt-C film enhances the L10 ordering to attain a very high coercivity exceeding 38 kOe. In this talk, we review how the micorstructuresof FePt thin films has been optimized and discuss how they must be optimized further for thermally-assisted magnetic recording.

2:25 PM Invited
Control of Texture and Morphology of Thin Films for Magnetic Recording Applications: *David Laughlin*[1]; En Yang[1]; Hoan Ho[1]; Vincent Sokalski[1]; Jimmy Zhu[1]; [1]Carnegie Mellon

Thin films used as magnetic recording media need to have a granular microstructure, with the magnetic grains (which are on the order of 5-8 nm) isolated from each other by a non-magnetic material. In this paper we review various methods used to produce such media in current and future applications. How the texture, morphology, crystal structure and magnetic exchange of Co alloys and FePt media is controlled during sputtering will be discussed.

2:50 PM
Combinatorial Search of Rare-Earth-Free Permanent Magnets: Magnetic and Microstructural Properties of Fe-Co-W Thin Films: Tieren Gao[1]; *Ichiro Takeuchi*[1]; Yaqiao Wu[1]; Matthew Kramer[1]; Iver Anderson[1]; Bill McCallum[1]; Kevin Dennis[1]; [1]University of Maryland

We are using the thin film composition spreads to search for rare-earth free permanent magnetic materials by ternary co-sputtering. As one of the initial systems, the structural properties of W doped Fe-Co films with different heat treatment are mapped by synchrotron diffraction. We find that there is a phase transition from a crystalline to an amorphous state at about 10% atomic W composition in the as deposited state. The W concentration in phase transition area increases with increasing annealing temperature. By using SEM and TEM, we found that the grains of low W content Fe-Co films which show enhanced coercive fields vertically standing platelet-like structures. The angular dependence of the switching field of Fe-Co-W films indicates that the magnetic reversal process evolves from domain wall displacement to coexistence of domain wall displacement and coherent rotation with increasing W content.

3:05 PM
Effect of Rapid Annealing on the Microstructure of FeSiNbBCu Alloys: *Pradeep Konda Gokuldoss*[1]; Pyuck-pa Choi[1]; Dierk Raabe[1]; Giselher Herzer[2]; [1]Max Planck Institute for Iron Research GmbH; [2]Vacuumschmelze GmbH & Co. KG

Fe-Si-Nb-B-Cu model alloys have been studied for years because of their excellent soft magnetic properties. Upon annealing the melt-spun amorphous Fe-Si-Nb-B-Cu ribbons undergo nanocrystallization, where soft magnetic Fe-Si nanocrystals are formed. The process of Fe-Si nucleation is reported to be heterogeneous, wherein the nucleation sites are clusters of Cu atoms. In the present work an optimised composition of Fe73.5Si15.5Nb3B7Cu1 melt spun alloy was annealed under a small tensile stress for a short duration of about 4s at temperatures ranging from 500 – 700 °C, about 100 °C higher than the conventional prolonged heat treatments. Such a difference in heat treatment has an effect on the size and number density of Cu clusters, the expected nucleation sites for Fe-Si nanocrystals. The samples were studied by atom probe tomography, transmission electron microscopy and x-ray diffraction. Surprisingly, the crystallite sizes of the Fe-Si nanocrystals remain well below 15 nm.

Large Abnormal Grain Growth Behavior in Galfenol Rolled Sheets: *Qingfeng Xing*[1]; Adam Boesenberg[2]; Eric Summers[2]; Thomas Lograsso[1]; [1]Ames Laboratory; [2]ETREMA Products, Inc.

Galfenol alloys (Fe-Ga alloys) exhibit large magnetostrictions along the <100> magnetic easy axis directions. One requirement for practical applications is to cost-effectively produce thin sheets with strong <100> texture components. Rolling followed by recrystallization and heat treat processes produce large Goss grains {110}<001> in excess of 125 cm^2 in the sheet plane with magnetostrictions > 250 ppm. Niobium carbide additions are critical in obtaining this large abnormal grain growth response. In the present work, thin sheets are sliced from non-rolled drop cast ingots with a range of carbon concentrations and annealed to investigate the effect of carbon concentration on abnormal grain growth. Normal grain growth is observed in a carbon free alloy and an alloy with high carbon concentration. An alloy with medium carbon concentration displays abnormal grain growth from the edges. This suggests carbon concentration is a key factor in achieving an abnormal grain growth response.

4:05 PM Invited
The Role of Crystallographic Texture in Microwave and Millimet: Yajie Chen[1]; Anton Geiler[2]; Trifon Fitchorov[1]; Andrew Daigle[2]; Carmine Vittoria[1]; *Vincent Harris*[1]; [1]Northeastern University; [2]Metamagnetics Inc.

Crystallographic texture in the hexaferrites is closely related to magnetocrystalline anisotropy energy and fields. The magnetic anisotropy in turn is valuable in defining both the ferromagnetic resonance frequency and the frequency dependence of permeability. The setting of the FMR frequency determines among other things the operational frequency and frequency agile device performance. Here, we review the role of crystal texture in determining the magnetic anisotropy fields of a series of hexaferrite materials including the M, Y and Z type structures. Furthermore, the ability to strongly texture materials as powder compacts, and thick and thin films is explored in detail. Strategies to realize crystal texture include lattice matching of substrates and buffer structures as well as the use of magnetic fields during processing. The application of hexaferrites in microwave circulators, phase shifters, and in the design and processing of low profile antennas are demonstrated.

4:30 PM
Role of Alloying Elements in Improvement of Alnico Permanent Magnet Alloys: *Scott Long*[1]; R.W. McCallum[1]; M.J. Kramer[1]; Kevin Dennis[1]; D.T. Cavanaugh[1]; Y.Q. Wu[1]; I.E. Anderson[1]; [1]Ames Laboratory

The historical development of Alnico permanent magnets was mainly empirical. A variety of transition metals were identified that improve Alnico performance, but the reasons are not well understood. We focused on identifying the role of these previous additions and other promising elements in formation of the initial aligned solidification microstructure (e.g. Nb, and Ta) and on controlling the spinodal decomposition process (e.g. Cu and Ag) that forms the anisotropic Fe-Co precipitates. Initial microprobe results of directionally solidified structures show fluctuations in composition within the grains indicating possible dendritic growth. Further castings will be studied which are produced from more closely controlled solidification, with and without additional alloying elements. Typical spinodal spacing in Alnico is ~50 nm, adjustments in this spacing by alloying additions and various heat treatments will be studied. Characterization methods include TEM, SEM, electron microprobe, and VSM. Funding provided by DOE-EERE-FCVT Office through Ames lab Contract DE-AC02-07CH11358.

4:45 PM
Structure and Chemistry of the Alnico Spinodal: *Matthew Kramer*[1]; YaQiao Wu[2]; V. Antropov[2]; S. Long[2]; K. Dennis[2]; R. McCallum[2]; I. Anderson[2]; S. Constantinides[3]; [1]Iowa State University; [2]Ames Laboratory; [3]Arnold Magnetic Technologies

Modeling of the magnetic structure reveals that the size and shape of the FeCo cells and chemical gradient between the FeCo and AlNi phases are critical to their magnetic properties. A high resolution and analytical TEM study of an Alnico 5-7 alloy along the transverse and longitudinal orientations were performed. The spinodal's separation in the transverse orientation is ~ 50 nm while the individual cells are in excess 100 nm. The FeCo bcc lattice aligns with the primitive cubic lattice of the AlNi ({001} || {001} and <100> || <100>). The HRTEM of the alloy reveals the nearly perfectly coherent interface between the FeCo and the AlNi phases. While structurally sharp, concentration profiles obtained indicate that the chemical gradient is ~ 10 nm and the AlNi phase contains a significant amount of Co and Fe. Implications of the chemical gradient and its effect on the magnetic properties will be discussed.

Radiation Effects in Ceramic Oxide and Novel LWR Fuels: Effects of Radiation on Thermal Transport and Fuel Performance

Effects of Radiation on Thermophysical Properties of Ceramic Oxide Fuels: *Dragos Staicu*[1]; [1]European Commission, Joint Research Centre, Institute for Transuranium Elements

Knowledge of the thermophysical properties of the fuel of a nuclear reactor is required for the prediction of fuel performance, in particular for the determination of the temperature distribution and of the fission gas release. The principal objectives of this presentation are to give elements useful to understand the phenomena causing the evolution of the thermophysical properties during irradiation, in particular the degradation of the thermal conductivity, and to provide guidance for the interpretation and comparison of in-pile or out-of-pile measurements, especially as a function of burn-up and for samples having different irradiation temperatures, in-pile histories and microstructures. The importance of such studies is renewed when the discharge burn-up of the fuel is increased and with the formation of the high burn-up structure. The impact of the introduction of plutonium or additives (Gd, Cr, etc.) in standard UO2 is also reviewed. Various approaches, from correlations to atomistic modelling, are presented.

2:30 PM
Effect of Dislocations on Thermal Conductivity of UO_2: *Bowen Deng*[1]; Aleksandr Chernatynskiy[1]; Priyank Shukla[2]; Susan Sinnott[1]; Simon Phillpot[1]; [1]Unieversity of Florida; [2]Georgia Institute of Technology

The microstructure of a UO_2 fuel pellet evolves considerably during burn-up. Such microstructural evolution has considerable effects on the thermal transport properties. In a highly burn-up fuel, dislocations have a density as high as about $5\times10^{14}m^{-2}$, which can affect the thermal conductivity through phonon-dislocation scattering. Here we use molecular-dynamics simulations to explore the decrease in thermal conductivity caused by incorporating a dipole of straight dislocations into perfect single crystal UO_2. Comparisons are made between different dislocation densities and different types of dislocations. These results are compared with Klemen's classic calculations, and the differences explained. This works was supported by the Center for the Materials Science of Nuclear Fuel, a DOE-BES Energy Frontiers Research Center.

2:45 PM
Radiation-Enhanced Diffusivity Measurements of Nd in Single Crystal Thin Film UO2.: *Xiaochun Han*[1]; Brent Heuser[1]; [1]University of Illinois

We present measurements of the radiation-enhanced diffusion (RED) of Nd, a +3 impurity and high-yield fission product, in single crystal thin film UO2 as a function of temperature, heavy-ion bombardment fluence and fluence rate. We use SIMS to characterize the broadening of a discrete Nd layer in our UO2 thin films up to 1100K and burnup to 2% FIMA. The use of thin films allows us to simulate uniform fission product damage with heavy-ion bombardment and to apply microanalytical techniques such as SIMS. We present diffusivities as a function of temperature, fluence, and fluence rate in the single crystal matrix. The application of kinetic rate theory yields the cation impurity migration energy under recombination-limited kinetics without the convolution of grain boundary diffusion. We have performed similar measurements of La RED in single crystal ceria; discussion of our results will focus on important differences in mass transport in the two systems.

3:00 PM
Thermal Properties of ThO_2-Based Fuel Using Atomic Level Simulations.: *Rakesh Behera*[1]; Aleksandr Chernatynskiy[2]; Simon Phillpot[2]; Chaitanya Deo[1]; [1]Georgia Institute of Technology; [2]University of Florida

Thorium-based nuclear fuel cycles are promising for their intrinsic proliferation resistance and greater thorium abundance. In this presentation we will focus on the thermal properties of ThO_2 using atomic level simulations. We have developed several empirical interactions to describe the properties of bulk ThO_2. Molecular dynamics is used to evaluate the effect of temperature using these developed interatomic potentials. We will present the thermal expansion and thermal conductivities of ThO_2 and compare the predicted values with available experimental results. Phonon dispersion curves and phase stability of ThO_2 will be discussed along with implications for the properties of mixed ThO_2-UO_2 oxide fuels. This research is being performed using funding received from the DOE Office of Nuclear Energy's Nuclear Energy University Programs.

3:15 PM
Thermal Transport in Uranium Dioxide from First Principles: *Aleksandr Chernatynskiy*[1]; Simon Phillpot[1]; [1]University of Florida

Thermal transport is one of the most important performance metrics of nuclear fuel. Uranium dioxide is by far the most widely used fuel material. Yet, detailed understanding of the thermal conductivity in uranium dioxide, UO_2, is missing: the only first principles calculations in the literature estimate thermal conductivity from Gruneisen parameters; moreover the calculated thermal transport properties differ sharply from measurements. To date, calculations based on lattice dynamics and Boltzmann Transport Equation currently have being performed only for classical interatomic potentials and they are also disagree with the experimental data for the phonon properties, such as lifetimes. We present the results of thermal conductivity calculations within the lattice dynamics framework in UO_2 using DFT calculations. Comparison of the phonon lifetimes with the recently measured lifetimes is provided. This work was funded by the Center for the Materials Science of Nuclear Fuel, a DOE-funded Energy Frontiers Research Center.

Simulation of the Pellet Cladding Interaction Phenomenon with the PLEIADES Fuel Performance Software Environment: *Bruno Michel*[1]; Chrystelle Nonon[1]; Jerome Sercombe[1]; Frederic Michel[1]; Vincent Marelle[1]; Isabelle Ramiere[1]; [1]CEA

This paper is focused on the simulation of Pellet Cladding Interaction (PCI) in Pressurized Water Reactor (PWR) under nominal, transient and accidental loading conditions. Scientific results presented are based on a cooperative program, between EDF, AREVA and the Atomic Energy Commission CEA, devoted to PCI modelling and the development of a unified fuel performance software environment called PLEIADES. First, the PLEIADES multi-concept fuel software environment is described. Attention is focused on the multi-dimensional PCI simulation with the fuel performance code ALCYONE of the PLEIADES platform. Improvements brought by the use of a multi-dimensional PCI modelling are detailed, in particular concerning the simulation of the coupling between gaseous swelling and mechanical behaviour of the fuel pellet. In the second part, 3D single pellet fragment simulation results are illustrated through the validation and sensitivity analyses of the PCI loading to material behaviour. To conclude, new functionalities of ALCYONE are presented.

4:10 PM Invited
Mechanistic Modeling of Fuel Microstructure Evolution and Fission Product Release under Irradiation: *Mikhail Veshchunov*[1]; [1]Nuclear Safety Institute (IBRAE) of Russian Academy of Sciences

The mechanistic code MFPR was developed for analysis of fission products (FP) release from irradiated UO2 fuel in collaboration between IBRAE and IRSN (Cadarache, France). The main outputs of the code are fuel microstructure, chemical speciation of solid-phase FPs, fuel oxygen potential evolution with burnup, densification, swelling and FP release. The code models self-consistently describes evolution of fuel micro-structure (point defects, such as vacancies and interstitials, and extended defects, such as gas bubbles, sintering pores and dislocations), which strongly influences intra- and intergranular diffusion transport of gas atoms in irradiated UO2, as well as fuel thermo-physical and mechanical properties. New microscopic parameters characterizing the crystal defect structure naturally arise, however, being physically grounded, these can be fixed from the analysis of available experimental data and/or from atomic scale investigations, and then used without any artificial tuning in further calculations.

4:40 PM
Theoretical Investigation on Interplay of Defect Clusters and Fission Gas in Uranium Dioxide: *Ying Chen*[1]; Hua Y Geng[2]; Yasunori Kaneta[3]; Motoyasu Kinoshita[4]; Shuichi Iwata[3]; [1]Tohoku University; [2]Institute of Fluid Physics; [3]The University of Tokyo; [4]Central Research Institute of Electric Power Industry

Interaction between the nuclear fuel and the fission gases product in nuclear reactor influences the performance of fuels remarkably. First-principles LSDA+U calculations have been performed taking Xe in UO_2 as a prototype to investigate the interplay of the defect clusters and gases in the fuel. A prominent effect of the self-defect clusters in bulk matrix on the thermodynamic behavior of fission gases is found, a thermodynamic competition between the uranium vacancy and tri-vacancy sites to incorporate xenon in hyper-stoichiometric regime at high temperatures is revealed. The observation that gas atoms are ionized to a charge state of Xe+ at a uranium vacancy site implies the possibility to control temperature to tune the preferred site of gas atoms and then the bubble growth rate. The quasi-annealing procedure, as a solution to the meta-stable states difficulty frequently encountered in DFT+U applications, is proposed and discussed over the example of UO_2-Xe system.

4:55 PM
Microstructurally Explicit Multi-Physics Simulation of Intergranular Mass Transport in Oxide Nuclear Fuels: *Harn Chyi Lim*[1]; Karin Rudman[1]; Kapil Krishna[1]; Robert McDonald[1]; Pedro Peralta[1]; Chris Stanek[2]; Kenneth McClellan[2]; [1]Arizona State University; [2]Los Alamos National Lab

Diffusion of fission products and the presence of large temperature gradients can affect the performance of oxide nuclear fuels. In particular, mass diffusion can be influenced by grain boundary (GB) characteristics, which suggests that microstructure could be manipulated to enhance fuel behavior. This research looks into the microstructure of depleted UO2 and simulates the effects of GB characteristics on mass transfer, as affected by large temperature gradients. The percolation behavior of mass transport is studied, along with the differences between dual (heat and mass) and single (mass) physics models. A 3D finite element model with microstructure information is created by serial sectioning of a depleted uranium oxide sample using Electron Backscattered Diffraction. The model contains information about the GB network, which is characterized based on misorientation angles and the Coincident Site Lattice model. Simulations reveal the development of percolating paths controlled by the contrast of local GB properties.

5:10 PM
Potential Performance Improvements of New Fuels: Ed Lahoda[1]; *Peng Xu*[1]; Sumit Ray[1]; Lars Hallstadius[1]; [1]Westinghouse Electric Company

Uranium dioxide fuel was picked as the fuel of choice in the late 1950's because its properties and performance in reactor were well known and because the performance expectations were quite low. In the last 50 years, issues such as minimization of spent fuel, increased cycle lengths by achieving higher burnups, and increased power density have become the major goals of the nuclear power industry. A preliminary screening was carried out of multiple fuel types that are currently being researched and several fuels that have the potential to out perform UO2 were identified. They do have issues, but their potential performance benefits will likely out weight the costs. This paper presents this evaluation, notes the issues, and lists the cladding requirements that if the goals of higher burnup and linear power are to be met.

5:25 PM Concluding Comments

Randall M. German Honorary Symposium on Sintering and Powder-Based Materials: Powder Processing and Consolidation III

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Powder Materials Committee
Program Organizers: K. Morsi, San Diego State University; Fernand Marquis, Naval Postgraduate School; John Meyer, Iowa State University; Ahmed El-Desouky, San Diego State University; Eugene Olevsky, San Diego State University

Wednesday PM — Room: Oceanic 2
March 14, 2012 — Location: Dolphin Resort

Session Chair: J. Sears, South Dakota School of Mines & Technology

2:00 PM
LASER Powder Deposition of AlMgB14-TiB2 Ultra-Hard Coatings on Titanium, Steel, and Cast Iron Substrates: *Jacob Fuerst*[1]; Michael Carter[1]; James Sears[1]; [1]South Dakota School of Mines and Technology

BAM is an ultra-hard ceramic compound created, at Ames Laboratory in 1999, by combining Aluminum Magnesium Boride (AlMgB14) and Titanium Diboride (TiB2). The high hardness, low coefficient of friction, and relative high temperature chemical inertness of BAM make it an ideal material for wear resistant coatings. Current BAM coatings are produced by Physical Vapor Deposition (PVD) or magnetron sputtering and are capable of only thin films. Using LASER Powder Deposition (LPD), high hardness (1300 HV) BAM coatings of 1 mm thickness, with increased fracture toughness were produced on Ti-6Al-4V, mild steel, and cast iron substrates. Initial tests demonstrate LASER Powder Deposition to be a capable means of manufacturing large, highly wear resistant surfaces.

2:15 PM
Pre-Sintered Preforms - Applications for Gas Turbine Components: *Jeremy Boyle*[1]; [1]AIM MRO

Advanced materials development in aero and industrial gas turbine components has been driven by increasing firing temperatures. These high performance superalloy articles must be repaired and refurbished to meet the expected life cycles and to assure the original equipment manufacturer's performance criteria. To meet these demands, preform brazing is becoming a vital process for airlines, utilities, and OEMs. This paper addresses the evolution and application of such processes.

2:30 PM
Modeling of Compaction Behavior Al6061 and SiC Powder by Semi-Solid Powder Forming: Yufeng Wu[1]; *Gap-Yong Kim*[1]; [1]Iowa State University

Semi-solid powder forming (S2PF) involves compaction of metallic alloy powders in temperature ranges where both solid and liquid phases coexist. In this work, compaction behavior of Al6061 and Al6061+SiC powders were modeled and compared with experimental results for liquid fractions up to 30%. A modified Shima-Oyane model was developed to predict the densification behavior of Al6061 powder. The model showed a good agreement with the experimental results below the liquid phase content of 20%. In this range, all the normalized pressure vs. relative density curves merged into one, which could be expressed in a simple exponential form for Al6061 powder. When the liquid phase content was above 20%, non-uniform distribution of the liquid phase was observed resulting in the deviation of the model from the experiments. Furthermore, a work in progress on modeling of the compaction behavior of Al6061+SiC powder is presented.

2:45 PM
Novel Amalgams for In-Space Fabrication of Replacement Parts: Calvin Cochran[1]; *James Van Hoose*[2]; Richard Grugel[3]; [1]Hendrix College; [2]Qualis/Jacobs; [3]Marshall Space Flight Center

Being able to fabricate replacement parts during extended space flight missions precludes the weight, storage volume, and speculation necessary to accommodate spares. Amalgams, widely used in dentistry, are potential candidates for fabricating parts in microgravity environments as they are moldable, do not require energy for melting, and do not pose fluid handling problems. Unfortunately, amalgams have poor tensile strength and the room temperature liquid component is mercury. To possibly resolve these issues a gallium-indium alloy was substituted for mercury and small steel fibers were mixed in with the commercial alloy powder. Subsequent microscopic examination of the novel amalgam revealed complete bonding of the components, and mechanical testing of comparable samples showed those containing steel fibers to have a significant improvement in strength. Experimental procedures, microstructures, and test results are presented and discussed in view of a simple model and further improving properties.

3:00 PM
Role of Al-Si Eutectic Powder on Sintering Aspects of Aluminum Alloy: *Gaurav Gupta*[1]; Anish Upadhaya[2]; O.P. Modi[1]; [1]AMPRI bhopal; [2]IIT Kanpur

The Al-Cu-Si alloy has been prepared from elemental powder of Alumium and copper blended with Al-Si eutectic powder instead of using pre-alloyed atomized powder as the matrix material. The present investigation looked into the effect of sintering temperature and Al-Si powder content on the sintering behaviour of the alloy. Compaction was done at 200 and 500 MPa. Sintering was carried out in Nitrogen atmosphere. Further the Densification parameter and hardness were measured of the sintered sample and microstructures were examined. Densification parameter increased with sintering temperature at both the compaction pressures due to enhanced diffusion. Densification parameter increased with Al-Si content at lower compaction pressure but trend reversed at higher compaction pressure. Higher liquid content with low level of porosity leads to swelling of the sample. Higher Hardness was obtained in all condition at higher compaction pressures due to low porosity and Hardness also increased with Al-Si content.

3:35 PM
Characterization of Surface Oxides on Steel Powders – Experiments and Modelling: *Karin Frisk*[1]; Sophie Caddeo Johansson[1]; Alexander Angré[1]; [1]Swerea KIMAB

Surface oxides on steel powders originating from the atomization and/or from powder handling, constitute an important source of oxygen in powder-based steel. The properties are detrimentally affected by oxygen and the content should be minimised, and it is thus of interest to characterise oxides, and the conditions where they are formed or reduced. In the present work different methods to investigate surface oxides on steel powder, and oxides in HIP-compacted steel, are presented. Experimental investigations, using Photo Acoustic Spectroscopy (PAS); analysis of oxygen contents in powder and in compacted samples produced in a lab-scale atomizer (10kg) equipped with an oxysensor; and by microstructure investigations using SEM / TEM with FIB (Focussed Ion Beam); are coupled with calculations of the stability of complex oxides to characterise the type of oxides.

3:50 PM
Corrosion Resistant Austenitic (316L) Stainless Steel through Sintering and Surface Modification by Electrostatic Spray Coating: *Kandala Ramakrishna*[1]; Kantesh Balani[1]; Anish Upadhyaya[1]; [1]Indian Institute of Technology

Powder metallurgical stainless steels are finding increased demand in automotive, marine, structural, biomedical and food industries applications due to their unique characteristics of low processing temperature, near net shape product with greater material utilization (>95 %) and more refined or homogeneous microstructure. However, the application of powder metallurgical stainless steel is limited by their inferior corrosion resistance and tribological properties. In the present study, an attempt has been made to enhance the corrosion resistance and tribological properties of sintered 316L stainless steel through surface modification. This study compares the electrochemical and wear behavior of electrostatically coated ultra high molecular weight polyethylene on conventional and microwave sintered 316 L (at supersolidus 1400°C for 1 h in reducing atmosphere). The corrosion behavior was investigated in 3.5% NaCl and 0.1N H_2SO_4 solutions by potentiodynamic polarization, electro chemical impedance spectroscopy (EIS) and surface characterization. The microstructure, processing and corrosion and wear behavior were correlated.

4:05 PM
Intense Pulsed Light Sintering Technique for Nanomaterials: *H. A. Colorado*[1]; S. R. Dhage[2]; J. M.[1]; H. T.[1]; [1]University of California, Los Angeles; [2]International Advanced Research Center for Powder Metallurgy & New Materials (ARCI)

The Intense Pulsed Light (IPL) from a xenon flash lamp can sinter nanoparticles in few milliseconds. Such a short reaction time prevents oxidation of the elements and second phase generation. Another valuable benefit of IPL sintering is that the materials can be sintered without damaging the glass or temperature-sensitive flexible polymer substrate materials. The solid state diffusion of nanoparticles in a very short reaction time of few milliseconds is great benefit of Intense pulsed light system over the conventional sintering methods. It is believed that if the particles have very high surface area-to-mass ratio, very little light is needed to activate and diffuse the particles. Melting and recrystallization of particles to larger grains without structural deformation and phase transformation are possible because of very shot reaction time. Thus, IPL can be a very promissory technique for ultra rapid processing of nanomaterials and thin films. Several study cases are presented.

4:20 PM
Reactive Spark Plasma Sintering of AlON Ceramics: *Halide Esra Kanbur*[1]; Burcu Apak[1]; Gultekin Goller[1]; Onuralp Yucel[1]; Filiz Cinar Sahin[1]; [1]Istanbul Technical University

In this study, aluminum oxynitride ceramics (AlON) with using AlN and Al_2O_3 starting powders were prepared by Spark Plasma Sintering (SPS) under nitrogen atmosphere. AlN and Al_2O_3 mixtures with sintering additives (Mg, La) were prepared. Several mixtures of Al_2O_3 and AlN were ball milled with alumina balls for 24 h. The obtained powder mixtures were sintered at several temperatures and periods at 40 MPa under nitrogen atmosphere by SPS system. The phase compositions of the samples were examined by X-ray diffraction (XRD) and microstructures were observed by SEM technique. The hardness and fracture toughness of the sintered samples were measured. The effects of SPS temperature, heating rate, soaking time and sintering additives on phase transformation, microstructure, mechanical properties, density and transparency of AlON were investigated.

4:35 PM
Spark Plasma Sintering of Silicon Carbide Ceramics: *Mehtap Unlu*[1]; Gultekin Goller[1]; Onuralp Yucel[1]; Filiz Sahin[1]; [1]Istanbul Technical University

SiC ceramics were fabricated by spark plasma sintering (SPS) technique with the use of sintering additives. The sintering process was carried out at four different temperatures in the range of 1800-1950°C applying two different pressures 40MPa and 80MPa under vacuum atmosphere. The effect of additives, different temperatures and pressures on density, vickers hardness, fracture toughness, and microstructure were examined. The hardness and fracture toughness of the samples were evaluated by the vickers indentation technique. Microstructure of spark plasma sintered SiC samples were characterized by using SEM technique.

4:50 PM Invited
Progress in Additive Manufacturing as a Powder Based Solution: *James Sears*[1]; [1]South Dakota School of Mines & Technology

Additive Manufacturing (AM) has matured in the last 20 years to a point it has become a viable powder-base solution for part manufacturing or enhancement. The application space that AM encompasses range from Aerospace and Defense to Bio-Medical. Additive Manufacturing comprises technologies that add material to existing structures for form and/or function. AM is a CAD/CAM solid freeform fabrication technology that uses metal powder and fusion for manufacturing or repairing of components without the use of hard tooling. Fusion can be invoked through laser, electron beam, and arc-based energy sources. AM is also achieved through solid state techniques that utilize friction and ultrasonic energy. Inherent to AM is the ability to add material for repair or manufacture of critical components with minimal heat affect to the under lying material. An overview of AM developments will be provided along with details of manufacturing and repair for several applications.

Reaching New Heights: Materials Innovation in the Aerospace Industry: Session I

Sponsored by:
Program Organizers: Robert Shull, National Institute of Standards and Technology; Jud Ready, Georgia Institute of Technology; George Gray, Los Alamos National Laboratory; Thomas Battle, Midrex Technologies

March 14, 2012 — Location: Dolphin Resort

Session Chair: Chuck Ward, US Air Force

2:00 PM Introductory Comments

2:05 PM
Materials Genome Initiative: *James Warren*[1]; [1]NIST

The Materials Genome Initiative is a new, multi-stakeholder effort to develop an infrastructure to accelerate advanced materials discovery and deployment in the United States. Over the last several decades there has been significant Federal investment in new experimental processes and techniques for designing advanced materials. This new focused initiative will better leverage existing Federal investments through the use of computational capabilities, data management, and an integrated approach to materials science and engineering. The development of advanced materials can be accelerated through advances in computational techniques, more effective use of standards, and enhanced data management. This talk will provide a brief introduction to the initiative, and set the stage for the case studies discussed in this session.

2:15 PM
ICME: Promise and Future Directions: *Robert Schafrik*[1]; [1]GE Aviation

At GE Aviation, we have demonstrated success of this strategy with a 2-year development time (from project start to full engine qualification) for two low rhenium single crystal airfoils alloys that entered production in 2009, and a 4-year development time for a new cast-and-wrought turbine disk alloy that will enter full scale production in 2012. In both these cases, a typical development cycle would have been 3 times as long. As we look to the future, we see several key ICME areas that need to be further developed to make ICME the standard development approach: i) cyber infrastructure that facilitates collaboration between various stakeholders; ii) federated heterogeneous databases; iii) further development of key M&P models across all material systems, including standard interfaces; and iv) standardized Terms & Conditions for licensed software.

2:45 PM
Lessons Learned from the Trenches and Implications on ICME and the MGI: *Charles Kuehmann*[1]; [1]QuesTek Innovations LLC

The President's Material's Genome Initiative (MGI) challenges us to innovate materials modeling and engineering methods, enabling new materials to reach commercial application in half the time of current capabilities. QuesTek's more than a decade of experience in applying Materials by Design technology and Accelerated Insertion of Materials (AIM) methods has taken four alloys to commercial production and flight qualification with many more in process. This unique experience provides key insights into a Materials Genome infrastructure and related Integrated Computational Materials Engineering (ICME) methods enabling the grand MGI vision. Important conclusions from recent materials commercialization successes can be made. First, a specific engineering problem must dictate the priorities for developing MGI and ICME related modeling, tools and data, not the other way around. And secondly, while challenging, the overall goal of the MGI is certainly achievable. A review of recent successes and implications of the MGI will be presented.

3:15 PM
Enabling the Era of Hybrid Materials - A Tipping Point of Change: *Michael Dudzik*[1]; Rick Barto[1]; [1]Lockheed Martin Corporation

The ongoing state of the art transition in the field of materials science from metal alloys to composites to hybrid materials offers the aerospace market unique design solutions to meet ever demanding requirements in product manufacturing cost reduction, system performance enhancement and total lifecycle sustainability. The rapidly growing interest in hybrid materials - those with multiple functionalities - has opened a new era in materials usage for advanced aerospace products beyond mono-functional materials. Since 2008, Lockheed Martin has been actively engaged in blending hybrid materials with ICME practices to create new solutions to complex design and manufacturing needs. The benefits of the Materials Genome Initiative will expand and accelerate the transition of hybrid materials across greater product applications. A review of recent successes achieved through better utilization of computational physics, material data management, certification, and the manufacturing supply chain will be presented.

Recent Developments in Biological, Electronic, Functional and Structural Thin Films and Coatings: Process-Properties-Performance Correlations II

2:05 PM
Near-Suface Residual Stress-Profiling by Incremental Micro-Slot Cutting Method: Assessment of Stress-Calculation Errors: *Bartlomiej Winiarski*[1]; Philip Withers[1]; [1]University of Manchester

This paper quantifies residual-stress (RS) calculation errors of the incremental micro-slot cutting method (IμSC) for the investigation of residual stress profile in near-surface layer on a submicron scale. We analyse five main sources of RS calculation errors: (a) displacement-measurement errors; (b) slot-depth-measurement errors; (c) slot-width-measurement errors; (d) incorrect material constants; and (e) unit pulses method (UPM) uncertainty. Within the scope of IμSC method the residual-stresses are inferred using Finite-Element Analysis (FEA) of the surface relaxation, as measured by Digital Image Correlation (DIC) from Field-Emission-Gun Scanning Electron Microscope (FEGSEM) images, which occur when a micro-slot is step-wise micro-machined by Focused Ion Beam (FIB). The calculation algorithm, which solves this inverse problem of residual-stress estimation, is based on UPM and is stabilised by Tikhonov Regularisation (TR). We demonstrate the influence of particular sources of errors on RS estimates in homogeneous materials and coatings, and we present a guidelines to minimise the uncertainties.

2:35 PM
Properties of Coatings Formed by Plasma Electrolytic Oxidation of AM60B Magnesium Alloy in Electrolytes Containing Al2O3 Suspension: Xijin Li[1]; *Mark Liu*[1]; Ben Luan[1]; [1]National Resaerch Council Canada

Magnesium alloys are attractive lightweight materials for many industrial applications, but their relatively low resistance to corrosion and wear is a key drawback of the materials. To improve the wear and corrosion resistance of an AM60B magnesium alloy, ceramic coatings were formed by plasma electrolytic oxidation (PEO) in aluminate electrolytes with and without Al2O3 particle suspensions. Pin-on-disc wear tests showed that the addition of Al2O3 suspensions in the electrolytes can significantly improve the wear resistance of the coatings. The mechanisms of coating performance improvements were investigated through examining microstructures, coating compositions and phase constituents of the coatings.

3:05 PM
Adhesion between Polymer/Metal interfaces: *Sina Youssefian*[1]; Nima Rahbar[1]; [1]Umass Dartmouth

Polymer-Metal interactions in majority of engineering polymers are experimentally difficult to measure. Molecular Dynamics (MD) simulation for quantifying the adhesion between PMDA-ODA polyimide and Aluminum (Al) and Aluminum Oxide (Al2O3) is used to have better understanding of the metal–polyimide interfacial properties. A model composed of a small molecular fragment of the polymer repeating units and a block of metal and metal oxide is used for the simulation. COMPASS force field methodology was used in MD simulations to calculate the energy of adhesion between the polymer and the surfaces. Results are shown that introduction of oxygen atoms to metallic surface significantly increases the adhesion energy. The energy of adhesion between PMDA-ODA and Al2O3 is more than that of with Al. Keywords: Adhesion, Polymers, Contact mechanics

3:25 PM
Hyperthermal Hydrocarbon Modification of PMMA: *Leah Hill*[1]; Travis Kemper[1]; Susan Sinnott[1]; [1]University of Florida

Ion beams and plasma can be used to functionalize or modify the surface of a polymer, which affects properties such as adhesion, biocompatibility and chemical resistance. Hydrocarbon molecules are used in plasma modification of surfaces. Here, molecular dynamics simulations are performed to examine the mechanisms by which hyperthermal hydrocarbon polyatomics, which are present in low-energy plasmas, modify polymer surfaces. The forces on the atoms are determined using the second generation Reactive Empirical Many-Body (REBO) potential. In particular, H, C_2H, CH_3, and C_3H_5 are deposited on a poly(methyl methacrylate) (PMMA) substrate at kinetic energies of 25, 50, and 100 eV. The effects of deposition on crosslinking are explored, and functionalization of the polymer substrate is evaluated to better understand the effects of ion beam depositions on plasma polymerization. This work is supported by the NSF (CHE-0809376).

4:00 PM
Mechanism of Creep Deformation in Porous Organosilicate Thin Films: *Emil Zin*[1]; Tingqin Zhao[1]; Nancy Michael[1]; Choong-Un Kim[1]; Huili Xu[1]; [1]The University of Texas at Arlington

Silicate based porous thin films are extensively used in many engineering structures and devices, including high efficiency catalyst and low-k for microelectronics devices. One of the presumption in the related field is that the film would maintain its structural integrity as long as load is kept below the yield point. However, our studies find that the prevailing belief is false as the films are found to exhibit creep. Detailed investigation on the mechanism, conducted at various temperature, loading condition, and film condition, indicates that the creep occurs by viscous flow due to chemical reaction. When the film is exposed to –OH, the hydration reaction results in the weakening of the local bond, which leads to body translation of the entire film. This paper presents 1) characterization methodology for creep deformation of porous silicate thin films, 2) kinetic mechanisms of creep and 3) chemical and mechanical mechanism leading to the creep.

4:20 PM
Characterization of Ceramic Layers on Al Alloy by Plasma Electrolytic Oxidation in Two Different Electrolytes Including Sodium Tungstate: *In Jun Hwang*[1]; Ki Ryong Shin[1]; Sang il Yoon[1]; Young Gun Ko[2]; Dong Hyuk Shin[1]; [1]Hanyang University; [2]Yeungnam University

This study demonstrated tribological properties of ceramic layers on Al alloy by plasma electrolytic oxidation (PEO) in two kinds of electrolytes, namely phosphate and silicate, including sodium tungstate. X-ray diffraction patterns revealed two crucial facts: Firstly, when PEO coating was carried out in phosphate electrolyte, the ceramic layer possessed a large quantity of WO3 compound since the electric potential of electro-migration for tungstate ions was abruptly reduced by phosphate ions which could be complexing agent. On the other hand, the mullite and a-Al2O3 compound was formed with ease in the ceramic layer with rapid growth rate during PEO treatment in the silicate electrolyte due to the intrinsic characteristics of silicate ions. Overall, predominant WO3 compound in the ceramic layer from phosphate electrolyte disclosed better tribological properties after short PEO-process time while silicate electrolyte was favorable to fabricate tribologically hard ceramic layer beyond relatively long process time.

4:40 PM
Characterization of High Temperature Mechanical Properties of Two Unique Experimental Coatings: *Amit Pandey*[1]; Vladimir Tolpygo[2]; Kevin Hemker[3]; [1]ORNL; [2]Honeywell; [3]JHU

Two coatings discussed here are coating “a” which is a typical NiCoCrAlY and was deposited by plasma spray and the coating “ß” is a modified Ni-base superalloy (i.e. two-phase gamma / gamma-prime Ni alloy) and was deposited by laser cladding. Results on thermal expansion experiments reveal that both coatings possess wide range of coefficient of thermal expansion (CTE) and the CTE curves follow distinct path dependency with temperature. It is found that the CTE mismatch between coating and substrate is significantly lower for the coating “ß”. Microtensile experiments at room temperature show that the coating “a” has slightly higher YS and a very low value of failure strain (ef) as compared to the coating “ß” and is very different at higher temperature. Results from this study indicate that coating “ß” could be a better choice for a thermal barrier system.

5:00 PM
Effect of Temperature on the Structure and Properties of Nano-Twin Cu Thin Film Deposited by Unbalanced Magnetron (UBM) Sputtering: *Kai Hung Yang*[1]; Fan-Yi Ouyang[1]; [1]National Tsing Hua University

Nano-twined Cu thin films were successfully deposited on Si (100) substrate using unbalanced magnetron sputtering (UBMS) system. The objective of this study was to investigate the effect of temperature on the structures and mechanical properties of Cu thin films. The electro-resistance was measured by four-point probe and the hardness was measure by nano-indentation. Transmission Electron Microscopy (TEM) was used to examine microstructure and preferred orientation of the nano twin. The residual stresses of all Cu films were also measured. The results show that (111) was the dominant preferred orientation in the Cu films. The effects of the temperature were strongly varied on the hardness, nano-twin spacing, and grain size. Furthermore, the results suggested nano-twin structure tended to form at lower temperature with high deposition rate. A possible mechanism of nano twin formation was also discussed in this paper.

5:30 PM
Formation of Crystalline and Amorphous Phases During Deposition of Ni_xTi_{1-x} Thin Film on Si Substrate – Interpretation of Experimental Results Using Molecular Dynamics Simulations: *Shampa Aich*[1]; Geetha Priyadarshini B[1]; M. Gupta[1]; Sudipto Ghosh[1]; Madhusudan Chakraborty[2]; [1]Indian Institute of Technology Kharagpur; [2]Indian Institue of Technology Bhubaneswar

This research was undertaken to study the crystallization and amorphization of magnetron-sputtered Ni_xTi_{1-x} thin films using composition variations and various substrate bias voltages. Variation of deposition efficiency with composition and bias voltage suggests that Ni resists re-sputtering. In case of Ti thin film, increase in negative bias voltage caused decrease in crystallinity due to re-sputtering. But, the bias voltage did not affect significantly the crystallinity of Ni thin film. On the other hand, high bias voltage induced crystallinity in otherwise amorphous Ni_xTi_{1-x} thin film. In order to explain some of the observed trends molecular dynamics simulations based on embedded atomic method (EAM) potential for Ni-Ti system were carried out. Simulations could explain the partial amorphization of crystalline film and partial crystallization of amorphous film which occurred due to re-sputtering.

Recycling General Sessions: Waste Utilization

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS Light Metals Division, TMS: Recycling and Environmental Technologies Committee
Program Organizer: Joseph Pomykala, Alter Trading

Wednesday PM	Room: Europe 4
March 14, 2012	Location: Dolphin Resort

Session Chair: Jeffrey S. Spangenberger, Argonne National Laboratory

2:00 PM
Experimental Research on Acid Magenta Dye Decolor Dynamics: *Ding Lichao*[1]; Chen Yunnen[1]; [1]Jiangxi University of Science and Technology

In this paper the simulated acid magenta dye discoloring the reaction process was researched. The results showed that it attained highest decolorization efficiency for acidic magenta simulation dye wastewater when pH 9 and reaction time 10 min. With the initial dye wastewater concentration increased, the decolored rate decreased. The decolored rate in general kept a tendency to increased with the temperature increased. Kinetics researches showed that when pH 9, reaction temperature 20 and 35 □, the decoloring reaction process for the dyes accorded with the first-order dynamic equation. The decoloring reaction rate constant was influenced by initial concentration of dye wastewater and temperature.

2:20 PM
Study on a River Containing Fluorine and the Pollution Control Method: *Luo Jianzhong*[1]; Zhang Zheng[1]; [1]Guangdong University of Technology

No matter the contents of fluorine in river is too high or too low ,they will have a bad effect on human health and habitats, and thus the study on fluoride pollutants in river is related to people's lives and health safety. The article studies the fluoride content in a stream of the Pearl River of China. The fluoride concentration is excessive all the time in this strenm, fluoride content in water is up to 1.65mg/L, exceeding 65%. Through the investigation of the key sources of pollution, there are 58 aluminum processing plants, 55 glass factories, 161 iron and steel factories, 199 ceramics factories, 30 brick factories and 38 cement factories in this near areas. These plants emitted high fluoride wastewater, and need to strengthen the fluoride pollution control, or close the factories which cannot reach the environmental standard.

2:40 PM
Study on a Stream Contained Fluorine Excessively and the Industry Pollution Control of Fluorine in the Stream: *Luo Jianzhong*[1]; Zhang Zheng[1]; Zhang Minyi[1]; Zhang Qian[1]; Luo Shuai[1]; [1]Guangdong University of Technology

No matter the content of fluorine is too high or too low in water, they will have a bad effect on human health and habitats, and thus the study on water fluoride pollutants is important to people's lives and health safety. The fluoride content in a stream water of the Pearl River in China is up to 1.65mg/L, exceeding standard 65%. Through the investigation of the key sources of pollution near this stream, there are 58 aluminum processing plants, 55 glass factories, 161 iron and steel factories, 199 ceramics factories, 30 brick factories, 38 cement factories. These factories emitted high fluoride wastewater, need to strengthen the pollution control, or close the factories which cannot reach the environmental standard.

3:00 PM
Investigation of Mo Extraction from a Spent Hydro-Cracking Catalyst by Fungi at Optimal Conditions: *Farnaz Amiri*[1]; [1]Sharif University of Technology

Spent hydro-processing catalysts have been identified as hazardous wastes by USEPA since 1999; so, recovery of the contained heavy metals in the spent catalyst is critical in view of environmental and economic benefits. Bioleaching has been considered as a possible alternative to polluting and costly traditional extraction methods such as hydro-metallurgy and pyro-metallurgy for the recovery of metal values from spent catalysts. Statistically based experimental designs, Plackett–Burman factorial design and central composite design, were applied respectively to screen and optimize the bioleaching of spent catalyst by *Aspergillus niger* and *Penicillium simplicissimum*. The production of organic acids as the main agent in fungal leaching and changes of the fungi dry weight with time were also investigated. The maximum Mo recoveries corresponding to optimal conditions were (98.8 ± 0.9) % and (99.5 ± 0.4) % achieved by *Penicillium simplicissimum* and *Aspergillus niger*, respectively, which were comparable to the conventional approaches results.

3:20 PM
Leaching Thermodynamics and Kinetics of Preparation of Synthetic Rutile: *Wu Zhang*[1]; Li Zhangli[1]; Xiang Feng[1]; [1]Northeastern University

Leaching thermodynamics and kinetics of preparation of synthetic rutile were discussed. Leaching Gibbs free energy change of reactions were calculated . The metal and water E-pH formula were obtained at different temperatures. Potential-pH formulas of reactions and Potential-pH diagram of MeO-H2O systems were drawn at the temperature of 298K and 313K when the ionic activity is 1.0. Kinetic experiments and calculations show that the leaching process can be modeled with the shrinking core model which indicates that the control factor of the leaching process is chemistry reactions. The apparent activation energy of alkali leaching process is 43.52kJ/mol.

3:40 PM Break

4:00 PM
Phase Equilibria and Liquidus in CaO-SiO2-FeOx-Al2O3 System in the Temperature Range 1673K to 1873K: *Cuihuan Huang*[1]; [1]Northeastern University

To provide essential data for efficient utilization of vitrified bottom ash slag, the thermodynamic properties of CaO-Al2O3-SiO2-FeOx-MgO-Na2O oxide system are highly required. In this work, the equilibrium phases and liquidus of CaO-SiO2-FeOx-Al2O3 system, one sub-system of the multi-component oxide systems, were investigated in the temperature range from 1673K to 1873K. The liquid phase regions enlarged with increase of temperature, while the primary phase fields reduced distinctly. The equilibrium phases of CaO-SiO2-FeOx-Al2O3 system systems were identified between 1673K to 1873K.

4:20 PM
Precipitation Selectivity of Perovskite Phase from Ti-Bearing Blast Furnace Slag under Reducing Conditions, Argon Atmosphere and Dynamic Oxidation Conditions: Li Zhang[1]; *Wu Zhang*[1]; [1]Northeastern University

The precipitation selectivity of perovskite phase from Ti-bearing blast furnace slag under reducing condition, an argon atmosphere and dynamic oxidation were investigated, respectively. The aim of this work was to investigate the effect of different modified conditions on the selective enrichment of Ti components into perovskite phase and precipitation of perovskite phase. The results under reducing conditions show that the higher melting temperature and slag basicity had little effect on the precipitation selectively of perovskite phase, and Ti components remained the dispersed distribution in various fine grained, almost same as un-modified slag; the results under an argon atmosphere show that the higher melting temperature and slag basicity promoted the precipitation of perovskite phase, but had little effect on the selective enrichment of Ti components into perovskite phase; the result under dynamic oxidation show that the dispersed Ti components were enriched into perovskite phase, and perovskite phase could be selectively precipitate.

4:40 PM
Recovery of Magnesium from Waste Effluent in Nickel Laterite Hydrometallurgy Process: *Ninglei Sun*[1]; Jinshan Liu[1]; Kuiting Wang[1]; Aiguo Dong[1]; Yeda Lu[1]; [1]China ENFI Engineering Co. Ltd.

Eliminating the environmental threat caused by waste effluent containing magnesium sulfate discharged from the process of nickel laterite sulfuric acid leaching and subsequent nickel precipitation is always a focus in the metallurgy field. A new flowsheet whose procedures include vaporization, crystallization, precipitation of magnesium by ammonia, secondary precipitation, causticizing treatment of filtrate and ammonia recycle was investigated. Both the details of the flowsheet and its application are described in this article. It is confirmed to be an effective and economical method to prevent the pollution by the waste effluent, in addition, a series of magnesium products recovered during the process own good economic returns.

5:00 PM
Recycling of Reverted IN738LC with Reference to Mechanical Properties and Control of Chemical Composition: *Reza Rahimi*[1]; Mahmood Nili Ahmadabadi[1]; [1]University of Tehran

Because of high cost and shortage of primary resources of Ni-base superalloys, researchers are looking for new methods to reach origin ingot without using pure metals or master alloys alone and one of the attractive resources that are suitable for gaining this goal is reverted alloy. The current study is based on recycling of IN738LC, a Ni-base superalloy, using 30% reverted alloy and 70% virgin raw materials. Therefore, it has been attempted to cast an alloy with references to standard chemical composition and mechanical properties. After charging and casting in vacuum melting furnaces, chemical composition verification and non-destructive tests (i.e. PT and RT), quality of samples were evaluated by various mechanical experiments such as stress-rupture as well as room and elevated temperature tension tests. Results acquired from chemical composition and mechanical tests indicate that cast ingots using 30% reverted alloy is reliable and consistent with the quality control requirements.

5:20 PM
A Kinetics Study on the Hydrometallurgical Recovery of Vanadium from LD Converter Slag in Alkaline Media: Amirhossein Shahnazi[1]; Fereshteh Rashchi[1]; *Ehsan Vahidi*[2]; [1]University of Tehran; [2]University of South Florida

During the oxidation process of the molten pig iron, contains high concentration vanadium bearing materials, vanadium transfers to the slag. In this research, recovery of vanadium from LD converter slag of steelmaking plant was investigated. The leaching residue was characterized by XRD, XRF and SEM/EDX techniques. The maximum vanadium recovery was achieved at 70°C, S/L:1/15, NaOH concentration:3M and leaching time:150min. It was determined that the dissolution rate increased with increasing NaOH concentration and decreasing particle size. The experimental data were treated graphically to explain the kinetics of the vanadium recovery process using shrinking core model (SCM). As a result, the controlling regimes in the SCM were analyzed separately using liquid-film diffusion control, solid-product diffusion control and reaction control mechanisms. Kinetic findings were in consistent with the activation energy and also a linear relationship between the rate constant and the inverse square of the initial particle diameter was observed.

Refractory Metals 2012: Alloy Predictions and Synthesis | Oxidation and Corrosion

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS: Refractory Metals Committee

2:00 PM
Ab Initio Phase Diagrams of Bcc-Based Transition Metal Alloys – Consequences on Properties: *Patrice Turchi*[1]; Vaclav Drchal[2]; Josef Kudrnovsky[2]; [1]Lawrence Livermore National Laboratory; [2]Institute of Physics, Czech Acadamy of Science

The unique properties of refractory metals and their alloys require a fundamental understanding of alloy phase stability and ordering based on a proper description of the scattering properties of the electrons. Phase stability properties of substitutional alloys of the fifteen combinations among the six bcc-based transition metals with prediction of equilibrium properties and coherent phase diagrams are discussed in the framework of the first-principles fully relativistic tight-binding linear muffin-tin orbital (TB-LMTO) method, within the coherent potential approximation (CPA) and the local density approximation of density functional theory. The statistical mechanics part of the problem is solved with a generalized mean-field approach with effective pair interactions obtained from the ab initio generalized perturbation method. We show that electron-driven tendencies toward order exist for some of these bcc-based alloys although the assessed phase diagrams indicate complete miscibility. Work performed under the auspices of the U.S. DOE by LLNL under contract DE-AC52-07NA27344.

2:20 PM
Bond-Order Potentials for bcc Refractory Metals: *Miroslav Cak*[1]; Thomas Hammerschmidt[1]; Ralf Drautz[1]; [1]ICAMS, Ruhr University Bochum

Refractory metals play an important role in many materials for high-temperature applications. These elements are involved in a variety of microstructural peculiarities ranging from the formation of topologically close-packed (TCP) phases to transitions between symmetric and asymmetric dislocation cores. An atomistic understanding of refractory metals requires a reliable and computationally efficient representation of the interatomic interaction. To this end we developed tight-binding based analytic bond-order potentials (BOPs) for the bcc refractory metals Tungsten, Molybdenum, Niobium and Tantalum. The potentials parameters were optimised for the equilibrium bcc structure and extensively tested for atomic environments far from equilibrium that were not included in the optimisation: structural energy differences; tetragonal, trigonal, hexagonal and orthorhombic deformation paths;formation energies of point defects and phonon spectra. A comparison with density-functional and tight-binding calculations shows very good transferability of our analytic BOPs. We show the application of the BOPs to the simulation of grain boundary properties.

2:40 PM
Effect of Alloying on Phase Stability and Deformation Behavior of Niobium Silicides: *Oleg Kontsevoi*[1]; Arthur Freeman[1]; [1]Northwestern University

Niobium silicide-based alloys are promising materials for ultra-high temperature applications with a potential to replace traditional Ni based superalloys. One of drawbacks is poor fracture toughness at room and intermediate temperatures. In order to develop a fundamental basis for a further enhancement of performance of these materials through alloying, we apply theoretical density-functional theory calculations to investigate the effect of Al, transitional metals (Ti, V, Cr, Fe) and refractory metals (Mo, Ta, W) on phase stability and deformation behavior of the multiphase Nb – Nb_3Si – Nb_5Si_3 system. We determine site preference, phase partitioning of alloying elements, and their effect on shear behavior and preferred deformation modes. The results are discussed in connection with possible ways of enhancement of deformation properties of niobium silicide alloys.

3:00 PM
Microstructure and Properties of New Refractory High Entropy Alloys: *Oleg Senkov*[1]; Svetlana Senkova[1]; Daniel Miracle[1]; Christopher Woodward[1]; [1]Air Force Research Laboratory

Results on the development of several new refractory high entropy alloys containing Nb, Mo, Ta, Hf, Cr, V, Ti, Zr and Al as principal alloying elements will be presented. Some of these multi-component alloys have a single-phase, disordered BCC crystal structure, while other alloys contain several crystal phases among which a disordered BCC phase dominates. The crystal types and chemical compositions of the phases, the alloy density, hardness, compression properties in a temperature range from 295 to 1473 K, and microstructures will be reported. Finally, the relationships between the composition, microstructure and properties will be outlined for these new alloys. This work was conducted under the U.S. Air Force contract FA8650-10-D-5226.

3:20 PM
Facile Synthesis and Characterization of Inexpensive Superhard Refractory Metals: *Richard Kaner*[1]; Reza Mohammadi[1]; Andrew Lech[1]; Miao Xie[1]; Christopher Turner[1]; Beth Weaver[1]; Michael Yeung[1]; Sarah Tolbert[1]; [1]UCLA

With the shortcomings of traditional cutting tool materials such as diamond (expensive) and tungsten carbide (low hardness), the search for new high-performance superhard materials has recently led to the exploration of dense transition metal borides. For example, we have synthesized rhenium diboride (ReB2) using arc melting at ambient pressure. This superhard material possesses excellent electrical conductivity and mechanical properties. Under an applied load of 0.49 N, we have measured a Vickers microindentation hardness of 48.0 GPa for ReB2. To further increase the hardness and lower the materials costs, we have begun exploring higher boron content metal borides including tungsten tetraboride (WB4). We have synthesized WB4 by arc melting and measured a Vickers microindentation hardness of 43.3 GPa under a load of 0.49 N. Solid solutions of this material with Re have resulted in a hardness of ~50 GPa when 1 at.% of W is substituted with Re.

3:50 PM
Microstructural Characterization of Mutlicomponent Nb-Ti-Si-Cr-Al-X Alloys: *Raghvendra Tewari*[1]; Hyo-Jin Song[2]; Amit Chatterjee[3]; Vijay Vasudevan[2]; [1]Bhabha Atomic Resrach Centre; [2]Department of Chemical and Materials Engineering, University of Cincinnati, OH, 45221-0012; [3]Rolls Royce Corporation

In the present work, microstructures of multicomponent Nb-Ti-Si-Cr-Al-X alloys were studied and effect of temperature and time on phase evolution was examined. Microstructures of the alloys comprised the matrix-β , silicides and Laves phase. The silicides in these alloys were generally stable during heat treatment, whereas the Laves phase was observed to dissolve or precipitate out depending upon temperature of aging. In addition, the β -matrix showed phase separation tendency. The volume percentage and chemical composition of each phase has been determined and the changes in microstructure have been rationalized in terms of the distribution of elements in various phases. The role of alloying elements on the formation of these phases has also been critically examined.

4:10 PM
Cobalt-Base Alloys for High Temperature Applications: *Rabindra Mahapatra*[1]; M. Ashraf Imam[2]; Charles Lei[1]; Jerry Feng[2]; [1]Naval Air Systems Command; [2]Naval Research Lab

The isothermal oxidation behavior and thermal stability of a cobalt base (Co-Al-Si-Cr-W-Ni-Ce-Hf) alloy were investigated up to a period of 312 hr in air from 1000 to 12000C. A comparison of oxidation behavior of this alloy with a conventional nickel-base superalloy (Inconel 713C) has been conducted in detail. The cobalt base alloy oxidizes by forming layers of Al2O3, Cr2O3, HfO, CoO and traces of SiO2 with WO2 oxides on the surface of the specimen in contact with air. Optical and scanning electron microscopy (SEM) were used to study the microstructure, morphology and compositions of oxides formed after the exposure. Thermal stability of the alloy after extended periods of exposures to air at 1000, 1100 and 12000C was studied using transmission electron microscopy (TEM).

4:30 PM
Oxidation Behavior of Nb-Ti-Si-Cr-Al-X Based Multi-Component Based Alloys: *Raghvendra Tewari*[1]; Amit Chatterjee[2]; F. J. Boerio[3]; Vijay Vasudevan[3]; [1]Bhabha Atomic Resrach Centre; [2]Rolls Royce Corporation; [3]University of Cincinnati

Several Nb-Ti-Si-Cr-Al-X alloys have been exposed in air for various temperature and time and nature and sequence of reactions that occur upon oxidizing in these alloys have been systematically studied. The morphology of oxide layer, formation of various oxides and ingress of oxygen into the base materials have been studied as a function of time and temperature. Complementary techniques like scanning electron microscope and x-ray photon spectroscopy have been used to understand the nature and sequences of the oxidation. The role of different alloying elements in the formation of the oxide layer has been examined and a possible mechanism of the oxidation has been proposed.

4:50 PM
Oxidation Behavior of the Nb-10Si-20Cr and Nb-10Si-20Cr-5Al Systems: *Victoria Rangel*[1]; S.K. Varma[2]; [1]The University of Texas at El Paso ; [2]The University of Texas at El Paso

The oxidation behavior of Nb-10Si-20Cr and Nb-10Si-20Cr-5Al has been studied in a range of temperature from 700 to 1400C in static air. Isothermal oxidation experiments indicate that addition of 5 atomic percent Al is beneficial in reducing the weight gain per unit area. The phases present include Nb solid solution, NbCr2, Nb5Si3 and Nb9Si2Cr3. However, low temperature pesting appears to be a problem especially at 800C. High temperature oxidation is characterized mainly by spalling. However, internal oxidation has been observed by the formation of Al2O3 along inter-phase interfaces. The characterization techniques include SEM and XRD including BSE, EDS and x-ray mapping modes in SEM.

5:10 PM
The Effects of Silicon on the Nb-Cr-Si Alloy System: *Daniel Voglewede*[1]; S. Varma[1]; [1]University of Texas at El Paso

The effect of Si on the oxidation resistance of the Nb-20Cr-(10-40) Si alloys have been studied. The major contribution of Si is to produce Nb5Si3 phase which helps for enhancing the oxidation resistance and the high temperature strength. A range of Si from 10 to 40 atomic percent allows to determine the microstructural stability especially for the silicides and Laves phase (NbCr2). It has been observed that the weight gain per unit area is lower with increased Si concentration. There may be other silicides besides Nb3Si3 which may be contributing to the results. Characterization has been performed using XRD and EDS, BSE and x-ray mapping modes in SEM. A comparison between the theoretically expected and experimentally observed microconstituents has been made.

Solid-State Interfaces II: Toward an Atomistic-Scale Understanding of Structure, Properties, and Behavior through Theory and Experiment: Grain-boundaries and Triple Junctions

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division, TMS: Chemistry and Physics of Materials Committee, TMS: Nanomechanical Materials Behavior Committee
Program Organizers: Xiang-Yang Liu, Los Alamos National Lab; Douglas Spearot, University of Arkansas; Guido Schmitz, University of Münster; David Seidman, Northwestern University

2:00 PM Invited
Thermodynamics and Kinetics of Grain Boundary Junctions: *Günter Gottstein*[1]; Lasar Shvindlerman[1]; Luis Barrales-Mora[1]; Bingbing Zhao[1]; [1]RWTH Aachen University

Grain Boundaries in polycrystals are connected by grain boundary junctions, which coordinate the kinetic behavior of connected grain boundary systems, like migration or segregation. Therefore, grain boundary networks are likely to behave differently from solitary grain boundaries. We show that grain boundary junctions are crystal defects on their own with specific thermodynamic and kinetic properties and that these properties affect microstructural evolution during grain growth. Novel experimental methods will be introduced on how to determine the thermodynamic and kinetic properties of junctions, and theoretical approaches will be proposed how to modify existing theories of polycrystal kinetics to account for junction effects. Finally, computer simulations of grain boundary motion and grain growth will be presented to demonstrate the effect of junctions on kinetics, grain size, and texture.

2:30 PM Invited
Interfaces, Grain Boundaries and TripleJunctions in Metallic Multilayers: *Zoltán Balogh*[1]; Patrick Stender[1]; Mohammed Chellali[1]; Guido Schmitz[1]; [1]Westfälische Wilhelms Universität, Münster

Triple junctions (TJs), the topological substructures where three grain boundaries (GBs) merge can have significant volume fraction, when the grain size decreases to about 10 nm. Yet, because of the difficulties in characterizing a thin, pipe-like tilted/curved structure, experimental results about these defects are rare. By using a tomographic atom probe one can reconstruct a 3D virtual representation of a specimen with subnanometer resolution in every directions. With this method identifying TJs and investigating their atomic transport properties is possible. We measured interdiffusion profiles in the Ni/Cu system along the TJs and the GBs as well as measured directly the GB width after different annealing treatments. Our results indicate that TJs are two-three orders of magnitude faster diffusion paths than standard high angle GBs.These experiments were part of a broader project, where other materials as well as the properties of the interfaces separating the layers were evaluated.

3:00 PM
Grain Boundary Junction Transitions during Annealing of a Model Columnar Microstructure: *James Belak*[1]; Bryan Reed[1]; Vasily Bulatov[1]; Ming Tang[1]; Tom Lagrange[1]; Joel Bernier[1]; Mukul Kumar[1]; [1]Lawrence Livermore National Laboratory

Grain boundary junctions play an important role during microstructure evolution [1]. A model columnar microstructure with [011] texture for MD simulations is used. The Finnis-Sinclear potential is used to represent copper during thermal coarsening. Our choice of GB misorientation leads to a microstructure consisting entirely of S3, S9 and S27. Depending on the orientation of nearby (111) planes to the junction, we observe the junction to transform into one with [111] symmetric tilt boundaries (STGB). These STGBs join with the original S3s at an unstable grain boundary kink. Further evolution occurs by dislocation emission from the asymmetric tilt boundaries, forming long twin segments. Results will be compared to experimental observations. [1] G. Gottstein, L.S. Shvindlerman, and B. Zhao, Scripta Materiala 62 (2010) 914-917. Work was performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344 and supported by the DOE Office of Basic Energy Sciences.

3:20 PM
Effect of Three-Dimensional Grain Boundary Structure, Crystallography and Chemistry on Sensitization in Al-Mg Alloys: *Alexis Lewis*[1]; Keith Knipling[1]; [1]Naval Research Laboratory

Aluminum-magnesium (5xxx series) alloys are widely used in Naval applications requiring lightweight, high-strength, formable, corrosion-resistant structural materials. These alloys, however, become susceptible to intergranular corrosion and stress corrosion cracking when exposed to elevated temperatures (70–200 °C). This "sensitization" of the grain boundaries has been attributed to elemental segregation and grain boundary precipitation of the ß phase, Al3Mg2. To date, most research has focused on the effects of bulk alloy composition and annealing treatment on grain-boundary ß precipitation. However, the nucleation and growth of grain-boundary ß is also strongly influenced by the grain-boundary character, with both misorientation and inclination influencing the precipitate nucleation rate and precipitate morphology. This study seeks to quantify the relationship between the complex polycrystalline grain boundary character and ß precipitate formation in AA5083, using 3D characterization techniques to understand and quantify the complex relationship of grain-boundary microstructure, crystallography, and chemistry to the resulting sensitization behavior.

3:40 PM Break

3:50 PM Invited
The Disconnection Mechanism of Coupled Migration and Shear at Grain Boundaries: *Robert Pond*[1]; Hassan Khater[2]; Anna Serra[2]; John Hirth[3]; [1]University of Exeter; [2]Universitat Politecnica de Catalunya; [3]Private individual

Disconnections are line-defects with dislocation and step character, so their motion along an interface produces concomitant migration and shear, or coupling. Extensive experimental evidence shows that disconnection motion is an active mechanism of coupling in high-angle grain boundaries, but less is known about low-angle cases. Here, we simulate the atomic structures of a series of [0001] tilt boundaries in an hcp metal. For each tilt angle, the perfect boundary is created, as well as one containing a disconnection capable of conservative motion. Both types of boundary are subjected to a simple shear strain parallel to the boundary. In all cases, coupled motion occurs at significantly lower applied stresses for boundaries containing a disconnection. The Peierls stress for disconnection motion increases monotonically in the low-angle regime, reaching a maximum of about 17MPa. However, this stress decreases precipitately in the high-angle regime, remaining around 2MPa. The reasons underlying this behaviour are discussed.

4:20 PM
Geometrical construction of 90° √Σ (hk0) Quasi-periodic Grain Boundaries in Cubic Crystals: *Mohammad Shamsuzzoha*[1]; [1]University of Alabama

A special category of quasi-periodic boundaries in cubic crystals termed as 90° √ Σ (hk0) quasi-periodic boundaries is geometrically constructed on the basis of the vector representation of lattice sites in participating grains. The construction process involves a 90° mutual rotation of a unique position vector, termed as the sigma generating vector (SGV), present in the common [hk0] projected zero-layer lattices of two grains. The mutual rotation allows the SGV of one grain to superimpose on the position vector that is coplanar normal to the SGV belonging to the other grain. The plane normal to the thus superimposed SGV of one grain and the coplanar normal vector of SGV become the boundary plane of such quasi-periodic boundaries. In these quasi-periodic boundaries, the stacking ratio of the lattices of opposing crystals that are aligned normal to the boundary plane assumes a value that is close to an irrational number, such as √2. Such a quasi-periodic boundary has been found to exist in the thin film of bcc $Fe_{81}Ga_{19}$ crystals.

4:40 PM
Observations and Trends of Shear-Coupled Grain Boundary Motion: *Eric Homer*[1]; Stephen Foiles[2]; Elizabeth Holm[2]; David Olmsted[3]; [1]Brigham Young University; [2]Sandia National Laboratories; [3]University of California, Berkeley

Analysis of grain boundary (GB) migration in a catalogue of 388 GBs has resulted in new observations of shear-coupled GB motion using the synthetic driving force method. This analysis includes observations of shear coupling in [100]-symmetrical tilt GBs that match previous results of Cahn, Mishin, et al. even though the driving force for the motion is different. In addition, we demonstrate observations of shear coupling in [110]- and [111]-symmetrical tilt GBs that, in general, match theoretical predictions of shear coupling obtained through the Frank-Bilby equation. Finally, we present temperature-dependent trends of shear coupling behavior where we see one of three trends in a single boundary as a function of temperature: (1) perfect shear coupling, which is independent of temperature; (2) decayed shear coupling, where coupling decreases in magnitude with increasing temperature; and (3) temperature-dependent shear coupling mechanisms, where the mechanism (and direction) of the shear coupling change with increasing temperature.

5:00 PM
Surface Effects and Resolving Apparent Inconsistencies in Grain Migration Rate Measurements in Aluminum: *Arkady Vilenkin*[1]; [1]The Hebrew University of Jerusalem

In experiments by Rath & Hu [Trans Am Inst Min Eng 1969;245:1577], in a wedge shaped bicrystal of aluminum, the grain boundary velocity was seen to be proportional to the power n=4, of the driving force, which was taken as the reciprocal of the radius of the cylindrically shaped grain boundary, and while according to well established theories the exponent n should be equal one. We show analytically that such kinetic effects could be caused by interaction of the grain boundary with the external surface, if velocity of the surface triple junction is taken to be proportional to the power n of the lateral force that the grain boundary applies to the junction because of a layer of alumina on the exterior surface. We discuss the possible influence of the layer on surface diffusion problem and on the mobility of the triple junction.

5:20 PM
Stress Induced Migration of Symmetric Tilt Grain Boundaries in Zinc: *Askar Sheikh-Ali*[1]; [1]Kazakh-British Technical University

Stress-induced behavior of high-angle coincidence, near coincidence and general boundaries has been examined in bicrystalline specimens of zinc. Symmetric tilt boundaries are characterized with <1010> axis of rotation and the following misorientations: 89±0.5, 123.6±0.5, 125.8±0.5 and 129.1±0.5 degrees. These boundaries were tilted at 45 deg with respect to the tensile axis. For different types of the boundaries, two different mechanisms of boundary migration have been identified: capillary driven boundary migration enhanced by grain boundary sliding (GBS) - for general boundaries, and the motion of extrinsic grain boundary dislocations - for coincidence and near-coincidence boundaries. The stimulation of migration of general boundary by GBS is explained by the increase in the reduced boundary mobility due to continuous change in grain boundary atomic structure during GBS. Different coupling factors in the case of coincidence and near-coincidence boundaries are explained by sensitivity of parameters of extrinsic secondary GBDs to boundary misorientation.

Symposium in Memory of Patrick Veyssière: Understanding the Mechanisms Controlling Plastic Flow: Deformation Mechanisms

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division

Deformation Mechanisms in B2 Intermetallic CoTi: *Rupalee Mulay*[1]; Sean Agnew[1]; [1]University of Virginia

Many B2 compounds, like NiAl, exhibit slip primarily on the <001>{110} slip systems, which provide only 3 independent slip systems and, hence, fail to satisfy von Mises criterion for polycrystalline ductility. Recent in-situ neutron diffraction measurements on CoTi coupled with elasto-plastic self consistent modeling have reinforced that the primary slip systems in this alloy are <001>{110}, but also exposed a transition in strain hardening beyond which a secondary deformation mechanism is activated. The present study examines the dislocation types present in B2

CoTi beyond this transition using g•b analysis in a transmission electron microscope (TEM) and in-grain misorientation axes (IGMA) obtained from electron backscattered diffraction. TEM and IGMA analysis shows the presence of <110> and <111> dislocations. Even a limited number of <110> or <111> dislocations can reduce stress concentrations that could otherwise lead to premature fracture. Source and mobility issues related to the activity of these dislocations are discussed.

Development of a Crystal Model for Twinning in Tantalum: *Jeffrey Florando*[1]; Nathan Barton[1]; James McNaney[1]; Luke Hsiung[1]; Mukul Kumar[1]; [1]Lawrence Livermore National Laboratory

A crystal level twinning model has been developed in an effort to examine the competition between dislocation slip and twinning in tantalum. A sensitivity study has been performed to assess the effect of the parameters on the overall twinning behavior. The model has been compared to single crystal plate impact experiments that were recovered and examined using EBSD and Transmission Electron Microscopy (TEM). The experimental results suggest a strong orientation dependence on the amount of twinning observed, and a change in the dependence at higher shock pressures. Utilizing the crystal model, simulations of the experiment suggest that the observed orientation dependence for twinning is strongly coupled to the initial dislocation density and its evolution.

3:00 PM Invited

Nucleation Versus Propagation of Deformation Twins in Tantalum Driven by High Shear Strain Rate at Low Temperature: *Changqiang Chen*[1]; Kaliat Ramesh[1]; Kevin Hemker[1]; Mukul Kumar[2]; Jeff Florando[2]; [1]Johns Hopkins University; [2]Lawrence Livemore National Laboratory

The competition between deformation twinning and dislocation slip, as well as the process of twin nucleation vs propagation in bcc metals, such as tantalum, has been a long standing issue. In this work, we use both laser shock and low temperature dynamic shear to drive the formation of deformation twins in polycrystalline tantalum. Transmission electron microscopy (TEM) and atomic scale TEM (HREM) have successfully captured the early stage of the formation of deformation twins. Consequently, the competition between nucleation, propagation, and coalescence of deformation twins are found to be responsible for several unique characteristics of deformation twins that are observed for the first time in tantalum, as well as for the formation of a unique twin network. A relationship between slip and twinning nucleation is also established in terms of the coalescence of twinning dislocations and dissociation of emissary dislocations.

Laser Shock Induced Changes in Microstructure, Residual Stress, Plasticity and Properties of Aero Engine and Other Alloys: Amrinder Gill[1]; Yixiang Zhao[1]; Abhishek Telang[1]; Zhong Zhou[1]; Seetha Mannava[1]; Dong Qian[1]; *Vijay Vasudevan*[1]; [1]University of Cincinnati

Laser shock peening (LSP) generates deep compressive residual stresses and near-surface microstructural changes through shockwaves, thereby leading to dramatic improvements in fatigue and crack propagation resistance of alloys. We report results of LSP effects on the behavior of IN718, IN718+, Ti64, Ti6242 alloys and alloy 600. Residual strains and stresses were characterized using high-energy synchrotron x-ray diffraction and conventional XRD. The near/sub-surface microstructure changes were studied using EBSD/OIM and TEM. Local properties were determined using nanoindentation, microhardness and micropillar compression tests. Fatigue tests were conducted and the thermal stability of LSP-induced microstructural changes and residual stress was also assessed. Finally, controlled experiments and analytical and finite element modeling and simulation were utilized to predict the laser shock induced residual stress and thermal relaxation thereof. The results showing the relationship between shock parameters, microstructure, residual stress, thermal stability, and mechanical properties, including hardening and fatigue, will be presented and discussed.

A Comparison of Dislocation Microstructures Formed during Severe Plastic Deformation of an Al-2.5 Mg Alloy at Room and Cryogenic Temperatures and Their Effect on Alloy's Room-Temperature Strength: *Jung Singh*[1]; Apu Sarkar[1]; Garima Sharma[1]; Jayanta Chakravartty[1]; [1]Bhabha Atomic Research Centre

This work reports a comparison of dislocation microstructures that formed in ultra-fine grains of a commercial Al-2.5 Mg alloy produced by equal channel angle pressing at room and cryogenic temperatures. Though the room- and cryogenic-temperatures pressing of the alloy produced ultra-fine grains of similar grain sizes for the same amount of equivalent strain, there was a significant difference in their respective room-temperature compression strengths. This observed difference in the room-temperature strengths corresponding to two microstructures has been attributed to differences in their dislocation substructures.

4:25 PM Invited

Relationship between Plasticity Mechanism and "Multiple-Slip" Volume in FCC Metals at Nanoscale: *Qing-Jie Li*[1]; Zhang-Jie Wang[1]; Zhi-Wei Shan[1]; Ju Li[2]; Jun Sun[1]; Evan Ma[3]; [1]Center for Advancing Materials Performance from the Nanoscale (CAMP-Nano) & Hysitron Applied Research Center in China (HARCC), State Key Laboratory for Mechanical Behavior of Materials, Xi'an Jiaotong University; [2]Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, MIT; [3]Department of Materials Science and Engineering, Johns Hopkins University

Plasticity mechanism for FCC metals at nanoscale is a fundamental scientific question. Two widely accepted and debated mechanisms are surface dislocation nucleation and single-arm dislocation operation. In the present work, we performed molecular dynamics(MD) simulations on compression of pristine gold particles and Aluminum pillars with multiple-slip orientation and found that a quite large volume of the samples is deformed by single-arm dislocations which is produced by the robust dislocation jamming(internal dislocation source) formed within a small volume directly beneath the indentor due to simultaneous multiple-slip. However, when sample size is sufficiently small, surface dislocation nucleation dominates the plasticity due to the lack of "multiple-slip" volume. This result indicates that "multiple-slip" volume which could be influenced by both sample size and preparation methods plays an important role in plasticity mechanism of nanoscale FCC metals. Key words: nanoscale FCC metals, plasticity mechanism, multiple-slip volume

Direct and Derived Dislocation Density Vectors: *Craig Hartley*[1]; [1]El Arroyo Enterprises LLC

Dislocation dynamics simulations produce detailed, 3-D pictures of the dislocation structure of deformed crystals. The development of these structures with increasing strain can be followed by constructing the Dislocation Density Vectors (DDV) formed from the projections of edge and screw components of dislocations on each active slip plane. Each of the vectors on an active slip system is composed of a Geometrically Necessary component and a Statistically Stored component which add up to the Total Dislocation Density Vector for the slip system. A composite DDV containing weighted contributions from all active slip systems in a computational volume can be constructed at each step of the simulation process and used to follow the evolution of dislocation structure resulting from deformation. Examples of the application of this method of representing dislocation structures for several simulations are presented and the relationship of the DDV to the kinematics of deformation is discussed.

Crack Initiation and Microstructurally Short Crack Growth of Ti-6Al-4V: *Hans-Juergen Christ*[1]; Helge Knobbe[1]; Philipp Koester[1]; Claus-Peter Fritzen[1]; Martin Riedler[2]; [1]University of Siegen; [2]Böhler Schmiedetechnik GmbH & Co KG

Ti-6Al-4V was investigated in two different forged conditions with respect to fatigue crack initiation and short crack growth characteristics. The experimental findings based on interrupted fatigue tests, thorough SEM examination in combination with orientation imaging and 3-D information from FIB-cuts were implemented into a mechanism-based short-crack model, which describes crack propagation as a partially irreversible dislocation glide on a crystallographic slip plane. The numerical model is based on dislocation dipole boundary elements. The non-uniform propagation kinetics of short cracks is considered by defining grain boundaries as obstacles to plastic slip and crack propagation. The described model was used to simulate crack propagation behavior for the purpose of life assessment. By means of virtual microstructures, microstructural parameters such as grain size and volume fractions can be varied in order to identify the optimum fatigue-resistant material condition.

Computational Indicators for Structure-Fatigue Property Relations in Ti Alloys: Craig Przybyla[1]; *David McDowell*[2]; [1]AFRL; [2]Georgia Institute of Technology

This paper discusses a methodology to estimate the microstructure dependence of the extreme value probabilities of fatigue crack formation at the scale of the grains in polycrystalline and polyphase alpha-beta Ti microstructures to facilitate preliminary parametric design exploration and property assessment. A simulation-based methodology is introduced for computing correlation functions of microstructure attributes marked by the extreme value microstructure-scale fatigue indicator parameters. Multiple statistical volume elements of microstructure are simulated using a crystal plasticity constitutive model via finite element analysis to characterize these extreme value marked correlation functions. By comparing marked correlation functions to traditional correlation functions sampled from the bulk material, the interacting microstructure attributes relevant to extreme value response(s) are identified. Effects of the a free surface are considered in terms of any effects on modification or amplification of fatigue indicator parameters relative to bulk regions.

Hierarchy of Fatigue Deformation Heterogeneities in a Titanium Alloy: A Pathway for Predicting Life-Limiting Failures: *Sushant Jha*[1]; Robert Brockman[2]; Christopher Szczepanski[3]; Craig Przybyla[3]; James Larsen[3]; [1]Air Force Research Laboratory/Universal Technology Corporation; [2]University of Dayton Research Institute; [3]US Air Force Research Laboratory

Fatigue damage can initiate by multiple mechanisms, even under a given microstructure and loading condition. Each mechanism is found to be associated with a microstructural arrangement, which can range from single microstructural unit to various combinations of many units. In terms of fatigue lifetime, this plurality of mechanisms produces increased variability. However, lifetimes often group into two divergent populations, which are termed as life-limiting and mean-dominating distributions. Furthermore, fatigue crack initiation appears to occur within the first few cycles in life-limiting failures. This presentation will discuss possible physical origins and probabilistic predictions of life-limiting events in the alpha+beta titanium alloy, Ti-6Al-2Sn-4Zr-6Mo. A crystal plasticity model was employed to calculate the distribution in cyclic strain based deformation parameters in an alpha+beta titanium alloy with duplex microstructure. The results were employed in a probabilistic fatigue model to quantify the propensity for life-limiting failures in Ti-6Al-2Sn-4Zr-6Mo.

3:30 PM
In-Situ Microscale Testing to Evaluate Fatigue Behavior: *Christopher Szczepanski*[1]; Sushant Jha[2]; Paul Shade[1]; Robert Wheeler[3]; James Larsen[1]; [1]US Air Force Research Laboratory; [2]AFRL/UTC; [3]UES

A recent study of fatigue crack-initiation mechanisms and their relationship to lifetime variability in bulk samples of Ti-6Al-2Sn-4Zr-6Mo has revealed that crack initiation can occur in a variety of characteristic microstructural neighborhoods. In many cases, specimens with similar crack initiation sites exhibit significantly different fatigue lifetimes and this scatter was shown to result from variability in crack initiation behavior. To characterize these mechanisms under controlled conditions, an in-situ micro-scale tensile testing technique has been adapted to complete fatigue tests in an SEM on micro-specimens extracted from representative fatigue-critical microstructural neighborhoods. EBSD has been completed and FIB markers were machined in micro-specimens to enable displacement mapping. Additionally, the use of micro-scale samples enables 3D microstructural characterization of the full specimen gage volume. The mechanical behavior and microstructural characterization of these experiments will be presented, with an emphasis on identifying microstructurally driven cyclic damage accumulation processes leading to fatigue crack initiation.

4:00 PM
Analysis of Dislocation Structures Underneath Nanoindents in an α-Ti Alloy: *J. Kwon*[1]; P.Sudharshan Phani[2]; M.C. Brandes[1]; A. Pilchak[3]; E.P. George[4]; G.M. Pharr[2]; M.J. Mills[1]; [1]The Ohio State University; [2]The University of Tennessee; [3]WPAFB; [4]Oak Ridge National Laboratory

The mechanical responses of alpha titanium alloys are well known to be both elastically and plastically anisotropic. Plastic anisotropy can be attributed to the large differences in the critical resolved shear stresses necessary to activate slip on <c> component slip systems. In this study, the plastic anisotropies of a polycrystalline, single-phase alpha Ti-7Al alloy are investigated via nanoindentation techniques where it has been found that the onset of plasticity depends on numerous factors. Observations of pop-in events were observed to be sensitive to crystal orientation, surface condition, and initial dislocation content. The dislocation structures under indents were characterized by post-mortem SEM, EBSD, and STEM imaging. Results show that dislocation configurations and slip system activity is dependent on grain orientation.

4:20 PM
Three-dimensional Investigation of the Microtexture near Tensile Crack Tip in Ti-6Al-4V: Xu Xu[1]; *Yau Yau Tse*[1]; Geoff West[1]; [1]Loughborough University

Ti-6Al-4V alloy with bimodal microstructure often contains microtextured regions which were reported to have a significant effect on the crack growth in fatigue experiments. An implicit quantitative relationship between the crystallographic orientation and crack growth remains to be established. It is found in this study that the microtextured regions in a hot rolled Ti-6Al-4V alloy are of about 30 \956m wide and contain elongated grains with the c-axis parallel to transverse direction.

The crack produced in an interrupted tensile test was characterized using electron back-scattered diffraction (EBSD). Particularly, 3D EBSD study was carried out at the crack tip to elucidate the relationship between crack growth and grain orientation. It has been found that trans-granular cracking occurs in grains with (0001) basal plane parallel to the transverse direction while most cracking paths are along grain or alpha-beta interphase boundaries. The implication of crystallographic orientations on the cracking will be discussed.

4:40 PM

TheEffect of Temperature and Stress on the Creep Deformation Modes of Ti-5Al-2.5Sn (wt.%): *Hongmei Li*[1]; Carl Boehlert[1]; Thomas Bieler[1]; Martin Crimp[1]; [1]Michigan State Univeristy

Creep deformation modes of a forged Ti-5Al-2.5Sn (wt.%) alloy were analyzed at elevated temperature using ***in-situ*** scanning electron microscopy. Creep tests were performed at temperatures between 455-500\176C and stresses between 200-300MPa, and electron backscatter diffraction was performed on the samples prior to testing. Grain boundary sliding was an active deformation mode for all the conditions examined. At 250MPa and 455\176C, about 10% of the grains observed ***in-situ*** exhibited basal slip and very few grains showed prism slip. At higher stresses, both basal and prismatic slip systems were active, suggesting basal slip operated at lower stress than prism slip and the activity of prism slip was increased by increased stress. Compared to the 455\176C and 250MPa condition, the 490\176C and 250MPa condition exhibited more slip activity and correspondingly, the prism slip activity was also increased. The evolution of slip and grain boundary sliding will be discussed.

5:00 PM

Comparison of CPFE and Experimental Results for the Study of Interaction between Grain Boundary and Dislocation Slip in Ti-5Al-2.5Sn: *Chen Zhang*[1]; Hongmei Li[1]; James Seal[1]; Martin Crimp[1]; Carl Boehlert[1]; Thomas Bieler[1]; [1]Michigan State University

The interaction between grain boundaries and dislocation slip plays an important role in anisotropic plastic deformation of polycrystalline materials like Ti-5Al-2.5Sn, yet its mechanism has not been fully understood. Crystal Plasticity Finite Element (CPFE) method is a dislocation slip based computation model. Unlike other commonly used computational models, it is developed to study the deformation process of polycrystalline materials at grain and sub-grain level, which makes it a suitable tool to study dislocation slip dominated deformation process. A CPFE mesh was generated based upon heavily characterized microstructure patch from a room temperature deformed Ti-5Al-2.5Sn sample. By comparing the CPFE simulation and experimental results, the interaction between grain boundary and dislocation slip can be studied to assess simulated vs. measured slip activity, which will bring new understanding of the grain boundaries role in the deformation process.

5:20 PM

Machining of Coarse Grained and Ultra Fine Grained Titanium: *Rimma Lapovok*[1]; Andrey Molotnikov[1]; Ashan Bandaranayake[1]; Yuri Estrin[1]; [1]Monash University

Machining of titanium is quite difficult and expensive. Heat generated in the process of cutting does not dissipate quickly, which affects tool life. In the last decade the ultra fine grained (UFG) titanium became an option for substitution of more expensive titanium alloys. Extreme grain refinement can be readily performed by so-called severe plastic deformation techniques. This grain refinement was shown to change both mechanical and physical properties of materials. A study of the microstructure and shear bands formation in chips in coarse grained and UFG titanium machined with three different depths and three different speeds has been conducted. A change in thermal characteristics of CP Ti with grain refinement has been studied through comparing heating / cooling measurements with an analytical solution of the heat transfer boundary problem. It is demonstrated that an improvement in overall wear of the machining tool can be expected for UFG titanium.

5:40 PM

Machinability of β-Titanium Alloy Ti-10V-2Fe-3Al with Different Microstructures: *Hendrik Abrahams*[1]; Christian Machai[1]; Dirk Biermann[1]; [1]Technische Universität Dortmund

The aerospace sector uses titanium-based materials to manufacture lightweight safety parts such as structural components, turbine disks and blades or landing gears. By heat treatment, β-enriched titanium alloys offer low, as well as the highest strength-to-weight ratio among all titanium alloys. Machining processes are strongly affected by the changes within the microstructure and the emerging mechanical properties of the material. Low cutting data and rapid development of tool wear lead to challenges in machining operations. Therefore the fundamental characteristics of machining differently microstructured β-titanium Ti-10V-2Fe-3Al rods and hollow shafts are presented. The experimental results identify varying static and dynamic process forces, tool wear mechanisms and process limitations depending on the microstructure. A presented adopted machining process by cooling with carbon dioxide snow can delay the development of tool wear and offers an increasing tool life and higher stock removal rates.

6:00 PM

Residual Stress Relaxation Effects on the Cracking and Wear Processes of Shot Peened Ti-6Al-4V Titanium Alloy under Fretting-Fatigue Loading: *Romain Ferre*[1]; Siegfried Fouvry[2]; Bruno Berthel[2]; Rémi Amargier[1]; Antoine Ferre[2]; [1]SNECMA; [2]Laboratoire de tribologie et Dynamique des Systèmes (LTDS)

This study focuses on shot-peened residual stress relaxation of Ti-6Al-4V titanium alloy under fretting-fatigue loading. This study highlights the fretting-fatigue life time increase due to residual stresses. Wöhler curves are plotted for Ti64 and Ti64 shot-peened of a cylinder/plane contact. Next part shows the competition between wear and cracks with "bell curves". Same surface treatments are performed for an industrial flat rounded contact.Shot-peening slow down crack initiation and increase the fatigue life time. For the second part, the used methodology sweeps a large range of fretting displacements and reveals several wear/cracks competition zones on "bell curves". Shot-peening rise is observed on the cracking domain without wear. The second zone presents a life time decrease and relaxation of residual stresses. With larger displacements, wear appears and leads to a life time increase of Ti64 specimens. This effect is not observed with shot-peened tests. The residual tensile zone explains this phenomenon.

Selecting the Right Filter Media for the Application: *William Wilkie*[1]; Robert Boller[1]; [1]Sefar Inc.

There is a wide variety of different types of woven filter media to choose from for hundreds of different filtration applications. Factors such as type of fiber, synthetic polymers used, weave style, fabric finishes and fabrication techniques all play an important part in selecting what is best for a specific type of filter and process application. The purpose of this paper is offer some basic knowledge of these factors and how they can impact the performance of a filter, the life of the media and the overall cost of operation though case studies of actual plant filtration applications.

2:20 PM

Thermodynamic Study for Removal of Phosphorus from Molten Silicon: *Takashi Nagai*[1]; Hideaki Sasaki[1]; Masafumi Maeda[1]; [1]The University of Tokyo

The production of solar cells is increasing dramatically and the shortage of polycrystalline silicon for these cells has become a serious problem, making development of a low-cost production process for solar grade silicon essential. An electron beam melting technique is known to be effective for the removal of phosphorus from molten silicon. Although the phosphorus is removed by preferential evaporation in this process, the rate of removal is not sufficient, and its improvement requires thermodynamic information on phosphorus in the molten silicon. In this research, the vapor pressure of phosphorus in equilibrium with a silicon-phosphorus alloy was measured by double Knudsen cell mass spectrometry with a system blowing gas into the Knudsen cell. Activity of phosphorus in silicon, Gibbs energy change of dissolution reaction of phosphorus to silicon, and other factors were estimated from the results. Using these data, we provided guidelines on how this process can be improved.

2:40 PM

Fatigue and Fracture Mechanics Characterization of Advanced Automotive Steels: Paolo Matteis[1]; Giorgio Scavino[1]; *Donato Firrao*[1]; [1]Politecnico di Torino

Advanced, high-strength steel sheets are increasingly used to make lighter cars. These sheets are manufactured by hot rolling, cold rolling and continuous heat-treating, and are cold drawn and welded to fabricate car bodies. This work aims to characterize their fatigue crack growth behavior and their fracture toughness, and to correlate them with microstructures, tensile properties and stress-endurance fatigue properties. Due to the small thickness, the fracture toughness is studied by resistance curve tests. Fracture mechanics properties are not presently considered in car-body design and verification, however, they are prominent in aeronautic design, in which weight is even more important; hence these fracture mechanics materials data are expected to be required by the car-building industry in future, in pursuit of further weight reduction. For example, knowledge of the steel fatigue crack growth behavior and fracture toughness would allow to evaluate the cracks which could arise from welding defects.

3:00 PM

Kinetic and Thermochemical Analysis of Rubidium Jarosite Decomposition in Alkaline Media: *Miguel Perez-Labra*[1]; Antonio Romero-Serrano[2]; Eleazar Salinas-Rodriguez[1]; Erika Avila-Davila[3]; Guillermo Juarez-Lopez[4]; Juan Hernandez-Avila[1]; [1]AACTYM UAEH; [2]IPN MEXICO; [3]Instituto Tecnológico de Pachuca; [4]Centro de Investigaciones en Nuevos Materiales Universidad Tecnológica de la Mixteca

Rubidium jarosite was synthesized as a single phase by precipitation from aqueous solution. X ray diffraction and SEM-EDS analysis showed that the synthetic product is a solid rubidium jarosite phase formed in spherical particles with an average particle size of about 35 μm. The chemical analysis showed an approximate formula Rb0.9432Fe3(SO4)2.1245(OH)6. The decomposition of jarosite in terms of solution pH was thermodynamically modeled using FACTSage by constructing the potential-pH diagram at 298.15 K. The E-pH diagram showed that the decomposition of jarosite leads to a goethite compound (FeO•OH) together with Rb+ and SO42- ions. The experimental Rb-jarosite decomposition was carried out in alkaline solutions with five different Ca(OH)2 concentrations. The decomposition process showed a so called "induction period" followed by a progressive conversion period where Rb+ and SO42- ions formed in the aqueous solutions, whereas calcium was incorporated in the solid residue and iron gave place to goethite. The kinetic analysis showed that this process can be represented by the shrinking core chemically controlled model with a reaction order with respect to Ca(OH)2 equal to 0.4342 and a calculated activation energy of 98.70 kJ mol-1.

3:40 PM

Phase Equilibrium and Characterization Studies of Binary Organic Thermal Energy Storage Materials: *Wen-Ming Chien*[1]; Ivan Gantan[1]; Amrita Mishra[1]; Dhanesh Chandra[1]; Vamsi Kamisetty[1]; Prathyusha Mekala[1]; [1]University of Nevada, Reno

The binary organic thermal energy storage materials have been performed the phase equilibrium and characterization studies by using high temperature X-ray diffraction (XRD) and differential scanning calorimetric (DSC) methods. The organic thermal energy storage materials undergo a solid-solid state phase transition before melting which will store large amounts of thermal energy. Three materials [tris(hydroxymethyl) aminomethane(TRIS), 2-Amino-2-methyl-1, 3-propanediol(AMPL) and Pentaglycerine (PG)] were used for this study. The binary samples of AMPL-TRIS and AMPL-PG were prepared to perform high temperature XRD characterization and DSC studies. The binary AMPL-TRIS and AMPL-PG phase diagrams were developed. The high temperature solid-state phases of AMPL and TRIS were characterized as a disordered BCC structure, and PG was characterized as FCC. Calculation of Phase Diagrams (CALPHAD) modeling technique is used to calculate the AMPL-TRIS and AMPL-PG binary phase diagrams by using the Thermal-Calc software.

4:00 PM

Laboratory Test Works and Plant Trials for Milling and Flotation of Slow Cooled Copper Slag: *Pengfu Tan*[1]; [1]Xstrata Copper

Laboratory flotation tests of the slow cooled converter slag have showed that 92.5% copper recovery at the copper cut-off grade of 24 – 25 % can be achieved using the 50:50 ratio of DSP330 and SIBX at the natural pH of 7 and grinding time of 18.5 minutes. 70μm is the P80 achieved at this grinding time. MIBC is the frother and 46% was the solid content in the flotation feed. In the plant trials, 2 types of collectors at 2 different feed particle sizes for both the normal and slow cooled slag were operated. The particle size was controlled by the feed rate. The P80 of 75 µm at the feed rate between 32 – 36 t/h were tested. The plant trials have demonstrated that the copper recovery in the milling and flotation process of the slow cooled slags have been improved by 3%.

4:20 PM

An Experimental Study of Chemical Oxygen Demand Removal from the Coking Wastewater Using Three-Dimensional Electrode Reactor: *Lei Zhang*[1]; Gai-Feng Xue[1]; J.Y Hwang[1]; [1]WISCO

The removal of chemical oxygen demand (COD) from coking wastewater was experimentally investigated using a three-dimensional electrode reactor. The experimental results showed that the refractory organics in coking wastewater can be effectively removed by this process, and COD removal efficiency was affected by the operating parameters, such as electrolytic time, particle electrode dosage, initial pH, current density, aeration amount and electrical conductivity, etc. Experimental results shows that the three-dimensional electrode could have a COD removal efficiency of more than 60% and running cost is no more 6YUAN/t(RMB), which revealed great potential of three-dimensional electrode reactor in engineering application as an advanced treatment of coking wastewater.

4:40 PM

Behavior of Various Impurities during the Precipitation of Hematite from Ferric Sulphate Media at 225°C: *John Dutrizac*[1]; Tzong Chen[1]; [1]CANMET-MMSL

Zinc, cadmium, copper, cobalt and thallium are not significantly incorporated in the hematite precipitates. The nickel contents increase to 0.22% as the Ni concentration increases to 60 g/L. However, part of the Ni may be present as tiny particles of NiSO4.H2O. Increasing germanium concentrations to 2,000 mg/L result in products containing up to 0.59% Ge. The Ge occurs either in solid solution in the hematite or is adsorbed on the nanometer-size hematite crystallites. Increasing As(V) concentrations to 10 g/L increase the AsO4 contents of the products up to 16%. The products consist of hematite together with AsO4-containing Fe(SO4)(OH) and an Fe-AsO4 species. Increasing Se(VI) concentrations to 2.0 g/L cause the SeO4 content of the products to increase to ~0.5%. All the hematite products contain ~1% SO4 which appears to be adsorbed on the hematite nanocrystallites composing the micron size hematite products.

5:00 PM

New Process for Granulation of Red Mud and Its Physical Property Assessment: Shuai-Dan Lu[1]; *Shaohua Ju*[1]; Jin-Hui Peng[1]; Sheng-Hui Guo[1]; Ya-Jian Wang[1]; Lei Guo[1]; [1]Kunming University of Science and Technology

The granulation of a red mud is of great importance for recycling the waste as adsorption material for waste water or gas. A new granulating process was proposed and its effect is evaluated. To reduce the cost of granulating process, the wet filter cake (containing 25% water) was directly mixed up with different cement content (4%, 6%, 8% and 10% based on wet material). And the mixtures were placed in a moist environment for 4 days, and then were washed with deioned water until the pH value is lower than 9.0. The mudding ratio, surface area and particle size of the aged mixture was detected respectively by bottle shaking experiments, N2 adsorption equipment and screening. The results showed that the best addition of cement is 8%, with a particle size of lower than 1 mm, mudding ratio of 9.5%, and with an adsorption surface area of about 30 m2/g.

3D-Architecturing Aluminium Sheets by ARB Processing with Graded Copper Particle Reinforcement: *Christian W. Schmidt*[1]; Mathis Ruppert[1]; Patrick Knödler[1]; Heinz Werner Höppel[1]; Mathias Göken[1]; [1]Friedrich-Alexander-Universität Erlangen-Nürnberg

In this work copper particles (d ~ 1 µm) are introduced in a highly controlled manner by airgun spraying from aqueous suspension into aluminium AA1050A during ARB. A 3D-architecture by controlling spatial distribution of particles is demonstrated. In sheet plane, spraying distance and feed rate of the air spray gun are used to control the particle content. In sheet height certain distributions including homogeneous and stepwise graded distributions are generated by a smart stacking sequence during ARB processing. In the system Al-Cu continuous and stepwise gradation of particle distribution are proven by solutionizing and subsequent mechanical testing as well as through visualisation by micro-computer-tomography. With this freedom of design concerning particle distribution, the material properties of ultrafine-grained sheets can be adjusted within one tailored sheet in a certain range with a desired 3D-profile. In the case of Al-Cu a combination of high strength with high electrical conductivity is exemplarily demonstrated.

2:15 PM

Advantageous Anisotropy: Designed Performance in Mg Alloy: *David Foley*[1]; Sonia Modarres-Razavi[1]; Suveen Mathaudhu[2]; Laszlo Kecskes[3]; Ibrahim Karaman[1]; K. Hartwig[1]; Vince Hammond[3]; [1]Texas A&M University; [2]US Army Research Office; [3]US Army Research Laboratory

One general characteristic of wrought Mg alloys is a strong texture developed during forming. These strong textures, combined with high critical resolved shear stress ratios between deformation mechanisms, result in large mechanical anisotropy. While some alloying elements and processing conditions can weaken this texture and encourage more isotropic deformation, this is not always desirable. For example, if component failure is only expected under only one loading direction, enhanced performance in that deformation condition may be advantageous even at the expense of others. This talk will cover SPD and post-SPD thermomechanical processing methods to engineer mechanical response in AZ31B. Strain path and temperature control result in high strength UFG materials with twice the strength of the starting wrought material.

2:30 PM
Analysis of Microstructure and Microhardness of Zr-2,5%Nb Processed by High Pressure Torsion (HPT): *Mychelle Companhoni*[1]; Jose Matheus[1]; Andre Pinto[2]; [1]Military Institute of Engineering (IME); [2]Brazilian Center for Physics Research (CBPF)

Nanostructured materials have been widely studied due the improvement of their mechanical properties comparing to coarse grain materials. The present work intended to analyze the microstructure and microhardness of Zr-2,5%Nb processed by high-pressure torsion (HPT), one of the severe plastic deformation (SPD) techniques. The deformations were carried out atroom temperature using a pressure of 5 GPa and five anvil turns. Vickers indentation was used to evaluate the microhardness of the samples. Transmission electron microscope (TEM) and X-ray diffraction were used to analyze the microstructure. The results showed a significant refinement from the initial microstructure achieving nanometric grain size lower than 50 nm and phase transformation $\alpha \rightarrow \omega$ induced by shear. The Vickers microhardness values of material submitted to HPT technique were significantly higher than non-deformed material. Also, HPT procedure resulted in a huge grain refinement of the material and phase transformation.

2:45 PM
Combining Extrusion and ECAP – an Efficient Processing Route for Large Scale UFG Materials: *Philipp Frint*[1]; Matthias Hockauf[1]; Thorsten Halle[1]; Gernot Strehl[2]; Martin F.-X. Wagner[1]; Thomas Lampke[1]; [1]Chemnitz University of Technology; [2]S+C Extrusion Tooling GmbH

The use of ultrafine-grained materials processed by equal-channel angular pressing (ECAP) in industrial applications is limited because of the small volumes of the billets and difficulties in integrating them into conventional extrusion processes. Here, we propose a combination of extrusion and large scale ECAP (cross section: 50mm x 50mm) performed at room temperature as an efficient two-step process followed by a suitable heat treatment. We demonstrate that, for the aluminum alloy 6060, an improvement of yield and tensile strengths by up to 20% can be achieved – without a further reduction of ductility – compared to "conventionally" ECAPed material. Microstructural analysis shows that this excellent combination of strength and ductility can be related to the beneficial effects of fine precipitates, ultrafine grains and a recovered microstructure. These results highlight the potential of our combined ECAP/extrusion process for the production of homogenous, high performance aluminum materials on an industrial scale.

3:00 PM
Consolidation of Nanostructured Copper and Copper Based Alloys via High Pressure Torsion: *Hamed Bahmanpour*[1]; Daria Setman[2]; Jelena Horky[2]; Michael Kerber[2]; Susi Kahofer[2]; Suhrit Mula[1]; Michael Zehetbauer[2]; Ronald Scattergood[1]; Carl Koch[1]; [1]North Carolina State University; [2]Faculty of Physics, University of Vienna

Samples of pure Cu, and Cu alloyed with Zn and Nb were processed by high energy ball milling. Small flakes with homogeneous nanostructures revealing grain sizes below 40nm were produced after milling at 77K. The milled flakes were used as a precursor for consolidation with high pressure torsion (HPT). The resulting samples were analyzed by means of XRD, TEM and mechanical tests not only comprising microhardness but also tensile tests. HPT processing yielded entirely flaw-free samples with only slightly increased grain sizes provided more than 50 revolutions and hydrostatic pressures of about 8 GPa were carried out. For example, those samples exhibited values of UTS up to 892 MPa (Cu) and 1240 MPa (Cu-10%Zn), and values of tensile strain up to 5.8% (Cu) and 10% (Cu-10%Zn), which all seem to be outstanding compared to data published so far in literature on SPD consolidated powder materials.

3:15 PM
Effects of Post Process Treatments on the Mechanical Stability of Rolled Nanostructured Aluminum: *Jacob Kidmose*[1]; Lei Lu[2]; Grethe Winther[1]; Niels Hansen[1]; Xiaoxu Huang[1]; [1]Risoe DTU; [2]Institute of Metal Research

Nanostructured aluminum produced by cold rolling to high strains shows an early onset of localized necking causing a low ductility during straining in tension. In order to improve the properties, post-process treatments such as annealing and cold deformation have been applied to aluminum sheets produced by accumulative roll bonding. The treatments have been followed by tensile testing where in-situ high resolution maps of the strain distribution over the tensile sample gauge length and thickness have been obtained by using a commercial ARAMIS system. These maps allow localized and diffuse necking to be characterized and to obtain correlation between the mechanical behavior and the structural changes being a result of the post-process treatments.

3:30 PM
Nanoindentation Analysis for Local Properties of Ultrafine Grained Copper Processed by High Pressure Torsion: *Hyeok Jae Jeong*[1]; Eun Yoo Yoon[1]; Nack Joon Kim[2]; Hyeong Seop Kim[1]; [1]Department of Materials Science and Engineering, POSTECH, Korea; [2]Graduate Institute of Ferrous Technology, POSTECH, Korea

Recently, severe plastic deformation (SPD) techniques have been available for producing bulk UFG metallic materials. High pressure torsion (HPT) leads to smaller microstructures than those achieved using the other SPD processes because of its higher strain. It is known that HPT processed metals show highly heterogeneous not only along radius due to the nature of torsional deformation but also through the thickness. Since the sample size for the HPT is small, the local properties of the HPT processed samples have not been investigated yet. Recently we propose a method converting the nanoindenting curve to stress-strain curve combining the finite element method and the recursion method. In this presentation, we employ the nanoindentation technique in order to elucidate the local mechanical properties especially stress-strain curves. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST) (No. 2010-0026981).

4:00 PM
Strengthening of Al through Addition of Fe and by Processing with High-Pressure Torsion: *Jorge Cubero-Sesin*[1]; Zenji Horita[1]; [1]Kyushu University

Iron (Fe) is a common impurity element in aluminum (Al) and is expected to be used in a controlled manner. In this work, High-Pressure Torsion (HPT) was applied to 10 mm in diameter bulk disk-type samples of Al-Fe alloys with different Fe weight fractions: 0.5%, 1%, 2% and 4%, and initial states: as-cast, extruded, and annealed at 500ºC for 1 hour. Powder samples were also consolidated in the HPT facility with similar Fe contents including an additional 10% Fe. HPT was carried out at room temperature under a pressure of 6 GPa for several numbers of revolutions: 1, 10, 20, 50 and 75. Vickers microhardness and tensile tests were performed on specimens extracted from the disks. Microstructural analyses by transmission electron microscopy and x-ray diffraction revealed significant potential to improve mechanical properties via microstructure refinement, supersaturation of Fe and dispersion of intermetallic phases throughout the Al matrix.

4:15 PM
Structural Parameters and Strengthening Mechanisms in Cold-Drawn Pearlitic Steel Wires: *Xiaodan Zhang*[1]; Andy Godfrey[2]; Xiaoxu Huang[3]; Niels Hansen[3]; [1]Tsinghua University, Risø DTU; [2]Tsinghua University; [3]Risø DTU

Pearlitic steel wires have a nanoscale structure and a strength which can reach 5 GPa. In order to investigate strengthening mechanisms, structural parameters including interlamellar spacing, dislocation density and cementite decomposition, have been analyzed by transmission electron microscopy and high resolution electron microscopy in wires cold drawn up to a strain of 3.7. Three strengthening mechanisms, namely boundary strengthening, dislocation strengthening and solid solution hardening have been analyzed and good agreement has been found between the measured flow stress and the value estimated based on an assumption of linear additivity of the three contributions.

4:30 PM

Study of Grain Boundary Weakening using In-Situ Synchrotron X-Ray Diffraction of Ultrafine Grained Materials: *Jennifer Girard*[1]; Jiuhua Chen[1]; Helen Couvy[2]; Xiaoyang Liu[3]; [1]Florida International University; [2]University of Michigan; [3]Jilin University

When size of crystal grain decreases down to nanometers, volume fraction of near surface atoms becomes significant. Comparative in situ synchrotron x-ray diffraction at high pressures on micron and nano crystalline powder samples has been conducted to determine the effective bulk modulus of grain boundary. The volume vs. pressure data of the micron and nano specimens obtain from the x-ray diffraction are used to determine their bulk moduli through equation of state. Using a shell/core grain model, the bulk modulus of grain boundary is derived from the moduli of micron-size sample and nano-size sample (representing significant contribution from the shell). The result indicates that the bulk modulus of grain boundary is remarkably smaller than that of the core, by 37% in magnesium silicate, Mg2SiO4, and by near 50% in metal(Ni). While strengthening by smaller grain size is expected by Hall–Petch law, these results reveal an inverse Hall–Petch relation.

4:45 PM

Understanding the Ultrafine Grain Formation and Recrystallization Mechanisms in Magnesium through Extrusion-Machining: *Mert Efe*[1]; Dinakar Sagapuram[1]; Wilfredo Moscoso[2]; Srinivasan Chandrasekar[1]; Kevin Trumble[1]; [1]Purdue University; [2]Pontificia Universidad Catolica Madre y Maestra

Large Strain Extrusion Machining (LSEM), a constrained chip formation SPD process, is demonstrated as a method for producing ultrafine grained sheet/foil of magnesium AZ31. Temperature is varied locally in the deformation zone through adiabatic heating due to the high strain rate nature of the process. Ultrafine grain formation and recrystallization mechanisms responsible for various microstructures are explained as a function of temperature and strain rate. Continuous dynamic recrystallization (CDRX) is shown to operate at low temperatures (below 170°C) and results in ultrafine grain sizes (100-200 nm), high hardness values (120 HV) and non-basal textures. At high temperatures (above 170°C), the recrystallization mechanism switches to discontinuous dynamic recrystallization (DDRX), which results in fine grain sizes (2-3 μm), low hardness (50 HV) and basal-type textures. Implications for formability and mechanical properties will be discussed.

5:00 PM

Reinforcement Phase Size Effects on a Cryomilled Al – B_4C Nanocomposite: *Hanry Yang*[1]; Troy Topping[1]; Zhihui Zhang[1]; Enrique Lavernia[1]; Julie Schoenung[1]; [1]University of California Davis

Cryomilled Al 5083 - boron carbide (Al-B_4C) metal matrix composites (MMCs) are of interest due to their light weight and high strength. Cryomilling is a mechanical milling process during which the powder is ball milled in a liquid nitrogen slurry at cryogenic temperatures. In addition to generating nanocrystalline powder, cryomilling breaks up the nascent oxide layer on the as-received Al powder and introduces nitrides into the microstructure. The dispersed nano-metric inclusions enhance the thermal stability of the powder for subsequent consolidation and thermomechanical processing, ensuring the MMC retains an ultra-fine grained (UFG) microstructure. In this study, the effect of milling time, B_4C particle size, and consolidation variables on the microstructure and mechanical properties of consolidated bulk nanocomposites was investigated. Specific attention was placed on the differences resulting from the incorporation of 0.5 μm and 6 μm B_4C particulates. The relationship between microstructure and mechanical properties of the nanocomposites are discussed.

5:15 PM

Homogenizing Process and Strain Hardening Behavior of a Two-Phase Cu-Ag Alloy Processed by High-Pressure Torsion (HPT): *Y.Z. Tian*[1]; Z.F. Zhang[1]; R.B. Figueiredo[2]; N. Gao[3]; T.G. Langdon[4]; [1]Institute of Metal Research,Chinese Academy of Sciences; [2]Federal University of Minas Gerais; [3]University of Southampton; [4]University of Southern California

Disks of a two-phase Cu-28 wt.% Ag alloy were processed by high-pressure torsion (HPT) from 1 to 20 revolutions to reveal the microstructural evolution and the mechanical properties. It is shown that the deformation starts at the outer region of the disks in the form of local vortices and then spreads inwards with increasing the number of revolutions. Deformation patterns were also observed near the center of the disk after HPT for 20 revolutions. It is found that the Cu-Ag alloy displays a much stronger strain hardening capability than Cu due to a continuous refinement of the microstructure. A two-stage Hall-Petch relationship was obtained for the Cu-Ag alloy which is attributed to the development of multiple strengthening mechanisms.

5:30 PM

Microhardness and Microstructural Evolution in Cu-Zr Alloy after High-Pressure Torsion Processing: *Jittraporn Wongsa-Ngam*[1]; Megumi Kawasaki[1]; Terence Langdon[1]; [1]University of Southern California

A copper alloy, Cu-0.1% Zr, was subjected to severe plastic deformation at room temperature using the procedure of high-pressure torsion. Disks were strained through different numbers of revolutions up to 10 turns with an applied pressure of 6.0 GPa in order to examine the evolution of hardness and microstructure. Microhardness results reveal lower values in the center regions in the early stages and there is a high degree of hardness homogeneity after 5 and 10 turns. For these conditions, the average grain sizes and the distributions of grain boundary misorientations are similar in the center and at the periphery of the samples. It is shown that there is a gradual evolution in both hardness and microstructure with increasing numbers of turns.

Ultrasonic Fatigue of Advanced Materials and Systems: Ultrasonic Fatigue of Metals and Alloys II; Very High Cycle Fatigue of Composites and MEMS

Sponsored by: The Minerals, Metals and Materials Society, State Research Center for Mathematical and Computational Modelling, University of Kaiserslautern, Germany, State Research Focus "Advanced Materials Engineering", University of Kaiserslautern, Germany, TMS Light Metals Division, TMS Structural Materials Division, TMS: Advanced Characterization, Testing, and Simulation Committee, TMS/ASM: Computational Materials Science and Engineering Committee, TMS: Materials Characterization Committee, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Young Leaders Committee
Program Organizers: Frank Balle, University of Kaiserslautern; Dietmar Eifler, University of Kaiserslautern; Guntram Wagner, University of Kaiserslautern

Wednesday PM — Room: Europe 1

Session Chairs: J. Wayne Jones, University of Michigan (USA); Hans-Juergen Christ, University of Siegen (Germany)

2:00 PM
Very High Cycle Fatigue (VHCF) Behavior of Sn-Rich (Pb-Free) Solder Joints: *Martina Zimmermann*[1]; Kyle Yazzie[2]; Martin Cremer[1]; Hans-Juergen Christ[1]; Nikhilesh Chawla[2]; [1]Universitaet Siegen; [2]Arizona State University

Solders are an integral part of electronic packaging. Recently, there has been a significant drive to replace Pb-Sn solders with Pb-free, environmentally-benign solders. Given the widespread use of Pb-Sn solder in the manufacture and assembly of circuit boards, a fundamental understanding of microstructure evolution and deformation behavior of Pb-free solders is crucial for the successful substitution of these materials in the electronics industry. Reliability of electronic devices is controlled by fatigue behavior at very high frequencies due to mechanically induced vibrations during application. However, damage evolution during cyclic deformation in the VHCF range has not yet been investigated. In this study soldered Sn-rich alloys/Cu samples were tested by means of ultrasonic fatigue testing. This technique enabled a peak stress amplitude to be applied solely in the center region of the specimen allowing a systematic evaluation of the effect of the microstructural features on fatigue life beyond N > 10E7 cycles.

2:20 PM
Ultrasonic Fatigue of Ti6Al4V in the Very High Cycle Fatigue Regime: Stefan Heinz[1]; Guntram Wagner[1]; Frank Balle[1]; *Dietmar Eifler*[1]; [1]University of Kaiserslautern

At the Institute of Materials Science and Engineering of the University Kaiserslautern an ultrasonic testing facility (UTF) was developed to perform experiments in the VHCF regime. The individual design of the testing facility allows to control the process parameters and to measure the relevant fatigue data in detail. Furthermore for the first time high resolution 3D-laser measurements were carried out to describe the oscillation behavior of ultrasonic fatigue specimens under load. To investigate the fatigue behavior in the VHCF-regime load increase tests were performed with the titanium alloy Ti6Al4V. Based on the high-frequency measurements of the displacement of the specimen at their free end a correlation between the frequency and the actual fatigue state was realized. In constant amplitude tests cyclic deformation curves as well as damping curves of Ti6Al4V in the range 10^{10} were determined.

2:40 PM Invited
Combining Ultrasonic Fatigue with Synchrotron X-radiograhy and in situ Nonlinear Ultrasonic Measurements to Detect Crack Initiation: *Naji Husseini*[1]; Clinique Brundidge[1]; Anish Kumar[1]; Tresa M. Pollock[1]; J. Wayne Jones[1]; [1]University of Michigan

Ultrasonic fatigue testing provides and excellent method to examine the unique nature of crack initiation and early crack propagation in the very high cycle fatigue regime. This presentation reviews two recently developed in situ techniques for examining fatigue crack initiation and early crack propagation during ultrasonic fatigue in a wide range of structural alloys. In the first case, a technique has been developed to allow in situ imaging of propagating fatigue cracks by synchrotron x-ray imaging. The technique involves employs a "carrier specimen" cycling in resonance at 20kHz to which is attached a foil specimen ranging in thickness from 100-300µm. Examples from crack propagation nickel base superalloys, aluminum and magnesium alloys will be described. In the second case, a technique for in-situ characterization of fatigue damage accumulation and the crack initiation lifetime using nonlinear ultrasonic measurements via analysis of the feedback signal of a closed-loop ultrasonic fatigue system is described.

3:00 PM
In-Situ Characterization of the Damage Evolution of Welded Aluminum Alloy Joints during Very High Cycle Fatigue (VHCF) with Nonlinear Ultrasonic Technique: *Martin Cremer*[1]; Martina Zimmermann[1]; Hans-Jürgen Christ[1]; [1]University Siegen

Fatigue behaviour in the very high cycle range is dominated by local plastic deformation caused predominantly by microstructural defects. In case of welded joints process-related imperfections such as pores, hot cracks or incomplete fusions act as local stress raisers, leading to a pronounced scattering of fatigue results. Depending on the severity of the defect-related notch effect, VHCF life is dominated by the stress concentration factor, the remaining cross section and the corresponding crack growth behaviour. With crack propagation emanating from the specimen's interior, a characterization of crack growth behaviour with conventional optical methods is impossible. In the given study welded samples from the aluminium alloy EN AW 6082 are tested by means of ultrasonic fatigue testing, thus reaching number of load cycles N > 10E8. Damage evolution, i.e. crack growth, is characterized in-situ by the change in higher harmonics registered by the non-linear feedback signal of the ultrasonic system.

3:20 PM Break

3:40 PM
Ultrasonic Fatigue of Aluminum Matrix Composites (AMC) in the VHCF-Regime: *Guntram Wagner*[1]; Matthias Wolf[1]; Dietmar Eifler[1]; [1]University of Kaiserslautern

At the Institute of Materials Science and Engineering of the University of Kaiserslautern ultrasonic testing facilities (UTF) are used to perform fatigue experiments in the VHCF-regime. With the USF it is possible to characterize the actual fatigue state by changes of different process parameters such as the generator power, the dissipated energy or the oscillation amplitude. Furthermore the experiments can be interrupted to investigate the formation of intrusions or extrusions as well as changes of the electrical resistance. With the UTF load increase as well as constant amplitude tests can be realized. The microstructure of the investigated AMC was characterized by EDX- and EBSD-analysis and consists of an AlCu4Mg1 (AA2124) matrix reinforced with 25 vol. % SiC particles. The appropriate geometry for the ultrasonic fatigue specimens was determined by FE-simulations based on ABAQUS CAE.

4:00 PM
Ultrasonic Fatigue Testing System Combined with Nondestructive Online Testing for Carbon Fiber Reinforced Composites: *Frank Balle*[1]; Daniel Backe[1]; Thomas Helfen[2]; Ute Rabe[2]; Sigrun Hirsekorn[3]; Dietmar Eifler[1]; Christian Boller[3]; [1]University of Kaiserslautern; [2]Saarland University; [3]Fraunhofer Institute for Nondestructive Testing, Saarbrücken, Germany

The fatigue properties of carbon fiber reinforced polymers (CFRP), especially in the Very High Cycle Fatigue (VHCF) regime, are rarely investigated. To analyze the VHCF properties and the specific failure mechanisms of CFRP a new ultrasonic testing system for 3 and 4-point cyclic bending in combination with nondestructive online testing was developed. The oscillation to realize cyclic bending is generated by an ultrasonic resonance system with a frequency of 20 kHz at a stress ratio of R > 0.1. As a representative material a carbon fiber reinforced polyphenylensulfide (CF-PPS) has been chosen. The fatigue process is split up in pulse and pause sequences to hold the specimen in a temperature range well below the glass transition temperature. The current fatigue status of the specimen during ultrasonic testing will be detected via thermography, laser vibrometry, microwave analysis and non-linear ultrasound techniques.

4:20 PM
Small-Scale Multiaxial Fatigue Experiments in the Very High Cycle Regime: *Thomas Straub*[1]; Tobias Kennerknecht[1]; Paulin Robin[2]; Morgan Tort[2]; Geoffroy Kieffer[2]; Yuri Lapusta[2]; Christoph Eberl[1]; [1]Karlsruhe Insitute of Technology (KIT); [2]French Institute of Advanced Mechanics (IFMA)

Small-scale fatigue takes place in many applications such as micro-electro-mechanical-systems, surface acoustic wave devices and microelectronics, in which cyclic loading leads to failure. Multiaxial fatigue experiments with micro samples at kHz frequencies require novel experimental setups. Therefore, resonant micro fatigue systems for uniaxial and multiaxial cyclic loading have been developed. Finite Element simulations have shown that dimensions of the samples can be chosen in a way that the resonant frequencies of bending and torsional modes are very close, which is a requirement for multiaxial cyclic loading. For the initial tests, samples made from copper, aluminium, or nickel with a rectangular cross section of 500 µm by 200 µm have been used. Hence, scaling and size effects are expected to dominate reliability of such components. The recent experiments show that the resolution of the resonant system allows to observe and study the initiation of slip bands and short cracks.

4:40 PM
High and Very High Cycle Fatigue in Al and Cu Thin Films on Si Substrate: *Sofie Burger*[1]; Christoph Eberl[1]; Alexander Siegel[2]; Alfred Ludwig[2]; Oliver Kraft[1]; [1]Karlsruhe Institute of Technology; [2]Ruhr-Universität Bochum

In technical applications like MEMS devices thin films undergo cyclic loading and will fail eventually due to fatigue. The mechanisms in the high cycle and very high cycle fatigue regime are still not well understood, although the mechanical properties of thin films have been studied extensively in the past years. To better understand these mechanisms we investigate the fatigue processes by a novel resonant bending fatigue setup for thin films on Si cantilever substrates after up to 10^9 cycles. The cyclic bending of the Si substrate induces a strain amplitude gradient in the thin film. The maximum can be found at the fixed end and the in situ observation of the damage front allows to derive one lifetime diagram per cantilever. We investigated the microstructural evolution in pure Al and Cu during fatigue. All films show extrusion and pore formation but differ in shape and number, which will be discussed.

5:00 PM
Environmental Effects on Fatigue Crack Initiation in the HCF and VHCF Regimes for LIGA Ni Thin Films: Eva Baumert[1]; *Olivier Pierron*[1]; [1]Georgia Tech

The present study investigates the fatigue degradation properties of 20-micron-thick, electrodeposited Ni films (columnar microstructure) in a mild (30° C, 50% RH) and humid (80°C, 90%RH) environment, using Ni MEMS micro-resonators. The specimens are tested under bending and subjected to fully-reversed loading at resonance (~8 kHz) for a large range of strain amplitudes encompassing the HCF and VHCF regimes. The change in resonant frequency resulting from a change in compliance of the structure is monitored throughout the fatigue tests. In addition, the fatigued sidewalls of the Ni thin films are periodically observed using SEM to detect the onset of fatigue crack initiation. It is found that the resonant frequency provides an accurate metric for detecting the degree and rate of fatigue crack initiation in the Ni thin films. The influence of the environment on the fatigue properties and the implications on reliability of Ni MEMS devices will be discussed.

5:20 PM Concluding Comments Dietmar Eifler, Symposium organizer

Wettability and Interfacial Phenomena between Metals and Ceramic/Refractory Materials: Session I

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, Not Applicable

2:00 PM
Chemical Wear of Basic Brick Linings in the Non-Ferrous Industry: *Dean Gregurek*[1]; Alfred Spanring[1]; Marcus Kirschen; Christian Majcenovic[1]; [1]RHI AG

In the non ferrous metals industry particulary in the copper and lead smelting furnaces the working lining made of magnesia-chromite bricks is exposed to several stresses. These can be classified as chemical, thermal and mechanical stresses occurring as a single wear factor or in combination. The chemical factors include corrosion caused by slag and/or gaseous SO2 diffusion, redox effects and hydration.In most of the non-ferrous metallurgical processes the chemothermal load by Fe-silicatic slags of fayalithic type is a common wear mechanism of the magnesia-chromite bricks. Nevertheless the extraordinary massive SiO2-supply caused by changes in the processing and the uncontrolled addition of silica sand results in a severe formation of forsterite respectively in a volume expansion due to "forsterite bursting". Such a wear phenomenon is experienced seldom in the non-ferrous applications but quite typical for the regenerator chamber in the glass industry in case of extreme SiO2 supply ("carry over").

2:20 PM
Diffusion Bonding between Ti_3SiC_2 and NiTi Shape Memory Alloy: *Ankush Kothalkar*[1]; Patrick Mahaffey[1]; Sandip Basu[1]; Miladin Radovic[1]; Ibrahim Karaman[1]; [1]Texas A&M University

Diffusion kinetics and bonding between Ti_3SiC_2 and NiTi is studied in the range of 800 to 1200°C. The microstructure of the interfacial layer, formed at different temperatures and after different bonding times, has been characterized using scanning electron microscopy and microprobe elemental analysis to determine its phase composition and mechanism of diffusion bonding. At 1200°C, the bonding mechanism observed is liquid phase whereas solid state diffusion bonding was observed at lower temperatures. The interfacial layers form by diffusion of Si from Ti_3SiC_2 into the interface and its subsequent reaction with NiTi to form Ni-Ti-Si ternary phases. Elastic modulus and hardness of different phases present in the interfacial layer are determined using nanoindentation. Vickers hardness data shows considerably higher hardness at the interface layer compared to both Ti_3SiC_2 and NiTi. However, the absence of any significant cracking near the indents confirms a high fracture toughness of the interfacial bonding phase.

2:40 PM
Effect of Surface Modification of Al2O3 Particles on the Microstructure and Mechanical Properties of Al-Al2O3 Nanocomposites: *Hossein Beygi*[1]; Seyyed Abdalkarim Sajjadi[1]; Seyyed Mojtaba Zebarjad[1]; [1]Ferdowsi University of Mashhad

Aluminum matrix composites containing dispersed Al2O3 nano-particles are widely prepared through stir casting method; however in this method wettability of reinforcement particles within the matrix melt is really poor. In this study in order to improve wettability of Al2O3 particles in Al matrix, surface of Al2O3 particles (50nm diameter) were modified with metallic Cu layer (20nm thickness) by using two step electroless coating techniques. Subsequently Cu coated Al2O3 particles were annealed at temperature of 450 °C and then injected into the molten Aluminum. Nanocomposite samples containing different weight percentage of Al2O3 particles were prepared by stir casting. Products were characterized using SEM, TEM and EDX. The results show when copper coated particles are applied, reinforcement wetting by molten matrix significantly improves, strong interfacial bonding appeared due to the formation of CuAl2 intermetallics in matrix/reinforcement interface, reinforcement's segregation limited and uniform distribution of Al2O3 nano particles within Al matrix observed.

3:00 PM
Study on Wettability of Cu and 85Cu-15Ni Alloy on 18NiO-NiFe2O4 Composite Ceramics: *Jinjing Du*[1]; Yihan Liu[1]; Guangchun Yao[1]; Zhigang Zhang[1]; Guoyin Zu[1]; [1]Northeastern University

The wetting wettability of Cu, 85Cu-15Ni alloys on 18NiO-NiFe2O4 composite ceramics was investigated by a sessile drop method. The contact angles of the two metal systems on the ceramic matrix were measured in various temperatures with time. The results show that 85Cu-15Ni alloy exhibits a better wetting ability on 18NiO-NiFe2O4 composite ceramics than that of Cu. With introducing 1wt% MnO2 into the 18NiO-NiFe2O4 composite ceramic substrates, the wettability between Cu, 85Cu-15Ni alloy(s) and substrate is improved. In addition, the morphology of metal/ceramic interface is observed by means of scanning electron microscopy (SEM), X-ray diffraction (XRD), and energy dispersive spectroscopy (EDS). Observation of 85Cu-15Ni alloy /ceramic interface shows a good solubility between Cu and Ni in the droplet, and partial Cu diffused into the NiFe2O4 substrates.

3:20 PM
Wetting and Wicking Behavior of Refractory Coatings Used in Lost Foam Casting: *Robin Woracek*[1]; Indraneel Sen[1]; Dayakar Penumadu[1]; [1]University of Tennessee

The wetting and wicking behavior of polymer melts with refractory coatings (Mica and Silica based), as used in the Lost Foam Casting (LFC) process for obtaining near net shape aluminum castings, are characterized in this study. Refractory coating applied on the Expanded Polystyrene (EPS) foam pattern surface plays a key role in controlling the metal flow and overall success of the LFC process, as the EPS foam pyrolysis takes place while the casting mold is being filled. An experimental system, incorporating a modified Wilhelmy plate technique, was custom developed for investigating the dynamic advancing and receding force between PS melt and coated probe and the related hysteresis loop. Results associated with polymer surface tension and advancing/receding contact angles for PS melts at temperatures between 220-300°C, where they show pronounced viscoelastic behavior, are included. The experimental system is well suited to study nearly any liquid-solid interface for temperatures between 0-800ºC.

3:40 PM
Interfacial Reactions in the Liquid/Solid and Liquid/Vapor Interfaces of Al-Si-Mg Alloys and B12 (Bc2) Substrates: Oziel Herrera-Romero[1]; *Martin Pech-Canul*[1]; Zariff Chaudhury[2]; Golam Newaz[3]; [1]Centro de Investigacion y de Estudios Avanzados del Instituto Politecnico Nacional; [2]Arkansas State University; [3]Wayne State University

Interfacial reactions between the Al-6 Si-14 Mg alloy and B12 (BC2) substrates were studied in wettability tests by the sessile drop technique using an L8 Taguchi experimental design. Specimens of the alloy in the form of cubes were placed on boron carbide substrates prepared by the uniaxial compaction of B12 (BC2) powders. Sessile drop tests were conducted varying the following parameters: temperature (1000 and 1200 °C), time (90 and 120 min), atmosphere (N2 and Ar \149; N2), and substrates prepared with uncoated and coated powders with colloidal SiO2. The contact angles were measured from photographs, the interfaces were characterized by XRD and SEM, and the thermodynamic feasibility of possible reactions in the system was determined using the HSCTM software and data bases. The nonwetting contact angles observed and the detachment of the metal drop from the substrate can be attributed to the formation of MgO and Al2O3 on the meniscus surface.

2012 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: Joint Session with "2012 Surface and Heterostructures"

8:30 AM Invited

Modification of Micro-Stereolithography-Fabricated Microneedles Using Pulsed Laser Deposition: Shaun Gittard[1]; Philip Miller[1]; Chunming Jin[1]; Timothy Martin[1]; Ryan Boehm[1]; Bret Chisholm[2]; Shane Stafslien[2]; Justin Daniels[2]; Nicholas Cilz[2]; Nancy Monteiro-Riviere[3]; Adnan Nasir[4]; *Roger Narayan*[1]; [1]Univ of North Carolina & North Carolina State Univ; [2]North Dakota State University; [3]North Carolina State University; [4]University of North Carolina

Hollow microneedles are small-scale hypodermic needle-like structures, which may be used for transdermal delivery of nucleic acid-containing agents, protein-containing agents, and other pharmacologic agents. Translation of microneedles to clinical use would benefit from the development of cost-effective microneedle fabrication techniques. A rapid prototyping technique known as visible light dynamic mask micro-stereolithography was used to create solid microneedle arrays; this technique uses digital light projection to selectively polymerize a liquid resin. Pulsed laser deposition was then used to deposit silver and zinc oxide thin films on the surfaces of the visible light dynamic mask micro-stereolithography-fabricated acrylate-based polymer microneedle arrays. In vitro studies were used to demonstrate the antimicrobial activity of the silver- and zinc oxide-coated microneedle array structures. This work shows that visible light dynamic mask micro-stereolithography and pulsed laser deposition may be used to create antimicrobial microneedles for treating local skin infections.

9:05 AM

Nanosphere Lithography of Co/Pd Multilayer Film for Advanced Media: *Suzanne Kornegay*[1]; Shraeyansh Thakur[1]; Erica Barnes[1]; Anondo Bannerjee[1]; Marely Villanueva[1]; Hao Su[1]; Zhenzhong Sun[1]; Dawen Li[1]; Subhadra Gupta[1]; [1]The University of Alabama

We reported for the first time nanosphere lithography (NSL) of perpendicular anisotropy Co/Pd multilayer film for advanced media application. NSL is an inexpensive patterning technique that includes the formation of a monolayer of polystyrene spheres, shrinking of the nanospheres, and then ion milling of the film into nanopillars with reduced nanospheres acting as a mask. Polystyrene nanospheres were shrunk under different conditions of oxygen plasma ashing. Field emission scanning electronic microscopy (FESEM) and X-ray diffraction (XRD) were employed to observe the morphology and the crystal structure respectively of magnetic nanocolumn arrays. Alternating gradient magnetometer (AGM) was used to characterize the magnetic properties, such as Mst, Mrt and squareness of patterned films and correlated structural properties. We have developed a hard mask technique compared with NSLto further decrease the nanopillar size to ~10nm for improved recording density.

9:20 AM

Optimization of CoPt-AlN Granular Media for High Density Applications: *Hao Su*[1]; Anusha Natarajarathinam[1]; Elizabeth Philip[1]; Kristy Tippey[1]; Subhadra Gupta[1]; [1]The University of Alabama

The effects of AlN volume and thermal annealing on CoPt-AlN granular media have been studied. CoPt/AlN multilayers were first deposited, and then thermally annealed to fabricate the granular media. AlN layers were deposited by reactive sputtering from an Al target while CoPt was co-sputtered using cobalt and platinum targets. Various ratios of Co and Pt, ranging from Co80Pt20 to Co50 Pt50, were used to deposit CoPt-AlN mutlilayers with different thicknesses of AlN layers, after which they were post-deposition annealed in vacuum from 300 to 600 C. X-ray diffraction (XRD), transmission electron microscopy (TEM), local electrode atom probe (LEAP), and alternating gradient magnetometer (AGM) were employed to characterize the structural vs. magnetic properties. The Co-Pt phase diagram was used to predict the magnetic vs. structural ordering temperatures for each CoPt alloy, and compared with the experimental results.

9:35 AM

Reproducible Resistive Switching Behavior in Sputtered TiOx Films: *R. J. Jeng*[1]; W. Z. Chang[1]; J. P. Chu[1]; [1]National Taiwan University of Science and Technology

The electronic industries have been attempting to improve the cache memory and flash device performance to be fast, small, and less energy consuming. Although the studies on RRAM have shown some results recently with the transition metal oxide, tintation, more detailed microstructure and crystallographic analysis rtanium oxide (TiOx), there still needs more stable and better memory properties. This study is thus directed toward improving RRAM properties of TiOx. In the two conditions of the sputtering atmosphere, which were 75% and 100% of the oxygen, the as-deposited TiOx had the good switching effects. The switching voltages from set to reset were 1.9 V and 2.0V for 75% and 100% oxygen sputtering atmospheres, respectively, whereas from reset to set the voltages were 0.87 V and 0.77 V. In this preseesults are revealed and discussed.

9:55 AM

Improving Resistance Switching Behavior of HoScO3 Film for the RRAM Application: Effects of Annealing: *W. Z. Chang*[1]; S. F. Wang[2]; J. P. Chu[3]; [1]Graduate Institute of Engineering, National Taiwan University of Science and Technology,; [2]Department of Materials and Minerals Resources Engineering, National Taipei University of Technology; [3]Graduate Institute of Engineering and Department of Materials Science and Engineering, National Taiwan University of Science and Technology,

A 35nm-thick of HoScO3 (HSO) thin films were deposited by r.f. magnetron sputtering, followed by annealing at 200 °C and 400 °C. The effects of annealing atmospheres as well as annealing temperatures on the resistance switching behavior of the HSO films were investigated in this study. As-deposited HSO film did not show the resistance switching behavior with high resistance, while it had unipolar switching behavior after annealing in high vacuum or in N2 atmosphere. The reliability improved with increasing annealing temperature. The formation and redistribution of defects such as metal ion and oxygen vacancy during thermal annealing are considered to be responsible for those variations in resistance switching properties.

10:10 AM Break

10:25 AM
Environmental Cracking Susceptibility of a Surface Nanocrystallized Stainless Steel in Contrast to its Coarse Grained Counterpart: *Indranil Roy*[1]; Jian Lu[2]; Yuntian Zhu[3]; Colin Longfield[1]; Rashmi Bhavsar[1]; Enrique Lavernia[4]; Farghalli Mohamed[5]; [1]Schlumberger; [2]City University of Hong Kong; [3]North Carolina State University ; [4]University of California, Davis; [5]University of California, Irvine

Stressed C rings of a surface nanocrystallized precipitation hardened stainless steel were exposed to high pressure high temperature (HPHT) hostile environments (acid gas and corrosive high density zinc based uninhibited completions brine) per NACE TM0177 – Method C. Susceptibility to environmental cracking (EC) of the surface nanocrystallized alloy was assessed in contrast to its untreated coarse grained counterpart. It is evident from the experimental results that surface nanocrystallized steel performed better in (a) HPHT sour hostile environments (b) high density low pH (~ 3.5) tri-salt brine and (c) acidizing environments in comparison to untreated counterparts without any indication of EC. Microstructural data and a comparative analysis of pits are discussed. Moreover, the results show that the compressive stress induced on the surface due to the ultrasonic shot peening in conjunction with the effect of grain boundary orientation due to grain refinement abets EC resistance of the treated alloy.

10:45 AM
Investigation of Al2O3 Nanostructures Using Charge Optimized Many Body Potentials: *Dundar Yilmaz*[1]; Bryce Divine[2]; Simon Phillpot[1]; Susan Sinnott[1]; [1]University of Florida; [2]U.S. Army Engineer Research and Development Center

Aluminum oxide nanostructures have drawn attention due to their interesting physical and optical properties. In particular, Photoluminescence peaks for these systems are attributed to oxygen vacancies.Here, we develop third-generation Charge Optimized Many Body (COMB) potentials for the Al-Al2O3 system. These potentials are used to investigate the properties of Al2O3 nanostructures. COMB potential not only simulates chemistry of the system but also handle realistic sized systems with an accuracy close to the first principles methods which are limited to small sized systems. In particular, the elastic properties and local atomistic strain distribution are calculated. The vibrational spectra are determine from the velocity auto correlation function. The effect of oxygen vacancies on the local strain and vibrational spectra are also characterized and analyzed. This work is supported by NSF/DMR under Grant No. 1005779.

11:05 AM
Microstructure, Interfaces, Intermixing and Magnetic Properties of FePd/MgO/FePt/Pt/CrRu Films Deposited on SiN/Si Substrate: *Ramasis Goswami*[1]; Shu Cheng[2]; Konrad bussmann[2]; [1]SAIC/Naval Research Laboratory; [2]Naval Research Laboratory

We have investigated the microstructure, interfaces and intermixing in sputter-deposited FePd/MgO/FePt/Pt/Cr90Ru10/Si3N4/Si magnetic tunnel junctions by high-resolution transmission electron microscopy (HRTEM) and correlated these results to the magnetic properties. Cr90Ru10 is used as a texturing layer for the growth of perpendicular magnetic anisotropy (PMA) films. HRTEM confirmed the formation of the desired (001) texture in cubic Cr90Ru10 as well as in the L10-FePt layer using our growth methods. A 2.5 nm layer of MgO was deposited as a tunnel barrier. The HRTEM observations show that the MgO layer was crystalline but randomly oriented. The FePd layer was also found to grow as discrete islands having a width of 5 to 10 nm with random orientations. The magnetic properties show out of plane coercivity larger than that of the in-plane values but with a loss of squareness in concert with the loss of (001) texture in the top magnetic layer.

11:25 AM
Fluorescence from Polymers in Uniaxially Stretched Electrospun Nanofiber Mats: *Stephen Young*[1]; Indraneel Sen[1]; Rohit Uppal[1]; Dayakar Penumadu[1]; [1]University of Tennessee, Knoxville

Electrospun polymer nanofibers are attractive due to their volume-to-space, electrical, chemical, and unique optical properties. Uniaxially stretched polymer thin films have shown a change in optical properties with increasing applied tensile strain. High molecular weight polyvinylcarbazole (PVK) and polystyrene (PS) blends of various concentrations were electrospun and aligned by traditional electrospinning methods. Fiber mats were characterized using scanning electron microscopy (SEM) for morphology, fourier transform infrared spectroscopy (FTIR) and x-ray diffraction (XRD) to obtain polymer chain orientation, and fluorospectroscopy for optical properties. The fiber mats were then mounted onto a custom tensile stage where steady-state fluorescence properties of electrospun nanofiber mats were studied under tensile loadings at room temperature.

11:40 AM
Synthesis and Characterization of Core-Shell TaN_x Nanocomposites: Lianyun Liu[1]; *Kai Huang*[1]; Zheng Wang[1]; Jungang Hou[1]; Hongmin Zhu[1]; [1]University of Science and Technology Beijing

Core-shell TaN_x nanocomposites were prepared through the in-situ coating process on the basis of synthesis of $TaN_{0.5}$ nanoparticles. The X-ray diffraction results showed the nanocomposites consisted of TaN and $TaN_{0.5}$ crystalline phase. TEM and SEM images demonstrated that TaN nanopowders as a coating layer grew on the surface of $TaN_{0.5}$ nanoparticles, producing TaNx nanocomposites with core-shell structure. The specific surface area of nanocomposite powders was as large as $4.87m^2g^{-1}$-$6.13m^2g^{-1}$, indicating that such TaNx nanocomposites exhibited great potential of application to the capacitor with ultra high specific capacitance.

11:55 AM Concluding Comments

3rd International Symposium on High Temperature Metallurgical Processing: Treatment and Recycling of Solid Slag/Wastes

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Energy Committee, TMS: Pyrometallurgy Committee
Program Organizers: Tao Jiang, Central South University; Jiann-Yang Hwang, Michigan Technological University; Patrick Masset, TU Freiberg; Onuralp Yucel, Istanbul Technical University; Rafael Padilla, University of Concepcion; Guifeng Zhou, Wuhan Iron and Steel

Thursday AM — Room: Southern II
March 15, 2012 — Location: Dolphin Resort

Session Chairs: Xiangxin Xue, Northeastern University; Zhiwei Peng, Michigan Technological University

8:30 AM
An Integrated Strategy for Whole Ecological Utilization of Typical Industrial Solid Wastes in China: *Xiangxin Xue*[1]; He Yang[1]; Tao Jiang[1]; Yong Li[1]; [1]Northeastern University

In this paper, we describe the current status and research progress on the utilization of typical industrial solid wastes in China. We propose a creative method called “eco-utilizing wastes” with an aim of both integration and increment but without second-time waste and pollution, in terms of the characteristics of typical industrial solid wastes, such as titanium-bearing blast furnace slag, high-silicon iron tailing and boron-enriched slag as well as oil shale.

8:45 AM
Chlorination Behaviors of Copper Phases by Calcium Chloride in High Temperature Oxidizing-Chloridizing Roasting: *De Qing Zhu*[1]; Dong Chen[1]; Jian Pan[1]; Tie Jun Chun[1]; Guo Lin Zheng[1]; Xian Lin Zhou[1]; [1]Central South University

The high temperature oxidizing-chloridizing roasting is one of useful methods to separate nonferrous metals from pyrite cinder and metallurgy slag. However, as one kind of main nonferrous metals in pyrite cinder and metallurgy slag, copper's chlorination behavior is not demonstrated. In the present study, chlorination behaviors of CuO, Cu2O and CuS at the temperature range of 1025-1175°C in air by simulating the chloridizing roasting process of pyrite cinder and metallurgy slag have been investigated. It is shown that Cu2O and CuS is much easier to remove, CuO is refractory to remove. In addition, the presence of SiO2 and CaO increases the Cu removal rate from CuO while the presence of SiO2, Al2O3, CaO and MgO decreases the Cu removal rate from Cu2O. Fe3O4 influences the Cu removal rate from CuO and Cu2O positively.

9:00 AM
Decomposition of Zinc Ferrite in Zinc Leaching Residue by Reduction Roasting with Carbon: *Mi Li*[1]; Bing Peng[1]; Liyuan Chai[1]; Jiming Wang[1]; Ning Peng[1]; [1]Central South University

Abstract: Decomposition of zinc ferrite in zinc leaching residue (ZLR) into zinc oxide and magnetite by reduction roasting with carbon as reducing agent was conducted in a muffle furnace under nitrogen atmosphere. The effects of roasting temperature, roasting time and the mass ratio of reducing agent to ZLR on the decomposition rate of zinc ferrite were investigated. The results showed that roasting temperature and usage amount of reducing agent were significant on the decomposition rate of zinc ferrite. More than 90% of zinc ferrite was decomposed after roasted at temperature over 850°C for 2h under carbon to ZLR mass ratio of 10%. The phase changes during reduction roasting process were detected by using XRD and SEM-EDS for the roasted and unroasted ZLR. A new flow sheet of ZLR treatment for the recovery of zinc and iron was proposed.

9:15 AM
Effect of Iron Containing Metallurgical Byproducts on Pulverized Coal Combustion Efficiency: *Zou Chong*[1]; Wen Liangying[1]; Zhang Shengfu[1]; Bai Chenguang[1]; Tan Xiuqin[1]; [1]Chongqing University

Eight typical metallurgical byproducts containing iron were selected based on the effect of the chemical composition, particle size, additives on the burnout degree of pulverized coal. Effect of three typical byproducts including fine iron ore, BOF dust and BOF sludge on combustion reactivity and combustion efficiency were investigated using TG-DSC method. The results indicated that the three additives have obvious catalytic effects on pulverized coal. By comparison, the relative active sequence of byproducts to the catalytic combustion can be described as follows: BOF dust>BOF sludge>fine iron ore. Moreover, adding BOF dust as component of additives also shows significant catalytic effects on combustion efficiency during rapid heating process.

9:30 AM
Effect of SiO2 Addition on Production of Fe-Si-Mn Alloy from Adjusted Converter Slag: *Cuihuan Huang*[1]; Min Chen[1]; [1]Northeastern University

Production of Fe-Si-Mn alloy from adjusted converter slag was investigated by thermodynamic analysis. The calculated results showed that the solubility of SiO2 in slag increased with increment of temperature, and the solubility was about 80% at 1800°C. With increment of SiO2 content, MnO activity and CaO activity decreased, while FeO activity increased to the maximum when SiO2 content was about 30%. As a result, Fe was reduced from the adjusted converter slag firstly, followed by the reduction of Mn, P and Si. The reduction order was Fe→P→Mn→Si when SiO2 content in the slag was from 46.4% to 54.2%, and changed to the order of Fe→Si→P→Mn when SiO2 content exceeded 54.2%. The mass fraction of Si in the alloy phase increased with increasing of SiO2 content in the slag, and the mass fraction of Si in the alloy reached to 62.2% at 1800°C.

9:45 AM
Experimental Research on Recovery of Heavy Metals from EAF Stainless Steel Dust: *Canguo Wang*[1]; Fei Jin[1]; Guodong Sun[1]; Mei Zhang[1]; Min Guo[1]; [1]University of Science and Technology Beijing

EAF stainless steel dust contains some valuable metals such as Fe, Cr, Zn, and Ni. To recycle these heavy metals, it is quite important to know the reactivity and metallurgical behavior of these heavy metals contained in EAF stainless steel dust. According to thermodynamic analysis, the reduction temperature of ZnFe2O4, Fe2O3, NiO, ZnO and Cr2O3 by carbon was 848K, 978K, 708K, 1218K and 1534K, respectively. The heavy metals can be recycled from EAF stainless steel dust by selective reduction with carbon. In the present study, the effects of temperature and time on the reduction ratio of the metals were investigated with 200ml/min N2 and (mass%dust)/(mass%C)=4 at 1773K, 1823K and 1873K. It was found that the reduction ratio of metals (Fe, Ni and Cr) increased with the increase of the reaction time and the temperature. In 20 minutes, the reduction ratio of metals reached 90% or so at 1873K.

10:00 AM
Research on the Control Model of Vanadium Recovery by BOF Process Based on Neural Network: *Qingyun Huang*[1]; Bing Xie[1]; Yugang Li[1]; Chongyang Zhao[1]; [1]Chongqing University

Manual operation dependent on experience and feeling of operators is applied in Pan Steel for vanadium recovery from low V-bearing hot metal by BOF process, which would lead to unstable quality of vanadium slag and semi-steel. On the basis of analyzing extraction vanadium in BOF characteristics, a control model based on neural network with ability of self-adaptive and self-learning is established. The model includes coolant sub-model, oxygen-blown volume sub-model and prediction sub-model. Added coolant and oxygen-blown volume were calculated, and the quality of semi-steel and vanadium slag was taken as control target. Industrial experiment in Pan Steel shows that the calculation is satisfying and the control strategy is effective, which could afford good guidance to the production of vanadium extraction.

10:25 AM
Solidification of EAF Stainless Steel Dust: Bing Peng[1]; Ji Peng[1]; Liyuan Chai[1]; *Di Yu*[1]; [1]Central South University

Electric arc furnace (EAF) stainless steel dust has been classified as a hazardous waste by various government regulatory agencies as it releases heavy metals to environment. The solidification of EAF dust is to stabilize the hazardous components to the amorphous silica-alumina-based clays. The process of solidification is investigated and the softening temperatures of dust and additive clay mixtures are measured for economical thermal treatment. The results indicate that the mixture of dust and local clay with the ratio of 1:1 has the lowest softening temperature 1100°C and it could pass the toxicity characteristics leaching procedure (TCLP) test for the environmental regulatory limits after thermally treated at softening temperature for 15 min. Major phases of thermal solidification product clinker are CaAl2Si2O8, (Fe, Cr)2O3, (Fe, Mg)(Cr, Al)2O4 and Al6Si2O13.

10:40 AM
Study on Cementing Material Making with Electrolytic Manganese Residue: Wang Jia[1]; *Peng Bing*[1]; Chai Li-Yuan[1]; Zhang Qiang[1]; Liu Qin[1]; [1]Central South University

Electrolytic Manganese Residue (EMR) was used as the main material to prepare cementing material activator for the utilization of the residue from electrolytic manganese dioxide (EMD) or electrolytic metallic manganese (EMM) production. The effects of chemical activation, thermal activation and mechanical activation on retarding activity and excitation activity of EMR were investigated according to the setting time and activity index of EMR-slag cementing material. The results showed that the EMR exhibited good activating performance after being ball-milled for 18 min and then treated for 1-2 hours at temperature range of 350-450℃. The optimal properties of cementing material activator were achieved at the weight percent ratio 30 : 3 : 5 of EMR/Ca(OH)2/cement clinker.

10:55 AM
Utilization of BF Ash and BOF Sludge to Produce Burden of Blast Furnace: Xiulan Deng[1]; Tiejun Chun[1]; Jian Pan[1]; [1]Central South University

BF (Blast furnace) ash and BOF (basic oxygen furnace) sludge are solid waste containing ferrous in iron and steel company, and they are not utilized due to the high zinc content. In this paper, the utilization of BF ash containing 26.40%Fe and 5.77%Zn, and BOF sludge containing 56.30%Fe and 2.27%Zn was conducted. The pellets were made by blends of BF ash, BOF sludge and pyrite cinder. The final product pellets, assaying Fetotal 64.23% and 0.016% Zn and compressive strength of 1440N per pellet was obtained under the conditions of reduction temperature at 1300oC for 15min and C/Fe (mass ratio) of 0.5, which can be used the burden for blast furnace.

11:10 AM
Study on the Desulfuration of Pyrite Cinder Pellets: Zhiyong Ruan[1]; Deqing Zhu[1]; Tiejun Chun[1]; Jian Pan[1]; *Zhao Qiang*; [1]Central South University

In this paper, the desulfuration of pyrite cinder pellets was carried out. Phase analysis shows that most sulfur of pyrite cinder exists in the form of elementary sulfur. Compared to roasting stage, most sulfur was removed in preheating stage. 81.25% sulfur was removed and the average SO2 concentration of exhaust gas was 1365ppm when the pellets was preheating at 950℃ for 9 min. The final product, assaying 62.42wt%Fe and 0.02wt% S content at 96.88% desulfuration was achieved under the conditions of preheating at 950℃ for 9 min and roasting at 1200℃ for 15 min, which can be used the burden for blast furnace.

Integrated Desalination and Primary Aluminium Production: *Anders Sorhuus*[1]; Geir Wedde[1]; Dario Breschi[1]; Guillaume Girault[2]; Nolwenn Favel[2]; [1]Alstom; [2]Rio Tinto Alcan

Primary aluminium is produced increasingly in regions where there is a scarce supply of clean and fresh water. A self sustainable, secure supply of fresh water is of strategic importance for aluminum smelters. Desalination plants can be installed in combination with gas-fired power plants, and it is shown that part of the natural gas consumed for production of water in the desalination process can be replaced with waste heat from the aluminium smelter pot gas. Besides, installation of heat exchangers allows a significant downsizing of Gas Treatment Centers as well as improved control of stack fluoride emissions. It is shown that a compact, robust double-effect desalination plant can provide the water required during predicted variations in water consumption and profitably use wasted heat for a typical AP40 smelter. The corresponding calculated cost of water is comparable to the cost of water available commercially.

8:50 AM
Busbar Displacement Study of Aluminum Reduction Cell: *Xiquan Qi*[1]; [1]Northeastern University Engineering and Research Institute, Co., Ltd

With the increasing of cell capacity, busbar length, current load in each branch and the magnetic field intensity around the cell all are increasing consequently, so are the electro-magnetic forces on each busbar and the thermoelectric stress inside the busbar. As a result, big displacement occurs on busbars and even worse, the insulation bricks are crushed by busbar movement. Displacement of busbars leads to deformation of flexes, which will also be detrimental to cell life. With the longest and highest-current branch as an example, busbar displacement and stress status are studied systematically for a large reduction cell.

9:10 AM
Impact of Amperage Creep on Potroom Busbars: Thermal-Mechanical Aspects: *Andre Felipe Schneider*[1]; Daniel Richard[1]; olivier charette[1]; [1]HATCH Ltd.

The mechanical performance of pot-to-pot busbars is intimately linked to the temperature and thermal expansion of conductors. With amperage creep, busbars are typically running hotter than they were at start-up, so that adequate temperature fields for both standard and bypass conditions must be considered to accurately represent the thermal stresses acting over the system. To assist smelters to evaluate the performances of busbars systems under realistic operating conditions, a methodology was developed using ANSYS™-based numerical simulation, where the temperature field obtained from a thermal-electrical model is applied as a load to a thermal-mechanical model. The bolted connections at the shunting-clamping stations, the weld plates and the contact mechanics between bars are taken into account explicitly. A test case based on a demonstration busbar system is presented and the typical impact of line current and selected operational procedures on thermal-mechanical performance and reliability of specific design features is discussed.

9:30 AM
Effective Insulation Control Monitoring System: The CANDI™ Solution for a Safer Production: Anne-Gaëlle Hequet[1]; *Serge Despinasse*[1]; [1]ECL

The key to the chemical reaction necessary to convert alumina to metallic aluminium is the running of an electrical current through the cryolite/alumina mixture. The process requires the use of direct current. In the meantime, various interventions performed by the PTM, electrically connected to the ground,are required on the electrolysis cells to complete the smelting process. Thus, contact with electricity while performing on the potlines may result in hazardous situation and serious injuries for the operator (electrocution due to overvoltage up to 2 000 volts). Hence the importance of insulating electrically the driver's cabin, the tool trolley and the tools themselves to avoid often irreparable situations. To prevent such risks and above all to make the work environment safer, ECL™ designed an efficient device capable of monitoring the insulation level to earth and giving an audible and visual indication of abnormally low insulation values: the CANDI solution.

9:50 AM Break

10:10 AM
Potline Open Circuit Protection: *Laurent Troubat*[1]; Roland Mathevon[1]; Pierre Marcellin[1]; Didier Lamant[1]; Michel Jacon[1]; Dominique Duval[1]; Andy Johnston[1]; [1]Rio Tinto Alcan

A potline open circuit event is a catastrophic danger. It results in a high power arc, which feeds oneself as the DC current is not cut. It can escalate into an explosion, destroying not only the equipment in question but potentially anything within proximity. The consequences can include loss of the potline. To reduce the risk, the potline and the substation must be protected against the danger of open circuit. The protection system settings must be optimised according to the operating conditions (potline current, potline restart after shutdown, pot stopped, anode effects, etc.). It must be well engineered to achieve effective protection so that quick tripping of the rectifying groups occurs when the open circuit is detected, while avoiding an inappropriate potline shutdown. The theoretical aspects of potline opening circuit and the behaviour of rectifying groups are presented. An overview of the protection systems deployed in RTA smelters is shown.

10:30 AM
Maximize Efficiency and Safety of Smelters through Advanced Multipurpose Simulator Solution: Anne-Gaëlle Hequet[1]; *Denis Chapdelaine*[1]; [1]ECL

Modern smelters have made the reduction process efficiency and safety a key issue: produce more, faster in a safer environment. By designing and developing highly technical automated machines, equipment suppliers greatly help and support smelters in their objective. However it must be acknowledged that despite such innovation, human remains at the very heart of any reduction process operation and has a significant impact on it. To avoid production losses, reduce maintenance cost and increase safety reflexes of the crane operators in case of emergency, ECL™ has recently endowed its PTM simulator with some new revolutionary functions. The operator, facing a double screen on which a 3D virtual potroom is generated, will be now equipped with some 3D glasses putting him in a total virtual reality. (Cabin rotation, cranes translations). Well trained, the operator will fully contribute to improve production and increase safety of the smelter.

10:50 AM
Challenges in Using Discrete Logistics as a Management Decision Tool for Aluminium Production: *Maarten Meijer*[1]; Rienk Bijlsma[2]; Martijn Riesenkamp[2]; [1]Hencon; [2]Systems Navigator

Discrete event simulation software has been used in multiple ways for various logistics projects in the Aluminium Industry; as a strategic decision support tool during major investments and upgrades of Aluminium smelters. Although it can predict and simulate operational behaviour of the system before and after the investment, it very often is not considered to be a management tool for operational and or tactical decisions. Since 2007 we used simulation software to make a realistic discrete models of many events involved with Aluminium production and introduced these models to various operational teams to support them in making decisions. In this paper we will describe our experiences and how these models have been used to support both capital investment decisions as well as day to day operational decisions.

8:30 AM
Current Distribution and Lorentz Field Modelling Using Cathode Designs: A Parametric Approach: *Subrat Das*[1]; [1]Deakin University

A mathematical model of magnetohydrodynamic (MHD) effects in an aluminium cell using numerical approximation of a finite element method is presented. The model predicts the current distribution in the cell and calculates Lorentz force from the external magnetic field in molten metal for different size and shape of cathode blocks. The electrical conductivity of the cathode-block and the collector bar is so poor relative to the molten metal that the outer third of the collector bar and cathode, nearest the sidewall of the cell, carries the most of the current load, creating a very uneven current distribution within the cathode. Such distribution has not only an impact on cathode-surface phenomena but also influence the current distribution in metal. The predicted results show that the cathode shapes have significant impact on current distribution in the metal and thereby would have a great relevance to cell stability and energy savings.

8:50 AM
Electromagnetic and MHD Study to Improve Cell Performance of an End-to-End 86 kA Potline: *Amit Gupta*[1]; Manoj Chulliparambil[1]; Sankar Namboothiri[1]; Satheesh Mani[1]; Biswajit Basu[1]; Jinil Janardhanan[2]; [1]Aditya Birla Science & Technology Company Ltd.; [2]Hindalco Industries Ltd.

Electromagnetic forces in the electrolyte and metal pad region of aluminum reduction cells affect the metal/electrolyte flow pattern and hence the cell performance, indicated by current efficiency and specific energy consumption. Numerical simulation has become an effective tool for analyzing such complex physics. In this paper, an electromagnetic and MHD study conducted for an 86 kA end-to-end potline is described. A detailed three-dimensional electromagnetic model was built in commercial ANSYS software package and steady state MHD (velocities and metal heave) in the cell were computed using CFX software. Magnetic field from the model was validated with the plant measurements. Various busbar configurations were analyzed using the developed model. The results show that new magnetic compensation designs effectively improve the magnetic field, the metal flow profile and the metal heave, thereby providing conditions for improving cell performance.

9:10 AM
Study on the Influences of Potline Status on the Magnetic Fields of Aluminum Reduction Cells: *Xiquan Qi*[1]; [1]Northeastern University Engineering and Research Institute, Co., Ltd

The principle of busbar current balance and its criteria are presented. A coupled modeling algorithm of electro-magnetic field of reduction cells has been systematically introduced. With this algorithm, magnetic fields of cells at different location in the potline and under different potline status are computed. It is found that Bx pattern in the cells is generally identical for cells at different locations, while their By and Bz vary both in distribution and in values. With adjacent cell being bypassed cells, US-bypassed cell has bigger adverse influence on the operating cell than that of the DS-bypassed cell. Feed-in-end cells are more stable than those feed-out-end cells. If one cell is bypassed, its influence on non-adjacent operating cells decreases drastically with operating cells standing between. Of all factors on cells stability, Bz pattern and |Bz|ave values play the biggest role.

9:30 AM
Modeling of Interface Wave of Electrolyte/Aluminum Melt in Aluminum Reduction Cell with Novel Cathode Structure: *Baokuan Li*[1]; Fang Wang[1]; Xiaobo Zhang[1]; Naixiang Feng[1]; [1]Northeastern University

A finite element model has been developed is used to examine the electromagnetic field and interface wave of electrolyte/aluminum melt in aluminum reduction cell with the novel cathode structure. Magnetic vector method and edge-based method are used to solve the Maxwell equations. The result shows that the current density distribution in the novel cathode structure aluminum reduction cell becomes more uniform than the traditional cells,weak horizontal current appears on the convex surface, and weakened the longitudinal waves of molten aluminum. The voltage drop of the entirely novel aluminum reduction cell has reduced. Simulated flow field shows that the movement of molten aluminum affected by the electromagnetic force dominates and two reverse eddies in horizontal plane arise in aluminum reduction cell. The velocity and amplitude of molten aluminum wave reduce in the novel cathode structure aluminum reduction cell.

The Use of Vortex Method in the Analysis of Multiphase Flow in Aluminum Reduction Cells: Zhang Hehui[1]; *Zhang Hongliang*[1]; Li Jie[1]; Xu Yujie[1]; Yang Shuai[1]; Lai Yanqing[1]; [1]School of Metallurgical Science and Engineering, Central South University

As the principal character of flow pattern, the vortex distribution plays a dominant role in the flow behavior of aluminum reduction cells, thereby affecting the cell performance. Based on the commercial CFD software CFX12, the methods of vorticity and swirling strength were introduced to analyze vortex structures of the bath and metal phases quantificationally in a 300 kA cell, in which both the influences of electromagnetic forces (EMFs) and gas bubbles were included. Research results prove that, compared with velocity vector distribution and streamline picture, it can provide more flow field information with the above method, which may help to the optimization of alumina feeding points configuration. Vortexes usually occur as reverse symmetrical pairs. The single factor comparative study shows that the EMFs tend to trigger large vortexes near the upstream side, while gas bubbles mainly stir the bath and generate small ones around anodes.

10:30 AM
Anodic Bubble Behavior in Hall-Héroult Cells: *Kristian Etienne Einarsrud*[1]; Stein Tore Johansen[2]; Ingo Eick[3]; [1]Norwegian University of Science and Technology; [2]SINTEF Materials and Chemistry; [3]Hydro Aluminium Deutschland GmbH

A phenomenological model for the creation and transport of anodic gas bubbles in Hall-Héroult cells is presented. Due to the large variation in bubble topology and length scales, a multiscale approach is introduced in which molecular gas is assumed to be formed as supersaturated CO2 in the electrolyte. This paper describes models and constitutive relations that are intended for the simulation of anodic gas bubbles, ranging from the generation of molecular gas species through Faraday's law and subsequent bubble nucleation, to the evolution of macroscopic bubbles by means of a volume of fluid model. The coupling between macro- and micro scales is performed by means of a population balance. The model is applied to a 2D-cross section of a lab scale electrolysis cell, showing that essential properties are well represented by the proposed approach. Finally, the influence of Lorentz forces on the global bubble behaviour is investigated.

10:50 AM
Numerical Investigation of Bubble Dynamics in Aluminium Electrolytic Cells: Kaiyu Zhang[1]; Yuqing Feng[2]; *Phil Schwarz*[2]; Mark Cooksey[2]; Zhaowen Wang[3]; [1]Northeastern University & CSIRO; [2]CSIRO; [3]Northeastern University

Gas generated beneath anodes in aluminium electrolytic cells play an important role for the circulation of the bath, alumina mixing, and heat balance. Those bubbles cause an extra voltage drop, which is largely affected by the amount and shape of the bubbles beneath anodes. Therefore, understanding the dynamic behaviour of bubbles in aluminium electrolytic cells has been a major research focus worldwide in recent decades. This paper presents a numerical investigation of the motion of single bubble beneath an anode and its escaping from the anode edge. Using 2 dimensional geometry of part of a real cell, the motion of different sized bubbles has been simulated. It was found that the bubble size affects bubbling dynamics significantly as is measured by bubble shapes, sliding velocity beneath anodes and bubble induced turbulence. Simulations have been also conducted using an air-water system to check its relevance to the CO2-Cryolite system.

Battery Recycling: Session I

8:35 AM
Economic and Environmental Trade-Offs for Li-Based Battery Recycling: *Gabrielle Gaustad*[1]; Matthew Ganter[1]; Xue Wang[1]; Chelsea Bailey[1]; Callie Babbitt[1]; Brian Landi[1]; [1]Rochester Institute of Technology

Current trends, motivated by fossil fuel dependence and unprecedented GHG emissions, show lithium-ion batteries (LIBs) emerging as a competitive energy storage technology due to higher power and energy densities compared to Pb-acid and Ni-metal hydride chemistries. These trends may be of concern, however, as environmental impacts are not well understood for either the LIB itself, or for the nanoparticles consumed or released during the battery's production, use, or end-of-life. This study combines economic modeling, dynamic material flow analysis, and fundamental material characterization methods in order to quantify some of the economic and environmental trade-offs for LIBs at their end-of-life. As expected, results show that as chemistries transition from Li-Co based cathodes to Li based Fe, Mn, and S cathodes, LIB recovery value decreases dramatically. These initial results aim to inform collection policies being proposed currently as well as enable future deployment of novel recycling techniques.

9:00 AM
Impacts of the Manufacturing and Recycling Stages on Battery Life Cycles: *John Sullivan*[1]; Jennifer Dunn[1]; Michael Barnes[1]; Linda Gaines[1]; [1]Argonne National Laboratory

The life cycle of batteries includes four stages: 1) material production, 2) component manufacture and battery assembly, 3) battery application, and 4) battery end of life. The first two of these stages represent the cradle-to-gate (CTG) components of the battery life cycle. This work provides new information on the battery materials production stage. Further, a detailed analysis is presented on the battery manufacturing stage, where anodes and cathodes are made and assembled with other components into batteries. This new battery production information (energy, carbon dioxide and other emissions) has been derived from suppliers and Argonne's research production line. As recycling doesn't necessarily reduce stage 2 impacts, reliable manufacturing data is especially important, as previous work suggests its magnitude is comparable to material production from virgin materials. The significance of this stage and battery material production will be compared to the overall life cycle of batteries.

9:25 AM
Battery Recycling by Hydrometallurgy: Evaluation of Simultaneous Treatment of Several Cell Systems: *Carlos Nogueira*[1]; Fernanda Margarido[2]; [1]LNEG; [2]IST - Instituto Superior Técnico (TULisbon)

A research work has being carried out aiming at evaluating the possibility of treating several electrochemical systems of spent batteries using the same process, in order to overcome the high costs and difficulties of selective collection and sorting. Zn-MnO_2 systems, representing more than 75% of portable battery market, shall be treated in dedicated processes. The treatment assessment of the other major systems (NiCd, NiMH and Li-ion), having Ni and Co as main metals, by a single hydrometallurgical process, was the aim of the research work here reported. The leaching with sulphuric acid was demonstrated to be adequate for dissolving more than 90% of the metals of interest contained in batteries. The subsequent separation of metals by solvent extraction, using organophosphorous extractants like DEHPA and Cyanex 272, allowed the production of pure solutions of rare earths, cadmium/manganese, cobalt, nickel and lithium, allowing their further recovering.

9:50 AM
Hydrometallurgical Process for Manufacturing of Cathode Active Materials from Spent Lithium Ion Battery Packs in Used Hybrid Electric Vehicless: *Soo-Kyung Kim*[1]; Jeongsoo Sohn[1]; Kang-In Rhee[1]; [1]Korea Institute of Geoscience and Mineral Resources

The physical treatment/chemical treatment for recycling of cathodic active materials from the batteries were performed. The result by physical treatment showed that over 95% ternary cathodic active material was concentrated in -65mesh with 88% Al elimination from the batteries. Through reductive leaching with H2O2 and H2SO4, leaching efficiency of valuable metals with -65mesh powder was over 99% Co, Mn, Ni and Li under the condition of 2M H2SO4, 5 Vol% H2O2, 60°C, 300rpm, 50g/500ml, and 2h. After removing some impurities such as Cu, Al, and Fe the leaching solutions containing Co, Mn, Ni, and Li could be utilized for manufacturing precursor of cathodic active material of Li ion battery. The precursor was manufactured by co-precipitation from the filterate under the condition over pH11, 60°C, 300rpm, 5h. The filterate after co-precipitation was used for Li recovery as a Li2CO3 by addition of Na2CO3 solution under the condition of 60°C, 300rpm, 5h.

10:15 AM Break

10:25 AM
Recycling Yearly Up to 7,000 Tons of Rechargeable Batteries: *Mark Caffarey*[1]; [1]Umicore USA

Umicore started its UHT battery recycling facility May 2011 at its Hoboken, Belgium facility. The Ultra High Temperature process is the only recycling process that combines superior recycling efficiency, low energy usage and low environmental impact with less than 3% of material destined for landfill. Any Li ion and Ni metal hydride battery chemistries can be processed. Recoveries of high value materials are ongoing while recovery of lower value metals (Li,...) and difficult to recover materials (rare earths,..) are being studied. Materials recovered are used in battery or added value concrete applications. A detailed overview of this industrial recycling process will be given.

10:50 AM
The Use of Liquid–Liquid Extraction and Electroplating to Metals Recovery from Spent Batteries: *Kellie Provazi*[1]; Denise Espinosa[1]; Jorge Tenório[1]; [1]University of São Paulo

The purpose of this paper is to study metal separation and recovery from a sample composed of a mixture of the main types of spent household batteries, using liquid–liquid extraction and metals electroplating. The preparation of the solution consisted of: grinding the waste of mixed batteries, reduction and volatile metals elimination using electric furnace and acid leaching. From this solution were studied the liquid–liquid extraction using Cyanex 272 [bis(2,4,4-trimethylpentyl) phosphoric acid] with tributyl phosphate as extracting agent. After study of solvent extraction and stripping has been recover and separate the metallic ions and with electroplating was recovered the manganese, copper, nickel and cobalt in their metallic forms.

11:15 AM
Distribution Logistics and Proper Disposal of Batteries for Downhole Oilfield Operations: *Amit Mohan*[1]; Indranil Roy[1]; David Wang[1]; Ryan Davies[1]; Jack Booker[1]; [1]Schlumberger

Schlumberger is the Oil&Gas Industry leader in introducing new tools & technology to enable oilfield operations through cutting-edge research. Most of the downhole tools used in field operations need some kind of power source to operate. While most of the wireline tools have a power and telemetry cable linking downhole tools to surface control for power, communications and conveyance, almost all other electronically operated downhole tools use batteries as a power source (for example - production logging tools, downhole testing, completions, drilling, slickline, coil tubing etc.). These are qualified for various operating environments including high temperatures and pressures. As Schlumberger operates across 160 countries in thousands of field locations, handling very large volumes of batteries is a mammoth task. This paper will deal with the processes in place within Schlumberger to handle distribution logistics and proper disposal of batteries for downhole oilfield operations in large quantities in a global setup.

11:40 AM Concluding Comments

Biological Materials Science Symposium: Bio-Inspired Materials: Implants and Devices

8:30 AM Keynote
Structural Testing at the Micro and Nano Scales: Breaking Invisible Specimens with Zero Force: *Roberto Ballarini*[1]; [1]University of Minnesota

I will describe the use of microelectromechanical systems (MEMS) platforms to measure the mechanical response of materials and structures at the micro and nano scales. Selected examples include measurements of strength, toughness, high cycle and static fatigue of brittle MEMS materials, the strength, ultimate strain capacity and viscoelasticity of individual collagen fibrils, and the fracture energy of the carbon nanotube-epoxy matrix interface. A brief description of several the theoretical and computational models that were inspired by the experimental observations will also be presented.

9:10 AM
Nanoengineering of Implant Surfaces for Enhanced Biointegration: *Fereydoon Namavar*[1]; Renat Sabirianov[2]; Alexander Rubinstein[1]; Geoffrey Thiele[1]; Laura Koepsell[1]; John Sharp[1]; Roxanna Namavar[1]; Hani Haider[1]; Kevin Garvin[1]; [1]University of Nebraska Medical Center; [2]University of Nebraska - Omaha

By mimicking the nanostructure of the lotus leaf and applying ion beam assisted deposition, we have demonstrated the fabrication of pure cubic ZrO_2 coating with 2-25 nm grain size which is comparable to the protein dimensions. Adhesion and proliferation experiments were performed with a bona fide mesenchymal stromal cells cell line (OMA-AD) on the nano-structured coatings and compared to CoCr, Ti, and HA. Our experimental results indicated that nanoengineered coatings are superior in supporting growth, adhesion, and proliferation. Absorption experiments with fibronectin from human plasma using an ELISA-based technique resulted in higher fibronectin adsorption on nanoengineered surfaces as compared to other conventional orthopaedic materials. These experiments indicated a clear correlation between cell adhesion and fibronectin adhesion. We examined possible mechanisms of the enhanced protein absorption using quantum mechanical force field parameterization of protein-surface interactions and Monte Carlo simulations of the fibronectin fragment (13FN3-14FN3) absorption on designed nanostructured ZrO_2 surfaces.

9:30 AM
New In Vitro and In Vivo Approaches in Evaluating Bioabsorbable Metal Candidates for Stents: Jeremy Goldman[1]; Patrick Bowen[1]; Jesse Gelbaugh[1]; Jessica Rhadigan[1]; Jon Stinson[2]; Heather Getty[2]; *Jaroslaw Drelich*[1]; [1]Michigan Technological University; [2]Boston Scientific Corporation

A series of unconventional approaches are under development at Michigan Technological University which aim to screen candidate materials for use in bioabsorbable stents and reduce the scale of necessary animal studies. Using a novel in vivo approach, metal wires are implanted into the wall of the coronary artery of rodents for several weeks to gauge the host response, measure the severity of in vivo degradation, and characterize the resulting products. An in vitro method is being developed to identify bioabsorbable candidate materials, reproduce the corrosion products formed in vivo, and predict the degradation rate of stents. To accomplish this goal, wires encapsulated in an extracellular matrix are corroded in a cell culture medium. Encapsulation of the wires is necessary to slow down the material degradation process and mimic in vivo conditions. After in vivo and in vitro tests, wires undergo tensile testing to quantify the rate of material degradation.

9:50 AM
Investigation of Structure-Mechanical Property Relationship of Porous Titanium and Titanium Alloys: *Ziya Esen*[1]; Sakir Bor[2]; [1]Cankaya University; [2]Middle East Technical University

In this paper attention has been focused on the deformation characteristics of biomedical titanium and Ti6Al4V alloy foams under compression loading together with their energy absorption capabilities under quasi static conditions. Porous titanium and Ti6Al4V alloy foams were manufactured using powder metallurgy in which magnesium powders were utilized to create porosities via their evaporation. The cold compacted Ti/Ti6Al4V-Mg powder mixtures were slowly heated under high purity argon gas to sintering temperature of 1200oC where all the samples were sintered and the magnesium was eliminated completely by leaving the porosity in the structure. Then, the manufactured titanium and Ti6Al4V alloy foams containing porosities in the range 42-82 vol.% were characterized mechanically under quasi static conditions using compression loads and energy absorption characteristics of foams were characterized using energy efficiency approach. Microscopy studies have been carried out on the cross-sections of the samples using optical and scanning electron microscopes.

Design of Biomaterials – Achieving Targeted Properties and Manufacturability with Topology Optimization: *James Guest*[1]; [1]Johns Hopkins University

This paper will present recent advances in topology optimization for the computational design of material structures, or architectures, that achieve targeted homogenized properties and prescribed constitutive symmetries. While useful in a wide-range of settings, we focus on the application of topology optimization to the design of bone scaffolds. Various surrogates have been proposed in literature for use in the design process to enhance delivery of biologics and enable regeneration, including (for example) thermal conductivity, fluid permeability, and diffusion. Optimal material architectures found considering these objectives will be discussed, as will extensions to including manufacturability and uncertainty into the multi-physics scaffold design formulation.

10:40 AM
Investigation of Sr and Ca Containing Mg Alloys for Biodegradable Implant Applications: Harpreet Brar[1]; *Ida Berglund*[1]; Benjamin Keselowsky[1]; Malisa Sarntinoranont[1]; Michele Manuel[1]; [1]University of Florida

Biocompatibility, mechanical strength and controlled degradation are essential requirements for a material to be used as a biodegradable implant for orthopedic applications. Magnesium (Mg), with its non-toxicity, high specific strength and elastic modulus comparable to bone, is an ideal candidate for such applications. However, the low corrosion resistance and yield strength of pure Mg hinder its possible use as an implant material. In the present study, strontium (Sr) and calcium (Ca) were investigated as prospective alloying elements due to their biocompatibility, strengthening potential, and grain refining properties. The degradation behavior of binary Mg-Sr and ternary Mg-Ca-Sr alloys in simulated body fluid was investigated and an in-vitro cytotoxicity evaluation of the alloys was conducted on osteoblastic cells using the LDH cytotoxicity assay. Furthermore, the effect of alloying additions on the microstructure and mechanical properties was analyzed.

11:00 AM
The Effect of Sr and Ca on Corrosion Behavior of Magnesium as Biodegradable Implant: *Mandana Bornapour*[1]; Mihriban Pekguleryuz[1]; [1]McGill University

Having specific properties such as light weight, similar mechanical properties to that of human bone and non-toxicity, Mg is known as a potential element to serve as biodegradable metallic implant. In this study, we developed particular Mg alloy with controlled degradation rate. The microstructure, surface characteristics and corrosion behavior of Mg with addition of Sr and Ca was investigated by using SEM, X-ray diffraction, XPS, immersion tests and electrochemical experiments. The results of invitro corrosion tests in simulated body fluid (SBF) indicated that the degradation rate of Mg alloys can be adjusted by addition of 0.5-0.7wt% of Sr and Ca. The microstructural observation revealed that the grain boundaries are the prone regions to be degraded in SBF. The formation of hydroxyapatite was demonstrated on the surface of Mg after in-vitro corrosion test. The indirect cytotoxicity test revealed that Mg content 0.5-0.7wt% Sr or Ca did not show any toxicity effect.

11:15 AM
Chemotherapy-Induced Surface Degradation and Thrombogenicity of Intravascular Catheters: A Preliminary In-Vitro Study with Focus on Breast Cancer: Minoo Arzpeima[1]; Annika Rosén[1]; Emma Strömberg[1]; Javier Sanchez[2]; Gunilla Björling[2]; Sigbritt Karlsson[1]; *Ragnhild. E Aune*[3]; Samuel Rotstein[2]; [1]Royal Institute of Technology; [2]Karolinska Institute; [3]Norwegian University of Science and Technology (NTNU)

Vascular Access Devices (VADs) are commonly used for administration of chemotrapeutic drugs in treatment of patients with breast cancer, and are associated with an increased risk for complications i.e. nosocomial infections and thrombosis. In turn, this may subsequently lead to prolonged care, increased patient suffering and health care costs.In order to investigate the degradative effect of the chemotrapeutic drugs on Peripherally Inserted Central Catheter (PICC), chemotrapeutic treatment was step by step simulated in detail during 18 weeks (6 treatments). The inner surface of the catheters was studied after each treatment using different characterisation techniques; Scanning Electron Microscopy (SEM), Atomic Force Microscopy (AFM), and Fourier Transform Infrared Spectroscopy (FT-IR). Moreover, the thrombogenicity of both uncoated and coated catheters was analysed both before and after exposure to the drugs. The results clearly indicate an association, as a function of time, between the observed surface changes and an increased thrombogenicity.

11:30 AM
LASER Powder Deposition of Titanium - Tantalum Alloys Surfaces for Use in Biomedical and Corrosion Resistant Applications: *Jacob Fuerst*[1]; Michael Carter[1]; Dana Medlin[1]; James Sears[1]; [1]South Dakota School of Mines and Technology

Tantalum is commonly used in industry as a cladding in highly corrosive environments. It has also garnished interest in the biomedical community for increased biocompatible and osseointegrative properties compared to other metals. The high cost of tantalum makes it prohibitively expensive to use in bulk. Cladding a tantalum surface to a titanium substrate is inherently difficult because of the small difference between the melting temperature of tantalum, 3017°C, and the boiling point of titanium, 3287°C. LASER Powder Deposition (LPD) is a fusion operation using a Nd:YAG LASER to melt a small volume of substrate into which metal powder is sprayed. This produces a surface layer of tantalum or a tantalum/ titanium alloy depending on the desired properties and the powder deposited. Cell culturing to test the biomedical applications of LPD tantalum alloy surfaces has shown this material to have increased osseoconductive properties compared to other orthopedics titanium alloys.

11:45 AM
In Vivo Osseointegration of Nano-Designed Composite Coatings on Titanium Implants: *Sybille Facca*[1]; Debrupa Lahiri[2]; Florence Fioretti[3]; Nadia Messadeq[4]; Didier Mainard[5]; Nadia Benkirane-Jessel[3]; Arvind Agarwal[2]; [1]FIU ; [2]FIU; [3]INSERM U977; [4]IGBMC; [5]CNRS UMR 7561

This in the first in vivo study of carbon nanotube (CNT) reinforced hydroxyapatite (HA) coating on titanium implants embedded in rodents' bone. Three types of titanium pieces were implanted: uncoated, and with HA and HA-CNT coatings. After one month, implants were retrieved and bone around coated implants was compared using TEM and histological observations. Elastic modulus of new bone was compared with the modulus of HA-CNT/bone interface to understand the mechanical integrity of the implant. No adverse effect or cytotoxicity of CNT addition on bone tissues, and cells was observed. Normal bone growth was observed around HA-CNT coated implants.CNT addition induces higher osseointegration as compared to HA. Our study proved CNTs could be used as reinforcement to plasma sprayed HA coatings for orthopedic applications.

Bulk Metallic Glasses IX: Mechanical and Other Properties

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee

Structure and Relaxation of Zr-Cu-Al Bulk Metallic Glass from Hybrid Reverse Monte Carlo Modeling of Fluctuation Electron Microscopy Data: *Paul Voyles*[1]; Jinwoo Hwang[1]; Zenon Melgarejo[1]; Don Stone[1]; Ilkay Kalay[2]; Matt Kramer[2]; [1]University of Wisconsin, Madison; [2]Iowa State University

We have used hybrid reverse Monte Carlo modeling based on fluctuation electron microscopy (FEM) experimental data and an empirical interatomic potential to determine the structure of $Zr_{50}Cu_{45}Al_5$ bulk metallic glass. In addition to quasi-icosahedral Voronoi polyhedra (VP), we find a significant density of more crystal-like VPs with rectangular and hexagonal faces. Our models also have strong medium-range order, consisting of groups of like VPs. The crystal-like VPs form a three-dimensional structure, while the icosahedral-like VPs form chains. A model refined against only the potential shows primarily quasi-icosahedral VPs, but it shows no agreement with the FEM data. Models refined against data from samples relaxed below the glass transition show a trajectory with increasing annealing from crystal-like VPs, through mixed VPs with some crystal-like and some icosahedral-like character, ending in icosahedral-like VPs. This is the first experimental result showing significant structural evolution with relaxation in a glass.

8:50 AM
Evaluation of Microstructure and Mechanical Behavior of Cu Based Bulk Metallic Glass-Carbon Nanotube Composites: *Jonathan Nguyen*[1]; Troy Topping[1]; Hidemi Kato[2]; Yizhang Zhou[1]; Enrique Lavernia[1]; [1]University of California, Davis; [2]Tohoku University

Cu-Zr and Cu-Zr-Al bulk metallic glasses (BMG) have become a subject of recent interest due to their high strength and enhanced ductility. In this study, wet process dispersion of multi-wall CNT using a zwitterionic surfactant has been used to synthesize CNT reinforced BMG. A fundamental criterion is that the surfactant used must functionalize the CNTs thereby enabling it to attach to metallic powder surfaces. Spark plasma sintering was used to consolidate the BMG composite powders with 0.1 wt% CNT. The microstructural evolution and the interface between the CNT and the BMG matrix were characterized using electron microscopy, DSC and Zeta potential measurement. Compression tests were carried out to evaluate the mechanical behavior of consolidated bulk samples. Particular emphasis has been placed on establishing the structural and mechanical interaction at the interface between CNT and the BMG matrix.

9:00 AM Invited
Oxidation Resistance of Zr- and Ti- Based Bulk Metallic Glasses in the Supercooled Liquid Region: Ka Ram Lim[1]; Sung Hyun Park[1]; Min Young Na[1]; Se Yun Kim[2]; Sang Soo Jee[2]; Eun-Sung Lee[2]; Won Tae Kim[3]; *Do Hyang Kim*[1]; [1]Yonsei University; [2]Samsung Advanced Institute of Technology; [3]Cheongju University

Recently, it has been shown that the bulk metallic glasses (BMGs) can be successfully applied for fuel cell catalyst or Ag paste binder for screen printing Si solar cell due to high thermo-plasticity and good wetting characteristics in the supercooled liquid (SCL) state. Therefore, it is highly required that the BMGs should have a good oxidation resistance particularly in the SCL state. In the present study oxidation resistance of Zr-, and Ti-based BMGs in the supercooled liquid region has been investigated. The results show that the oxidation resistance of SCL state widely varies with alloy chemistry of BMGs. For example, the oxidation resistance of Cu45Zr45Al8Be2 in the SCL state is much higher than that of Cu46Zr46Al8, although the oxidation rates in the crystallized Cu46Zr46Al8 and Cu45Zr45Al8Be2 are almost same. Detailed oxidation mechanism has been unveiled by analyzing oxide layer cross section prepared by FIB technique.

9:20 AM
Study of Plastic Deformation in Structural Modified Zr-Cu-Al Metallic Glasses by Broadband Nanoindentation Creep: *Zenon Melgarejo*[1]; Jinwoo Hwang[1]; Chuan Zhang[1]; Joseph Jakes[2]; Eren Kalay[3]; Matt Kramer[3]; Paul Voyles[1]; Donald Stone[1]; [1]University of Wisconsin-Madison; [2]Performance Enhanced Biopolymers, United States Forest Service, Forest Products Laboratory; [3]Iowa State University

Plastic deformation models in metallic glasses (MGs) theorize shear transformation zones (STZs) as the elementary units of plastic deformation. Activation energy for shear of an STZ depends on stress. Activation parameters should vary systematically with atomic structure including short and medium range order and should be sensitive to composition, quenching rate, and annealing. In this study we employ broadband nanoindentation creep (BNC), to measure hardness across 5-6 decades of deformation rate and characterize activation volume as a function of the stress in Zr-based MGs. Additionally, BNC enables to assess the form of the activation energy function and estimate STZ size. Bulk and ribbon Zr54Cu38Al8 (Tg = 676K) and Zr50Cu45Al5 (Tg = 667K) are studied. Annealing treatments are performed in a differential scanning calorimeter (DSC) at 573°K and at slightly above the glass transition temperature. Effects of annealing treatments on hardness, activation parameters and STZ sizes for these alloys are reported.

9:30 AM Invited

Potential Energy Landscape of Glasses: Distributions of Activation Energies, Volumes and Attempt Frequencies: *David Rodney*[1]; Pawel Koziatek[1]; Peter Derlet[2]; Jean-Louis Barrat[3]; [1]INP Grenoble; [2]Paul Scherrer Institut; [3]Université Jospeh Fourier

Molecular dynamics is a powerful tool to simulate the atomic-scale processes that occur in bulk metallic glasses either at rest during aging or under plastic deformation. This technique is however limited to short-time dynamics and does not give access to the slow thermally-activated events that progressively dominate the glass dynamics when the temperature and/or the strain rate are decreased. We report here results obtained with a saddle-point search method, the Activation-Relaxation Technique, used to determine thermally-activated paths in glasses. From the paths, we determined the distributions of activation energies, activation volumes and attempt frequencies, the three parameters that characterize thermally-activated processes. We studied in particular the influence by the history and level of relaxation of the glass on the above distributions, with a special attention paid to the effect of a plastic deformation.

Weibull Analysis of Fracture Strength for Zr_{55} Ti_2 Co_{28} Al_{15} Bulk Metallic Glass: Tension-Compression Asymmetry and Porosity Effect: *Jian Xu*[1]; Hui-li Gao[1]; Yong Shen[1]; [1]Institute of Metal Research, Chinese Academy of Sciences

In this work, two- and three-parameter Weibull statistics were used for analyzing the variability of fracture strength for Zr_{55} Ti_2 Co_{28} Al_{15} bulk metallic glass (BMG), both in compression and tension testing. In contrast to the compression in which the specimens fail via the massive shear-off, however, failure mode in tension for the as-cast BMG is flaw-controlled crack opening due to the presence of cast defects. For the BMG rods of 6 mm in diameter, three-parameter Weibull modulus m_{3p} and threshold stress is 3.4 and 1780 MPa, respectively. However, tensile fracture strength of the BMGs manifests a large variability. The specimen failure at different stress is associated with two types of defects: large pores on/near the surface of specimens and small internal pores. Using bimodal and three-parameter Weibull analysis, Weibull modulus m_1 and threshold stress σ_{u1} at lower stress level is 1.8 and 250 MPa, respectively.

10:25 AM

Quantitative Microstructural Characterization of Metallic Glass/Crystalline Composites: *Nicholas Hutchinson*[1]; Katharine Flores[1]; [1]The Ohio State University

Bulk metallic glasses are limited in application by their propensity for highly localized deformation with little ductility when loaded in tension. In order to control this localization, a number of Ti-Zr metallic glass/crystalline composites with highly interconnected microstructures have been created. The effectiveness of the crystalline reinforcement phase on improving toughness and ductility depends upon the transfer of deformation across the glass-crystalline interface, which depends on both composition and the local microstructure. In the present work, we characterize two composite systems with vastly different mechanical properties. Three-dimensional microstructural features are characterized using serial sectioning techniques. In addition to critical average length scales, such as reinforcement size and spacing, this technique enables local, quantitative descriptions of the interface, such as its principal curvatures. Finite element analyses of models based on the 3D microstructure are used to measure the strain distribution in the microstructure under tensile loading for comparison with experimental measurements.

10:35 AM Invited

Micromechanisms of a Dendrite/Zr-Based Bulk-Metallic-Glass Composite Subjected to Plastic Deformation: E-Wen Huang[1]; Junwei Qiao[2]; Bartlomiej Winiarski[3]; Richard Moat[3]; Andrew Chuang[4]; Mario Scheel[5]; Marco Michiel[5]; Philip Withers[3]; *Yu-Lih Huang*[1]; Yong Zhang[6]; Peter Liaw[4]; [1]National Central University, Taiwan; [2]Taiyuan University of Technology, Taiyuan, China.; [3]University of Manchester, Manchester, United Kingdom; [4]The University of Tennessee; [5]European Synchrotron Radiation Facility Beamline ID15; [6]University of Science and Technology Beijing

In the current study, a Zr-based BMG that contains a dendritic crystalline phase performs remarkably with a large plastic strain. The plastic-deformation micromechanisms of the dendrite/Zr-based bulk-metallic-glass-matrix composite (BMGMC) are revealed. A three-dimensional (3-D) tomography experiment was carried out using the European Synchrotron Radiation Facility (ESRF). The correlating successive images qualitatively indicate the load-sharing micromechanisms. Meanwhile, we simultaneously measured the Bragg peaks with in-situ synchrotron x-ray. During loading-unloading cycles, there is asymmetric Bragg-peak evolution subjected to different levels of deformation. The in-situ peak profile analyses suggest that there is asymmetric load sharing between the amorphous matrix and the crystalline dendrites. The relationship between the microstructures and mechanical properties of the BMGMC materials is summarized. PKL and AC appreciate the support of NSF in the Division of CMMI under CMMI-0900271 and CMMI-1100080, and the Materials World Network Program, under DMR-0909037. EWH and YLH is grateful for the support by NSC-100-2221-E-008-041 Program.

Load Relaxation Behavior Of Fe-Based Metallic Glass Supercooled Liquid: *Rui Yamada*[1]; Noriharu Yodoshi[1]; Akira Kawasaki[1]; [1]Tohoku University

The load relaxation behavior within the supercooled liquid region of Fe-based metallic glass [(Fe0.5Co0.5)0.75Si0.05B0.2]96Nb4 was investigated. A spherical particle of the metallic glass with a diameter of about 500 µm was uniaxially compressed. A crosshead was kept constant at a certain strain level and the load relaxation was then recorded as a function of time. The relaxation time was determined as the normalized load f/f0 reaching 1/e. A micro-compressive test was conducted at various crosshead speeds for various temperatures in the supercooled liquid region. Our study has revealed that the relaxation behavior can be well fitted by the Kohlrausch-Williams-Watts (KWW) relation. The temperature dependence of the relaxation time was described by an Arrhenius relation and the corresponding apparent activation energy was found to be anomaly high. The high value of activation energy might suggest the presence of a co-operative movement of a large number of atoms during the relaxation.

Tensile Micromechanism Crossover for Bulk-Metallic-Glass-Matrix Composites: From Working Hardening to Softening: *Junwei Qiao*[1]; A.C. Sun[2]; E.W. Huang[3]; Y. Zhang[4]; P.K. Liaw[5]; C.P. Chuang[5]; [1]Taiyuan University of Technology; [2]Yuan Ze University; [3]National Central University; [4]University of Science and Technology Beijing; [5]The University of Tennessee

A Ti-based bulk-metallic-glass-matrix composite (BMGMC) with a homogeneous distribution of dendrites and with a composition of Ti46Zr20V12Cu5Be17 is characterized by a high tensile strength of ~1,640 MPa and a large tensile strain of ~ 15.5 % at room temperature. After tension, the fragmentation of dendrites is responsible for the distinguished tensile ductility. The subdivisions within the interior of dendrites are separated by the shear bands and dense dislocation walls, and the local separation among dendrites under modes I and II prevails. Theoretical analyses reveal that the constitutive relations: the elastic-elastic, elastic-plastic, and plastic-plastic stages of the dual-phase BMGMCs, generally correspond to deformation stages: (1) elastic, (2) working hardening, and

(3) softening, respectively. The capacity of the work-hardening behavior is highly dependent on the large plastic deformation of dendrites and high yielding strength of glass matrix. The present study provides a fundamental basis for designing work-hardening dual-phase BMGMCs exhibiting remarkably homogeneous deformation.

11:25 AM
Evaluations of Physical and Optical Properties of Metallic Glass Patterns Formed in Micro/Nano Scales: *Y. C. Chen*[1]; S. Song[2]; T.R. Tsai[2]; J. S. C. Jang[3]; Y. M. Chen[1]; S. E. Lee[1]; Jinn P. Chu[1]; [1]National Taiwan University of Science and Technology; [2]National Taiwan Ocean University; [3]National Central University

Metallic glasses (MGs) exhibit viscous flow at high temperatures in the supercooled liquid region; thus they can be used to produce devices via micro-/nano-imprinting and a candidate for molding material because of its high strength, hardness and elastic limit. The simplified fabrication process of imprinting mold prepared with BMG is achievable when comparing to the conventional lithography and patterning technique. In this study, we demonstrate that micro-/nano-patterns of Pd-based BMG can be imprinted from a mold in air. We further used the patterned BMG as a mold to replica patterns on PDMS, a commonly used polymer for precision patterns. The physical and optical properties of the BMGs and PDMS parts formed in micro/nano scales are evaluated and the evaluation results are discussed. The obtained results suggest that the BMG is a suitable material for micro-/nano imprinting, and is also a good mold material for imprinting.

Effect of Structure on the Devitrification Pathways in Al-Tb System: *Matthew Kramer*[1]; Y. Kalay[2]; Paul Voyles[3]; Hwang Jinwoo[3]; Ryan Ott[4]; Matt Besser[4]; Ying Zhang[4]; YaQiao Wu[4]; [1]Iowa State University; [2]Middle East Technical University; [3]University of Wisconsin, Madison; [4]Ames Laboratory

We compare the glassy state of a rapidly solidified Al90Tb10 alloy to that of a magnetron sputtered film. To study the as-deposited state, a 70 nm thick film deposited simultaneously on a thin carbon substrate and an array of thin Si tip for TEM and atom probe tomography (APT). Electron and X-ray diffraction of the vapor deposited films are very similar to the melt spun alloys with thickness of 25-30 µm. The thermal analysis shows a very different devitrification pathways between the melt spun and sputtered films. High resolution TEM and APT results show Al-rich and Al-depleted regions within the melt spun alloys. A network structure of Tb-rich regions divides the matrix into ~ 1-2 nm isolated Al-rich clusters. Preliminary TEM and APT of the thin films suggest that the high cooling rate of sputtered films suppress the formation of the nm clustering resulting in a different pathway for devitrification.

8:50 AM
Thermomechanical Joining of Bulk Metallic Glass Composites: *Scott Roberts*[1]; Douglas Hofmann[2]; William Johnson[1]; [1]California Institute of Technology; [2]NASA - JPL

Bulk metallic glasses (BMG) and bulk metallic glass matrix composites (BMGMC) are cutting edge materials with the potential for high performance structural applications. Crystallization and embrittlement of these materials when heated limits their ability to be welded effectively. Thus, other joining techniques that preserve the high strength and amorphous nature of BMGs and BMGMCs are required. This presentation introduces an improved thermomechanical joining strategy for assembling and welding BMGMC components. Tension test results demonstrating that the strength of the parent glass can be obtained in the weld region and samples of several monolithic cellular structures assembled through this process will be exhibited.

9:00 AM Invited
Dynamics of Shear Banding in Bulk Metallic Glasses: *Jörg Löffler*[1]; David Klaumünzer[1]; Robert Maass[1]; [1]ETH Zurich

New insights into the mechanism of shear banding in bulk metallic glasses can be gained by combining time-resolved compression tests with in-situ acoustic emission monitoring. The load and displacement data using high acquisition rates allow for a characterization of the shear-band propagation, which is found to be thermally activated and in the mm/s range at room temperature. In addition the propagation follows an intermittent, stick-slip process, which is also known across macroscopic underlying length scales ranging from granular systems to tectonic faults. We are able to attribute the acoustic emission signal, which reflects the moment of shear-band initiation, to a mechanism of structural dilatation by inferring a model picture from stick-slip in granular media. The critical volume change associated with this shear-band initiation is evaluated to be a few percent only, which is the typical excess free volume found in the undercooled liquid region near the glass transition temperature.

9:20 AM
Thermodynamics of Isolated Bi-Atomic Clusters: *Garth Wilks*[1]; Jose Reveles[2]; Daniel Miracle[1]; Shiv Khanna[2]; [1]Air Force Research Laboratory; [2]Virginia Commonwealth University

Recent efforts have confirmed that atomic clusters with specific coordination and mixed occupancy of species are the fundamental structural units of nearly all metallic glasses. In this work, a quasi-chemical approach is used to determine the total energy of each possible bi-atomic configuration in a 12-fold coordinated (icosahedral) cluster containing Cu and Zr. This defines a configurational density of states from which the enthalpy, entropy, and free energy of Cu-Zr and other such isolated clusters can be determined via a statistical-mechanics-type analysis. Results of this analysis are contrasted with a parallel approach based on ab initio techniques to determine the total energy of each Cu-Zr cluster in the same ensemble configuration space. These results are then compared with known data to assess the efficacy of using such an analysis of bi-atomic clusters as a proxy for the thermodynamic properties of Cu-Zr-based metallic glasses.

Primary Transformation Kinetics and Mechanical Properties of Zr-Al-Ni-Cu-Based Metallic Glass in Various Relaxation States: *Junji Saida*[1]; Albertus Setyawan[1]; [1]Tohoku University

It is well known that the relaxation state of glassy structure correlates to the structure, transformation behavior, mechanical and magnetic properties of metallic glasses. The authors can prepare the primary quasicrystal (QC)-forming Zr65Al7.5Ni10Cu12.5Pd5 bulk metallic glasses (BMGs) in various relaxation states under different cooling rates. The grain growth rate of QC at the crystallization temperature is approximately 1×10-9 m/s in less relaxed (i.e. higher cooling rate) BMGs and it increases approximately twice as large in relaxed (i.e. lower cooling rate) BMGs. The homogeneous nucleation rate of the less relaxed samples is 5×1019 – 1×1020 /m3s, which is five to ten times higher than those in the relaxed BMGs. The compressive plasticity is also lost with the relaxation. We conclude that the relaxation state has a marked effect on properties of glassy alloys. The results also provide useful information on the application as well as structural control of BMGs.

9:50 AM
Ion Irradiation Induced Nanocrystallization of Metallic Glasses: *Lin Shao*[1]; [1]Texas A&M University

The effect of gas implantation in metallic glass was investigated for its application in radiation environments. We have shown that upon high fluence helium ion irradiation, metallic glass Cu50Zr45Ti5 becomes highly porous at the depth of helium projected range, featured by the formation of a tunnel like structure and self-linkage of nanometer size gas bubbles. Furthermore, the irradiation leads to randomly distributed nanometer size CuxZry crystals. The finding evidences that He-filled bubbles have attractive interactions and expose considerable mobility. The bubble movement was believed to be assisted by ballistic collisions. A multiscale modeling by combining Monte Carlo simulation and finite element analysis has been carried out to simulate thermal spike quenching upon ion irradiation. We have found that the nanocrystal formation is not induced by localized phase transition upon ion hitting, since the heating quenching is faster than the critical cooling rate required for metallic glass formation.

Pressure-Induced Phase Transitions in Metallic Glasses: *Jianzhong Jiang*[1]; [1]University of Tennessee

The nature of amorphous-to-amorphous transition induced by pressure has been a topic of considerable research activities in several directional substances, e.g., ice, silicon, silica, and carbon. These structural polyamorphic transitions from a low-density amorphous (LDA) state to high-density amorphous (HDA) state often result from an increase in atomic coordination. Metallic glasses have many unique properties which have put these materials at the cutting edge of materials research. However, their disordered structure and electronic behavior are far less understood than other disordered amorphous materials such as network-forming glasses. Such coordination increase, and thus polyamorphism, was thought to be impossible in nondirectional, densely-packed metallic glasses that already have the maximum coordination number (12-14) of random nearest neighbors. In this talk, we review recent progress of phase transitions in Ce-containing metallic glasses. The origin for the transitions will be addressed.

10:35 AM
Crystallization Kinetics of Ca-Based Bulk Metallic Glasses: *Lei Hu*[1]; Feng Ye[1]; [1]University of Science and Technology Beijing

Several Ca-based bulk metallic glasses (BMGs) with diameter of 7 mm were fabricated by unidirectional quenching into water-cooled Ga-In-Sn liquid alloy. Thermal stability and crystallization kinetics have been investigated by differential scanning calorimeter (DSC). For Ca65Mg15Zn20, the kinetics studies show that glass transition as well as crystallization behaves in a typically kinetic nature with Kauzmann temperature Tk about 267K and activation energies of Eg=126 kJ/mol and Ex=116 kJ/mol for glass transition and crystallization, respectively. The unusual phenomenon that Eg is close to Ex was discussed in this paper. The liquid fragility of Ca-based BMGs was studied by Vogel–Fulcher–Tammann (VFT) equation. The large fragility parameter D* comparable to SiO2 suggests the strong liquid behavior, which is one of the reasons for their excellent glass-forming ability (GFA). Furthermore, the glass transition temperature, crystallization temperature and their apparent activation energy are markedly affected by preannealing induced relaxation.

10:45 AM Invited
Effects of Alloying On the Glass Forming Ability and Mechanical Properties of Ti-Based Bulk Metallic Glasses: *Ke-Fu Yao*[1]; Pan Gong[1]; [1]Tsinghua University

Ti-based bulk metallic glasses are very attractive due to their low density, high strength, good anti-corrosion properties, low cost, and so on. However, compared with other alloy systems, the glass-forming ability (GFA) of Ti-based BMGs is relatively small. According to the reported results, the critical size of most T-based BMGs is smaller than 5 mm. Then improving the GFA of Ti-based BMGs, together with enhancing their mechanical properties, is necessary and important for their application. In present work, the effects of alloying elements on the glass-forming ability and mechanical properties of Ti-Zr-Be glassy alloys have been studied. It has been found that the glass forming-ability and mechanical property of the Ti-Zr-Be alloys could be significantly improved by alloying methods. Some of them exhibit large supercooled liquid temperature range □T, large critical size, and good mechanical properties. The related mechanism has been discussed.

11:05 AM
Study on Fracture Strength Reliability of Mg-Zn-Ca Bulk Metallic Glasses: *Junhua You*[1]; [1]Shenyang University of Technology

Mg70-xZn25+xCa5(x =1,2,3,4) amorphous alloys with a diameter of 2 mm were fabricated by cooper mold casting method. The microstructures,phase constituents,thermal and mechanical properties were investigated using scanning electron microscopy (SEM),x-ray diffractometer (XRD),differential scanning calorimentry (DSC) and universal electronic material testing machine,respectively. The results show that the crystallization processes consist of 3 to 4 steps for these bulk metallic glasses. The first onset crystallization temperature increases with Mg content. Meanwhile,the high strength and certain plastic strain can be attained for these amorphous alloys. Weibull statistic analysis shows that there exists different fracture strength reliability for the investigated alloys. The alloys with vein pattern fracture surfaces have higher Weibull modulus,which is corresponding to better fracture strength reliability.

Tensile Fracture Criterion of Metallic Glasses: *Zhefeng Zhang*[1]; R. T. Qu[1]; [1]Institute of Metal Research

We find that the classical failure criteria, i.e. maximum normal stress criterion, Tresca criterion, Mohr-Coulomb criterion and von Mises criterion, cannot satisfactorily explain the tensile fracture behavior of the bulk metallic glass (BMG) materials. For a better description, we propose an ellipse criterion as a new failure criterion to unify the four classical criteria above. In order to distinguish the normal stress effect, the Mohr-Coulomb criterion (M-C) and the Ellipse criterion are further compared and the normal stresses acting on the tensile fracture planes were controlled and varied in a wide range by introducing inclined notches with different inclination angles to a series of Zr-based MG specimens. The experimental results reveal that the Ellipse criterion gives a better prediction than the M-C criterion for the tensile fracture behaviors of the investigated Zr-based MG in a wide normal stress range.

11:35 AM
The Deformation Modes and Universal Scaling Properties in Metallic Glasses: *Pengyang Zhao*[1]; Ju Li[2]; Yunzhi Wang[1]; [1]The Ohio State University; [2]Massachusetts Institute of Technology

Using a mesoscale model we study the deformation modes of metallic glasses. The effect of strain-induced softening on promoting the shear band is demonstrated in both 2D and 3D computer simulations. The role of free surface is also investigated to compare simulation results with experiments on deformation of nanopillars. In particular, the mechanical and structural heterogeneities near the free surface are introduced to study their effects on the initiation of shear bands. Furthermore, statistical analysis is performed and a universal scaling relationship is found in the distribution of local plastic avalanches. By reversing the softening sign, i.e. designing a "work-hardening" metallic glass, the same scaling relationship persists, but with a different scaling exponent. These distinct exponents could be employed to distinguish different deformation modes.

11:45 AM Invited
Evolution of the Mechanical, Magnetic and Anti-Corrosion Behavior of Fe-Co-B-Si-Nb Bulk Metallic Glass during Thermally-Induced Devitrification: Jordina Fornell[1]; Sergio González[1]; Emma Rossinyol[1]; Eva Pellicer[1]; Santiago Suriñach[1]; Dimitri Louzguine[1]; Akihisa Inoue[1]; Jordi Sort[1]; Josep Nogués[1]; *Maria D Baró*[1]; [1]Universitat Autònoma de Barcelona

$Fe_{36}Co_{36}B_{19.2}Si_{4.8}Nb_4$ bulk glassy rods with 2 mm in diameter were manufactured by copper mould casting. The effects of annealing treatments on the microstructure, mechanical, magnetic and anticorrosion properties of this alloy are investigated. Annealing below the glass transition temperature causes the formation of small atomic clusters showing a pseudo-tenfold symmetry quasicrystal-like structure with close relationship to the $Fe_{23}B_6$ phase. This phase is actually the first to crystallize upon annealing, although two further crystallization events occur at higher temperatures. The as-cast alloy exhibits ultra-high hardness (> 14 GPa), high Young's modulus (> 200 GPa) and good wear resistance. These properties are further enhanced after thermal treatments. In turn, the coercivity of the as-cast alloy also increases after thermally-induced devitrification. Electrochemical measurements show that both the as-cast and annealed specimens exhibit good corrosion resistance. The possible mechanisms responsible for these annealing-induced changes in the behavior of the Fe-based metallic glass are discussed.

12:05 PM
Fabrication and Mechanical Properties of Melt-Extracted Fe-Based Amorphous Wires: *Weibing Liao*[1]; Yong Zhang[1]; [1]University of Science and Technology Beijing

Metallic glasses often show good mechanical and physical properties as a consequence of their random atomic packing. However, as a new kind of potential engineering material, metallic glasses have proposed new requirements to traditional processing methods. In current study, the Fe74.5Cr3.5Si10B12 amorphous wires at micro scales with a smooth surface and negligible fluctuation in diameter were prepared by the melt-extraction method. The mechanical properties were evaluated by carrying out tensile and bending tests, and their reliability was estimated using Weibull analysis. High bending ductility implies the ability of the wire to bend through 180° without fracture.

CFD Modeling and Simulation in Materials Processing: Modeling of Steelmaking Processes

Transport and Entrapment of Particles in Steel Continuous Casting: *Brian Thomas*[1]; Quan Yuan[2]; Rui Liu[1]; Sana Mahmood[1]; Rajneesh Chaudhary[1]; [1]University of Illinois at Urbana-Champaign; [2]Dow Chemical Company

A particle-entrapment model based on local force balances has been developed, implemented into computational models of turbulent fluid flow, and applied to simulate the entrapment of slag inclusions and bubbles during the continuous casting of steel slabs. Turbulent flow of molten steel is computed in the nozzle and mold using transient CFD models. Next, the transport and capture of over 30,000 particles are simulated using a Lagrangian approach. Particles touching the dendritic interface may be pushed away, dragged away by the transverse flow, or captured into the solidifying shell according to the results of a local balance of ten different forces. This criterion was validated by reproducing experimental results in two different systems. Finally, the model is applied to predict the entrapment distributions of different sized particles in a typical slab caster. Although more large particles are safely removed than small ones, the capture rate as defects is still high.

9:00 AM Invited
Mathematical Modeling of a Compressible Oxygen Jet Interacting with a Free Surface in a Basic Oxygen Furnace for Steel Production: *Koulis Pericleous*[1]; Bruno Lebon[2]; Georgi Djambazov[2]; Mayur Patel[2]; [1]University of Greenwich; [2]University of Greenwich

High speed compressible jets are used in a number of steel-making applications. In the case of the BOF, a compressible oxygen jet reacts with a carbon-rich iron bath to reduce carbon levels and produce steel. The intensity of the process is governed by the speed of the jet and depression created in the metal and slag free surface. This is a difficult CFD problem, since there are compressible and incompressible regions in the flow domain, which need to be handled differently in a FV pressure-correction scheme. Also, standard turbulence models do not account for compressibility, or the large difference in density between the cold oxygen jet and the hot reacting surround. Corrections are introduced to the k-γ turbulence model to remedy this deficiency and the results validated against experimental data. The compressible/incompressible boundary is handled through a transition region at the free surface, based on Mach number.

9:25 AM
CFD Model for Prediction of Liquid Steel Temperature in Ladle during Steel Making and Casting: *Anurag Tripathi*[1]; J.K. Saha[1]; J.B. Singh[1]; S.K. Ajmani[1]; [1]Tata Steel Ltd

The quality of steel is a major concern in the metallurgical industry. The control of liquid steel temperature can enhance the level of cleanliness in steel. Ladle is one of the major vessels used to transfer liquid steel between different stations. The heat transfer phenomenon taking place in this vessel needs to be monitored for controlling the liquid steel temperature. A CFD model was developed for prediction of liquid steel temperature during complete process cycle of ladles in direct heats. The model was validated with liquid steel temperature measured at on-line purging station and tundish during teeming from one of the actual steel plant. The accuracy of model was 96 %. The results obtained show insignificant effect of slag thickness, tapping temperature and ladle life on liquid steel temperature in the ladle. However, the importance of initial refractory temperature was noticed. The CFD model developed in present work can generate the thermal history of liquid steel and refractory walls of any ladle at any stage.

9:45 AM
Multiphase Flow in a Steelmaking Converter Using an Unconventional Lance: *Miguel Barron*[1]; Isaias Hilerio[1]; Antonio de Ita[1]; [1]Universidad Autonoma Metropolitana Azcapotzalco

The influence of an unconventional lance on the multiphase fluid flow in a steelmaking converter is studied in this work by means of CFD simulations. The lance has four peripheral supersonic nozzles and a vertical central nozzle. The oxygen flow in the central nozzle is considered independent from the main oxygen supply. Transient two-dimensional numerical simulations were carried out considering just molten steel and gaseous oxygen as the existing phases. Numerical results show that bath agitation and droplet generation are enhanced as a result of the central nozzle. However, the performance of the unconventional lance strongly depends on the distance of the lance tip to the molten steel surface and the velocity of the oxygen jet.

10:05 AM Break

10:25 AM
Fluid Flow and Inclusion Removal in Multi-Strand Tundish with Nozzle Blockage: *Pradeep Jha*[1]; Sabin Mishra[1]; Satish Sharma[1]; Satish Ajmani[2]; Manas Mahapatra[1]; [1]IIT Roorkee; [2]Tata Steel

Due to mechanical/ electrical failure in the C.C. line or inadequate availability of molten steel from coming ladle, sometimes one/two outlets of a multi-strand tundish in continuous casting unit is closed. Closing any of the outlets affects the flow distribution inside the tundish which in turn governs the quality of steel coming out. Hence it is important to study which of the outlets should be closed to have proper results in terms of flow behavior and inclusion removal inside the tundish. Present study aims at finding the effect of closing one or two outlets on flow behavior and inclusion removal in a multi strand tundish. It was found that closing the near outlet (outlet near to the inlet) increases the inclusion removal tendency than closing the other two outlets in a six-strand billet caster tundish (only three outlets are considered because of symmetry).

10:45 AM
CFD Modeling of Fluid Flow Behavior and Bath Surface Deformation in LD Converter: *Tarun Kundu*[1]; [1]IIT Kharagpur

Concrete understanding of fluid dynamics properties inside basic oxygen furnace (LD converter) and hot-metal surface deformation by impinging oxygen jet is important for optimization of reaction kinetics and maximization of productivity and refractory lining life. In this study various k-γ turbulence models and volume of fluid (VOF) method have been used to model fluid flow and interaction of impinging oxygen jet with hot metal for an industrial scale top blown LD converter. RNG, standard and realizable k-γ turbulence models are used to study velocity magnitude, stream function, turbulence intensity profiles. Turbulence kinetic energy, turbulence eddy dissipation, velocity magnitude and probable mixing time have been calculated in three locations inside the converter. The average rate of oxygen jet penetration, location of vortex formation, centre line and superficial velocity of impinging oxygen jet, probability of emulsification are studied by VOF method. These studies provide better understanding of phenomena occurring inside LD converter.

11:05 AM
Effect of Thermal Buoyancy Force on the Flow, Temperature Distribution and Residence Time Distribution of Molten Steel in the Slab Casting Tundish: *Haibo Sun*[1]; Bo Yan[1]; Jiaquan Zhang[1]; [1]State Key Laboratory of Advanced Metallurgy, University of Science and Technology Beijing

Based on the validation of steady-state isothermal mathematical model by a 0.4-scale water model for the single-strand slab casting tundish, the effect of varying pouring temperature on the flow, temperature field, and residence time distribution(RTD) of the liquid steel was studied by a transient hydrodynamic model. Due to the decreasing temperature of ladle stream over a casting period of 50 min, the direction of vortex flow at the downstream side of dam changes to clockwise from the anticlockwise at 4 min after the new teeming, and reverts to anticlockwise direction again at 43 min. Meanwhile, the melt flow state in the hole of the dam is also varying with time. For conventional isothermal water modeling, the RTD parameters obtained are much different as compared with the non-isothermal ones. For the flow control devices(FCD) design, however, the same optimal scheme can be concluded from the point of view of isothermal modeling.

11:25 AM
Time Zone Analysis of F-Curve for Intermixing during Ladle Change-Over: Pradeep Jha[1]; *Suman Kant*[1]; Pradeep Kumar[1]; Anand Kumar[1]; [1]IIT Roorkee

It has been a major challenge to reduce the intermixed grade formation during ladle change-over operation in continuous casting process of tundish steelmaking. The F-curve generated by step input of the tracer (new grade steel) tells about the intermixed grade amount for different grade specifications. While use of flow modifiers is beneficial in reducing the intermixed grade because of the change in slope (in different time zones) and position of the F-curve due to their placement at tundish bottom. Present study aims at investigating the role of dam placed before the outlet in a multi-strand tundish with reference to the slope behavior of F-curve in different time zones during the teeming operation plays an important role in determining the intermixed amount.

Thermal Properties of Polyester Composites Incorporated with Coir Fiber: *Helvio Santafé Júnior*[1]; Noan Simonassi[1]; Sérgio Monteiro[1]; [1]Universidade Estadual do Norte Fluminense-Darcy Ribeiro

The fiber extracted from the husk of coconut fruit, known as coir fiber, has been extensively investigated as a second phase incorporation into polymer composites. However limited attention has been given to the effect of the temperature on the thermal stability of coir fiber reinforced composites. This work investigated the thermal properties of polyester matrix composites incorporated with coir fiber. Specimens with up to 30% wt% of continuous and aligned coir fibers were thermogravimetric evaluated by TGA/DTG technique and analyzed by differential scanning calorimetry, DSC. It was found a marked loss of mass from 150 to 500°C due mainly to the degradation of the polyester matrix. The DTG peaks also revealed evidence of lignin and cellulose degradation in the coir fiber. DSC peaks could be associated with the release of formation water in both the polyester and coir fibers.

8:45 AM

High Temperature Plastic Crystal Structure Characterization Studies of Orientationally Order/disordered Organic Compounds - Pentaglycerine and 2-Amino-2-methyl-1, 3-propanediol Binary System: *Wen-Ming Chien*[1]; Ivan Gantan[1]; Amrita Mishra[1]; Dhanesh Chandra[1]; [1]University of Nevada, Reno

The binary orientationally order/disordered organic compounds, Pentaglycerine (PG) and 2-Amino-2-methyl-1, 3-propanediol (AMPL), have been performed the phase equilibrium and characterization studies by using high temperature X-ray diffraction (XRD) and differential scanning calorimetric (DSC) methods. The organic compounds (also called as thermal energy storage materials) undergo a solid-solid state phase transition before melting which will store large amounts of thermal energy. The binary samples of PG-AMPL were prepared to perform high temperature XRD characterization and DSC studies. The XRD results show that low temperature order solid state phase of PG was characterized as the tetragonal structure, and AMPL was the monoclinic structure. The high temperature orientationally disordered (plastic) phases of PG and AMPL were characterized as the FCC and BCC, respectively. Experimental binary PG-AMPL phase diagram were also developed, and the calculated PG-AMPL phase diagram was obtained by using the Calculation of Phase Diagrams (CALPHAD) modeling technique and Thermal-Calc software.

9:00 AM

Investigating the Rheology of LCPs through Different Die Geometries: Arash Ahmadzadegan[1]; *Michael Zimmerman*[1]; Anil Saigal[1]; [1]Tufts University

The rheology of liquid crystalline polymer melts through different die geometries is simulated using Polyflow™. The main goal here is to develop the necessary rheological model to simulate the orientation effects due to flow. Rheological properties of the LCPs are close to long chain polymers and their directionality is close to those of small molecule liquid crystals. As a result, different rheological models (both viscoelastic and generalized Newtonian) for long chain polymers were chosen based on the available capillary rheometer data. Using different parameters it is possible to model shear viscosity, normal stress differences and relaxations times. The free surface of the extrudate coming out of the die is simulated and the amount of die swell is compared. This study allows us to determine which of the available rheological models best apply to main-chain thermotropic LCP materials and to predict the orientation of crystallines inside and outside the die.

9:15 AM

Characterization of Graphite from PAN Aerogels: Shruti Mahadik[1]; *Clarissa Wisner*[1]; Anand Sadekar[1]; Abhishek Bang[1]; Massimo Bertino[2]; Chariklia Sotiriou-Leventis[1]; Nicholas Leventis[1]; [1]MS&T; [2]Virginia Commonwealth University

Bundles of carbon microrods similar to those observed in some natural graphites were "grown" by pyrolysis of polyacrylonitrile (PAN) aerogels. The latter were synthesized in toluene by free radical co-polymerization of acrylonitrile with two variable-length bi-functional acrylates, ethylene glycol dimethylacrylate (EGDMA) and hexamethylene diacrylate (HDDA). PAN aerogels were aromatized oxidatively at 240°C and further treated pyrolytically to graphite under helium atmosphere at 2300°C for 24 hours. Properties of each graphitized form as well as of intermediates after pyrolysis at 800°C and 1600°C were characterized by scanning electron microscopy (SEM), high resolution transmission electron microscopy (HRTEM), X-ray powder diffraction (XRD), and Raman spectroscopy studies. Although the two crosslinkers, EGDMA and HDDA, are decomposed completely by 800°C, their original signature remains through to the crystalline order of each graphitized form.

9:30 AM

Effect of the Fiber Equivalent Diameter on the Elastic Modulus and Density of Sisal Fibers: *Artur Camposo Pereira*[1]; Sergio Monteiro[1]; Wellington Inácio[1]; [1]Universidade Estadual do Norte Fluminense

Natural fibers are currently gaining attention as reinforcement of polymer composites for uses in engineering parts for automobile and building construction. In spite of environmental, economical and societal advantages, the natural lignocellulosic fibers are not as uniform in their dimension and properties as compared to synthetic. In recent works it was found that the variation in strength could be correlate to the equivalent diameters for several lignocellulosic fibers including the sisal fibers. In the present work an investigation on a possible correlation of the equivalent diameter with changes in density and elastic modulus was carried out. Precise measurements of the equivalent diameter, conducted in a profile projector, were correlated with the density and the elastic modulus by means of the Weibull statistic analysis. The results showed that an inverse correlation with the diameter also applies for both the density and the elastic modulus with a high degree of prevision.

9:45 AM

Tensile Fracture Analysis of Polymer Matrix Composites: *Jeongguk Kim*[1]; Sung-Cheol Yoon[1]; Jung-Seok Kim[1]; Hyuk-Jin Yoon[1]; Sung-Tae Kwon[1]; [1]Korea Railroad Research Institute

The tensile failure behavior of glass fiber reinforced epoxy polymer matrix composites (PMCs) was investigated during tensile testing. The PMCs have been used for railway bogie materials application for the purpose of lightweight in bogie. Through tensile testing, the fracture initiated at the epoxy matrix, and the brittle failure mode was observed. In order to monitor tensile damage evolution of PMC sample, a high-speed infrared camera was used to measure surface temperature changes during tensile testing. Through the thermographic image analysis, crack initiation and propagation were qualitatively monitored. Moreover, the microstructural characterization using scanning electron microscope (SEM) was performed to correlate the mechanical failure mode with thermographic results. In this investigation, an IR camera and SEM investigation were used to facilitate a better understanding of damage evolution and failure mode of PMC materials during tensile testing.

10:00 AM

Correlation between the Density and the Diameter of Buriti Fibers: *Anderson Barbosa*[1]; Michel Oliveira[1]; Alex Almeida[1]; Núbia Santos[2]; Frederico Margem[1]; Sergio Monteiro[1]; [1]State University of the Northern Rio de Janeiro, UENF; [2]State University of Pará

Environmental considerations in addition to technical, economical and societal benefits are increasingly promoting the substitution of natural fibers for glass fiber in polymer matrix composites. However, natural fibers are heterogeneous in their dimensions, specially the cross section, which plays an important role in their mechanical strength. The fibers extracted from the petiole of the buriti palm tree is a promising stiff natural fiber for composite reinforcement. In this work, a statistical analysis of the density of buriti fibers using the Weibull methodology was performed. An attempt to correlate the fiber density with the diameter, precisely measured by means of a profile projector, was carried out. The results revealed an inverse dependence between the buriti fiber diameter and corresponding density. Fracture tip observation by SEM suggested a possible mechanism that could justify this inverse correlation.

10:15 AM

Thermal and Morphological Behavior of EVOH/Piassava Fiber Composites: Beatriz Nogueira[1]; Anne Chinellato[2]; *Angel Ortiz*[1]; Arifa Parveen[3]; Vijaya Rangari[3]; Esperidiana Moura[1]; [1]Instituto de Pesquisas Energéticas e Nucleares - Ipen-Cnen/Sp; [2]Universidade Federal do ABC - UFABC; [3]Tuskegee University

Composite consisting of ethylene vinyl alcohol (EVOH) with short piassava fibers were prepared by extrusion process and their thermal and morphological behavior were investigated. The EVOH reinforced with 5 and 10 % of piassava fiber particle, based on the percentage weight ratio (wt %), untreated and treated with a commercial silane coupling agent, were prepared and the influence of fiber loading and the effect of chemical treatment on their thermal and morphological behavior were evaluated by SEM, DSC and TG analyses. Melt flow index (MFI) of the composites have been determined to evaluate the effects of fiber reinforcement on dynamic viscoelastic melt of the EVOH. In addition, piassava fibers characterization by SEM, FTIR, and organic and inorganic composition have also been carried out. The SEM results of the composites showed surface micrographs without microvoids and a good distribution, dispersion and compatibility between the fillers and the EVOH matrix.

10:30 AM

Characterization of Thermal Behavior of Epoxy Composites Reinforced with Banana Fibers by TGA/DTG and DSC: *Nathalia Rosa*[1]; Lucas Martins[1]; Sergio Monteiro[1]; Ruben Rodriguez[1]; Tereza Castillo[1]; [1]UENF

The fibers extracted from the pseudostem of the banana plant have been studied as possible reinforcement in polymer composites due to their environmental and technical advantages. Some possible uses above room temperature require information on the thermal behavior of composites reinforced with banana fibers. Therefore, the objective of the present work was to investigate the thermal behavior of epoxy matrix composites incorporated with up to 30% in volume of banana fibers. Thermogravimetric analysis TGA/DTG and differential scanning calorimetry were used in this investigation. It was found that thermal degradation associated with weight loss occurred in two stages. Changes were also observed from 150 to 400°C in the DTG peaks. Moreover, the DSC results showed endothermic events associated with water release and possible molecular chain degradation. Comparison with similar composites permitted to propose mechanisms that explain this DSC thermal behavior.

10:45 AM

Comparative Studies OF Crushing Behavior of Various Fiber Reinforced Skin Polyurethane Foam Cored Composite Sandwich Structures: *Krishna Sharma*[1]; Sripathy Mallaiah[1]; [1]Bangalore University

The conventional fiber reinforced plastic does not participate in the plastic deformation or enter the large plastic deformation state during collision. The objective of this study is focused on investigating the crushing of sandwich structure made of sisal / coir / bamboo / glass fabrics acting as the reinforcement materials and with polyester resin to form the composites skin with polyurethane foam as core. Experiments showed that the underlying crushing mechanism of sandwich structures is very different from that of solid-section thin-walled structures. When a sandwich structure is subjected to crushing, the core deforms in the shear mode whereas the face undergoes bending independently. The damage is through the width zone of crushed foam core accompanied by a residual dent in the skin. It is shown that such damage causes a significant reduction of compressive strength.

11:00 AM

Elastic Modulus Variation with Diameter for Ramie Fibers: *Alice Bevitori*[1]; Isabela da Silva[1]; Renan Carreiro[1]; Sergio Monteiro[1]; [1]UENF

The ramie fiber is one of the strongest lignocellulosic fibers with applications ranging from simple items such as fabrics and ropes to engineering composites for automobile parts and building panels. Characterization of the ramie fiber has recently been conducted for physical and mechanical properties. In principle, thinner ramie fiber could be comparatively stronger and consequently more effective as a composite reinforcement. In this work an attempt to correlate the ramie fiber elastic modulus obtained in tensile test with its corresponding diameter, precisely measured by means of a profile projector, was carried out. Tensile results analyzed by the Weibull statistic showed a significant increase in elastic modulus with decreasing the diameter of ramie fiber. Scanning electron microscopy observation of the fracture of selected ruptured fiber revealed possible mechanisms that could justify the elastic modulus/diameter inverse dependence.

11:15 AM

Comparative Study of the Sugarcane Bagasse Fiber/HDPE Composite Properties Using Electron-Beam and Gamma Radiation Treatments: Amanda Pereira[1]; Alejandra Soria[2]; Anibal Abreu[2]; Anne Chinellato[3]; Nélida del Mastro[1]; *Esperidiana Moura*[4]; [1]Instituto De Pesquisas Energéticas E Nucleares - IPEN-CNEN/SP; [2]Laboratório Tecnologico del Uruguay; [3]Universidade Federal do ABC - UFABC; [4]IInstituto De Pesquisas Energéticas E Nucleares - IPEN-CNEN/SP

This work presents a comparative study of the thermo-mechanical and morphological properties of sugarcane bagasse fiber/HDPE composite treated with electron-beam and gamma radiation. The composite samples obtained by extrusion and injection molding processes were irradiated at 50 and 90 kGy using either a 1.5 MeV electron beam accelerator or gamma irradiator EMI-9, at room temperature in presence of air. The irradiated and non-irradiated samples were submitted to thermo-mechanical tests, differential scanning calorimetry (DSC), thermogravimetric analysis (TGA), scanning electron microscopy (SEM) X-ray diffraction (XRD) and sol-gel analyses and the correlation between their properties was discussed. In addition, the MFI tests were done to evaluate the effects of bagasse fiber on dynamic viscoelastic melt of the HDPE. It was found that by using electron-beam or gamma radiation treatment, the properties of the bagasse fiber/HDPE composite were improved.

11:30 AM
Effect of Diameter on the Density and Tensile Elastic Modulus of Curaua Fibers: *Felipe Lopes*[1]; Renan Carreiro[2]; Noan Simonassi[2]; Ailton Ferreira[3]; Sergio Monteiro[2]; [1]IME; [2]UENF; [3]UFF

The fibers extracted from the leaves of curaua plant (Annanas erectifolius) are among the strongest lignocellulosic and being already applied as reinforcement of polymer composites in engineering applications. It was recently found that the tensile strength of the curaua fiber is markedly depend on its diameter. For very thin fibers strength above 1200 MPa were reported. In the present work the density and tensile elastic modulus of curaua fibers were evaluated as a function of the equivalent diameter measured by profile projector. Using the Weibull statistic analysis it was verified that both the density and elastic modulus follow inverse correlation with the diameter. An additional investigation on the microstructure of the fiber and its tensile fracture, by means of scanning electron microscopy, revealed that the distribution of defects and participation of microfibrils play a relevant role on the variation of the curaua fiber properties with the diameter.

Characterization of Minerals, Metals, and Materials: Characterization of Light Metals

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Materials Characterization Committee

March 15, 2012	Location: Dolphin Resort

Session Chairs: Xuewei Lv, Chongqing University; Gulhayat SAYGILI, Istanbul Technical University

8:30 AM
Influence of Deformation on the Properties of carbon-Fiber Reinforced 2024 Alloy Matrix Composites: *Wu Linli*[1]; [1]Northeastern University

The influence of deformation on the properties of short-carbon-fiber reinforced 2024 alloy matrix composites was investigated in this study. It was found that the distribution of carbon fibers changed from the random state before deformation to the ordered state that carbon fibers arranged along the direction of rolling and extruding after deformation. Under the temperature range in control, the increase of rolling and extruding temperature would benefit to improve strength and elongation of composites, but was not conductive to enhance the hardness of composites. With the increment of total deformation, all the strength and hardness of composites became greater, nevertheless the elongation decreased. Moreover, after being rolled and extruded, the strength and hardness of composites are improved. Strength of extruded 2024 alloy matrix composites was higher than that of rolled 2024 alloy matrix composites under the same heat treatment conditions.

8:45 AM
Microstructure and Deformation Behavior of Mg-Zn-Al-Re Magnesium Alloy: *Jing Zhang*[1]; Fusheng Pan[1]; Chenguang Bai[1]; [1]Chongqing university

The microstructure and hot deformation behaviour of an Er-modified Mg-Zn-Al alloy were evaluated. The results showed that the addition of rare-earth Er changed the morphology of the quasi-continuous grain boundary networked eutectic compound to globular particles. Moreover, a self-strengthening effect was identified for the alloy, which determined its deformation behavior. After hot extrusion, the yield strength and elongation to failure of the Mg-Zn-Al-Re alloy at 200 were increased by 105% and 120%, respectively, due to an emerged dynamic precipitation strengthening mechanism.

9:00 AM
Microstructures and Properties of Solid and Open-Cellular γ-TiAl Fabricated by Electron Beam Melting (EBM): *J. Hernandez*[1]; L. E. Murr[1]; S. M. Gaytan[1]; S. J. Li[2]; X. Y. Cheng[2]; Y. X. Tian[2]; F. Medina[1]; R. B. Wicker[1]; [1]University of Texas at El Paso; [2]Shenyang National Laboratory for Materials Science

Gamma TiAl has been considered to be an ideal replacement for Ni-base superalloy aerospace applications, particularly weight-critical applications. While bulk, fully dense gamma-TiAl is 50% less dense than Ni-base superalloys, it also has excellent mechanical properties at high temperature (up to ~800°C). In this study we have fabricated solid and open-cellular prototypes of gamma-TiAl by electron beam melting (EBM) from pre-alloyed Ti-48Al-2Cr-2Nb precursor powder. The solid prototype density (ρ_s) was ~4.0 g/cm^3 while mesh and foam prototypes were fabricated with relative densities as low as $\rho/\rho_s = 0.12$. Corresponding dynamic stiffness (or elastic modulus) measurements indicated an ideal foam behavior. The solid and open-cellular component microstructures were observed by optical metallography and TEM, and supported by XRD analysis. The exhibited duplex microstructure composed of relatively equiaxed **γ** grains and interspersed lamellar colonies characterized by thin a_2 plates having an orientation relationship: $(111)_\gamma||(0001)_{a2}$.

9:15 AM
Microstructures and Tensile Mechanical Properties of Mg-9Zn-0.6Zr-2Er Magnesium Alloy Processed by Hot Rolling and Heat Treatment: Jing Zhang[1]; *Baoxiang Zhang*[1]; [1]Chongqing University

As extruded Mg-9Zn-0.6Zr-2Er magnesium alloys were hot-rolled at 400°C,followed by solution treatment at 400°C for1.5h and artificial aging at 200°C for 10h. Microstructures and tensile mechanical properties of the alloys after hot rolling,solution and aging treatment were examined respectively. Optical micrographs of the as-rolled and as-solution alloys showed fine grain structures, due to the formation of Er- and Zn- bearing compounds at grain boundaries which obviously improved the thermal stability of the alloy. Yield strength as high as about 335 MPa was obtained for the as-rolled alloy, showing that the mechanical properties of the alloy was greatly benefit from the grain refinement and dynamic precipitation of fine MgZn2 during hot rolling. Due to solution heat treatment, vast majority of the Mg-Zn phases dissolved into the matrix, and precipitated out again as fine dispersoid during the subsequent aging, resulting in an enhanced aging-hardening effect.

9:30 AM
Nanobond - The Perfect Refractory Choice for Quick Lining and Repairing of Aluminium Melting Furnaces: *Thomas Schemmel*[1]; Helge Jansen[1]; Bertram Kesselheim[1]; Uwe Kremer[2]; [1]Refratechnik Steel GmbH; [2]TRIMET Aluminium GmbH

During the last decades the refractory life time of the different aggregates of the secondary aluminium production was improved significantly. Anyhow, each repair and installation of refractory material affects the operating schedule and can cause costs in the million range. The downtime of only one melting furnace generate costs of 100.000 to 400.000 $ per day. Besides cooling down of the kiln and its repair, the heating-up procedure takes the longest time of the shutdown. Usually, heating-up of low cement or ultra low cement castables takes 120 to 150 hours. In order to reduce such expensive downtimes Refratechnik developed a unique and novel product series: Nanobond. These materials can be heated up in only a third of the usual time. This paper talks about the theoretical aspects as well as the mechanical and physical properties and especially practical experience.

9:55 AM
Study on Graphitization of Cathode Carbon Blocks for Aluminum Electrolysis: *Gao Feng*[1]; FengNai Xiang[2]; Yang Jian Zhuang[2]; Niu Qing Ren[3]; He Hua[3]; Han Li Guo[3]; [1] Northeastern University; [2]Northeastern University; [3]Qingtongxia Aluminum Limited Corporation, Qingtongxia

High quality graphite cathode carbon blocks require low resistivity, strong resistant erosion to melt salt and liquid aluminum in the aluminum electrolytic cells. It not only can decrease cathode voltage drop and reduce the powder consumption, and but also can improve service life of the cell. Applying hot mould technology under 40 MPa pressure, different amount petroleum coke in anthracite mixtures is graphitized in graphitized furnace. By the X-ray diffraction parameters, density, compressive strength and resistivity drop measured, the experimental results show that compressive strength and volume density of graphite containing 30% of petroleum coke block respectively are 1.366 g/cm3 and 4.8 MPa, resistivity drop from 114μO • m to 13μO • m, most confirms to the production requirements.

10:10 AM
Wear Resistance of Graphite /Aluminum Compound Material that Prepared by Stirring Casting: *Wu Linli*[1]; Yao Guangchun[1]; [1]Northeastern University

The graphite reinforced aluminium matrix composites were prepared by stir-casting, reinforcement of graphite particles coated with oxide, and the friction behavior was investigated perfectly. The results indicated that, the aluminium matrix composites reinforced with 6 wt.% graphite particles coated with oxide have a good property of self-lubrication under the condition of dry friction with a pressure of 40 N, a relative rate of 2.62 m/s of frictional backing gear, a wear time of 60 min, in addition, the friction factor and wear capacity of the graphite / aluminium matrix composites were less than those of bulk alloy. Moreover, the friction factor and wear capacity of the graphite / aluminium matrix composites decreased with an increase in mass fraction of the graphite coated with oxide, and the friction factor of composites became bigger while the fraction of the graphite particles was over 6wt.%.

10:25 AM
Characterization of Grit Blasted Metallic Biomaterials by Thermoelectric Power Measurements: *Hector Carreon*[1]; Sandra Barriuso[2]; Jose Luis González-Carrasco[2]; Francisca Garcia-Caballero[2]; Marcela Lieblich[2]; [1]UMSNH; [2]Centro Nacional de Investigaciones Metalúrgicas (CENIM-CSIC)

The grit blasting, a surface improvement treatment is used to enhance mechanical fixation of the implants through increasing their roughness. As a result of the severe plastic surface deformation, it produces additional effects such as grain refinement, hardening and compressive residual stresses which are generally evaluated with destructive techniques. In this research work, we present preliminary results of the non-contacting and contacting thermoelectric power measurements in blasted Ti-6Al-4V and 316LVM specimens using Al2O3 and ZrO2 particles respectively. This study correlates the microstructural changes induced by the grit blasting treatment and the limitations and advantages of each of the nondestructive thermoelectric techniques based on Seebeck effect used to evaluate these biomaterials.

10:40 AM
Exploring Microstructure-Corrosion Property Correlations in 5000-Series Alloys Using Higher-Order Statistical Metrics: *Daniel Satko*[1]; Jonathan Kaufman[1]; Joshua Shaffer[1]; Roger Doherty[1]; Surya Kalidindi[1]; [1]Drexel University

The non heat-treatable aluminum alloys of the 5000 series are known to be susceptible to intergranular corrosion and stress corrosion cracking upon exposure to slightly elevated temperatures for Mg content in excess of about 3 wt%. Sensitization of these alloys is due to precipitation of a continuous film of anodic Al_3Mg_2 intermetallic \946 phase along grain boundaries. It has been shown that 1-point metrics, based on volume fractions, are inadequate to describe the salient microstructural features. In this paper, we specifically explore correlations between higher-order spatial statistical metrics obtained from datasets combining EBSD orientation information with \946-phase distributions and susceptibility to intergranular corrosion of selected high-Mg alloys from this series.

10:55 AM
Modeling the Mechanical Response of Aluminum A359-SiCp-30%: *James DeMarco*[1]; Justin Karl[1]; Yongho Sohn[1]; Ali Gordon[1]; [1]UCF MMAE Dept.

Various aluminum metal-matrix composites (Al-MMCs) are currently under consideration for use in structural components of next-generation heavy ground vehicles. However, processing remains costly, due in part to material loss through edge cracking. In recent work, the authors have investigated the dependence of mechanical properties of as-cast A359-SiCp-30% on strain rate and temperature. The observed trends in material behavior were used to calibrate and test a multiaxial temperature- and strain rate-dependent constitutive model which allows numerical simulation of hot rolling. A damage model which is also temperature- and strain-rate dependent is used to predict failure.

First Principles Modeling of Solid-Solid Interfaces: *Christopher Woodward*[1]; [1]Air Force Research Laboratory

Over the last decade there have been significant advances in our ability to predict the spatial and chemical morphology of solid interfaces. Simultaneously, characterization methods based on electron microscopy (i.e. High Angle Annular Dark Field Scanning Transmission Electron Microscopy) and Local-Electrode Atom-Probe tomography have advanced to the level of chemical resolution at the atomic-scale. The combination of emerging modeling and characterization methods provides a potent tool for exploring boundary properties and validating computational methods. Progress in modeling of interfacial boundaries will be illustrated using examples in (Ni and Al) engineering alloys, with the focus primarily on first principles methods that include entropic contributions to the free energy. While these methods are typically limited to coherent interfacial boundaries, there are examples of first principles calculations of incoherent metal-oxide boundaries without entropic contributions. Time permitting, examples on how such results inform meso and macro scale models will also be presented.

8:55 AM Invited

Grain Boundary Energy Function for FCC Metals: *Vasily Bulatov*[1]; [1]LLNL

To quantify the driving forces acting on the GB networks under thermal coarsening and/or irradiation conditions, it is desirable to express the GB energy as a function of five macroscopic degrees of freedom. The very existence of such a function has been controversial but recent computer simulations suggest that such a function should exist. In this development we focus on the global topology of the functional 5-space of the GB energy function and examine positions and connectivity of its singular points – cusps. The resulting energy function reflects all relevant symmetries of the bi-crystal, its functional form is universal for FCC crystallography but contains material-specific parameters that can be fit to energies measured or computed for just a handful of special boundaries. The resulting function provides a high quality fit to the extensive data sets of GB energies computed by Olmsted et al.

9:20 AM

Topological Evolution of Grains in 3D Monte Carlo Modeled Grain Growth: *Burton Patterson*[1]; Robert DeHoff[1]; Veena Tikare[2]; David Rule[1]; Amy Adams[1]; [1]University of Florida; [2]Sandia National Laboratories

Grains traverse a complex path of topological states during 3D grain growth. Their numbers of faces increase and decrease through the three fundamental topological events of grain encounter, grain separation and contact with disappearing tetrahedra. These topological changes control their individual growth and shrinkage rates, which are tied to their integral mean curvature, in turn related to their number of faces. 3D Monte Carlo simulation has enabled monitoring the traversal of individual grains up and down the Schlegel tree of topological states. This previously inaccessible information provides a valuable first look at these fundamental processes of grain growth.

9:35 AM

Modeling the Asymptotic Grain Face Distribution in Terms of Tological Event Rates: *Robert DeHoff*[1]; Burton Patterson[1]; Veena Tikare[2]; David Rule[1]; Amy Adams[1]; [1]University of Florida; [2]Sandia National Laboratories

The steady-state grain face frequency distribution during grain growth has been modeled in term of kinetic topological parameters obtained from 3D Monte Carlo (3DMC) simulations. Each face class experiences six fluxes of grains into and out of it due to the different fundamental topological events occurring in it and the adjacent face classes. Equations for the net gain and loss of grains from each face class were constructed in terms of the relative rates of these events in the system and the participation probabilities of each face class for those events. Simultaneous solution of the set of equations for all face classes provided the asymptotic distributions for those event rate ratios. Event ratios were obtained from 3DMC simulations with different initial volume distribution widths, producing different asymptotic volume and face distributions and event rates. Solutions based on these event ratios successfully modeled the asymptotic 3DMC distributions from which they came.

9:50 AM

4D Grain Growth Kinetics in High-Purity Aluminum: *Anthony Johnson*[1]; Stefan Poulsen[2]; Andrew King[3]; Wolfgang Ludwig[3]; David Rule[4]; Burton Patterson[4]; Peter Voorhees[1]; Erik Lauridsen[2]; [1]Northwestern University; [2]Risø National Laboratory for Sustainable Energy; [3]European Synchrotron Radiation Facility; [4]University of Florida

We have employed Diffraction Contrast Tomography (DCT) and a multi-order parameter phase-field model to study 4D grain growth kinetics in aluminum. DCT was used at the European Synchrotron Radiation Facility to produce 3D grain maps of a high-purity aluminium sample at nine time steps during an anneal. The annealing temperature was chosen such that grain boundary movement was small but finite, in order to accurately measure grain boundary velocities. These velocities, along with the grain boundary and triple line curvatures, are compared with the MacPherson-Srolovitz equation for the evolution of individual grains. The data set is also used as initial conditions for a multi-order parameter phase field simulation, to test the validity of the model, measure the degree of grain boundary mobility and energy anisotropy, and to determine the role of triple line energy and mobility in the grain growth process observed in the experiments.

Grain Boundary Migration and Grain Growth: What I Do & Do Not Understand: *David Srolovitz*[1]; [1]Institute for High Performance Computing, Agency for Science, Technology and Research, Singapore

In this presentation, I will examine several topics in grain boundary migration and grain growth. The topics are heavily biased towards my own interests and hence the coverage is idiosyncratic. I will first discuss grain boundary migration mechanisms. What have we learned from molecular dynamics simulations and dislocation dynamics models? What happens as we change bicrystallography, temperature, the form of the driving force,... Next, I will discuss several fundamental issues in normal grain growth: recent extensions of the Mullins-von Neumann description to all integer dimensions (>1), differences between 2 and 3 dimensions, correlations in geometry and topology in normal grain growth microstructures,... I will conclude with a "shopping list" of open questions in both areas that I believe require more attention and opportunities presented by recent advances in the 3d characterization of microstructure.

11:00 AM Invited

The Mobility of Interfaces and Grain Boundaries from Molecular Dynamics Simulations: H. Song[1]; M. J. Rahman[1]; *Jeffrey Hoyt*[1]; [1]McMaster University

Molecular dynamics (MD) simulations have proven to be quite useful in extracting thermodynamic and kinetic properties of crystalline interfaces. In this work we will review various techniques that have been developed recently to compute grain boundary mobilities in pure metals. The techniques include: curvature driven growth, the random walk method, equilibrium boundary fluctuations, stress driven migration and the artificial driving force method. MD derived mobility vs. misorientation data will be summarized for several systems and new results will be reported for the temperature dependent mobility of a low angle 112 tilt boundary in Al. In addition, the application of MD to the case of an FCC-BCC interphase boundary in pure Fe will be discussed and the atomistic growth mechanisms as well as the temperature dependence of the mobility will be presented.

11:25 AM

Lattice Monte Carlo Determination of Harrison Kinetics Regimes for Grain Boundary Diffusion In Materials with Inhomogeneous Grain Structures: *Irina Belova*[1]; Graeme Murch[1]; Thomas Fiedler[1]; [1]The University of Newcastle

Identification of the Harrison kinetics regimes (Types A, B and C) has been investigated by the authors for the case of grain boundary self-diffusion in materials with grains of the same size. Real materials of course generally have much more complicated grain size distributions. For the first time, we analyse the grain boundary diffusion problem with an inhomogeneous grain structure by means of the Lattice Monte Carlo (LMC) method that has been extensively developed by the authors to address phenomenological diffusion problems. The LMC method is used here for to determine the transitions that occur between the Harrison grain boundary kinetics regimes. Importantly, it is shown that the distributions of grain sizes can contribute significantly into the resulting concentration profiles with possible consequent overestimation of both lattice and grain boundary diffusion coefficients. It is shown that a new approach for calculating the diffusion parameters for Harrison classification purposes is needed.

11:40 AM
Molecular Dynamics Study of Solid-Liquid Interface Migration in Ni-Zr Alloys: *Mikhail Mendelev*[1]; [1]Ames Laboratory

While several dozens of molecular dynamics (MD) simulation works reporting the solid-liquid interface (SLI) velocities in pure metals have been published the number of works where the SLI migration was studied in alloys is very limited. I will present the results of the MD simulations of the SLI migration in the Ni50Zr50 and NiZr2 alloys. The crystal phases in these alloys are congruently melting stochiometric compounds and a potential development procedure which allows fitting the melting temperatures for these compounds will be discussed. The developed semi-empirical potential allows in the case of the Ni50Zr50 alloy the simulation of the SLI migration for both B2 and B33 phases. The temperature dependence and anisotropy of the SLI velocity and point defect formation during solidification will be discussed.Work at the Ames Laboratory was supported by the Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-07CH1135.

Electrode Technology for Aluminium Production: Inert Anode and Wettable Cathode Materials

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee
Program Organizer: Morten Sorlie, Alcoa Norway

Thursday AM	Room: Americas Seminar

8:30 AM
Electrolysis Expansion Performance of Modified Pitch Based TiB_2-C Composite Cathode in $[K_3AlF_6/Na_3AlF_6]$-AlF_3-Al_2O_3 Melts: Fang Zhao[1]; Xu Jian[2]; Hou Jin-Long[2]; Li Lin-Bo[1]; *Zhu Jun*[1]; [1]School of Metallurgical Engineering, Xi'an University of Architecture and Technology; [2]School of Metallurgical Science and Engineering, Central South University

Electrolysis expansion of pitch, modified by furan, phenolic-aldehyde and epoxy, based TiB_2-C composite cathodes in $[K_3AlF_6/Na_3AlF_6]$-AlF_3-Al_2O_3 melts were investigated, and EDS as well as TGA were respectively used to conduct elemental micro-analysis and study dynamics relate to pyrolytic process. The results show that compared with the electrolysis expansion of unmodified pitch based composite cathode, pitch modified by furan, phenolic-aldehyde and epoxy based composite cathodes all exhibit lower electrolysis expansion which are 1.61%, 1.62% and 1.68% respectively. The maximum depressed amplitude can reach 13.77%. Apparent activation energy(AAE) concerning pyrolysis process of pitch is related to electrolysis expansion of composite cathodes. The higher the AAE, the lower the electrolysis expansion. The AAE of unmodified pitch is 47.21kJ/mol, while the AAE of pitch modified by furan, phenolic-aldehyde, and epoxy are 66.25kJ/mol, 57.07kJ/mol and 63.24kJ/mol. The values of them can account for test result of electrolysis expansion mentioned above.

8:55 AM
Pulse Electrodeposition of TiB2 onto Graphite from TiO2-B2O3-KF-LiF Melts: *Bing Li*[1]; Lushan Jiang[1]; Heng Wang[1]; [1]East China University of Science and Technology

TiB2 has attracted much attention for being the most suitable cathode material in the aluminum electrolysis process. Electrodeposition of TiB2 coating provides a convenient and low-cost way.In this paper, TiO2 and B2O3 were selected as the active components, KF-LiF as the supporting electrolyte. Ti4+ ions and B3+ ions reduction processes in TiO2-B2O3-LiF-KF melts were investigated by cyclic voltammograms, square-wave voltammograms and chronopotentiograms, respectively. And electrodeposition of TiB2 on graphite substrate was carried out from TiO2-B2O3-LiF-KF melts at 800°C by using CCP (continuous current plating) and PCP (pulsed current plating). The effects of cathodic current density, pulse current on and off ratio and B/Ti molar ratio on the coatings were examined by SEM (electron scanning microscope). The coatings prepared by PCP exhibit better qualities compared with those obtained by CPC, they were uniform, dense , adherent and fewer cracks with metallic brightness.

9:20 AM
Ball-Milled Cu-Ni-Fe-X Materials as Inert Anodes for Al Production in KF-AlF3 Low-Temperature Electrolyte: *Sébastien Helle*[1]; Valery Ouvarov-Bancalero[1]; Boyd Davis[2]; Daniel Guay[1]; Lionel Roué[1]; [1]INRS-Énergie, Matériaux et Télécommunication; [2]Kingston Process Metallurgy Inc

In our previous works, we have identified the mechanically alloyed Cu65Ni20Fe15 compound as a promising inert anode material for Al production. However, the purity of the produced Al is still insufficient (99.3%) and thus, further works are required for improving its corrosion resistance. In this context, Cu-Ni-Fe-X materials are prepared by ball milling, consolidated to form dense electrodes and then evaluated as inert anodes for aluminum production in low-temperature (700°C) KF-AlF3 electrolyte. Their morphological, structural and chemical characteristics are studied at different stages of their preparation and after 20 h of electrolysis. The key role played by the element X on the electrode corrosion resistance is highlighted. Some of these Cu-Ni-Fe-X materials are identified as promising inert anodes for producing aluminum with a good purity (= 99.7%).

10:00 AM
Effect of Nanopowder Content on Properties of NiFe2O4 Matrix Inert Anode for Aluminum Electrolysis: *Zhigang Zhang*[1]; Yihan Liu[1]; Guangchun Yao[1]; Di Wu[1]; Junfei Ma[1]; [1]Northeastern University

Two-step sintering process was adopted to prepare NiFe2O4 matrix inert anode for aluminum electrolysis in this research. In the process of synthesizing NiFe2O4 spinel, Fe2O3 and NiO powders as raw materials added additives were synthesized at 1000°C for 6h. Through crushing and screening, adding NiFe2O4 nanopowder, particle gradation and compression molding, the nickel ferrite matrix ceramic inert anode was sintered secondarily at 1300°C for 6h. The effect of NiFe2O4 nanopowder content on the density and porosity, bending strength and impact toughness was investigated in details. The results showed the addition of NiFe2O4 nanopowder had considerable influence on the properties of NiFe2O4 matrix ceramic inert anode. Inert anodes had the best comprehensive properties while adding 30wt% nanopowder. The values of density and porosity were 4.86g/cm3 and 3.5% respectively, the value of bending strength was 42.47MPa and the value of impact toughness was 3.31J/cm2.

10:25 AM
Effect of MnO2 Addition on Early-Stage Sintering Behavior and Properties of NiFe2O4 Ceramics: *Jinjing Du*[1]; Yihan Liu[1]; Guangchun Yao[1]; Xiuli Long[1]; Xiao Zhang[1]; [1]Northeastern University

The samples with small amounts of MnO2 (0, 0.5, 1.0, 1.5, 2.0, 2.5 wt%, respectively) were prepared via ball-milling process and two-step sintering process from commercial powders (i.e. Fe2O3, NiO and MnO2). Micro-structural features, phase transformation, the early-stage sintering behavior and mechanical properties of Mn-doped NiFe2O4 composite ceramics have been investigated. Results indicate that the reduction of MnO2 into Mn2O3 and following the reduction of Mn2O3 into MnO existed during sintering process. No new phases are detected in the ceramic matrix, the crystalline structures of the ceramic matrix are still NiFe2O4 spinel structure. MnO2 addition can promote the sintering process. The temperature for 1wt% MnO2-doped samples to reach the maximum shrinkage rate is 59°C lower than that of un-doped samples.

10:50 AM
Study on the Inert Anode for Al Electrolysis Based on the NiFe2O4 Spinel Ceramics: *Yihan Liu*[1]; Ming Zhao[1]; Jing Li[1]; [1]Northeastern University

A kind of cermet inert anode for Al electrolysis based on NiFe2O4 had been studied in this paper. Firstly, the effect of NiFe2O4 pre-sintering temperature on properties of inert anodes was researched, and then the appropriate technological conditions were determined by the orthogonal test. The properties such as density, conductivity, corrosion rate, mechanical property and thermal shock resistance have been used as controlling parameter to obtain the optimum technological condition. The inert anode sized F50mm×15mm is prepared and tested as anode for 10h Al electrolysis in laboratory. This anode behaves good corrosion resistance to cryolite molten salt. The result gives that the corrosion rate of the anode was 1.5×10-4g•cm-2•h-1 after the 10h electrolysis, and the purity of the aluminum gained from Al electrolysis test was 92%~93%. The analysis shows the main contaminations in the raw aluminum are Fe,Ni and Ag.

Multi-Physics Functional Design of HeteroFoaM Nanomaterials for Energy Systems: *Ken Reifsnider*[1]; Fazle Rabbi[1]; Rassel Raihan[1]; [1]University of South Carolina

In 2007 a group of scientists introduced the concept of HeteroFoaMs, a contraction of Heterogeneous Functional Materials. The functional focus of these materials is typically energy conversion and storage devices, such as solid oxide fuel cells (SOFCs). The multiphysics of HeteroFoaMs typically involves balance of mass, momentum, energy and charge, reflecting the fact that mass (fuel, electrons, and ions) are usually transported in such devices, electrochemistry occurs, and the devices are electrical circuits during operation. The functional design of these materials requires the coupled balance of mass, momentum, energy and charge, to embrace chemical, electrochemical, thermal, mechanical, and electrical functionality. The present paper will discuss some examples of such energy nanomaterial design, with a special focus on design for conductivity and dielectric charge management.

8:55 AM
Electrochemical Properties of Hydride Reduced $LaSrCoO_{4\text{-}\backslash 948}$ as IT-SOFC Cathode Material Based on $Ba(Zr_{0.1}Ce_{0.7}Y_{0.2})O_3$ Electrolyte: *Bo Peng*[1]; Gang Chen[1]; Tao Wang[1]; Jun Zhou[1]; Jiaojiao Guo[1]; Yonghong Cheng[1]; Kai Wu[1]; [1]Xi'an Jiaotong University

Efficient intermediate temperature (600°C-800°C) solid oxide fuel cells (IT-SOFCs) demand catalytically active cathodes and highly conductive electrolytes. In the present study, we utilize solid state reduction, with CaH_2 as the reducing agent, to introduce abundant oxygen vacancies to the K2NiF4-type $LaSrCoO_{4\text{-}\backslash 948}$ phase. Electrochemical properties of the composite cathode, which include both the hydride reduced phase (H-$LaSrCoO_{4\text{-}\backslash 948}$) and a high performance proton conductor $Ba(Zr_{0.1}Ce_{0.7}Y_{0.2}O_3)$ (BZCY), are investigated by means of ac impedance spectroscopy and dc polarization measurements. At 750°C, the cathode shows a polarization resistance of 0.229O•cm^2. And a cathodic overpotential of 25mV is also detected at a current density of 150mA•cm^{-2} at 750°C. These good properties can be attributed to the high oxygen vacancy concentration of the H-$LaSrCoO_{4\text{-}\backslash 948}$ phase which enhances some key steps of the cathodic oxygen reduction reaction (ORR).

9:10 AM
Crystallization and Electrochemical Performance of LSCF-CGO Thin Film Cathodes Processed by Single Solution Spray Pyrolysis: *Elliott Slamovich*[1]; Bainye Angoua[1]; Patrick Cantwell[2]; Eric Stach[3]; [1]Purdue Univeristy; [2]Lehigh University; [3]Brookhaven National Laboratory

La0.6Sr0.4Co0.2Fe0.8O3-d-Ce0.8Gd0.2O1.9 (LSCF-CGO) thin films obtained by spray pyrolysis of a single precursor solution were investigated by XRD, TEM and impedance spectroscopy at annealing temperatures ranging from 500-900°C. Films annealed at 600°C contained a mixture of amorphous regions and crystalline regions composed of fine crystallites (< 5 nm). Annealing above 600°C increased the ratio of crystalline to amorphous material and led to film segregation into distinct LSCF and CGO phases. At testing temperatures of 400°C and below, the polarization resistance of films with lower annealing temperatures was larger than the polarization resistance of films with higher annealing temperatures. However, at testing temperatures of 500°C and above this trend was reversed. The varying electrical behavior may be related to microstructural changes that made bulk diffusion the rate-limiting step in films with lower annealing temperatures and oxygen dissociation the rate-limiting step in films with higher annealing temperatures.

Oxides as Energy Materials: *Shriram Ramanathan*[1]; [1]Harvard Univ

I will discuss some examples concerning phase transitions in functional oxides and their applications in solid state devices for energy conversion and electronics. The talk will center on problems concerning ionic-electronic transport, point defect thermodynamics in low-dimensional oxides and experimental methods to study these rigorously. Thin film solid oxide fuel cells as portable power sources will be used an example to illustrate broader relevance. Experimental routes to fabricate high performance electrodes for low temperature oxide-based fuel cells will be considered. Finally, I will point out the inevitable convergence of electrochemistry and solid state physics towards solving pressing societal problems.

9:45 AM Invited
A Quantitative Understanding of Interface Dynamics in Complex Oxides with In Situ TEM: *Mitra Taheri*[1]; [1]Drexel University- Department of Materials Science & Engineering

Understanding atomic scale mechanisms in oxides is a crucial step toward the realization of these materials in a multitude of applications, ranging from solid oxide fuel cells to magneto-electric devices. Magneto-electric coupling in BiFeO3 (BFO), for example, allows control of the ferroelectric and magnetic domain structures via applied electric fields. Because of these unique properties, BFO and other magneto-electric multiferroic oxides constitute a promising class of materials for incorporation into high-density ferroelectric and magnetoresistive devices. However, the magneto-electric coupling in BFO is mediated by volatile ferroelastically switched domains that make it difficult to incorporate this material into devices. To facilitate device integration, an understanding of the microstructural factors that affect ferroelastic relaxation and ferroelectric domain switching is needed. In this study, domain switching behavior was examined using in situ biasing in TEM. Specifically, the evolution of ferroelastically switched ferroelectric domains in BFO thin films during many switching cycles was investigated.

Design of Light Weight Structure for Wind Turbine Tower by Using Nano-Materials: *Ying Li*[1]; Jian Lu[1]; [1]City University of Hong Kong

Wind power develops very fast nowadays. The engineering base and computational tools have to be developed to match machine size and volume. This paper reports a new design scheme of light weight structure for wind turbine tower. This design scheme is based on the integration of the nano-structured materials produced by the Surface Mechanical Attrition Treatment (SMAT) process. This process creates a nano-crystallized layer on the metal surface which can effectively improve the yield strength of the original metal material while keep the material's ductile at certain level. The objective of this study is to accomplish the weight reduction by optimizing the wall thickness of the tower while combining the appropriate material properties into optimization. Two main kinds of static loads on the tower are bending and buckling. The individual as well as the combined influence of loads are studied. The eccentric compression on the tapered tube will be discussed.

10:40 AM
Improved Design of Metal-Organic Framework Family for Efficient Hydrogen Storage: *Sang Soo Han*[1]; William Goddard[2]; [1]Korea Research Institute of Standards and Science; [2]California Institute of Technology

Recently, Yaghi and co-workers pioneered the metal-organic frameworks (MOFs), covalent-organic frameworks (COFs), and zeolitic imidazolate frameworks (ZIFs), new class of ordered, three-dimensional extended solids composed of metal ions and organic linkers that comprise promising material for H2 storage. Therefore we investigated the materials as practical hydrogen storage media with ab-initio based grand canonical Monte-Carlo (GCMC) simulations, providing a good agreement with experimental H2 adsorption isotherms of the MOF, COF, and ZIF. And we discussed several strategies for the improvement of hydrogen storage in the porous materials. The strategies include appropriate pore size, impregnation, substitution of metal oxide with lighter metals, functionalized organic linkers, open metal sites with transition metals and alkali metals. Among them, the Li-doped MOF can store H2 of more than 6wt% near room temperature, indicating that it could be a promising candidate for practical hydrogen storage.

10:55 AM
Magnesium-Based Hydrogen Storage Nanomaterials: *Hongmin Kan*[1]; Ning Zhang[1]; Xiao-Yang Wang[1]; Hong Sun[1]; [1]Shenyang University

An overview of recent advances in the application of Magnesium-based nanostructured materials in hydrogen storage is presented in this review. The main focus is on Magnesium NC/polymer composites, Magnesium alanate, Al-Mg Alloy powders and other Magnesium-based metal hydrides. Recent advances in the area of Magnesium NC/polymer composites show they broke through the basic thermodynamic and kinetic barriers and made a good combination material in the design of nanocomposite material. The polymer in new composite materials and nano-metal particles can be effectively balance; Nanocrystallinity of the Magnesium alanate material is synthesized. Due to its high hydrogen content of 9.3 wt. %, a maximum reversible content of 7 wt. % may be expected if reaction can be made reversible; The hydrogen storage properties of magnesium can be effectively modified by alloying with aluminum. The thermodynamical properties (lower desorption temperature), and kinetics of hydrogenation/dehydrogenation are improved.

11:10 AM
TEM Guided Microstructural Design of MgH2 Powders and Thin Film Alloys with Room Temperature Volumetric Hydrogen Cycling Ability: *David Mitlin*[1]; Peter Kalisvaart[1]; Mohsen Danaie[1]; Shu Tao[2]; Ben Zahiri[1]; Helmut Fritzsche[3]; [1]University of Alberta and NINT NRC; [2]Eindhoven University of Technology; [3]SIMS-CNBC NRC

This presentation is separated into two sections: We will first discuss our recent cryogenic stage transmission electron microscopy (TEM) – based findings on the MgH2 to Mg (and vise versa) phase transformation in high-energy milled powders. We show that both reactions are nucleation limited, rather than core shell, and identify the dominant metal - hydride orientation relationships. By performing cryo-TEM on ball milled powders we discovered deformation twins in the microstructure. Density functional theory (DFT) analysis demonstrates that the twins significantly affect the kinetics of hydrogen diffusion. In the second portion of the presentation we highlight our recent alloy design efforts for both "bulk" thin films and thin film multilayers. The research culminates in the creation of several classes of catalysts that enable for relatively rapid room temperature volumetric sorption over multiple cycles. The same catalysts allow for ultra-rapid 250+ cycles elevated temperature absorption/desorption at pressures of 1-3 atm.

11:25 AM
Development of Novel Nanostructured Electrolytes for Low Temperature Solid Oxide Fuel Cells Applications: *Hoda Amani Hamedani*[1]; [1]Georgia Institute of Technology

High performance low-temperature solid oxide fuel cells (SOFCs) require design of new electrolyte architectures with enhanced ionic transport properties at low temperatures. In this work, fabrication and characterization of one-dimensional composite nanostructures of yttria-stabilized zirconia (YSZ) and Sr-doped TiO2 as potential material system with high ionic conductivity at low temperatures is reported. The morphological and structural characteristics of the composite nano-architectures were studied using scanning electron microscopy coupled with scanning transmission electron microscopy, X-ray diffraction and atomic force microscopy. Preliminary studies of ion transport properties by electrochemical impedance spectroscopy were performed to investigate oxygen-vacancy formation and revealed enhanced oxygen exchange at the YSZ/Sr-doped TiO2 interface of these nano-architectures.

Development of Superhydrophobic Nano-structured Surfaces for High Efficiency Power Generation: *Ghazal Azimi*[1]; Kripa Varanasi[1]; [1]MIT

Developing robust nanoengineered surfaces and coating technologies for the efficiency improvement of phase change processes has been a subject of intense research over the past decades. Although it has been known since the 1930s that heat transfer coefficients for dropwise condensation are significantly higher than those of filmwise condensation, there has not yet been any successful method commercialized for promoting dropwise condensation due to the lack of suitable material candidates. To address these challenges, herein, we developed novel hydrophobic materials that surpass their counterparts in ability to repel water droplets, while offering other unique properties, including thermal stability and chemical inactivity. Nanoengineered embodiments of these new materials possessed dropwise condensation with remarkably improved heat transfer coefficient, when tested in a condensation chamber under simulated industrial conditions. Such designs are envisioned to enhance the overall performance of various industrial applications.

Energy Opportunities in the Aluminum Processing Industry: *Cynthia Belt*[1]; [1]Consultant

Energy management is critical to aluminum processing given the high energy requirements of melting and processing aluminum. Energy costs have always been high percentage of the total production costs within this industry. Energy management at many plants relied on better technology that many times required high capital. As carbon management has grown in importance and project payback becomes more critical, a larger view of a plant's process is required. This paper looks at the energy requirement due to current typical practices in overall product recovery, metal loss, utilization, and technology to understand potential methods of reducing overall energy within a plant and within the aluminum processing industry.

8:55 AM
An Overview of Energy Consumption and Waste Generation in the Recovery of Cobalt from Copper Sulphide Smelting and Converting Slag and the Proposed Solution: Animesh Jha[1]; *Yotamu Hara*[1]; [1]University of Leeds

High Curie temperature and large magnetic anisotropy make cobalt an important magnetic material for power engineering applications of magnets operating above ambient. It is also an essential constituent of modern lithium-cobalt oxide batteries, without which modern electronic gadgets will be functionless. Both these applications of cobalt save energy and reduce CO2 emission. Ironically, however the production of cobalt from copper and nickel smelting in the world remains one of the least energy efficient process. The paper analyzes the energy balance, material and process chemistry of overall cobalt recovery and the waste generated, which entail the process limitations. We discuss a novel approach of mineral reduction with CaSO4, permitting better separation of metals from slag and generating higher concentrations of SO2 seems to be an alternative energy efficient option for processing and further purifying cobalt. The results are discussed in the context of process thermodynamics and reaction kinetics for Co-alloy production.

9:15 AM
High Thermal Energy Storage Density LiNO3-NaNO3-KNO3-KNO2 Quaternary Molten Salts for Parabolic Trough Solar Power Generation: *Tao Wang*[1]; Divakar Mantha[1]; Ramana Reddy[1]; [1]The University of Alabama

A new eutectic LiNO3-NaNO3-KNO3-KNO2 quaternary molten salt system was calculated using thermodynamic modeling. The eutectic temperature was predicted to be 100°C. The melting point and heat capacity of the salt eutectic composition were determined using DSC. The experimentally determined melting point is an excellent agreement with the predicted value. The melting point is 122°C lower than that of the KNO3-NaNO3 solar salt. The density of the molten salt was experimentally determined as function of temperature. Using the density, heat capacity and the melting point, thermal energy storage density and gravimetric storage density of the quaternary molten salt were calculated and compared with that of solar salt. The larger storage density value of this molten salt indicates that this salt has a better energy storage capacity for solar power generation systems.

9:30 AM
Global Primary Aluminium Industry 2010 Life Cycle Inventory: *Chris Bayliss*[1]; Marlen Bertram[1]; Kurt Buxmann[1]; Bernard de Gelas[1]; Samantha Jones[1]; Linlin Wu[1]; [1]International Aluminium Institute

Environmental management is one of the industry cornerstones of sustainable development. In order to understand fully the environmental aspects associated with the raw material acquisition, production, use, and end-of-life operations of aluminium products, the Aluminium Industry has developed an approach based on Life Cycle Analysis (LCA) methodology. Within this framework, the Primary Aluminium Industry has established a global Life Cycle Inventory (LCI) data set. Inventory flows include inputs of raw materials, energy and water, emissions to air and water, and solid waste. This paper presents the latest LCI data update by the International Aluminium Institute for the year 2010, based on a survey of aluminium plants globally, including bauxite mining, alumina refining, anode production, electrolysis and casting. This update also includes some performance tracking based on the last LCI data collection in 2005, reflecting progress in efficiency and technology, as well as changes in the geographical location of the industry.

9:55 AM
Analysis of Combustion Efficiency Using Laser-Induced Fluorescence Measurements of OH-Radicals: *Matthias Schnitzler*[1]; Ralf Bölling[1]; Herbert Pfeifer[1]; [1]IOB RWTH Aachen

To transform metals high temperatures are usually needed. A fast and efficient heating can reduce the CO2 emitted. The fastest way to heat metals is called direct flame impingement (DFI). The flame impinges upon the item being heated. For this method it is important to know the shape and length of the flame. Laser-induced fluorescence (LIF) technology allows measurements of a two-dimensional field without influencing the reaction or the flow. Commonly used is the measurement of OH-radicals, an indicator of the reaction zone. In the presented study measurements of a turbulent diffusion flame are shown. The position of the reaction zone and the influence of the distance between the item being heated and the burner are investigated. Conventional measurements and LIF-measurements are compared and the potential of DFI to increase the efficiency of heating metals is discussed.

10:10 AM
A Solid State Thermoelectric Power Generator Prototype Designed to Recover Radiant Waste Heat: *Marit Takla*[1]; Odne Burheim[1]; Leiv Kolbeinsen[1]; Signe Kjelstrup[1]; [1]Norwegian University of Science and Technology

This paper presents a Seebeck-type solid state thermoelectric power generator unit, designed to investigate the possible recovery of radiant waste heat at a silicon plant in Norway where roughly 70 % of the total input energy leaves the process as waste heat. The unit is 0.5 m x 0.5 m and is built of 36 commercially available thermoelectric devices based on bismuth telluride p - and n - type semiconductors. Thermoelectric devices directly convert fractions of a heat flux into an electric current (and vice versa) and may therefore be convenient for recovery of waste heat when the heat source is discontinuously available. The purpose of the thermoelectric unit is to give a proof of principle of direct thermoelectric energy conversion on a large scale. We present the initial test results for the generator. At an average temperature difference between the heat reservoir and the heat sink of 98 °C, we measured an open ciruit potential of 23.44 ±0.06 V and the matched load power output was 39.4 W. At a temperature difference of 220°C, we predict the generator open circuit potential to be 40.8 V, which corresponds to an efficient Seebeck coefficient of 242 µV/K per pair of semiconductor, and matched load power output to be 120 W.

10:25 AM
Study on Smelting Reduction of Coal-Containing Pellets of V-Ti Bearing Beach Placers by Combined Rotary Hearth Furnace and Direct Current Arc Furnace: *Huimin Lu*[1]; Jingbo Xu[1]; Qiang Li[1]; [1]Beihang University

The smelting reduction of vanadic-titanomagnetite sand by combined rotary hearth furnace and direct current arc furnace was studied in laboratory. It takes the aid of back propagation (BP) neural network theory to build the nonlinear mapping relations between the crucial process variables such as content of carbon, temperature and time and the degree of reduction and separation of iron and slag. Then by the integrating BP neural network and genetic algorithm (GA), the optimized process parameters for the high degree of reduction and separation of iron and slag were searched. The comparisons between experiment results and neural network simulation results show that GA-based on BP method can predict the degree of reduction and separation of iron and slag with higher prediction accuracy. Calculations show that the integrated energy consumption of new technology is 580kgce/tHM, less than the current existing blast furnace.

10:40 AM
A Novel Method Combined Ionothermal Synthesis and Microwave Energies for Rapid Production of ZIFS: *Lisha Yang*[1]; Huimin Lu[1]; Shi Zhou[1]; [1]Beihang University

The Zeolitic imidazolate frameworks (ZIFs) were successfully rapid synthesized by applying a combination of ionothermal synthesis and microwave energies. The synthesis was proceeded under various conditions including different raw materials, reaction temperature as well as microwave irradiation time. Zeolitic imidazolate frameworks (ZIFs), also known as coordination polymers, are new type of porous materials formed by inerratic polyhedral in three-dimensional. They are the ideal crystalline substances for gas separation and storage. The as-synthesized samples were characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM), thermal gravimetric analysis (TGA) and CO2 adsorption test. Results illustrated that the synthesized samples had stable structure, high thermal stability (up to 530°C) and CO2 adsorption capacity (1.63 cm3/g at 273 Kelvin under ambient pressure). This novel method also showed great advantage with high energy efficiency, safe synthesis conditions, and rapid crystallization time (about 60 minutes).

10:55 AM
The Relationship between Energy Consumption and CO2 Emissions in Iron and Steel Making: *Hao Bai*[1]; Xin Lu[1]; Hongxu Li[1]; Lihua Zhao[1]; Xueting Liu[1]; Ning Li[1]; Wei Wei[1]; Daqiang Cang[1]; [1]University of Science and Technology Beijing

Based on the principle of carbon balance, a model was built to calculate CO2 emissions of each process and correspondingly the total course of production in iron and steel making. The data from a typical integrated steelworks in China was applied in the model. The results show that the BF and coking process account for the most emissions. Generally, CO2 emissions in integrated steelworks depend on three factors, resources utilization efficiency, energy utilization efficiency and energy consumption structure, which were considered in an equation in this paper. Especially, General Emission Factor (GEF) was proposed to assess the relationship between CO2 emissions and energy consumption. The results show that, higher GEF will result in more CO2 emissions with the same energy consumption and in iron and steel making, the optimization of energy structure and development of eco-industrial park both have significant benefit on the carbon reduction.

11:10 AM
Development and Application of Shaft Kiln in China: Zhen Guo Li[1]; *Dong Li*[2]; Guang Zhen He[3]; [1]Shanghai Cadre Environment Energy Science and Technology Co., Ltd; [2]Shanghai Cadre Environment Energy Science and Technology Co., Ltd; [3]Shenyang He Carbon Furnace Design Institute

The new type shaft kiln is developed and designed by CADRE itself on the basis of the conventional shaft kiln. The actual application in a number of calcination plants have proven that they are of very good effect. Calcined coke heated by the shaft kiln have high quality, lower lost by fire. The shaft kiln need no additional fuel when it is working. Anode Carbon Plant and calcined coke Plant commonly used the shaft kiln in domestic. The waste heat from the shaft kiln can be recuperated to generate electricity and to make the steam or power for produce. This paper introduces the working principle and characteristics of the shaft kiln. It also demonstrates measured process parameters of the new type shaft kiln. The shaft kiln proves its own technical characteristics and advantages: higher capacity, high quality products,provides more energy for power generation,Equipment operation and maintenance costs lower.

11:25 AM
Preparation of Biodiesel by Transesterification of Canola Oil Using Solid Base Catalyst KOH / γ-Al_2O_3: *Seyed Mojtaba Sadrameli*[1]; Mohamad Omraei[1]; [1]TMU

The aim of this research work was to produce biodiesel (fatty acid methyl esters, FAME) from canola oil using KOH loaded on γ-Al_2O_3 support as a heterogeneous catalyst. Different parameters such as effects of the molar ratio of methanol to oil, catalyst amount and reaction time on the yield were investigated. Scan electron microscope (SEM) and X-ray diffraction (XRD) were used for characterization of the catalysts. A biodiesel yield of 86.67% was obtained under catalyst preparation and transesterification conditions of calcinations temperature of 773 K, 4 h of reaction time at 338 K, and using 3.5 wt% catalysts and molar ratio of methanol/oil of 15:1. The leaching of potassium species in the spent catalyst was observed.

8:35 AM Keynote
Crack-Tip Process Zones in Piezoelectric Ceramics under Mechanical and Electrical Quasistatic and Fatigue Loading: *Mark Hoffman*[1]; [1]The University of New South Wales

Crack growth in piezoelectric ceramic is dependent upon the extent of domain re-orientation that occurs at the crack tip. This is known to depend upon both the magnitude of the load and whether it is mechanical or electrical. Under cyclic load, there is frequency dependence. The process is also influenced by pre-poling conditions. In this work, domain orientations around a mechanically and electrically-loaded crack in poled and unpoled PZT have been resolved using high-energy synchrotron x-rays, at both the crack tip and in the crack wake. This elucidates the size of the process and wake zones and the strains which are expected in these zones and may be used to explain observed crack-growth resistance behaviour. It is shown that when the crack is cyclically loaded the extent of ferroelastic domain movement at the crack tip is cycling frequency dependent with the size of residual zones decreasing with increasing frequency.

9:15 AM
In Situ Ultrahigh Temperature X-Ray Microtomography Facility for New Generation Structural Material: *Hrishikesh Bale*[1]; Abdel Haboub[2]; James Nasiatka[2]; Alastair MacDowell[2]; Brian Cox[3]; David Marshall[3]; Robert Ritchie[1]; [1]University of California, Berkeley; [2]Lawrence Berkeley National Lab.; [3]Teledyne Scientific LLC

Textile composites comprising of Carbon-Carbon and Carbon-SiC systems are excellent candidates for high temperature applications in the field of hypersonics and other ultra high temperature (>1200°C) applications. The material properties and performance of these materials is however intricately linked on several features that exist on a hierarchy of length scales. Due to the hierarchical structure of these materials, failures are generally complex and often occur/initiate at multiple length scales, in the form of fiber breaks, matrix cracking, multiple fiber bundle fractures etc. X-ray computed micro-tomography is an invaluable tool for providing the 3D structural information non-destructively at a relevant length scale ranging from a few micrometers to several millimeters. In the present work, we present first-time results obtained using our newly developed in-situ ultra-high temperature X-ray micro-tomography facility, wherein micro-structural features and their associated structure-property relationships that control the ultimate performance of these materials are being studied in three dimensions.

9:30 AM
Investigation of the Mechanical Properties of Ti_2SC & Ti_3SiC_2 via In-Situ Neutron Diffraction and Elasto-Plastic Self-Consistent Modeling: *Mohamed Shamma*[1]; Volker Presser[1]; Bjorn Clausen[2]; Don Brown[2]; Michel Barsoum[1]; [1]Drexel Univesity; [2]Los Alamos National Laboratory

Herein we report on the results of in-situ neutron diffraction experiments on fine-grained polycrystalline Ti_2SC and Ti_3SiC_2 with two different grain sizes. The macroscopic and individual planes' strains are modeled via elasto-plastic self-consistent (EPSC) model. We not only show that the response of Ti_2SC to stress is linear elastic up to 700 MPa but that the ab initio derived elastic constants can accurately model this response. In the case of Ti_3SiC_2, the response was typical of kinking nonlinear elastic, KNE, solids. The in situ results confirm that neither slip nor twinning is responsible for the KNE response. The response, however, is consistent with the formation of incipient kink bands, the micromechanism proposed to explain KNE behavior.

9:45 AM
Multi-Scale Energy Absorption Mechanisms in Micro-Architected Materials: *Lorenzo Valdevit*[1]; Alan Jacobsen[2]; Tobias Schaedler[2]; William Carter[2]; [1]University of California, Irvine; [2]HRL Laboratories

Recent progress in advanced manufacturing enables fabrication of macro-scale metallic lattices with unit cells in the millimeter range and sub-unit cell features at the nano-scale, thus yielding a topologically architected cellular material with structural hierarchy spanning seven orders of magnitude in length scale. When appropriately designed, these materials exhibit unique damping characteristics, unprecedented for a metallic system. The energy dissipation involves mechanisms occurring at three different length scales. We present an experimental protocol, which enables characterization of such mechanisms, allowing identification of the most relevant phenomena and the dominant length scale. By combining the experimental investigation with numerical modeling, clear guidelines for the optimal design of cellular materials for maximum energy absorption are extracted. The same design tools can be applied to the simultaneous optimization of damping and strength (typically antagonistic objectives), revealing the unique benefits of micro-architected materials.

Effect of Grain Neighborhood on Pseudoelastic Performance of Polycrystalline Shape Memory Alloys: Harshad Paranjape[1]; *Peter Anderson*[1]; [1]The Ohio State University

Simulations of polycrystalline NiTi shape memory alloys show a grain-to-grain variation in pseudoelastic strain of 2% to 6%. Moreover, the strain varies by 2% among grains with a similar orientation. This grain "neighborhood" effect is assessed by studying trends in local stress-strain response and the types of martensite habit plane variants (plates) formed. Stress redistribution tends to suppress the performance of favorably-oriented grains and enhance that of unfavorably-oriented grains. The net effect, however, is to reduce polycrystalline performance, relative to a collection of single crystal counterparts. A primary culprit is that neighboring constraint induces less favorable habit plane variants, particularly in less-favorably-oriented grains. Despite these drawbacks, predictions are shown where stress redistribution and constraint enable dramatic, sometimes beneficial manipulation of polycrystalline shape memory alloy response.

10:30 AM
Novel Characterization of the Martensitic Transformation Temperature of NiTi Shape Memory Alloys via Micro-Indentation: *Bin Gan*[1]; Sara Cantonwine[1]; Mathilde Gatepin[1]; Sammy Tin[1]; [1]Illinois Institute of Technology

Nickel-Titanium (NiTi) shape memory alloys possess an extraordinary capability to recover plastic strain and return to its original shape when heated above the martensite transformation temperature. Using a high temperature instrumented micro-indentation system, we have demonstrated the ability to perform in-situ measurements of the martensitic transformation temperature of NiTi alloys. Following indentation of the material at room temperature, the system was heated while the indenter remained in contact with the surface while maintaining a constant load. The onset of martensitic transformation was determined by plotting the resulting displacement of the indenter as a function of temperature. Results from the depth sensing experiments were compared and found to be consistent with Differential Scanning Calorimeter (DSC) measurements and conventional mechanical tests followed by heating. Results from the study will be presented and the implications of the novel characterization technique will be discussed.

10:45 AM
Fatigue Life-Prediction of Nitinol under Multiaxial Loading: *David Xu*[1]; Robert Ritchie[1]; [1]UC Berkeley

Modern measurements of medical implants are providing new information on the magnitude of complex in vivo loads. Thin-walled tubes of Nitinol were tested in tension and torsion to investigate the fatigue behavior and develop a life-prediction model for multiaxial loads based on uniaxial behavior. The strain-life torsional e-N curve for superelastic Nitinol at zero mean strain and positive mean strain results appear to collapse reasonably well. However some high mean strain tensile data fails to merge under such technique. An alternative approach using transformation strain is found to collapse all data reasonably. This holds promise for normalizing cyclic fatigue data with a strain-based methodology. The improved approach can be expressed in terms of a Coffin-Manson type formulation where the alternating equivalent transformation strain is related to the -1/2 power of cycles to failure. It allows a satisfactory normalization for all testing modes studied over the entire range of strain ratios.

11:00 AM
Adhesion of Nickel-Titanium Shape Memory Alloy Wires to Polymeric Materials: Theory and Experiment: *Louis Hector Jr*[1]; Federico Antico[2]; Pablo Zavattieri[2]; [1]GM R&D Center; [2]Purdue University

A combined experimental/theoretical study of adhesion between a Nickel-Titanium (NiTi) shape memory alloy wire embedded in a Thermoplastic Polyolefin (TPO) matrix is presented. NiTi wire surfaces were modified to improve adhesion by functionalizing with an acid etch or chemical coupling agent or application of a surface microgeometry. Wire surface features from each treatment were examined with atomic force microscopy. Pull-out tests were conducted and the extent to which each treatment increased the pull-out force was quantified. Results from a nonlinear finite element analysis wherein the NiTi/TPO matrix interface is modeled with a cohesive zone model suggest that the interface behavior strongly depends on the cohesive energy during pull-out, and less on the cohesive strength. Additionally, a parametric analysis is performed to take into account how the residual stresses from manufacturing process affect the local mode mixity during debonding.

11:15 AM
Toughening in Bio-Inspired Shape Memory Alloy Embedded Composites: *Fatmata Barrie*[1]; Michele Manuel[1]; [1]University of Florida

Shape memory alloy (SMA) reinforced composites are being investigated due to their enhanced mechanical properties over monolithic materials, namely increased strength, dampening abilities, and toughness. The focus of this study is to characterize the effect of the SMA reinforcement phase transformation properties on the composite toughening behavior. These composites are inspired by biological systems like mollusks whose increased toughness can be attributed to the presence of a ductile reinforcement in a brittle matrix. The results of a systematic investigation of SMA embedded composites using the J-integral fracture toughness testing method will be presented to reveal underlying structure-property relationships. In addition to extrinsic toughening mechanisms, the R-curve behavior is quantified and correlated to the underlying martensitic transformations in the SMA reinforcement. The results will lead to a deeper understanding of fracture and deformation mechanics driving toughening behaviors in composites with ductile-like, phase transforming reinforcements. The authors would like to gratefully acknowledge the support of the National Science Foundation under grant number CMMI-0824352.

11:30 AM
The Effect of Morphology on the Mechanical Behavior of Cu(Ni)-C Nanocomposites: *Alan Jankowski*[1]; Tanvir Ahmed[1]; [1]Texas Tech University

Nanostructures synthesized with a composition fluctuation along the growth direction are metastable engineered nanolaminates with physical properties that can range far from equilibrium. Common to each nanolaminate is the interface structure and the periodic or random distribution of interfaces. The ability to form a well-defined layered structure is affected by both the chemical solubility of constituent elements as well as superlattice distortions. Both of these attributes are present in the copper(Cu)-nickel(Ni)-carbon(C) alloy system. Transition from a 3-D to 2-D nanostructure occurs as the morphology changes from dispersed Cu(Ni) nanoparticles in a C-based matrix, to distinct a nanolaminate structure as the Ni concentration is increased within the Cu layer. Results are presented on the effects that strain and chemically solubility have on the morphology and the mechanical properties of nanocrystalline Cu(Ni)-C as assessed using high resolution electron microscopy, and dynamic nanoindentation test methods in the scratch and tapping mode.

Magnesium Technology 2012: Advanced Processing and Joining

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Magnesium Committee
Program Organizers: Suveen Mathaudhu, U.S. Army Research Office; Wim Sillekens, TNO; Norbert Hort, Helmholtz-Zentrum Geesthacht; Neale Neelameggham, U.S. Magnesium

Thursday AM — Room: Southern V
March 15, 2012 — Location: Dolphin Resort

Microstructure and Creep Properties of MEZ Magnesium Alloy Processed by Thixocasting: Emma Deyanira Morales Garza[1]; Hajo Dieringa[1]; *Norbert Hort*[1]; [1]Helmholtz-Zentrum Geesthacht

Whereas in most magnesium applications die casting is the dominant manufacturing process, thixocasting recently came into focus of producers. This is mainly due to the improved microstructure, reduced porosity and better mechanical properties. An important issue for the introduction and use of magnesium alloys in automotive industry is their creep resistance. Aluminium free magnesium alloys are known to show improved creep strength compared to conventional aluminium containing alloys due to the absence of beta phase (Mg17Al12). In this paper, the mechanical and creep properties from thixocast MEZ alloy are evaluated from creep tensile tests at temperatures of 135°C, 150°C and 175°C and at stresses between 60 and 100 MPa. The creep activation energy and the stress exponent are calculated and discussed. Optical and scanning electron microscopy of the microstructural features developed after the mechanical tests helps to understand the deformation mechanisms occurring during creep and to explain the improved creep properties after thixocasting.

8:50 AM
The Effect of Friction Stir Processing on Microstructure and Tensile Behavior of Thixomolded AZ91 Magnesium Alloy: *Bilal Mansoor*[1]; Raymond Decker[2]; Sanjay Kulkarni[2]; Steve LeBeau[2]; Marwan Khraisheh[1]; [1]Masdar Institute of Science and Technology, Abu Dhabi, UAE; [2]Thixomat Inc.

Friction Stir Processing (FSP) to partial sheet thickness can be utilized to engineer unique microstructures in metallic alloys. These composite microstructures consist of three distinct layers associated with stirred, transition and core microstructural regions. The stirred region is of particular interest where severe plastic deformation imparted by the rotating and translating FSP tool under frictional heat leads to grain refinement down to ~ 1 µm grain size. In this work, partial depth penetration into thixomolded AZ91 Mg plate from the top and bottom surfaces by friction stir processing is explored. Furthermore, low temperature aging treatments are applied to the processed material. The present results with AZ91 Mg show that FSP processed material exhibits higher strength (> 300 MPa), and improvement in ductility (> 7 % tensile elongation). It is found that in addition to Hall-Petch strengthening produced by ~ 1 µm grain size in the stirred region, the enhanced strength levels and ductility are strongly influenced by dispersoids of the intermetallic precipitates found in this alloy.

9:10 AM
Effect of Weld Structure on Fatigue Life of Friction Stir Spot Welding in Magnesium AZ31 Alloy: *Harish Rao*[1]; J Jordon[1]; [1]The University of Alabama

In this paper the fatigue behavior in friction stir spot welded coupons of magnesium AZ31 alloy manufactured under different welding conditions are investigated. Two sets of lap-shear coupons were welded based on varying the plunge depth and tool geometry. Metallographic analysis of the untested lap-welds revealed differences in microstructural and geometrical features. Results from the load controlled cyclic tests showed that one set of welds exhibited better fatigue performance compared to the other set. Optical fractography of the failed fatigue coupons revealed that fatigue cracks initiated at the weld interface in both sets of coupons. However, the fracture mode showed variability between the two sets of coupons. As such, the main conclusion of this study is that the effective top sheet thickness, which is largely determined by the shoulder plunge depth, plays a significant role in the fatigue behavior of the friction stir spot welds in magnesium alloys.

9:30 AM
Effect of Corrosion on the Tensile Properties of Friction-Stir Welded AZ31B Sheet: *Jennifer Thuss*[1]; Joseph Kish[1]; Joseph McDermid[1]; [1]Centre for Automotive Materials and Corrosion, McMaster University

To facilitate the use of magnesium and its alloys within automotive structures, it is necessary to characterize their corrosion and possible mechanical property degradation in typical application environments. This work examines the effect of exposure to NaCl-based corrosive environments on the mechanical properties of friction stir welded (FSW) AZ31B magnesium alloy sheet. A complete microstructural, electrochemical, residual stress and mechanical property characterization of the as-received FSW panels was performed. Samples were subsequently exposed to 0.01M and 0.1M NaCl solutions for a variety of times and any changes in mechanical properties as a function of exposure to the corrosive environment monitored. This paper will present the relationship between the changes in mechanical properties of the FSW joints resulting from exposure to the corrosive environment as a function of the FSW microstructure, localized electrochemical potentials arising from the FSW microstructure and residual stress in the welded joints.

9:50 AM
High Speed Rolling of AZ31 and Mg-Zn-Ce Alloys: *Mehdi Sanjari*[1]; Amir Farzadfar[2]; In-Ho Jung[2]; Steve Yue[2]; Masahiro Hattori[3]; T Sakai[3]; Hiroshi Utsunomiya[3]; Elhachmi Essadiqic[4]; [1]McGill ; [2]McGill; [3]Osaka University; [4]CANMET

One of the benefits of using high speed rolling for Mg alloys is for improving the hot rollability. In this study AZ31 and four Mg-Zn-Ce alloys were investigated under number of different rolling schedules. At a rolling temperature of 450 °C and rolling speed of 1000 m/min, the peak intensity of the (0001) pole figure tilted 10-15° towards the RD direction to form a double peak texture for both AZ31 and Mg-Zn-Ce alloys. A texture variation through thickness was observed. From the surface to the center of thickness, the direction of the (0001) peak TD-split rotated 90°. After annealing, the basal texture component of the Mg-1Zn-1Ce magnesium alloy sheets was weakened, and replaced by a new component rotated 45 ° towards the transverse direction. The hot tensile tests results confirm that the Mg-1Zn-1Ce alloy sheets with this non-basal texture component exhibit a higher ductility than the alloys with basal texture.

10:30 AM
On the Effect of Ti_2AlC on the Formation of Thermally Stable Mg Nano Grains: *Babak Anasori*[1]; Michel Barsoum[1]; [1]Drexel University

When Mg and Mg-alloys are reinforced with Ti_2AlC, - using a simple pressureless melt infiltration method – the result is nanocrystalline, nc, Mg-matrix composites with outstanding mechanical properties. As an added bonus, the nc Mg-matrix is extraordinarily thermally stable up to above the melting point of Mg. When Mg-alloy, AZ61, is used to infiltrate the Ti_2AlC preform, ultimate tensile stresses of 800 MPa are achieved. The reasons that lead to the formation of the nc-Mg are as of yet not understood. In this study, the different composite's microstructures are investigated by X-ray diffraction, scanning electron and transmission electron microscopy. The results shed light on why the Mg forms as nano-grains and why they are as stable as they are.

10:50 AM
Experimental Investigations on the Deformation Behavior of Thixo-Molded Mg Sheet Alloy: *Muammer Koc*[1]; Omer Cora[2]; Ryan Snell[3]; Ray Dekker[4]; Jack Huang[4]; [1]Istanbul Sehir University; [2]Karadeniz Tech Univ; [3]VCU; [4]Thixomat

Deformation behavior and formability limits of thixo-mold Mg alloy sheets at elevated temperature conditions were investigated experimentally. Uniaxial tensile, hydraulic bulge tests as well as closed-die hydroforming tests were conducted to understand the material behavior at temperatures ranging from 25°C to 300°C and strain rates at 0.0013, 0.013, and 0.13 s-1. As a result of the experimental findings, it was found that flow stress and the maximum plastic strain increased with increasing temperature and decreasing strain rate. Closed-die warm hydroforming tests were also performed to determine the process window for the alloy. Die cavity filling ratios and thinning of the sheet blanks were measured with non-contact optical photogrammetry. Results indicated that slower strain rates and higher temperatures increase formability, particularly after a temperature level of 200°C.

11:10 AM
Effects of High Temperature Shot Peening on Surface Characteristics and Fatigue Properties of Forged AZ31 Magnesium Alloys: *Ichihara Yuki*[1]; Masahumi Noda[1]; Kunio Funami[1]; [1]Chiba Institute of Technology

In this present study, the effect of high-temperature shot peening (HSP) on surface characteristics and fatigue properties of forged AZ31 magnesium alloy were investigated. HSP process were performed by peening pressure 0.2 MPa and time 6 s at peening temperature 523 K with the low-carbon steel ball. As the result, graded microstructures formed at the near surface region about 150 μm from surface edge. It was composed by ultra fain-grained region, residual working strain region and twin region. HSP processed material was increased fatigue strength compared with non-HSP processed material. From measurement of crack propagation rate, it was found that the improvement of fatigue properties was lead of the delay of crack propagation rate in the ultra fain-grained region and the residual working strain region.

11:30 AM
Solid Solution Hardening Effect of Aluminum on the Creep Deformation of AZ91 Magnesium Alloy: Farhoud Kabirian[1]; *Reza Mahmoudi*[2]; [1]University of Maryland, Baltimore County; [2]University of Tehran

It has been previously shown that separate additions of 2% rare earth elements (RE) and 0.6% Zr to the AZ91 base alloy improve creep properties. However, in this investigation using impression creep method, it is shown that simultaneous addition of these elements not only cannot improve creep properties but also leads to its deterioration. According to the creep deformation mechanism of the base alloy and microstructural evidences, it is believed that this drop in creep resistance mainly stems from depletion of grain interiors and the areas adjacent to grain boundaries from aluminum solute atoms. Reduction of aluminum content as solute atoms is due to the great affinity of RE and Zr atoms for aluminum. This leads to the weakening of Al solute atoms role as obstacles against dislocation movement, even though the volume fraction of the thermally stable particles tends to be high.

8:30 AM
Microstructure Modeling of Magnesium Alloys for Engineering Property Prediction: *Erin Barker*[1]; Dongsheng Li[1]; Xin Sun[1]; Mohammad Khaleel[1]; [1]Pacific Northwest National Lab

Magnesium alloys have found increasing application in the transportation industry due to their low weight and high strength. However, wider application is hindered by limited ductility. Microstructural features, such as porosity, brittle eutectics, and grain size, can significantly influence the macroscopic response of a component. These features can vary widely throughout a component. Our approach to studying the microstructures influence on bulk properties begins with measuring microstructural features in different regions of a component. These measurements are used to create statistically equivalent, 3D synthetic samples of the microstructure. The synthetic microstructures are meshed using finite elements and used to simulate the response and investigate the influence of specific features. We will demonstrate how the digital microstructure samples are generated, how variations in microstructural features influence the bulk properties, and how this methodology can be used to predict component performance and optimize processing.

8:50 AM
Microstructure Modification and Deformation Behavior of Fine-Grained AZ61 Sheet Produced by Thixomolding and Thermomechanical Processing (TTMP): *Tracy Berman*[1]; William Donlon[1]; Victoria Miller[2]; Jack Huang[3]; Raymond Decker[3]; Tresa Pollock[2]; J. Wayne Jones[1]; [1]University of Michigan; [2]University of California Santa Barbara; [3]nanoMAG, LLC

X-ray diffraction and hardness measurements are used to study recrystallization in fine-grained AZ61L sheet produced by warm-rolling of Thixomolded\174 material. The as-rolled sheet is partially dynamically-recrystallized, with a strong basal texture and a sub-micron grain size. Significant increases in ductility with moderate reductions in tensile strength were produced by annealing at temperatures greater than 250\176C. A weakening in basal texture was observed in samples annealed at over 250\176C. Static recrystallization was determined to be responsible for the reduction in texture and associated increase in elongation.

9:10 AM
Development of High Strength and Toughness Magnesium Alloy by Grain Boundary Control: *Hidetoshi Somekawa*[1]; Alok Singh[1]; Tadanobu Inoue[1]; Toshiji Mukai[2]; [1]National Institute for Materials Science; [2]Kobe University

The fracture toughness is one of the important mechanical properties to identify the safety and reliability for the structural parts; however, magnesium alloys is reported to be lower fracture toughness compared to that in aluminum alloys. Recent studies show that the grain boundary control, i.e., formation of sub-grain structure, is one of the effective methods to improve the fracture toughness with remaining high strength and ductility properties in magnesium alloy. This is resulted that the sub-grain boundaries are not the site for the micro-void formation; sub-grain boundaries can prevent or reduce the stress concentration by the free movement of dislocations. In this study, using AZ61 alloy, the fine grain structures, which were surrounded by sub-grain boundaries and dispersed with fine precipitate particles, were produced by the severe plastic deformation, i.e., caliber rolling. This alloy showed the high strength and fracture toughness balances corresponding to the conventional high strength aluminum alloys.

9:30 AM
Effects of Direct Extrusion Process on Microstructure, Texture Evolution and Yield Strength of Magnesium Alloy AZ31: Shiyao Huang[1]; *Mei Li*[1]; John Allison[2]; Shaorui Zhang[3]; Dayong Li[3]; Yinghong Peng[3]; [1]Ford Motor Company; [2]University of Michigan; [3]Shanghai Jiao Tong University

Direct extrusions of commercial as-cast AZ31 alloy were carried out at elevated temperatures with different extrusion velocities. Microstructure and texture distribution of extruded rods were investigated with optical microscopy (OM) and electron backscattered diffraction (EBSD). Tensile tests were conducted at room temperature using samples from both casting billets and extruded rods. The experimental yield strength can not be solely described by average grain size. In this paper, the grain size and orientation in the extruded samples were characterized by EBSD, and Hall-Petch equation was applied to each individual grain with the input from EBSD results (individual grain size and orientation). The yield strength of tensile sample (polycrystalline aggregate) and individual grain was related by Taylor assumption. The predicted yield strength showed the same trend as experiment results.

10:10 AM Break

9:50 AM
Comparison of Tensile Properties and Crystallographic Texture of Three Magnesium Alloy Sheets: *Junying Min*[1]; Ying Cao[1]; Jon Carter[2]; Ravi Verma[2]; [1]Tongji University; [2]GM R&D

The most common commercially available rolled magnesium sheet alloy is AZ31B (typ. 3% Al, 1% Zn, 0.4% Mn, balance Mg). One of the often-cited shortcomings of this sheet is its limited formability at room temperature, which is attributed in part to a strong crystallographic texture. Attempts have been made to avoid this rolling-induced texture by changing either (a) the alloy composition or (b) the rolling process. Specifically, sheet has been made using the conventional rolling practice, but changing the alloy to ZEK100 (typ. 1% Zn, 0.2 % Nd, 0.2% Zr, balance Mg), or by keeping the AZ31B composition but rolling at 100°C higher than conventional practice dictates. In this report, both types of sheet are compared with conventionally rolled AZ31B sheet. Both show reduced texture and attractive tensile properties, and therefore both are expected to show greater room-temperature formability than conventionally rolled AZ31B.

10:30 AM
Strain Hardening of ZK60 Magnesium Alloys: *Jaehyung Cho*[1]; Suk Bong Kang[1]; [1]Korea Institute of Materials Science

ZK60 alloys (Mg-Zn-Zr) had improved mechanical properties of high strength and high elongation, comparing other wrought magnesium alloys. In general, Mg-Zn system possessed precipitate hardening behaviors during aging. Rod- and disc-shaped precipitates were usually found, and microhardness and strength of the alloys changed with aging. The ZK60 alloys have finer grains and improved mechanical properties than the usual Mg-Zn system by addition of Zr element. In this research, we investigated precipitate variation with aging process. Two types of specimens, solution-heat treated (T4) and aged (T6) samples, were prepared to examine precipitates and mechanical properties. Casted ZK60 ingot was cut, and then solution-heat treatment was carried out 10 hrs at 400°C. Aging process was intended to have peak hardening and thus heat treatment was carried out 12 hr at 175°C. Deformation behavior of ZK60 alloys were also investigated by uni-axial compression. Precipitates and microstructure were investigated using TEM, and EBSD.

10:50 AM
Strain-Rate Effects of Sand-Cast and Die-Cast Magnesium Alloys under Compressive Loading: *J.P. Weiler*[1]; J.T. Wood[1]; [1]University of Western Ontario

The strain-rate effects of cast magnesium alloys were investigated with uniaxial compression and compressive impact testing. The compressive material response of specimens cut from sand cast AZ91, AE44, and AM60, and high-pressure die-cast AM60 was determined for strain-rates ranging from quasi-static levels to typical rates experienced during crash situations. Several different constitutive material models (Johnson-Cook, Cowper-Symonds, etc.) were used in an attempt to characterize the experimental results. These material models are typically available in commercial finite-element packages and can be used to model the resulting material response of die-cast automotive components produced with these alloys to more complex loading conditions. The resulting deformed microstructures and fracture surfaces of each alloy at different strain-rates were also analyzed.

11:10 AM
Mechanical Properties of Newly Developed Mg-Alloys AMX602 AND ZAXE1711 under Quasi-Static and Dynamic Loading: *Jianghua Shen*[1]; Weihua Yin[1]; Katsuyoshi Kondoh[2]; Tyrone L. Jones[3]; Suveen N. Mathaudhu[4]; Zhiliang Pan[1]; Laszlo Kecskes[3]; Qiuming Wei[1]; [1]UNC Charlotte; [2]Osaka University; [3]US Army Research Laboratory; [4]U.S. Army Research Office

We present some experimental results on two newly developed Mg-alloys, AMX602 and ZAX1711. We have evaluated the dependence of the mechanical properties of these alloys on the extrusion temperatures under both quasi-static (strain rate ~1X10-3 s-1) and dynamic (strain rate ~4X103 s-1) uniaxial compressive loadings. We have observed that the quasi-static yield strength of AMX602 exhibits slight dependence on the extrusion temperature, whereas the ultimate strength and the deformation-to-failure are absent of such dependence. On the other hand, the dependence of the mechanical properties of ZAXE1711 is much more complicated. We have also found that the deformation-to-failure of both alloys increases at increased strain rate. For comparison, we have tested two conventional Mg-alloys, WE43 and AZ91C under the very similar conditions. We have found that AMX602 and ZAXE1711 show significantly improved mechanical properties compared with WE43 and AZ91C under either quasi-static or dynamic loading.

11:30 AM
Phase Field Modeling of β_1 Precipitation in WE54 Alloy: *Yipeng Gao*[1]; Hong Liu[2]; Rongpei Shi[1]; Zhou Xu[2]; Jianfeng Nie[2]; Yunzhi Wang[1]; [1]The Ohio State University; [2]Monash University

WE54(Mg-5wt%Y-2wt%Nd-2wt%RE), which has high strength and light weight at elevated temperatures, has been identified as one of the most successful magnesium alloys. The strength of WE54 can be achieved via precipitation strengthening by aging at 150~250°C during which precipitations of intermediate phases β_1 and β' and equilibrium phase β take place. In order to understand the microstructure evolution of β_1 phase and its effects on β' and β precipitation, a phase field model of β_1 precipitation has been developed. Model inputs, including lattice parameters, precipitate-matrix orientation relationship, elastic constants and free energy data, are obtained from experimental characterization, ab initio calculations and thermodynamic databases. Through computer simulations, the equilibrium shape and spatial distribution of and stress field around the β_1 precipitates are quantitatively determined. The effect of elastic interactions among different precipitates on the multi-variant morphology is investigated and the corresponding effect on the strength of the alloy is discussed.

Magnetic Materials for Energy Applications II: Power Conversion and Microstructural Effects

Nanocomposite Alloy Design for High Frequency Power Conversion Applications: Shen Shen[1]; Paul Ohodnicki[2]; Samuel Kernion[1]; Alex Leary[1]; Vladimir Keylin[3]; Joseph Huth[3]; *Michael McHenry*[1]; [1]Carnegie Mellon University; [2]National Energy Technology Laboratory; [3]Division of Spang & Company

Recent DOE workshops highlight the need for advanced soft magnetic materials leveraged in novel designs of power electronic components and systems for power conditioning and grid integration. Dramatic weight and size reductions are possible in these applications through operating at increased frequencies. This manuscript discusses processing and composition design approaches for optimizing FeCo-based nanocomposites for higher frequency operation at 100 kHz and above. The proposed strategy involves starting with prior compositions known to exhibit high inductions, optimal field crystallization induced anisotropy, and excellent mechanical and high temperature magnetic properties. Proposed alloy modifications for the applications of interest would include increased amorphous phase resistance, optimum induced anisotropy, and minimized or carefully engineered magnetostriction. Relevant process developments would target reduction of ribbon thickness by optimizing the casting process or post-processing treatments such as chemical thinning or rolling. Three archetypes FeCo-based nanocomposites are described including near equiatomic FeCo-based, Fe-rich and Co-rich alloys.

9:00 AM Invited
Economic and Low-Temperature Fabrication of Highly-Textured Ferrite Films and Their Potential in Power-On-Chip Application: Y Yang[1]; Jun Ding[2]; [1]Natl. Univ. of Singapore; [2]National University of Singapore

Recently, magnetic films have been investigated for components in power supplier on chip, for example DC-DC converter. These devices can make IT products to be more energy-efficient. MnZn- and NiZn-spinel ferrites are microwave magnets used in inductors and other devices. Sol-gel has been widely used in the fabrication of spinel ferrite films. However, the formation of the spinel phase often requires a post-annealing at a high temperature. Components of power supplier on chip must be CMOS technology compatible. Therefore, temperature during fabrication should never exceed 400 °C. Most recently, our research work has achieved highly texture spinel ferrite films via a chemical route – thermal decomposition at a temperature below 300 °C. High values of magnetization with excellent soft magnetic properties have been obtained in MnZn- and NiZn-ferrite films. In this presentation, we will report synthesis, structure and magnetic properties of these spinel ferrite films and their potential applications.

9:30 AM
Magnetic Properties of Strontium Ferrite Prepared Using Submicron-Sized SrFe12-x AlxO19 Powders: *Vladimir Menushenkov*[1]; Vladimir Shubakov[2]; Sergey Ketov[2]; [1]National University of Science and Technology; [2]National University of Science and Technology,

The glass samples were obtained by melting of the oxides mixture SrO–Fe2O3–B2O3–(Al2O3) at 1250-1300°C with subsequent quenching of the melt on quickly rotating steel roller. Submicron-sized SrFe12-xAlxO19 particles were formed in glass-ceramic matrix during the crystallization aging of glass. The aging temperature Tag varied in the range 600–950°C. The submicron-sized hexaferrite powder was obtained by removing of the matrix phases using etching. The samples were characterized by X-ray diffraction, scanning electron microscopy and magnetization measurements. The glass-ceramic material exhibits very high coercivity value up to 10 kOe. The samples of magnets were obtained by pressing of the hexaferrite powder at RT and subsequent aging in the range 900–1200°C. The aged samples exhibit high coercivity value up to 8 kOe.

Effects of Magnetic Field on Microstructure Evolution in Decomposition Process: *Yongmei Jin*[1]; Stephen Hackney[1]; [1]Michigan Technological University

Decomposition processes in spinodal-type magnetic alloys under external magnetic field are investigated by phase field modeling and simulations. The model explicitly treats structural and magnetic domains and takes into account multiple thermodynamic driving forces, including chemical, interfacial, magnetostatic, elastostatic, magnetocrystalline, exchange, and external magnetic and mechanical loading. Various spinodal-type magnetic systems of different magnetic properties and misfit strains are considered. The simulations show the influences of magnitude and direction of applied magnetic field to the microstructure evolution in diffusional phase separation, and reveal the underlying mechanisms of magnetic domain formation and internal magnetic field development responsible for the two-phase morphology. The simulation results provide insights into the effective microstructure control in various spinodal-type magnetic alloys by magnetic annealing.

10:15 AM
Electrical and Structural Characteristics of Ba2DyNbO6: *Suharto Chjatterjee*[1]; Koushik Biswas[2]; Mukul Pastor[2]; [1]Ace Calderys Ltd; [2]Indian Institute of Technology, Karagpur, India

The electro ceramic material Ba2DyNbO6 has been prepared by a standard solid-state reaction technique. Structural analysis was performed with XRD in which dominant (98%) cubic perovskite phase was found. The tolerance factor of the sample was found to be 0.891 suggesting that the sample is stable. The FTIR analysis showed good bond strength in the sample. The experimental results of impedance spectrum indicate that the material exhibits (i) electrical resistance due to bulk material up to 575°C (ii) negative temperature coefficient of resistance (NTCR)-type behaviour and (iii) temperature-dependent relaxation phenomena up to 500°C. The behaviour of the modulus spectrum is suggestive of temperature-dependent ion hopping mechanism for electrical conduction (charge transport) in the system. The AC conductivity spectrum was found to obey Jonscher's universal power law. Conductivity phenomenon has been explained with respect to thermal activation resulting in mobile charges.

10:30 AM
Impact of Magnetic Fields on the Corrosion Degradation of Ferromagnetic Materials in Aqueous Electrolytes: *Ralph Sueptitz*[1]; Kristina Tschulik[1]; Margitta Uhlemann[1]; Ludwig Schultz[1]; Annett Gebert[1]; [1]IFW Dresden

Beside their magnetic properties, the corrosion resistance of magnetic materials is crucial for ensuring a low loss of efficiency during the life time of electromagnetic devices. While the corrosion behaviour of many magnetic materials is well known, the effect of superimposed magnetic field on the corrosion process is scarcely investigated. The impact of applied magnetic fields on the free corrosion and anodic dissolution of iron and NdFeB permanent magnetic materials was investigated. Low concentration electrolytes, relevant to current applications were also studied. After electrochemical tests the surface profiles of the electrodes were analyzed. The effects of magnetic field on the corrosion rate of these materials and the localization of the corrosion reaction is summarized. Depending on the magnetic field to electrode configuration, magnetically enhanced or reduced corrosion rates and localized material loss is reported. A mechanism of magnetic field action on electrochemical reactions in low concentrated electrolytes is described.

10:45 AM
Influence of Magnetization on the Hydrogen Embrittlement Behavior in AISI 4340 Steel: *Meenakshisundaram Ramanathan*[1]; Biswadeep Saha[1]; Chai Ren[1]; Sivaraman Guruswamy[1]; Micheal McCarter[1]; [1]University of Utah

Three-point bend test was used to study the effect of electrochemically charged hydrogen and magnetic field on the embrittlement behavior of AISI 4340 steel in this work. Acoustic emission signals were collected during the test and analyzed to gain an understanding of the crack growth process. Cathodic hydrogen charging in AISI 4340 steel resulted in drastic reduction of ductility and strength. Hydrogen embrittlement was characterized by a change in fracture surface from dimpled ductile surface to quasi cleavage type fracture. No significant effect was observed in the presence of magnetic field. The acoustic emission signals collected during the test provided an indication of the extent of energy released during the crack growth process.*Support of this work by NSF through the award DMR-0854166 is gratefully acknowledged

11:00 AM
The Effect of Dynamic Electropulsing on Mechanical and Microstructural Properties of Cold Rolled Fe-6.5%Si Alloy Sheet: *Yongfeng Liang*[1]; Feng Ye[1]; Hongchan Zhou[1]; Fuming Wang[1]; Guoyi Tang[2]; Junpin Lin[1]; [1]University of Science and Technology Beijing; [2]Tsinghua University

Fe-6.5%Si alloy is a very excellent soft magnetic material compared with conventional Si steel, especially in high frequencies with reduced iron losses and noises. But it is hard to be fabricated due to its brittleness at room temperature. Mechanical and microstructural properties are investigated with different electropulsing and strain rate. The dynamic electropulsing is applied to the cold rolled Fe-6.5%Si sheet during tensile deformation. It is found that the yield stress decreases and the elongation increases with application of dynamic electropulsing. It is indicated that the work hardening could be reduced with the dynamic electropulsing during deformation, which provides a promising way to fabricate this alloy sheet much easier.

Pressure Effects in Iron-Uranium Diffusion Couples: *Daniel Koury*[1]; Gerald Egeland[1]; Abu Iqbal[1]; Thomas Hartmann[1]; [1]Harry Reid Center, University of Nevada - Las Vegas

The interdiffusion of different metals has been widely studied. The properties of different couplings depend on such extrinsic variables as annealing time, annealing temperature, and intrinsic properties such as solubilities of each material in the other and surface morphology. The focus of this work is on pressure between two pure materials in a diffusion couple. Results of diffusion experiments, conducted to model the interaction of fast reactor fuel products and fuel cladding materials, have suggested that pressure affects the diffusion rate of one metal into another. This work consists of iron-uranium diffusion couples in a three-point flexural apparatus. The iron and uranium system has been studied and is well-suited to study pressure effects. The three-point flexural system provides pressure and tension zones that are modeled by finite element analysis to calculate stress gradients throughout the materials. The results of the simulations will be compared to the results of the diffusion.

8:50 AM
Thermodynamic Properties of Complex Actinide Alloys: *Patrice Turchi*[1]; Alexander Landa[1]; Per Söderlind[1]; [1]Lawrence Livermore National Laboratory

Nuclear fuels for fast spectrum nuclear reactors raise challenging questions on the role of minor actinides and fission products and gases on properties and performance. Hence, prediction of phase stability trends and phase diagrams of complex actinide-based alloys is undoubtedly required to be able to predict materials performance. CALPHAD, combined with first-principles electronic structure results, is a powerful tool to predict the thermodynamic properties of actinide-based multi-component alloys. After a brief review of the available knowledge on {Am,Np,Pu,U,Zr} that are the basis for candidate metallic fuels, we focus on two examples, Am-Pu and Mo-U, for which ab initio input provides useful guidance for well-chosen experiments that can lead to full validation and verification of the thermodynamic driving force that is critically needed for subsequent work on materials evolution and performance. Work performed under the auspices of the U.S. DOE by LLNL under contract DE-AC52-07NA27344.

9:10 AM
Effects of Stress on Void Formation under Irradiation: *Srujan Rokkam*[1]; Karim Ahmed[1]; Anter El-Azab[1]; [1]Florida State University

We investigate the effects of stress on the nucleation and growth of voids in irradiated materials with a phase-field approach. The formulation couples point defect dynamics and void evolution with elastic effects due to the non-uniform lattice relaxation defects and inhomogeneity effects introduced by voids. The coupled problem requires the solution of two Cahn-Hilliard equations for evolution of vacancy and interstitial concentration fields, an Allen-Cahn equation for void phase dynamics, and a subsidiary stress equilibrium problem. Analysis of the coupled model recovers the corresponding sharp interface formalism for point defects diffusion and void growth under applied stress, with zero traction boundary condition over the void surfaces. We present the formalism and discuss results showing the effect of applied stress on the defect migration, void growth, void-void interactions and void self-organization. This research was supported by the EFRC on Materials Science of Nuclear Fuel under subcontract 00091538 from INL to FSU.

9:30 AM
KMC Modeling of Helium-Vacancy Clustering in Iron: *Aaron Oaks*[1]; James Stubbins[1]; [1]University of Illinois, Urbana-Champaign

Ferritic alloys are considered candidate materials for advanced nuclear power systems as a result of their excellent resistance to void swelling, superior thermal conductivity, lower thermal expansion and acceptable high temperature mechanical strength compared to austenitic stainless steels. The FeCr-based alloy system is considered the lead alloy system for a variety of advanced reactor components and applications. In this modeling study, we will use kinetic Monte Carlo (kMC) to look at the effect of helium on the accumulation of defects and defect clusters in the iron system. Formation, migration, and binding energies from ab initio and molecular statics studies will be used as input to the kinetic Monte Carlo model to simulate defect diffusion and clustering over the relevant time scales. These results will help to provide a fundamental understanding of the interactions between vacancy defects and helium introduced as a result of irradiation.

9:50 AM
Radiation-Induced Compositional Patterning and Segregation in Concentrated Binary Alloys: *Santosh Dubey*[1]; Anter El Azab[1]; [1]Florida State University

A reaction-diffusion model to capture material redistribution in a concentrated binary alloy under irradiation will be presented. In addition to vacancies, three interstitial configurations are considered: AA, BB and AB dumbbells. The overall model tracks the space and time evolution of three species on the lattice (A, B atoms and vacancies) and three interstitial types. Atomic displacement cascades are modeled as stochastic events in space and time, with each cascade event introducing a source of point defects that is localized over a finite region. With this model we have quantified the formation of self-organized compositional patterns as a function of irradiation-specific control parameters. Using free boundary conditions, segregation of alloying elements and its effect on morphological changes at the free surfaces has also been studied. This work has been extended further to study the effect of segregation on phase stability and evolution of defect microstructures (voids) under phase field formulation.

10:10 AM
Interaction of Self-Interstitial Clusters with Carbon Atoms and Carbon-Vacancy Complexes in Fe-C Alloys: *Anna Serra*[1]; Napoleon Anento[1]; [1]Universitat Politecnica de Catalunya

The mobility of ½ <111> and <100> self-interstitial (SIA) clusters and glissile dislocation loops created in irradiated Fe-C alloys is affected by their interaction with interstitial carbon atoms (C) and carbon-vacancy complexes (Cn-Vm). The interaction energy maps of ½ <111> clusters of 7 and 61SIAs with a single C and {C-V, C2 –V, C-V2} complexes have been studied by molecular statics and molecular dynamics simulations using a metallic-covalent bonding interatomic model for the Fe-C system derived by Hepburn and Ackland (2008). The interaction energy of C with a ½ <111> {110} edge dislocation is presented as limiting case. C acts as a weak trap for clusters whereas C-V complexes are stronger traps. The stability of the cluster-(C-V) group is studied as a function of temperature. The interaction energy of C with <100> clusters from 9 to 361 SIAs is presented: C is a stronger trap for <100> clusters.

10:30 AM Break

10:40 AM
Interaction of ½<111>{110} Edge Dislocation With Interstitial Carbon Atoms in α-Iron: *Hassan Khater*[1]; Anna Serra[1]; Ghiath Monnet[2]; [1]Universitat Politecnica de Catalunya (UPC); [2]EDF – R&D

The atomic scale behaviour of a ½<111>{110} edge dislocation near a single and 400ppm carbon interstitial atoms (C) in α-iron has been simulated at T≥0K. The behavior is correlated with the stress tensor due to single C which can be high but effectively short ranged. The sites where C interacts significantly with the dislocation have been investigated as well as the critical stress for the dislocation to overcome a row of C. C close to the dislocation glide plane provides the strongest barrier to slip. The dislocation unpinning stress decreases at high temperatures and saturates to a constant value above 400K. C Jumps in the core of the dislocation occur before dislocation unpinning at relatively low temperatures and was found to be sensitive to strain rate. Dislocations in a distribution of 400ppm C glide at stresses less than that of a dislocation in pure iron for long dislocation lines.

11:00 AM
Structure of Overlapping Ions Tracks in Solids: *Andrii Demchyshyn*[1]; Pavel Selyshchev[2]; [1]Taras Shevchenko National University of Kyiv; [2]University of Pretoria

Formation of extensive structures from separate tracks depending on the characteristics of the projectile beam and on parameters of the swift heavy ions induced tracks were theoretically modelled. We examined tracks like a chain of deal spherical regions.The dependence of the sample surface area after exposure and removal of the modified substance from the irradiation dose and the swift heavy ions incidence beam angle were search out. Angular dependence of the sample surface area has maximum value at certain "critical" ions incidence angle. Based on the scaling hypothesis large-scale curve were constructed, critical exponents for this percolation model were established.Calculated values of critical exponents were compared with known values for the continuous percolation model. Correlation of individual track regions results in higher ratio of the critical exponents than in a continuous percolation model, that talks about the higher connectivity of track regions structure in this model.

11:20 AM
A New Model for Predicting the Oxidation/Gasification of Nuclear Graphite: *Ryan Paul*[1]; John Morral[1]; [1]The Ohio State University

A persistent concern for nuclear graphite is loss of graphite due to thermal oxidation in air or steam. This presentation will discuss a new analytical model for the oxidation/gasification of graphite that applies when reactions have a constant rate and only occur at the walls of pores that are open to the graphite free surface. Also, the model assumes there is an internal oxidation front that moves into the sample from the surface at a constant rate, thereby connecting closed pores in the graphite interior to the free surface. Pores are modeled either as a single sphere or as a cluster of spheres in order to imitate the pore structure of real graphitic materials. Both phase field simulations and TGA experiments on graphite in air have been performed to validate the analytical model.

11:40 AM
Cluster Dynamics Modeling of Microstructural Evolution in Ferritic/Martensitic Iron Chrome: *Aaron Kohnert*[1]; Brian Wirth[2]; Donghua Xu[2]; Djamel Kaoumi[3]; Arthur Motta[4]; Cem Topbasi[4]; [1]University of California; [2]University of Tennessee; [3]University of South Carolina; [4]Pennsylvania State University

The primary goal of this modeling is to investigate the development of defect clusters during exposure to heavy ion irradiation at a wide range of temperatures as observed at the IVEM facility at Argonne National Lab. The cluster dynamics model used in this study is an expansion of simpler rate theory models with added consideration of the possibility of defect reactions to form arbitrarily large clusters and to explicitly include spatially dependent defect sinks. Primary damage production is implemented with a multiscale approach using a database of molecular dynamics simulations of displacement cascades to implant damage in the form of defect clusters in addition to Frenkel pairs. Particular attention is given to determining the appropriate diffusivity for clusters of various sizes in light of the differences between experimental and computational studies of interstitial cluster mobility. The role of cascade-defect interactions in determining the ultimate mobility of defects is also considered.

12:00 PM
2D/3D Simulation of δ-Hydride Re-Orientation under External Load by Phase Field Approach in Zircaloy Matrix: *Lingfei Zhang*[1]; Ludovic Thuinet[2]; [1]Electricité de France (EDF) R&D MMC; [2]University of Lille 1

The mechanical property of hydrided-Zircaloy cladding under external load lies in the center of nuclear reactor safety. Numerous experimental studies revealed that hydride re-orients from circumferential to the radial direction under the hoop strength. However the true mechanism and kinetics of re-orientation is very complicated and still under investigation. Advanced in numerical simulation by phase field approach is made with newly developed 3D code by large scale parallel computing that enables us to investigate the hydride re-orientation from particular crystallographic plane in 2D to the whole space in 3D. The result showed that the hydride precipitation is more complex than thought to the external load assuming constant magnitude. The simulation also reveals that classical inhomogeneous solid theory has limitation in prediction of habit plane when hydride was considered as isolated particle in an infinite plane and modification has to be done. Phase field modeling provides proof to support such modification.

Microstructures of Ferritic-Martensitic Alloys Irradiated to High Dose at High Dose Rates: *Gary Was*[1]; Zhijie Jiao[1]; [1]University of Michigan

Ferritic-martensitic (F-M) alloys are attractive candidates for structural components in sodium-cooled fast reactors. To reach the high doses expected in this application, high dose rate self-ion irradiation is used. In this study, F-M alloys HT9, HCM12A, T91 and a model 9Cr alloy were irradiated at 400 or 500°C to doses of 30 to 500 dpa using 5 MeV Fe++ ions at 10-3 dpa/s. Samples were prepared using FIB for TEM to characterize dislocation microstructure, voids, and RIS, and for APT to characterize RIP. Results show that Cr enriches at the grain boundary and Ni/Si/Mn-rich and Cu-rich precipitates nucleate following Fe++ irradiations. At a very high dose of 500 dpa, a high density of radiation-induced Cr-rich carbides was observed in HCM12A. The evolution of RIS and precipitation at high dose and high temperature and their potential effect on the alloy mechanical properties will be presented and discussed.

9:00 AM
Irradiation Studies on Friction Stir Welded MA956 and MA754: *Ramprashad Prabhakaran*[1]; J Wang[2]; B Miller[1]; J Cole[1]; I Charit[3]; R Mishra[2]; K Murty[4]; [1]Idaho National Laboratory; [2]Missouri University of Science and Technology; [3]University of Idaho; [4]North Carolina State University

Efforts are ongoing to examine the feasibility of using oxide dispersion strengthened (ODS) alloys in the advanced nuclear reactors. Conventional fusion welding of ODS alloys could cause various undesirable effects such as coalescence of oxide dispersoids and significant porosity. Efforts are ongoing to optimize the friction stir welding technique with regard to joining ODS alloys, MA956 and MA754. In this study, MA956 and MA754 alloys were friction stir welded in a bead-on-plate configuration. Higher weld efficiencies have been achieved in both the alloys. Microhardness and shear punch testing of the fresh and irradiated (1 and 2 dpa) parent and processed materials were carried out to evaluate the mechanical properties. Optical microscopy, SEM, TEM and APT were used to study the microstructures of fresh and irradiated parent and processed materials. The study has been partially supported by an ATR National Scientific User Facility grant.

9:20 AM
The Use of a Local Electrode Atom Probe Method to examine the Microstructure of Zircaloy: *Brian Cockeram*[1]; Lance Snead[2]; M. Miller[2]; [1]Bechtel-Bettis; [2]Oak Ridge National Laboratory

Literature data has shown that the irradiation of Zircaloy at very low fluencies on the order of 7X1022 n/m2 (E<1MeV) or lower results in measurable irradiation hardening, but the defect clusters responsible for such hardening are below the resolution limit of electron microscopy. Efforts to analyze Zr-based alloys using conventional atom probe that could be applied to resolve defect clusters have been largely unsuccessful due to the poor electrical conductivity of zirconium at cryogenic temperatures that generally results in premature fracture of specimens prior to obtaining a viable dataset. In this work the parameters for a LEAP are optimized using non-irradiated material, and the applied to wrought Zircaloy-2 and Zircaloy-4 following neutron irradiation at nominally 358°C to a fluence of 2.9X1025 n/m2 in the High Flux Isotope Reactor (HFIR). These results are used to determine if solute clustering at <a> loops or fine defect clusters are formed during irradiation.

9:40 AM
Phase Stability and Elemental Redistribution under High-Dose Ion Irradiation in 14YWT Nanostructured Ferritic Alloy: *Yanwen Zhang*[1]; Zihua Zhu[2]; Chad Parish[1]; Philip Edmondson[1]; Michael Miller[1]; [1]Oak Ridge National Laboratory; [2]Pacific Northwest National Laboratory

Structural materials for advanced nuclear reactors require long-term stability and radiation tolerance at elevated temperatures over extended lifetimes. Ion irradiation can be used to simulate knock-on damage and evaluate radiation-induced microstructural instabilities that may occur as a result of accumulation of radiation damage during neutron irradiation. A 14YWT nanostructured ferritic alloy was irradiated with 10 MeV Au/Pt to a penetration depth of ~1.5 µm and doses up to ~500 dpa between -100 and 750°C. Heavy ions are used to maximize the deposited energy and minimize the implanted ion content for a given displacement damage level. The irradiation-induced redistribution of Cr, W, C, N, O, Ti and Y and the response of the microstructure to high doses were characterized by complementary techniques of electron microscopy, atom probe tomography, X-ray diffraction, and secondary ion mass spectrometry. This research was sponsored by the U.S. DOE-BES-MSED and SUFD (SHaRE [APT and TEM])

10:00 AM
Influence of Cr Content on Radiation Induced and Enhanced Precipitation in Neutron Irradiated Fe-Cr Model Alloys of Low Purity: Comparison with Ion Irradiation: *Philippe Pareige*[1]; Slava Kuksenko[1]; Cristelle Pareige[1]; [1]Rouen University

Fe-Cr model alloys of high-Cr ferritic-martensitic (FM) steels, which are candidates for structural materials in Generation IV reactors, are investigated in the framework of the GETMAT European project. 3D atom probe experiments have been performed in neutron irradiated Fe-Cr model alloys with different chromium content: 12at%Cr, 9%Cr, 5% and 2.5%Cr. These model alloys of low purity were neutron irradiated at 300°C up to 0.6 dpa. Two families of clusters have been revealed: alpha' clusters and NiSiPCr-enriched clusters. Depending on the Cr content, only one of the two families of clusters can be observed. Results obtained on the neutron irradiated Fe-9%Cr alloy are compared to data collected on the same alloy, irradiated at the same temperature, with Fe+ ions having three different energies (0.5, 2 and 5 MeV) in order to obtain a constant damage up to 1.4 µm, the radiation dose being equal to 1 dpa.

10:20 AM Break

10:30 AM
Study of Ion Irradiation Effects on Microstructure of ODS Ferritic Steels by Atom Probe Tomography: *Bertrand Radiguet*[1]; Yves Serruys[2]; Olena Kalokhtina[1]; Mathieu Couvrat[3]; Laurent Chaffron[3]; Fabrice Legendre[2]; Philippe Pareige[1]; [1]GPM UMR CNRS 6634 - Université et INSA du Rouen; [2]CEA Saclay - DEN - DMN - SRMP; [3]CEA Saclay - DEN - DMN - SRMA - LTME

Oxide dispersion-strengthened (ODS) ferritic steels are promising candidates as structural materials for fusion and Generation IV nuclear reactors. They exhibit a limited swelling under irradiation, characteristic of ferritic/martensitic (F/M) matrix, and excellent creep and tensile properties at high temperatures compared to standard F/M steels, thanks to reinforcement by dense nano-oxides dispersion. Because of the interest in ODS steels for nuclear applications, it is important to determine if the nano-oxides remain stable when exposed to irradiation up to high doses in terms of displacement per atoms (dpa). In this work, 5 MeV Fe ion irradiations were performed at 500°C (in JANNUS facility) on a Fe-18Cr-1W-0,3Ti-0,3Y2O3 ODS ferritic steel. Its microstructure was characterised at the atomic scale by atom probe tomography in order to study the stability of nano-oxides and the matrix under irradiation up to 50 dpa.

10:50 AM
Influence of Grain Boundary Character and Grain Orientation on Radiation Damage by Ion Irradiation and Implantation: *Dhriti Bhattacharyya*[1]; Yongqiang Wong[2]; Pranesh Dayal[1]; David Carr[1]; Amit Misra[2]; Robert Harrison[1]; Lyndon Edwards[1]; [1]Australian Nuclear Science and Technology Organization; [2]Los Alamos National Laboratory

In a metallic system the damage caused by ion implantation, in the form of point-defect clusters, voids, bubbles, and chemical segregation is influenced by the presence of grain boundaries. The nature of the grain boundaries in terms of their misorientation and crystallographic plane can control these effects significantly. In this study these grain boundary effects are studied in ion-irradiated metals by using electron backscatter detection (EBSD) to obtain grain misorientation information, followed by focused ion beam (FIB) extraction of transmission electron microscopy (TEM) samples from specific types of grain boundaries, and subsequent examination of the samples in the TEM. Diffraction contrast was used to image defect clusters, Fresnel contrast for imaging voids and bubbles, and energy dispersive spectroscopy (EDS) and energy filtered TEM (EFTEM) for studying chemical segregation. The preliminary results of these investigations are presented here.

11:10 AM
Corrosion of HT-9 in Contact with Molten Lead Bismuth Eutectic with and without Simultaneous 6 MeV Proton Irradiation: Staffan Qvist[1]; Magdalena Serrano de Caro[2]; Alan Bolind[1]; *Yongqiang Wang*[2]; Mark Bourke[2]; Peter Hosemann[1]; [1]University of California Berkeley; [2]Los Alamos National Laboratory

A major unknown in the development of materials for advanced nuclear systems is related to the question of corrosive materials degradation under "in-service" operating conditions. In this work, we describe the irradiation/corrosion experiment, namely ICE*, performed at LANL within the Los Alamos National Laboratory – University of California Berkeley (LANL-UCB) collaboration. The purpose of this work is to study synergistic effects of irradiation on steel corrosion, and investigate if and how a steady state concentration of defects continuously created by displacement cascades affects surface chemistry such as oxidation or dissolution. ICE* builds-up on the experience gained in a previous ICE-1 experiment, where HT-9 steel was exposed to proton irradiation in the presence of Lead Bismuth Eutectic (LBE) at high temperature. ICE* constitutes a natural continuation with improved capabilities, i.e. monitoring Oxygen content in LBE, ability to reach higher temperatures and dose values.

11:30 AM
On the Stability of Nanostructured 18-Chromium ODS Steels under High Dose Ion-Irradiation: *Marie-Laure Lescoat*[1]; Joël Ribis[1]; Emmanuelle MARQUIS[2]; Yimeng CHEN[2]; Aurélie Gentils[3]; Odile Kaïtasov[3]; Yves SERRUYS[1]; Patrick TROCELLIER[1]; Arthur Motta[4]; Yann de Carlan[1]; Alexandre Legris[5]; [1]CEA Saclay; [2]University of Michigan; [3]CSNSM, CNRS/IN2P3; [4]Pennsylvania State University; [5]Université de Lille 1

Ferritic-Martensitic Oxide Dispersion Strengthened (ODS) steels are promising candidates for fuel cladding of high burn-up fast neutron reactors. To meet requirements, the stability of reinforcing nano-oxides has to be settled in the irradiation and temperature service conditions. In this work, ion irradiations are performed on 18-Chromium ODS steels and the induced microstructural modifications are investigated by the Transmission Electron Microscopy and Atom Probe Tomography complementary techniques. In-situ irradiations (CSNSM-JANNuS Orsay) of Fe18Cr1W0.4Ti+O.6Y2O3 showed that Y-Ti-O nanoclusters are apparently stable up to 45 dpa at 500°C. However, at 235 dpa (SRMP-JANNuS Saclay), radiation-induced modifications of sizes and compositions were suspected.Furthermore, inert gaz irradiations (IVEM-Argonne) performed on a Fe18Cr1W0.8Ti+0.3MgO model ODS alloy showed that the coherency of oxide/matrix interfaces plays a key role on the nucleation of Kr-stabilized cavities at room temperature.

11:50 AM
Temperature Effects on the High Dose Radiation Resistance of Nano-Sized Clusters in Nanostructured Ferritic Alloys: *Alicia Certain*[1]; Satyanarayana Kuchibhatla[2]; Vaithiyalingam Shutthanandan[2]; Chad Parish[3]; Todd Allen[1]; David Hoelzer[3]; [1]University of Wisconsin-Madison; [2]Pacific Northwest National Laboratory; [3]Oak Ridge National Laboratory

Nanostructured ferritic alloys (NFAs) have been developed to operate at higher temperatures than traditional ferritic-martensitic steels, and are expected to play an important role as cladding for fission reactor fuels or fusion blanket structural components operating in the temperature range of 350–700°C and to doses up to 200 displacements per atom (dpa). These steels contain nanometer-sized Y–Ti–O clusters for additional strengthening. Nickel ion irradiations have been performed on the NFA 14YWT up to 100 dpa at a range of temperatures (-75°C to 600 °C.) Energy-filtered transmission electron microscopy (EFTEM) and atom probe tomography (APT) have been used to analyze the evolution of the nanoclusters post-irradiation. Preliminary interpretation of results indicates that clusters are not stable for the low temperature-high dose condition studied, but appear to be stable for the higher temperature irradiations. FIB supported by DOE-BES-SUFD (SHaRE).

12:10 PM
Planar Dislocations and Dislocation Channeling in Unirradiated and Irradiated Austenitic Stainless Steels: *Young Suk Kim*[1]; Young Suk Kim[1]; Dae Whan Kim[1]; [1]Korea Atomic Energy Research Institute

Tensile tests were conducted on 316L stainless steel with nitrogen over a temperature range of RT to 750oC at strain rates of 2x10-4/s. The 316L stainless steel (SS) showed serrated flow in a temperature range of 400 to 600oC where a linear increase of strain hardening was accompanied. Using neutron diffraction, the lattice contraction due to atomic ordering was seen to occur in the 40% cold-worked 316 SS on aging at 400oC. TEM microstructures showed the formation of planar dislocations in 316L SS upon tensile testing at 400oC where SRO and serrated flow appeared. This study demonstrates that SRO is the cause of planar dislocations and serrations in austenitic stainless steels. Given that neutron irradiation produces dislocation channeling and softening after yielding in austenitic stainless steels above some fluences, the cause of dislocation channeling and softening in irradiated 304 stainless steels is discussed with short range ordering.

Application of Microstructure Engineering to the Heat Affected Zone of Welds: *Warren Poole*[1]; Matthias Militzer[1]; Mehran Maalekian[1]; [1]UBC

There is currently a significant interest in understanding the development of microstructure in the heat affected zone (HAZ) of gas metal arc welded linepipe steels, particularly for applications in Arctic environments. In this work, we have developed an integrated model for microstructure development in HAZ which includes sub-models for i) austenite grain growth including dissolution of microalloying precipitates and ii) the subsequent decomposition of austenite. The sub-model for austenite grain growth has been developed using a novel laser ultrasonic measurement technique. The integrated model is applied into experimentally determined thermal cycles for actual weld trials to predict the spatial distribution of microstructure in the heat affected zone.

9:00 AM Invited
Weldable Materials System Design - Application of Computational Thermodynamics and Kinetics: *Sudarsanam Babu*[1]; [1]Ohio State University

With rapid progress in integrated computational materials science and engineering (ICME) models, it is quite possible to design new generation of steels with targeted high- and low-temperature mechanical properties. For example, advanced steels (e.g. BA160 and Hard bainite) with high strength, good toughness, and ballistic performance had been developed using ICME models, without experimental trial and error optimization. In contrast, welding system design, i.e., optimization of heat-affected-zone (HAZ) and weld metal (WM) properties, requires experimental trial and error optimization. The talk will provide highlights of the research on microstructure development in HAZ and WM towards developing a modeling framework to reduce this trial and error optimization. The methodology includes description of physical processes that occur during liquid-gas-slag metal reactions, solidification and solidification. Some of the challenges associated with non-unique solutions, scatter in properties and sensitivity to welder practice will be discussed.

9:30 AM

Effect of Pre-Weld Heat Treatment Environment on the Microstructure and Crack Behaviors in the Laser Repair Welded René 77 Nickel-Based Superalloy: Huei-Sen Wang[1]; *Sian-Jhih Deng*[1]; Chen Ming Kuo[1]; [1]I-Shou University

To study the effects of pre-weld heat treatment vacuum levels on the microstructure and crack behaviors of repair welded René 77 nickel-based superalloy, the preselected heat treatment conditions were operated under three selected vacuum levels i.e. under 1 atmospheric pressure shielding with pure argon, vacuum levels of 1×10-2 torrs and 1×10-4 torrs. After heat treated, the samples were welded using a pulsed Nd:YAG laser process with various welding parameters coupling with René 41 filler wire. The microstructure , cracking behaviors, mechanical properties in the weld metal (WM), heat affected zone(HAZ) and parent material (PM) were evaluated using a optical microscope (OM), scanning electron microscope (SEM) equipped with energy dispersive spectrometer (EDS) and microhardness. The experimental results showed that, the higher vacuum levels, the less volume of MC-type carbides and γ-γ' eutectic was observed and the liquation crack in the HAZ or around WFZ is significantly reduced.

An ICME Approach to Solder Joint Lifetime Prediction: Michael Neilsen[1]; Paul Vianco[1]; *Elizabeth Holm*[1]; [1]Sandia National Laboratories

Because solders operate at high homologous temperatures, microstructural evolution, cracking, and failure can occur during service. Since circuit boards must function reliably for thousands of thermal cycles in applications such as aircraft and satellites, lifetime prediction is critical for product design and maintenance. We have developed a combined experimental and computational approach to predict both aging (crack initiation) and failure (open circuit) during thermomechanical cycling of lead-tin and lead-free solder joints. By including microstructural evolution and damage parameters in a unified creep plasticity model, we accurately predict crack initiation, location and growth morphology during thermomechanical fatigue for a variety of solder joint geometries. At each step, experiments inform and validate from model predictions. The resulting ICME model for solder joint lifetime is used in materials selection, engineering design, and stewardship programs at Sandia and elsewhere.

Characterization of the Performance at High Temperature of an Incoloy 718 for Improving the Ring Production: *Martha Guerrero*[1]; Maribel de la Garza[1]; Patricia Zambrano[1]; Pedro Paramo[1]; [1]Universidad Autonoma de Nuevo Leon

Aeronautical, petrochemical and energy industries use the Incoloy 718, which exhibits good mechanical properties at high temperature thanks to the solid solution and precipitation phenomena taking place during the heat treatment. The aim of the present work is to improve the thermomechanical route for the production of rings. Cylindrical samples of the as received alloy of 150 mm x 125 mm height and diameter were forged in an industrial press at 980, 1000, 1020 and 1040°C, using 1 pass or 2 passes to achieve a reduction of 73% or 85%. Samples from the different reductions were obtained to undergo various heat treatments and mechanical testing at high temperature. After forging, heat treatment and mechanical testing samples were cut for advanced microstructural analysis, a microhardeness and grain size measurements. Results were analyzed to determine the influence of the different thermomechanical parameters on the final microstructure and mechanical properties.

11:00 AM

Heat Treatment Effects on Creep Behavior of Directionally Solidified CM247LC Superalloy: Ken-Tu Hsu[1]; Huei-Sen Wang[1]; *Wei Bin He*[1]; Chen-Ming Kuo[1]; Hui-Yun Bor[2]; Chao-Nan Wei[2]; [1]ISU University; [2]Chun-Shan Institute of Science and Technology

This study investigates how the heat treatments affect the creep behavior of directionally solidified CM247LC superalloy.Use two different heat treatment: (HT1) solution treatment at 1260°C for 2 h, then first aging at 1079°C for 4 h and followed by second aging at 871°C for 20 h; (HT2) solution treatment at 1230°C for 10 h, then the same aging procedure. The microstructural observations and quantitative statistical analyses indicate that heat treatments change the γ' characteristics: HT1 resulting in more regularly cuboid morphology of γ' particle and reduction of γ-γ' eutectic phase. Furthermore, the modification of γ' morphology in HT1 specimens enhances better creep rupture life under 760°C /724MPa creep test.The HT1 grains, dislocation motions are restricted because of more regularly cuboid morphology of γ' particle, which is conducive to against high temperature creep deformation. Nevertheless, the γ-γ' eutectic phase is the main cause of creep rupture of DS CM247LC superalloy.

11:20 AM

Influence of Processing Conditions on the Mechanical Properties of High-Nitrogen 18Cr-18Mn Austenitic Steels for Generator Retaining Ring: *Byoungchul Hwang*[1]; Jong-Ho Shin[2]; Tae-Ho Lee[1]; Heon-Young Ha[1]; Jong-Wook Lee[2]; Sung-Joon Kim[1]; [1]Korea Institute of Materials Science; [2]2 Doosan Heavy Industries & Construction Co., Ltd.

Retaining rings are used on the shaft ends of power generators and required to have non-magnetic, high strength, high ductility and good corrosion resistance. High-nitrogen 18Cr-18Mn austenitic steels with high yield strength have been recently developed and used for retaining ring material. In the present study, several high-nitrogen 18Cr-18Mn austenitic steels with different N content were fabricated and then tensile and Charpy V-notch impact tests were conducted on them in order to investigate the effect of processing conditions on the mechanical properties. The yield and tensile strengths usually increased with N content, but an increase in strength by cold working was varied depending on N content. Although both the yield and tensile strengths was rather increased after stress relieving, a variation in the strengths was largely affected by the amount of cold working. The cold working and stress relieving treatment also exerted a significant influence on the impact toughness.

11:40 AM

γ(Ni)/γ'(Ni3Al)-d(Ni3Nb)Eutectic Ni-Base Superalloys: The Relationship between Composition, Solidification Characteristics and Microstructure: *Mengtao Xie*[1]; [1]Illinois Institute of Technology

Polycrystalline γ(Ni)/γ'(Ni3Al)-d(Ni3Nb) eutectic alloys have been recently demonstrated to possess promising high-temperature properties for structural applications at temperatures below 800°C. Many of their unique attributes could be potentially harnessed to extend the temperature and pressure limits associated with the advanced turbine engine designs. However, studies regarding this class of materials are limited and qualitative in nature. To better understand this novel class of materials, a systematic study of the influence of various elemental additions on the solidification behavior and microstructural characteristics of this Ni-Al-Nb based γ/γ'-d eutectic system is necessary. The effects of Cr, Ta, W, and Mo additions on the solidification microstructure, phase volume fraction and phase transformation temperatures of this novel class of alloys were assessed. Results from this study will be presented and implications of these finding with respect to alloy design will be discussed.

Mechanical Behavior at Nanoscale I: Thin Film and Multilayers

Mechanics of Low Dimensional Material for Energy Harvesting and Storage: *Reza Shahbazian-Yassar*[1]; Hessam Ghassemi[1]; Kasra Momeni[1]; Anjana Asthana[1]; Yoke Yap[1]; Gregory Odegard[1]; [1]Michigan Technological University

Low dimensional materials have received considerable attention for their unique properties in energy storage (batteried) and energy harvesting (nanogenerators) devices. In this presentation, we cover the mechanics of Boron Nitride nanotubes (BNNTs), Zinc Oxide nanowires (ZnO NWs), and Silicon nanorods (Si NRs). Size scale effect on electromechanical properties of ZnO nanobelts (NBs) was studied using molecular dynamics (MD) simulations on graphical processing units (GPUs). The piezoelectric coefficient of ZnO nanobelts increases when the lateral dimensions are reduced. Size scale effects were observed in ZnO nanowires and were explained by the modification of atomic structure at the nanowire surface. In addition, the rippling and bifurcation of multiwalled BNNTs were observed upon buckling and were quantified in terms of number of walls and nanotube's diameter. We also studied the mechanics of lithiated Si NRs to understand the effect of lithium intercalation into the structure of NRs.

8:50 AM
Micro-Scale Grain Boundary Fracture in Copper and Nickel Alloys: *David Armstrong*[1]; Helen Dugdale[1]; Angus Wilkinson[1]; Sergio Lozano-Perez[1]; Steve Roberts[1]; [1]University of Oxford

Brittle fracture is often controlled by grain boundary behaviour. Until now measuring the fracture properties of single grain boundaries has required macroscopic bi-crystals. We have developed techniques to measure the fracture toughness of selected grain boundaries using micro-cantilevers (typically ˜5µm wide and 25µm long), made by focussed ion-beam machining, loading them using a nanoindenter. In bismuth-embrittled copper, grain boundary fracture toughness values were found to be between 1 and 7 $MPam^{0.5}$, with no strong correlation between crystallography and toughness. All brittle boundaries contained Bi; non-fracturing boundaries did not. In Ni alloy 600 embrittled in simulated reactor primary water at 340°C for 2000hrs, TEM analysis showed many surface-intersecting boundaries to be oxidised. In micro-cantilever tests, such boundaries fail by brittle fracture, with fracture toughness of ~7 $MPam^{0.5}$, while non-oxidised boundaries deform in a ductile manner.

9:10 AM
Plastic Strain Recovery in Nanocrystalline Nickel: *Marisol Koslowski*[1]; Yuesong Xie[1]; [1]Purdue University

Grain refinement in crystalline materials leads to an enhancement of several materials properties including yield and fracture strength and superior wear resistance. This reduction in grain size is also responsible for new deformation mechanisms like plastic strain recovery. Even though, plastic deformation is not recoverable in coarse grained crystalline materials, recent experiments in nanocrystalline aluminum, nickel and gold thin films and bulk nanocrystalline aluminum recovered more than 50% of plastic strain after unloading. We will present dislocation dynamics simulations of nanocrystalline Nickel that show that plastic strain recovery is observed only if the sample has a large scatter in the grain size distribution. These findings reveal that the average grain size itself is not enough for a complete characterization of the microstructure in nanocrystalline materials but variations in the grain size distribution should also be considered.

9:30 AM
Study on the Nanomechanical Properties of High Quality ZnO Microwires by Nanoindentation: *Zhi Lin*[1]; JianPing He[2]; ZhiWei Liu[2]; [1]State Key Laboratory for Advanced Metal Materials; [2]University of Science & Technology Beijing

Nanomechanical properties of high quality ZnO microwires that were synthesized by a simple chemical vapor deposition method were studied by nanoindentation. The hardness and elastic modulus of microwires were obtained and compared with the values of ZnO bulk and nanowire / nanobelt It was found that the two values of microwires are between those of the bulk and the nanowire/nanobelt. An interesting phenomenon of the shape self-healing was found and discussed. Moreover, the conductivity change of the ZnO microwires caused by indentation was also investigated. Based on the piezoresistive effect theory, the electromechanical phenomenon was explained. This work is believed to provide the initial information for safe working condition of devices that uses ZnO microwires as building blocks in MEMS engineering.

9:50 AM Invited
Defect and Interface Engineering in Semiconductor Nanowires: *Shadi Dayeh*[1]; Jian Wang[1]; Jian Yu Huang[2]; Samuel Thomas Picraux[1]; [1]Los Alamos National Laboratory; [2]Sandia National Laboratories

Semiconductor nanowires have emerged as building blocks for applications in sensing, (opto)-electronics, thermoelectrics, energy harvesting and storage. The purpose of this talk is to address the underlying science behind some of the challenges in controlling structure and morphology in semiconductor nanowires and show how this understanding establishes the structure-electronic property correlations in Ge/Si and InAs semiconductor nanowires. We distinguish between two defect types and discuss techniques to eliminate them. Stacking defects result in the pinning or rotating of nucleation sites along the vapor-liquid-solid interface in elemental (Ge, Si) as well as create spontaneous polarization charges in polymorph III-V nanowires (InAs). We then discuss the first experimental measure of critical thicknesses in core/shell Ge/Si nanowires, the type of dislocations by which they relax misfit strain, and the resulting corrections for current models on coherency limits.

10:10 AM
Deformation Hardening under Friction of Cu Samples with Different Virgin Grain Size in the Lubrication Conditions: *Alex Laikhtman*[1]; Lev Rapoport[1]; Alexey Moshkovich[1]; Vladislav Perfilyev[1]; Louisa Meshi[2]; Shmuel Samuha[2]; Sidney Cohen[3]; [1]Holon Institute of Technology (HIT); [2]Ben-Gurion University of the Negev; [3]The Weizmann Institute of Science

Friction and wear of copper rubbed with lubrication in wide range of loads and sliding velocities were studied. The results of friction and wear experiments are presented as the Stribeck curve: the boundary lubrication (BL), mixed, and elastohydrodynamic lubrication (EHL) regions are considered. The structural state of subsurface layers in different lubricant regions was studied by different spectroscopic and microscopic techniques. Dislocation density and nanohardness at thin surface layers in EHL and BL regimes was determined and compared. The dominant friction and wear mechanisms in different lubrications regions are discussed. Severe plastic deformation (SPD) of subsurface layers under friction is correlated with nanocrystalline structure obtained by different methods of grain refinement. It was found that SPD of thin surface layers under friction is accompanied by formation of shear bands in sublayers of contact spots. The main difference between the friction conditions is different gradients of strain, hardness and temperature.

10:40 AM
Effect of Indentation Depth and Displacement Rate on spherical Nanoindentation of NiTi Shape Memory Alloys: *Indrani Sen*[1]; Martin Wagner[1]; [1]Technische Universität Chemnitz

NiTi based shape memory alloys, owing to their superior recoverability, are finding applications in a wide variety of technologies and especially in miniaturized devices. Nanoindentations with spherical tip have been performed on this alloy to appreciate its small length scale pseudoelastic characteristics. From the typical load-displacement data, accurate estimation of zero-point and extraction of nano-scale stress-strain curves have been performed, which is otherwise difficult to obtain from conventional experiments. Effects of indentation depth varying between 100 to 1000 nm and displacement rate between 1 to 50 nm per second have been studied on the mechanical behavior of the alloy. With increasing indentation depth, a loss in pseudoelasticity with decrease in recoverable strain (by ~20%) has been observed. However, an isothermal stress state prevails at the applied strain rate range with no significant effect observed in the critical transformation stress of the alloy.

11:00 AM
A Versatile Microelectromechanical System for Monotonic and Fatigue Testing of Nanostructures: Ehsan Hosseinian[1]; Brian Allen[1]; Bhaskar Pant[1]; *Olivier Pierron*[1]; [1]Georgia Tech

Microelectromechanical systems (MEMS) were recently described as superior mechanical testing systems for nanomaterials. Currently, the most advanced MEMS setups are best suited for *in-situ* SEM or TEM studies, since they require high magnification images to measure strain. Here we present a MEMS material testing setup that relies on electronic measurements of nanospecimen elongation. Compared to previously demonstrated MEMS devices that rely on high magnification images to measure elongation, this MEMS is more versatile, allowing both *in situ* TEM testing and *ex situ* (e.g., in an environmental chamber) testing of nanomaterials with high accuracy and precision (sub nm). The MEMS device comprises two identical capacitive sensors on each side of the nanospecimen that are used to electronically measure the specimen gap change. The mode of operation of the MEMS setup is illustrated with *ex-situ* uniaxial tensile tests and fatigue tests of nanocrystalline nickel nanobeams.

11:20 AM
Tribological Properties of Nanocrystalline Metallic Contacts: *Michael Chandross*[1]; Shengfeng Cheng[1]; [1]Sandia National Laboratories

Gold is a desirable material for use in high performance electrical contacts because it offers low contact resistance, does not corrode or oxidize, and can be easily made into thin sheets. However, gold contacts generally suffer from high adhesion and friction. The tribological issues are mitigated in nanocrystalline gold alloys (with, for example, Ni or Co), which can exhibit both low friction and low contact resistance. The atomic scale mechanisms responsible for the change in frictional response are poorly understood. We will present the results of large scale molecular dynamics (MD) simulations which study the tribological response of nanocrystalline films of pure gold and alloys under a variety of sliding conditions. Our results indicate that cold welding and microstructural reorientation can lead to high friction in pure metals, while suppression of this behavior lowers the friction considerably.

11:40 AM
Nanoscale Investigation of Segregation and Embrittlement in \149; -Fe due to Hydrogen and Grain Boundary Character: *Kiran Solanki*[1]; Mark Tschopp[2]; Nathan Rhodes[2]; [1]Arizona State University; [2]Mississippi State University

Material strengthening and embrittlement are often controlled by interactions between dislocations and hydrogen-induced defect structures that can adversely affect deformation mechanisms. The objective of this research is to explore the role of grain boundary morphology on H segregation and embrittlement process in \149; -Fe. Molecular statics simulations were used to calculate the segregation energies H and subsequent fracture behavior for a wide range of grain boundary structures. Simulation results show that grain boundary morphology plays a significant role in the segregation and embritlement process in \149; -Fe. The significance of this work is that a better fundamental understanding of the role of grain boundary character in segregation and embrittlement may provide insight into how the ductility of polycrystalline materials can be improved. By engineering microstructure to change the hydrogen segregation and embrittlement process, the local deformation mechanisms can be tailored to improve ductility.

12:00 PM
Small Scale Mechanical Behavior of Silicon as a Function of Electronic Doping: *Jacques Rabier*[1]; Rudy Ghisleni[2]; Jean Luc Demenet[1]; johann Michler[2]; [1]CNRS; [2]EMPA

The effect of electronic doping on the mechanical properties of silicon at temperatures larger than 650°C are well documented. However it has been demonstrated by experiments under pressure and by atomistic simulations that at high stress and low temperature a different type of dislocations controls the plasticity of silicon: perfect shuffle dislocations. In this context deformation of nanopillars of silicon with different doping has been performed in order to check for the effect of doping on plastic deformation at high stresses. The mechanical tests are conducted on <123> oriented single crystal nanopillars with diameters ranging from 500 nm to 2 µm obtained by focused ion beam machining. Wafers with different electronic doping are tested: intrinsic (Nn <= 1014 cm-3): n type (Nn = 6*1018 cm-3), and p type (Np = 1*1018 cm-3). The results of in situ SEM deformation experiments at room temperature and up to 200°C will be discussed.

12:20 PM
Three-Dimensional Dislocation Dynamic Simulations in BCC Metal Micro-Pillars: *Ill Ryu*[1]; Wei Cai[1]; William Nix[1]; Christopher Weinberger[2]; [1]Stanford University; [2]Sandia National Laboratories

Recent micro-pillar experiments have shown strong size effects at small pillar diameters. This ‘Smaller is stronger’ phenomenon is widely believed to involve dislocation motion, which can be studied using dislocation dynamics (DD) simulations. In the present study, we make a 3-D DD model to study the collective dislocation behavior in BCC micro-pillars under compression. Following the work of Weinberger and Cai [1], we consider a surface-controlled cross-slip process, involving image forces and non-planar core structures, that leads to multiplication without the presence of artificial pinning points. We follow both the evolution of the dislocation structure and the corresponding stress-strain relation. In an effort to make the model conform to in-situ TEM experiments that seem to show persistent plastic flow even for very small pillars and low dislocation densities, the effects of point defects on dislocation dynamics are being explored. [1] Weinberger CR, Cai W., *Proc. Natl. Acad. Sci.* (2008)

Mechanical Behavior Related to Interface Physics: Dynamic Response of Interfaces: Experiment and Modeling

Interface Role in the Shock Response of Cu/Nb Metallic Multilayers: *Timothy Germann*[1]; Ruifeng Zhang[1]; Weizhong Han[1]; Jian Wang[1]; Shengnian Luo[1]; Irene Beyerlein[1]; Amit Misra[1]; [1]Los Alamos National Laboratory

Molecular dynamics (MD) simulations and post-mortem transmission electron microscopy (TEM) analysis of shock-recovered samples are used to study the role of interface structure and layer thickness on the mechanical response of Cu/Nb nanolayered composites to shock compression. Post-mortem TEM analysis indicates that deformation twinning in Cu layers is preferentially nucleated from Cu(112)//Nb(112) interface habit planes, as opposed to the more common Cu(111)//Nb(110) interfaces (with a Kurdjumov-Sachs orientation relationship in both cases). Non-equilibrium MD simulations of the shock loading of Cu/Nb multilayers containing exclusively one interface structure or the other confirm the key role which interface structure plays in this preference, and provide insight into the role of atomic Cu-Nb interface structures on the nucleation, transmission, absorption, and storage of dislocations during shock loading of Cu/Nb nanolayered composites.

9:00 AM

Dynamic Thermo-Mechanical Properties of Ferroelastic Reinforced Metal Matrix Composites: *Jack Tilka*[1]; Zachary Bryan[1]; Jacob Jones[1]; Michele Manuel[1]; [1]University of Florida

Previous research has shown that the presence of ferroelastic particles in a metal matrix could yield a composite with an anomalous dynamic elastic modulus. It is believed that the origin of this anomalous mechanical behavior is due to the thermo-mechanical coupling at the interface between the frequency-dependent ferroelestic particles and dampening metal matrix. A systematic study is presented that focuses on the interaction between barium titanate particles and a damping metal matrix in composites prepared using powder metallurgical techniques. Composites were characterized with microscopy, dynamic mechanical analysis, differential scanning calorimetry, and x-ray diffraction to determine the frequency and temperature dependence of the barium titanate phase transitions and their resulting effect on the mechanical behavior of the composite. These studies provide insight into the unique inter-relationship at the interface between phase transforming particles constrained in a non-transforming, dampening matrix. The authors would like to gratefully acknowledge the support of the National Science Foundation under grant number CMMI-0824352.

9:15 AM

Effect of Film Thickness on Mechanical Properties of Free-Standing Thermoset Nanofilms by Molecular Dynamics Simulations: *Chunyu Li*[1]; Alejandro Strachan[1]; [1]Purdue University

Free-standing polymer nanofilms have two solid/air interfaces. The potential applications of polymer nanofilms are in numerous areas. To fully realize the potential applications of polymer nano□lms, an in-depth understanding of their mechanical properties is critically necessary. Experimental efforts are very few because of the difficulties in nanoscale measurements. No modeling work at the molecular-level has been done on the mechanical properties of free-standing thermosetting polymer films. In this presentation, we will describe our recent molecular dynamics simulations free-standing nanofilms of thermosets (EPON825/33DDS) and the predictions of their mechanical properties. The effect of film thickness on the stiffness and yield stress is investigated. The conclusion is that Young's modulus and yield stress of nanofilms are lower relative to the bulk values but both increase with increasing film thickness and approach to the bulk values at about 100nm. Interestingly, the yield strains are all within 10~14% regardless of film thickness or bulk.

9:30 AM

Meso-Scale Simulations of Interface Configuration on Shock Wave Propagation in Multilayered Ni-Al Composites: Paul Specht[1]; *Naresh Thadhani*[1]; Timothy Weihs[2]; [1]Georgia Institute of Technology; [2]The Johns Hopkins University

The response of shock-wave propagation through multi-layered Ni-Al cold-rolled composites is investigated using meso-scale simulations performed employing real microstructures. The orientation of the layers is varied at 0o, 45o, and 90o to the direction of shock-front propagation, to determine the differences in the bulk shock-compression response and the effects of strain localization due to the mismatch in elastic and plastic properties across the interface. The results reveal noticeable differences in the pressure, temperature, and strain response. Geometric dispersion is seen to alter the shape of the resulting pressure pulse and inhibit the development of a steady-state shock wave in the laminated geometry. Strain-localization at the interfaces causes shock-wave dissipation through interfacial heating and shearing, resulting in high levels of viscosity and attenuation. The dissipative effects also alter the dependence of shock velocity on particle velocity, making it a major contributor to the bulk response of multilayered composites under shock compression.

9:55 AM Keynote

High Temperature Twinning Correlated with Grain Growth in a Nano-Grained Co Based Alloys: *Xuejun Jin*[1]; Jiayao Li[1]; Yao Shen[1]; [1]Shanghai Jiao Tong University

Twinning is one of structural changes of metals and ceramics in response to mechanical stresses with other changes being slip (by dislocation motion), phase transformations and fracture. Mechanical twinning observed at relatively low temperature can have two effects on plastic deformation: subdivision of grains; contribution to the amount of plastic deformation due to twinning shear. Here a high temperature twinning triggered by a grain growth was observed around 300°C in a nano-grained Co based alloys produced by electro-deposition, while the slip mechanism usually dominates in coarse-grained alloys with identical chemical composition at the same temperature range. A grain growth correlated competition mechanism of slip and twinning is proposed and discussed in association with temperature, nucleation parameters, phase transformation kinetics, grain sizes and stacking-fault energy. The introduction of twinning at high temperature is of significance to explore the optimal mechanical properties in various engineering alloys.

10:25 AM Keynote

Grain Boundary Mediated Deformation Mechanisms of Nanocrystalline NiFe Alloy under Cyclic and Dynamic Loading: *Yonghao Zhao*[1]; S. Cheng[2]; Y.Z. Guo[3]; Y,M, Wang[4]; Y. Li[1]; Q.M. Wei[3]; X.-L. Wang[5]; P.K. Liaw[2]; E.J. Lavernia[1]; [1]University of California Davis; [2]University of Tennessee, Knoxville, USA; [3]University of North Carolina, Charlotte; [4]Lawrence Livermore National Laboratory, Livermore; [5]Oak Ridge National Laboratory, Oak Ridge

Deformation mechanisms of nanocrystalline NiFe alloy with an average grain size of about 18 nm under dynamic and cyclic loading were investigated by employing post-mortem electron transmission microscopy. Upon dynamic loading, highly improved plasticity (from 8% deformation strain under quasi-static deformation to a maximum strain of ~22%) was achieved. Significant grain coarsening and de-twinning occurred due to grain rotation and grain boundary sliding (Adv. Mater. 21, 2009, 5001). Under compressive cyclic loading, a high fatigue life is obtained at high applied stress. Significant grain size coarsening was associated with the path of crack propagation and was realized mainly though the grain lattice rotation and coalescence under the high stress concentration at the crack tip. Away from the crack path, no apparent grain coarsening was observed. At the same time, loss of the growth twins was observed in the coarsened grains (Phys. Rev. Lett. 104, 2010, 255501).

10:55 AM

Fracture Toughness Testing of Sub-Micron Sized Bi-Embrittled Cu Bicrystals: *Mark McLean*[1]; Austin Wade[1]; Masashi Watanabe[1]; Rick Vinci[1]; [1]Lehigh University

It has long been known that impurity elements segregated to grain boundaries can cause significant reduction in the ductility of metals. However, despite the significant work done on the subject, the true mechanism responsible for boundary segregation-induced embrittlement is still unclear. We have developed a notched-tensile beam test technique for measuring the fracture toughness of individual grain boundaries at the sub-micron scale using a new SEM-compatible nanoindentation device. Using this technique, we have measured the fracture toughness of Bi-doped Cu bicrystals. Tests have been conducted on several different grain boundaries in order to determine the effect of boundary character on fracture behavior. In addition to fracture testing, samples have been prepared from the same boundaries for atomic-resolution STEM imaging in order to locate and quantify the segregant atoms contained in each boundary. Combining the results will provide vital information to include in atomistic simulations of grain boundaries.

11:10 AM

Molecular Dynamics Simulations of Plastic Deformation of Nanocrystalline FCC and BCC Metals in Tension and Compression: *Marc Meyers*[1]; Yizhe Tang[1]; Eduardo Bringa[2]; [1]UCSD; [2]U Nacional de Cuyo

In FCC metals the principal deformation mechanism in tension and compression is the emission of partial dislocations from GBs and their annihilation at an opposing GB. The conventional H-P relation breaks down at d~15-20 nm for Cu. Tensile failure starts at the GBs through void initiation associated with profuse dislocation emission. For BCC metals, the scenario is different. In tension, decohesion of GBs normal to loading direction occurs before emission of dislocations, due to the high resistance of the lattice to plastic deformation which exceeds the GB cohesive strength at that strain rate. In compression, plasticity occurs, but the defects are different. Perfect dislocations emitted from GBs dominate process at d>10 nm, while grain-boundary sliding dominates when d<10 nm. Grain rotation is found when d~5nm. The Hall-Petch transition (d>40 nm) is larger than for FCC metals. Few twins were found in samples with larger grain sizes. Funding: UCRL Program.

11:25 AM

Effects of H Impurities on Grain Boundary Cracking and Plasticity: *Diana Farkas*[1]; Martin Gamarra[1]; Laura Patrick[1]; [1]Virginia Tech

The effect of H impurities segregated to grain boundaries in FCC metals is studied. The deformation behavior under tension is modeled using molecular dynamics and embedded atom interatomic potentials developed for dilute interstitial H impurities. The digital samples have a polycrystalline thin-film configuration with randomly oriented grain boundaries. The results show that the samples containing the H impurities show decreased overall ductility, due to increased crack nucleation at the boundaries and triple junctions. The H impurities also had significant effects on the emission of dislocations from the grain boundaries and in the possibilities of grain boundary sliding and migration.

11:40 AM

Insights into Basal Slip Dominated Plasticity of Mg from In Situ TEM Tensile Testing: *Qian Yu*[1]; Raj Mishra[2]; Andrew Minor[1]; [1]UC Berkeley; [2]General Motors Research and Development Center

Magnesium is a lightweight metal that would be much more useful for structural applications than it currently is if not for its complicated and anisotropic plastic deformation behavior. Basal slip is the most important slip system for the plastic deformation of Mg because its CRSS is much lower than that of prismatic and pyramidal slip. Recently we have run a systematic series of in situ TEM tensile tests on pure Mg with different size crystals where we have quantitatively measured and characterized the basal slip behavior. Strong crystal size effects on basal slip were found. More interestingly, basal slip based on surface nucleation of dislocations is significant in samples with extremely small size, which can directly lead to the high strength and ductility of the nanoscale material.

Minerals, Metals and Materials under Pressure: Phase Transformations and Microstructure

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS Structural Materials Division, TMS: Chemistry and Physics of Materials Committee, TMS/ASM: Phase Transformations Committee

Program Organizers: Ellen Cerreta, Los Alamos National Laboratory; Richard Hennig, Cornell University; Dallas Trinkle, University of Illinois, Urbana-Champaign; Vijay Vasudevan, Univ. Cincinnati

Thursday AM — Room: Europe 9

Influence of Interstitial Content and Stress State of the Shock-Induced Phase Transitions in Zr, Ti, and Fe: *George Gray*[1]; Ellen Cerreta[1]; Larry Hull[1]; Paulo Rigg[1]; [1]Los Alamos National Laboratory

Dynamic and shock loading of materials is well known to induce a range of defects in metals and alloys, including dislocations, deformation twins, point defects, as well as shock-induced phase transitions in many select metals and alloys. In this paper, examples of the role of chemistry and stress state on transitions in Zr, Ti, and Fe will be discussed. Observations of the influence of interstitial content on the kinetics of the alpha-omega transition in Zr will be detailed including the results of diamond cell, gas gun, and Z-machine shock data. The alpha-omega transition in Zr is shown to strongly depend on interstitial oxygen content as well as differ significantly between diamond cell, shock loading, and ramp loading. Recent results of the effect of 1-D versus sweeping-detonation wave loading on the alpha-epsilon transition and substructure evolution in Fe will be presented.

9:00 AM
Probing the Role of Temperature on Texture Evolution in Tantalum during Dynamic-Tensile-Extrusion: *Carl Trujillo*[1]; Juan Escobedo[1]; Ellen Cerreta[1]; George Gray III[1]; Daniel Martinez[1]; [1]Los Alamos National Laboratory

The effect of high strain-rate and high strains on the mechanical behavior in Tantalum has been previously explored at room temperature. To incorporate and investigate the effect of temperature, a cross section of a gun barrel was converted into a furnace to allow specimens to be heated up to 600°C before acceleration. Specimens were machined in two directions from the as-received plate: In-plane(IP), parallel to the rolling direction, and through thickness(TT) of the plate. Using the dynamic tensile extrusion technique developed at LANL, Ta bullets were heated up to 600°C and accelerated up to velocities of 600m/s. Specimens were extruded through a high strength steel die. A combination of in-situ and post-mortem characterization techniques has been used, including Photonic Doppler Velocimetry to capture the time and extrusion velocity of the deforming specimen through the die. Quantitative examination of the influence of temperature, texture, and extrusion velocity will be presented.

9:20 AM
The Role of Interfaces on Shock-Induced Damage in Two Phase Metals: *Saryu Fensin*[1]; Ellen Cerreta[1]; Steven Valone[1]; Steven Valone[1]; George Gray[1]; Adam Farrow[1]; Carl Trujillo[1]; [1]Los Alamos National Laboratory

For ductile metals, the process of dynamic fracture during shock loading is thought to occur through nucleation of voids, void growth, and then coalescence that leads to material failure. Particularly for high purity metals, it has been observed by numerous investigators that voids appear to heterogeneously nucleate at grain boundaries. However, for materials of engineering significance, those with inclusions, second phase particles, or chemical banding it is less clear what the role of grain boundaries versus other types of interfaces in the metal will be on nucleation of damage. To approach this problem four materials have been systematically investigated: (1) high purity copper, (2) copper with 1% lead, (3) 260 brass, and (4) leaded 360 brass. The role of lead at grain boundaries and its behavior during shock loading will be discussed in conjunction with the results from experiments and Molecular Dynamics simulations.

9:40 AM
3-D Study of Microstructural Weak Links in Shock Loaded Copper Polycrystals with Incipient Spall Damage: *Andrew Brown*[1]; Quan Pham[1]; Kapil Krishnan[1]; Pedro Peralta[1]; Shengnian Luo[2]; Brian Patterson[2]; Scott Greenfield[2]; Darrin Byler[2]; Kenneth McClellan[2]; Aaron Koskelo[2]; [1]Arizona State University; [2]Los Alamos National Laboratory

Correlations between incipient spall damage and global and local microstructures were investigated in polycrystalline copper plates of varying microstructures. The samples were impacted by laser-driven flyer plates at low pressures (2-6 GPa) to encourage incipient spall damage. Serial sectioning and Electron Backscattering Diffraction (EBSD), along with through thickness optical microscopy and X-ray tomography, were used to create 3-D renditions of the voids and surrounding microstructure and compare local and global geometrical and crystallographic characteristics. The damage distribution along the spall plane in 3-D was correlated to grain boundary (GB) misorientations, GB inclination to the shock, and grain size. Preferred damage nucleation and localization sites were identified via statistical sampling from serial sectioning. Results indicate that pre-existing plastic deformation biases damage to the GBs, which have a misorientation dependent strength. When plastic deformation is removed via heat treatments, the grains become weaker, causing a mix of intergranular and transgranular damage modes.

10:00 AM
Characterization of Near-Surface Microstructures in IN718 Alloy Laser Shock Peened with and without an Ablative Overlay: Amrinder Gill[1]; *Vijay Vasudevan*[1]; S.R. Mannava[1]; Dong Qian[1]; [1]University of Cincinnati

Laser shock peening without a protective overlay has become of increasing interest because of the ability to reduce the process time. Peening without an overlay results in both mechanical and thermal loading of the material. Surface layers of the material experience melting and re-solidification along with deformation due to the shock wave. The recast layer hence formed was characterized. Coupons of the alloy were laser peened with and without a protective coating and the surface layers were characterized using various techniques including X-ray Diffraction, Nanoindentation, Transmission Electron Microscopy, Scanning Electron Microscopy, Electron Back scattered Diffraction and Energy Dispersive X-Ray Spectroscopy. The results show tensile residual stress state in near-surface regions to a depth of about 50 microns, followed by a compressive residual stress state. The presence of a non-uniform recast layer with increased surface roughness was observed, as well as areas with modified chemistry and the presence of nano particles.

Melting Line of Alkali Metals: Shanti Deemyad[1]; [1]Cornell University

Melting line of alkali metals have been of great interest for a long time. These elements generally exhibit very low melting temperatures and it has been shown in few cases that at very high pressures the melting line exhibits a maximum. Temperature determination between 400K and 700K is difficult in diamond anvil cell and the determination of onset of melting is another problem that makes these measurements very tedious. There has been inconstancy in several reports in past. Here I present a new experimental approach in measuring the melting at high pressure which can increase our accuracy in determination of the melting lines.

11:00 AM
Investigating the Effects of High Pressure Shock Loading on Ni-Al Mixtures Using a Laser-Accelerated Flyer Setup: *Sean Kelly*[1]; Naresh Thadhani[1]; [1]Georgia Institute of Technology

The effects of high-pressure dynamic loading on Ni-Al mixtures in various configurations and any subsequent phase transformations were investigated. Ni-Al mixtures represent an example of a Structural Energetic Material (SEM) that combines strength and stiffness with the energy-release capabilities of a molecular explosive. High-pressure shock-loading can cause intimate constituent mixing, leading to chemical reactions, forming an intermetallic, and releasing energy. Experiments were performed on different forms of nickel-aluminum mixtures (i.e. powder compacts, vapor-deposited foils, single layers) over a range of shock pressures using a laser-accelerated flyer system in attempt to characterize the processes leading to complete reaction. VISAR and PDV interferometry were used to infer the occurrence of any shock-induced chemical reactions. Post-mortem microstructural characterization was performed to identify the reaction products and isolate the processes that lead to reaction initiation. In this presentation, the influence of flyer momentum and Ni-Al reactant configuration on the reaction response will be discussed.

11:20 AM
Phase-Field Reaction-Pathway Method Coupled with Plasticity Theory of the Shock Induced Alpha-Epsilon Martensitic Transition in Iron: *Aurélien Vattré*[1]; Christophe Denoual[1]; [1]CEA

Pressure induced alpha-epsilon martensitic transition in iron is known to be very complex due to the interplay of transformation strains and long range stresses induced by the emerging microstructure. We propose a predictive modeling of this martensitic transition during shock loading by using a phase-field technique with reaction pathway (PFRP) coupled with plasticity theory. The hybrid method allows to define precisely both stored elastic energy and crystalline energy along the martensitic reaction path in iron. After a short introduction to PFRP, the microstructures obtained during shock and after reversion to alpha phase (just after shock release) with and without plasticity will be discussed.

11:40 AM
High Pressure Phase Transitions in Layered Tin Monoselenide Crystals: Ajay Agarwal[1]; *Paras Trivedi*[2]; Prakash Naik[2]; Dipesh Patel[3]; [1]Shree J P Arts & Science College ; [2]Shree J P Arts & Science College; [3]V S Patel College of Arts & Science

Tin monoselenide crystals belong to IV–VI layered binary semiconducting compound category. These semiconducting materials are useful because of their applications in holographic-recording systems, optoelectronics and memory switching. Several investigators have utilized Mossbauer Spectroscopy and Hydrostatic Pressure techniques to examine the bonding of the Sn atoms in SnS and SnSe. It is therefore thought worthwhile to study the effect of pressure on the thermoelectric power and the electrical resistance of SnSe crystals synthesized by a modified direct vapour transport technique. The electrical resistance has been found to be pressure dependent. The transition in electrical resistance behaviour, observed at 65 Kbar, has been explained on the basis of transition from a predominantly two-dimensional material to a more three-dimensional one. Similar to the resistance behaviour, the thermoelectric power is also found to be pressure dependent. The increase in thermoelectric power with pressure at the transition pressure of 65 Kbar has been explained.

Nanocomposites: Processing of Nanocomposites II

8:50 AM
Structural and Thermal Stability Properties of Cellulose Nanocomposites with Polylactic Acid Matrix: *Na Lu*[1]; [1]University of North Carolina at Charlotte

The use of cellulose nanowhiskers as reinforcement has captured great interests in nanocomposite community owing to their superior mechanical properties, large surface area and biodegradability. In this work, nanocomposite based on cellulose nanowhiskers (CNW) and polyactic acid (PLA) were prepared in various compositions ranging from 5 to 20% CNW volume fraction. The surface morphology of various nanocomposites were examined by scanning electron microscope (SEM). The optical transparency properties were studied by Fourier Transform Infrared Spectroscopy (FTIR). The results from the thermo gravimetric analysis (TGA) have showed great improvement in thermal stability with the higher CNW volume fraction. The dynamic mechanical thermal analysis (DMA) results indicated higher CNW volume fraction resulting in an improvement in storage modulus together with a shift in the Tan Delta.

9:10 AM
Synthetic Process Engineered Polyaniline Nanostructures: *Xi Zhang*[1]; Jiahua Zhu[1]; Suying Wei[1]; John Zhanhu Guo[1]; [1]Lamar University

In this talk, three methods are used to synthesize polyaniline at different synthetic conditions, which affect the quality of polyaniline nanostructures. Polyaniline nanofibers obtained by interfacial polymerization is studied and compared with polyaniline prepared by ultrasonic stirring and polymer acid methods. For polyaniline nanofibers, the effects of reaction time, interfacial area size, scale and concentration of the reactant on the crystalline structure, thermal stability, morphology, conductivity and dielectrical property are systematically studied and will be reported.

9:30 AM Invited
Nanoparticle-Enhanced Crystallization of Semicrystalline Polymer Nanocomposites: *Frank Fisher*[1]; [1]Stevens Institute of Technology

The introduction of nanoparticles into semicrystalline polymers can alter the development and influence of crystallization present within a semicrystalline polymer nanocomposite. For example, nanoparticles may act as heterogeneous nucleation sites, leading to an increase in nucleation rate, a decrease in crystallite sizes, changes in crystalline structure, and a change in the overall degree of crystallinity. Such differences are often observed and reported under quiescent loading conditions; however, we have found that such changes in crystallization behavior can be drastically accelerated and more pronounced if the crystallization occurs under an external applied loading. Such findings require further study as realistic industry-processed nanocomposites are typically manufactured via techniques that subject the polymer nanocomposite to a complex thermomechanical history. Our results indicate how nanoparticles, even at very small loadings, can significantly alter the processing-induced crystallization of semicrystalline polymer nanocomposites, and suggest pathways for leveraging this crystallization behavior in semicrystalline polymer nanocomposites.

10:10 AM
Processing-Structure-Property Relationships in Hydroxyapatite Nanocomposites with a Copolymer-Compatibilized Interface: *Meisha Shofner*[1]; Ji Hoon Lee[1]; [1]Georgia Institute of Technology

To date, much of the research concerning polymer nanocomposites has focused on creating randomly dispersed systems where individual nanoparticles are surrounded by and interacting with the polymer matrix. Beyond the fully dispersed morphology, research concerning directed assembly systems and purposefully inhomogeneously dispersed nanocomposites has shown that there are advantages to designing different nanocomposite morphologies. In this research, the substantial specific surface area available from nanoparticles and prescribed processing operations are used to direct nanocomposite component orientation and arrangement. Specifically, hydroxyapatite nanoparticles of two different shapes are synthesized using micelles formed from a poly(ethylene oxide)-b-poly(methacrylic acid) block copolymer in aqueous solution and subsequently dispersed in a poly(ethylene oxide) matrix. Experimental results concerning the effects of particle shape and loading on polymer crystallinity, thermal transitions and mechanical properties are presented to understand processing-structure-property relationships in these materials.

10:30 AM
Self-Healing, High Molar Mass Polymer Nanocomposites: *Julie Harmon*[1]; Roger Bass[2]; [1]University of South Florida; [2]Air Force

This research focuses on the development of high molar mass, self-healing polycarbonate-containing polyurethane (PCU) nanotube composites. Healing in these materials is: Autonomous- no intervention is needed to induce healing such as heat, light, continuous pressure or electrical stimulus. However, healing is accelerated by heat. Intrinsic- no sequestered healing agents are added to the matrix. Reversible- the composites and neat polymer are capable of multiple healing events. Processing, characterization and structure-property relations demonstrate that these PCUs and PCU composites are part of a new direction in materials development. Unlike most autonomous, intrinsic healing systems that use lower molar mass matrices held together by non-covalent interactions, this research demonstrates that a special class of high molar mass (covalently bonded) thermoplastic polyurethanes exhibit self-healing properties.

10:50 AM
Tacticity Effect Studies of PMMA and PMMA-QDs Composites: *Suying Wei*[1]; Narendhar Anumandla[1]; Jaishri Sharma[1]; [1]Lamar University

Polymer based composites have found wide applications in various fields including electronic, optical and biomedical; effects of filler choice, filler loading levels, and the interaction between the polymer matrix and the filler on the properties of polymer composites have attracted attention and been explored extensively. However, effects of stereochemistry of polymers on their physicochemical and biological properties have less been studied. In this paper, PMMA is chosen as a model polymer to study tacticity effect on its corresponding physicochemical properties. CdSe-ZnS core-shell quantum dots (QDs) are incorporated into different tactic PMMA polymers to form different PMMA-QDs nanocomposites in either film or fiber forms. The effects of tacticity on the fluorescence emission will be explored and rationalized. Chemical interaction between the polymer and QDs will be probed by attenuated total reflectance Fourier transform infrared spectroscopy (ATR-FTIR). Thermal stability and glass transition temperature will also be investigated.

11:10 AM
Thermal Properties of Hemp-High Density Polyethylene Composites: Effect of Two Different Chemical Treatments: *Na Lu*[1]; Shubhashini Oza[2]; [1]University of North Carolina at Charlotte ; [2]University of North Carolina at Charlotte

The drive towards environmentally sustainable materials has resulted in use of natural fibers as an alternative to glass fibers for reinforcement in composites. Hemp has a greatest potential of being used as a reinforcing fiber since it is one of the strongest and stiffest natural fibers along with being biodegradable, low cost and fast growth. However, the incompatibility of hemp fiber with thermoplastic matrix results in poor interface adhesion and lower thermal and mechanical properties. In this study, we have systematically investigated the effects of two chemical treatments of hemp fibers on the thermal stability of hemp-HDPE composites. Composites of various volume fractions were synthesized with sodium hydroxide and silane treated hemp fibers. Thermo-gravimetric analysis was used for thermal stability characterization. The results indicate that chemical treatment of hemp fibers with silane treated yield composites with better thermal stability compared to that of composites treated with NaOH or untreated hemp-HDPE.

11:30 AM Invited
Multifunctional Nanostructures through Functional Polymers: *Yuping Bao*[1]; Soubantika Palchoudhury[1]; Yaolin Xu[1]; [1]The University of Alabama

Functional polymers play an important role in many nanostructured materials. In this presentation, we will specifically discuss the roles of polymers in the formation of multifunctional nanoparticles, such as polyacrylic acids and polyethyleneimines. These polymers can be effectively attached onto iron oxide nanoparticle surfaces to increase the solubility of nanoparticles in water. The thickness of the polymers led to different magnetic properties and subsequent magnetic relaxivity. Further, using these polymers as linkers, we successfully attached sub-nanometer scale nanostructures onto the surface, such as Ag/Au nanoclusters and 2 nm Pt nanoparticles. The Ag/Au nanocluster attached iron oxide nanoparticles have both magnetic and fluorescent properties, offering a bifunctional imaging probe for bioimaging. The small Pt-attached iron oxide nanoparticles have potential in both catalytic and therapeutic research.

12:10 PM
Organic to Inorganic Conversion Process of PDMS: *Jihoon Lee*[1]; Hyun Ae Lee[2]; Umesh Singh[3]; Cheol-Woong Yang[2]; Hyoung Jin Cho[3]; Hyoungsub Kim[2]; [1]Sungkyunkwan University ; [2]Sungkyunkwan University; [3]University of Central Florida

Polydimethylsiloxane (PDMS) resin has been widely used for replicating nano- to micro-scale features with high precision due to its low viscosity and no shrinkage during casting process. PDMS has been crucial to soft lithography and microfludic applications1. However, features of elastomeric PDMS that are subjected to high stress can be easily distorted. In addition, permeable PDMS can be swollen when exposed to organic solvents. In this work, we studied the conversion process of PDMS into inorganic silicon compound by annealing at high temperature in reducing gas ambient, by which rigid and chemically inert structures could be formed. Micro-scale features were predesigned and analyzed before and after the conversion process. The mechanical and chemical characteristics of the PDMS as a function of annealing temperature will be presented, which were obtained using micro-indentation, DTA, FTIR, SEM, AFM, and XPS analyses. The proposed method could make the PDMS-based components suitable for demanding environments.

Neutron and X-Ray Studies of Advanced Materials V: Centennial: Dislocations, Strains, Deformation II

8:30 AM Keynote
In-Situ, Time-Resolved Diffraction Studies in Thermo-Mechanic Processing: *Klaus-Dieter Liss*[1]; [1]Australian Nuclear Science and Technology Organisation

Neutron and synchrotron radiation have been employed and analysis methods developed to follow materials undergoing plastic deformation, giving direct insight into the crystalline arrangements of the bulk of the materials, in-situ, in real time and in multiple dimensions. Neutron white beam Laue diffraction on very grained, quasi single-crystalline copper and magnesium probes the entire orientation sphere during ongoing plastic compression and delivers mosaic broadening, subgrain formation or twinning. In contrast, the fine size of a high-energy X-ray beam, penetrating through a bulk specimen, probes a small but representative number of embedded grains. The discontinuous illumination of the diffraction rings allows to conclude on the behavior of the microstructure, such as phase composition, grain size, orientations, grain rotation, subgrain formation, dynamic recovery and recrystallization, strain and texture. Those primary results allow to conclude on the deformation mechanisms, the kinetics and the phase transformations. Examples are presented on selected high-temperature deformation processes.

8:50 AM Invited

Dislocation Densities, Burgers Vector Populations and Slip System Activity in Different Texture Components Determined by Diffraction Peak-Profile Analysis: *Tamás Ungár*[1]; [1]Eötvös University Budapest

The deformation of polycrystalline materials is heterogeneous on all different scales. Heterogeneity on the grain scale is strongly coupled to texture. In different texture components the dislocation density, the Burgers vector population and slip activity is usually very different. The method of diffraction peak-profile analysis can be applied to obtain the sub-structure in different texture components. Parallel beam high resolution diffractometry is used with systematically varying the angle between the incident-beam and specimen normal. Complementary texture data along with relative peak intensity evaluation are used to select the peaks corresponding to specific texture components. The method is used to characterize the sub-structure in different texture components in polycrystalline austenite and Mg, in Cu-Nb multilayers and in thin films.

9:10 AM

In-Situ Study of Fatigue Damage in a Ni-Based Superalloy by Synchrotron X-Ray Diffraction: *Michael Hemphill*[1]; Andrew Chuang[1]; Yan Gao[2]; Jon Almer[3]; Tim Hanlon[2]; Liang Jiang[2]; Peter Liaaw[1]; [1]University of Tennessee; [2]General Electric Global Research; [3]Argonne National Lab

Nickel-based superalloys are ideal for use in various components under complex thermo-mechanical stresses at elevated temperatures due to their high strengths, phase stability, and corrosion resistance. An important consideration in component design is the fatigue behavior under these complex conditions. The microscopic deformation behavior of a fine-grained, fatigued superalloy was studied by high-energy synchrotron x-ray diffraction (XRD). Specimens were fatigued to 0.5%, 10%, 50%, and 75% of the expected life with a virgin sample used as a reference. They were further subjected to a tensile force at elevated temperature. Under these conditions, in-situ strain and microstructure maps of the specimens were obtained through transmission-based XRD measurements. The damaged zones were identified, and the deformation behaviors at different fatigue lifetime periods were revealed.

9:25 AM

Investigation of Hydride Phase Transformations at Dislocations in Deformed Pd Using Neutron Scattering and Advanced Computational Techniques: *Brent Heuser*[1]; Hyunsu Ju[1]; Dallas Trinkle[1]; Douglas Abernathy[2]; Terrence Udovic[3]; [1]University of Illinois; [2]ORNL; [3]NIST

While Pd is not an advanced material, our use of small-angle neutron scattering (SANS) and incoherent inelastic neutron scattering (IINS) to study the phase behavior of hydrogen trapped at dislocations represents a body of experimental work that is unique to date. Our ability to resolve the specific behavior of only hydrogen trapped at dislocations is due to the use of the strongest neutron sources (HFIR, SNS, and NIST) available in the US. Our interpretation of these results is dependent on the development of advanced computational results within the DFT framework. Discussion of our results will focus 1) the observation of a phase transformation of trapped hydrogen versus temperature, 2) the loss of degeneracy due to the local strain of the dislocation core and near-core trapping sites, and 3) the prediction of the phase transformation and loss of degeneracy of hydrogen trapped at dislocations with DFT and continuum elasticity theory.

9:40 AM

In-Situ Neutron Diffraction Study of Nanobainitic Steels in Conjunction with Transmission Electron Microscopy: *Khushboo Rakha*[1]; Hossein Beladi[1]; Saurabh Kabra[2]; Sean McTrustry[2]; Stewart Pullen[2]; Ilana Timokhina[1]; Peter Hodgson[1]; Klaus-Dieter Liss[2]; [1]Centre for Material and Fibre Innovation, Deakin University, Victoria 3216, Australia; [2]Bragg Institute, Australian Nuclear Science and Technology Organisation, Lucas Heights, NSW 2232, Australia

In-situ neutron diffraction, together with a new thermal quench environment was employed to monitor the evolution of nano-strctured bainitic ferrite during low temperature isothermal heat treatment of austenite. This was undertaken to study the widely debated transformation mechanism for the formation of nanostructured bainite at low temperatures. The neutron peak characteristics were quantified and linked to changes in lattice parameter, volume fraction and carbon content and provided evidence of carbon partitioning during transformation. The results were compared with previous studies using different characterization techniques. The lath characteristics (i.e. size, size distribution) were determined from changes in Full Width Half Maximum (FWHM) of the diffraction peaks. The same characteristics were also studied via transmission electron microscopy and were found to differ from the neutron diffraction results. These differences were attributed to the presence of dislocation build up during low temperature isothermal transformation.

9:50 AM

In-Situ Neutron-Diffraction Study of a Ferritic Superalloy during Tensile Deformation at Room and Elevated Temperatures: *Shenyan Huang*[1]; Yanfei Gao[1]; Ke An[2]; Wei Wu[1]; Lili Zheng[1]; Michael Rawlings[3]; David Dunand[3]; Peter Liaw[1]; [1]University of Tennessee; [2]Oak Ridge National Laboratory; [3]Northwestern University

The ferritic superalloy, Fe-10Ni-6.5Al-10Cr-3.4Mo strengthened by coherent coplanar ordered (Ni,Fe)Al B2-type precipitates, is a candidate material for ultra supercritical steam-turbine applications above 923 K. However, the creep resistance of this material at high temperatures needs to be further improved, which requires a fundamental understanding of the deformation micromechanisms at the local phase and grain levels. In-situ neutron diffraction has been utilized to investigate the lattice strain evolution during tensile deformation at room and elevated temperatures. The neutron diffraction experiments were conducted at VULCAN diffractometer, Spallation Neutron Source, ORNL, with the state-of-art thermomechanical loading capabilities. Evolution of internal stresses and load-sharing mechanisms are revealed in both elastic and plastic deformation regimes. Finite-element simulations based on crystal plasticity are employed to compare with the experimental results, qualitatively and quantitatively. Insights into the microscopic deformation mechanisms and their dependence on temperature are discussed from the interphase and intergranular levels.

10:00 AM

Exploring Dislocation Source Strengths in Nanocrystalline Ni Using X-Ray Diffraction Footprints: *Lin Li*[1]; Steven Van Petegem[2]; Helena Van Swygenhoven[2]; Peter Anderson[1]; [1]The Ohio State University; [2]Paul Scherrer Institut

X-ray diffraction measurements show that NC metals display trends in intergranular stress vs. uniaxial deformation that are different from coarse-grained counterparts. The NC trends are also inconsistent, with tensile vs. compressive vs. negligible shifts observed among different samples. This peculiarity is investigated using Quantized Crystal Plasticity (QCP) simulations [1], which model the intergranular stress redistribution when dislocations propagate unstably across individual NC grains. These finite element-based simulations are interrogated to produce diffraction spectra for specific <hkl> peaks. A principal conclusion is that the grain-to-grain distribution of dislocation source strengths for electrodeposited NC Ni has a different, truncated form compared to coarse-grained counterparts. The seemingly inconsistent experimental trends are attributed, in part, to different prior deformation histories. This experiment-simulation approach is also applicable to study deformation physics in ultra-fine grain metals and dislocation cell structures. [1] L. Li et al., Acta Mater. 57, 812 (2009).

10:10 AM

Time-Resolved X-Ray Tomography of Semi-Solid Alloy Deformation: *Kristina Maria Kareh*[1]; Peter Lee[2]; Christopher Gourlay[1]; [1]Imperial College London; [2]The University of Manchester

During the casting of aluminium alloys, regions of the casting are commonly a mixture of numerous equiaxed crystals and liquid. This two-phase mixture is deformed by phenomena such as shrinkage, and defects including segregation and cracking can result. In this work, Al-

15 wt.% Cu with a solid fraction of approximately 0.7 and with globular morphology has been deformed during time-resolved x-ray synchrotron tomography to understand the dynamic crystal-scale response to load. The rotation, translation and deformation of individual globules has been quantified during macroscopic deformation. A particular focus is given to the behaviour of agglomerates under load, allowing globule-scale deformation mechanisms to be compared with those suggested from past post-mortem studies on semi-solid deformation.

10:20 AM Break

10:25 AM Invited
Investigation of Residual Stress in Key-Hole Laser Formed Weldments Measured by Neutron and Synchrotron Diffraction: *Anna Paradowska*[1]; Wojciech Suder[2]; Stewart Williams[3]; T. Connolley[4]; U. Lienert[5]; [1]ISIS, Rutherford Appleton Laboratory; [2]Cranfield University; [3] Cranfield University; [4]Diamond Light Source; [5]Advanced Photon Source,

There is a new generation of lasers available for materials processing. The new lasers include fibre and disc laser are characterized by very high beam quality at very high power levels providing extremely high energy density. In general laser welding is selected over other welding processes because of the minimisation of the heat input, residual stresses and distortion, for this reason they are increasingly popular over a wide range of industries. The narrowness of the welds makes it challenging to resolve the details of the residual stresses produced by the welding process. Residual strain/stress measurements in weldments produced using the fibre laser were performed on Engin-X, at ISIS and on 1-ID at Advanced Photon Source. Across the weld and through thickness line distributions as well as maps are reported in this paper.

10:45 AM
Study of Embryos and Nanoscale Precipitates in a Ferritic Steel by Small Angle Neutron Scattering and Atom Probe Tomography: *Z. W. Zhang*[1]; C. T. Liu[2]; X.-L. Wang[1]; K. C. Littrell[1]; M. K. Miller[1]; K. An[1]; B. A Chin[3]; [1]Oak Ridge National Labs; [2]City University of Hong Kong; [3]Auburn University

State-of-the-art microstructural characterization techniques of small angle neutron scattering and atom probe tomography have been applied to characterize the evolution of solute-enriched embryos into nanoscale precipitates. Both techniques are able to detect number densities of sub-nanometer sized embryos that were higher than randomly expected within the solid solution in an as-quenched multicomponent ferritic steel. The results indicated that the nanoscale precipitates nucleate from the embryos and that the growth of the precipitates is dictated by volumetric diffusion. This type of mechanistic understanding of the nucleation and growth behavior of nanoscale nanoclusters is essential for the design of new classes of precipitation-strengthened materials. Research supported by Auburn University, City University of Hong Kong, NJUST Research Funding (No. 2010GIPY031), National Natural Sciences Foundation of China (No. 50871054), MSED (MKM, XLW, ZWZ) and SUFD (ORNL SHaRE User Facility (APT), HFIR, and Spallation Neutron Source) BES, U.S. DOE.

11:00 AM
Effect of Oxygen Content and Processing on Deformation Modes in a Zirconium Alloy: *Christopher Cochrane*[1]; Song Cai[1]; Mark Daymond[1]; [1]Queen's University

In situ neutron diffraction tests were performed during compression on samples of the two-phase alloy, Zr-2.5wt%Nb, used in pressure tubes in CANDU nuclear reactors. Three alloys with different oxygen concentrations were each prepared with three different heat treatments. The different heat treatments resulted in changes to crystallographic texture and microstructure. Oxygen is an interstitial solid solution element in zirconium alloys that results in a significant strengthening. Macroscopic stress-strain analysis showed the expected contribution to strengthening, while analysis of the neutron diffraction patterns reveals the role of oxygen on specific deformation modes. Changes in the onset of twinning and the load sharing between alpha and beta phases was identified. Combining the experimental results with an elastic-plastic self-consistent (EPSC) model allows for the quantitative determination of the role of oxygen interstitials on specific slip / twinning systems. These studies highlight the role of neutron diffraction in potential alloy optimization.

11:10 AM
Study the Hydrogen Induced Volume Expansion and the Embrittlement of Zr-Based Bulk Metallic Glasses: *Chih-Pin Chuang*[1]; Wojciech Dmowski[1]; Yun Liu[2]; Terrence Udovic[2]; Peter Liaw[1]; Lu Huang[3]; [1]University of Tennessee; [2]National Institute of Standards and Technology; [3]Beihang University

We report the hydrogen-induced structural change of Zr-based bulk metallic glasses. The hardness of hydrogen-charged sample was increased, but was accompanied by the significant reduction in the toughness and strength. The featureless, smooth fracture surface after hydrogenation suggests the embrittlement of the sample. The changes of the local atomic structures of amorphous alloys were investigated by the radial-distribution-function (RDF) analysis using high-energy X-ray, and the hydrogen occupation sites were determined by neutron vibrational spectroscopy (NVS). The results indicate that hydrogen expands the whole amorphous matrix by selectively occupying the 4-Zr tetrahedral sites. Locally, hydrogen only increase the Zr-Zr inter-atomic distance, but, globally, create a long range stress field in the amorphous matrix. The comparison of RDF of the hydrogenated sample with the as-cast sample under a tensile stress suggest that the hydrogen induced structural changes is equivalent to the changes produced by the tensile stress of 1.2 GPa.

11:20 AM
Characterization of Residual Stress in Laser Shock Peened IN718 SPF Alloy with X-Rays of Different Wavelengths: Amrinder Gill[1]; S.R. Mannava[1]; *Vijay Vasudevan*[1]; Dong Qian[1]; Gokul Ramakrishnan[1]; Mohammed Belassel[2]; [1]University of cincinnati; [2]Proto Manufacturing Limited

X-ray diffraction is widely used to determine residual stresses in variety of materials. In the current study, coupons of IN718 SPF alloy were laser shock peened and through thickness residual stresses were determined by measuring strain in different sets of lattice planes: (331), (220) and (311) using Cu-Kalpha, Cr-Kalpha and Cr-KBeta/Mn-Kalpha radiations, respectively. X-ray Elastic constants were also measured using a four-point bend fixture. The results showed large variations in the residual stress values, with those measured in the near-surface regions using Cu-Kalpha x-rays being much lower than those measured using Mn-Kalpha and Cr-Kbeta. The values were more or less similar in regions far below the surface. It is believed that this difference is due to plastic anisotropy, which can result in widely different strain responses in different lattice planes. Samples were also characterized using Synchrotron with conical slits for high spatial resolution and results compared with conventional XRD.

11:30 AM
In Situ Time-of-Flight Neutron Diffraction Study of the Phase Transformation in a TC18 Titanium Alloy: *Xiaopeng Liu*[1]; Ru Lin Peng[2]; Yandong Wang[3]; Shuyan Zhang[4]; Sten Johansson[2]; [1]Northeastern University; [2]Linköping University; [3]Beijing Institute of Technology; [4]Rutherford Appleton Laboratory

The high strength TC18 titanium alloy is of particular interest to the aerospace industry for its applications as bogie frames of aircraft landing gears. The mechanical properties of the alloy depend on its microstructure consisting of an hcp (a) and a bcc (ß) phase, which can be influenced by thermal or thermomechanical process. For a better understanding of the development of phase-to-phase strain/stress and phase transformation behaviour, in-situ neutron diffraction experiments under cyclic heating and cooling between 20 and 900°C were performed on a TC18 rod material using ENGIN-X diffractometer at the ISIS Facility in UK. The evolution of diffraction spectra with temperature was monitored, based on which detailed information such as changes of the relative volume fraction and lattice parameters for both a- and ß-phases was analysed. The present study provides material parameters required for establishing further a FEM-based micromechanical model of titanium alloys with phase transformation.

11:45 AM
Non-Destructive Evaluation of Strain-Stress and Texture in Cold Drawn Tubes by Neutrons and Hard X-Rays: Adele Carradò[1]; Thilo Pirling[2]; Robert Wimpory[3]; Heinz-Guenther Brokmeier[4]; *Heinz Palkowski*[4]; [1]IPCMS, UMR 7504 UDS-CNRS; [2]Institut Laue-Langevin; [3]Helmholtz Zentrum Berlin; [4]Clausthal University of Technology

Seamless tubes are used for applications where strength, resistance to corrosion, microstructure and extended product life can be important design parameters. Cold drawing is widely applied in the industrial production of seamless tubes, employed for various mechanical applications. During pre-processing, deviations in tools and their adjustment lead to geometrical inhomogeneities – e.g. eccentricity - of the tubes as well as in the flow behaviour and cause a gradient in residuals and texture. In this paper the residual stress state and the texture in SF-copper tubes, drawn under controlled laboratory conditions, are presented. The residual stresses were evaluated by neutron diffraction on SALSA at the Institute Laue Langevin (France) and on E3 at Helmholtz-Zentrum Berlin (Germany), the texture by synchrotron radiation on the high energy beam line BW5 at DESY HASYLAB (Hamburg, Germany). The aim is to use the results for defining the process parameters for an optimized production process.

New Advances in Synthesis, Characterization, and Application of Layered Double Hydroxides: Session I

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division, TMS: Chemistry and Physics of Materials Committee
Program Organizer: Jewel Gomes, Lamar University

Thursday AM	Room: Oceanic 2
March 15, 2012	Location: Dolphin Resort

Session Chairs: Hylton McWhinney, Prairie View A&M University; Jeanne Hossenlopp, Marquette University; Jewel Gomes, Lamar University

8:30 AM Introductory Comments Hylton McWhinney, Prairie View A&M University

8:35 AM Invited
Advances and Biochemistry of Using Layered Double Hydroxides in Treatment, Health and Wellness: *David Cocke*[1]; Gary Beall; [1]Lamar University

Layered double hydroxides (LDHs) are being explored as vehicles for organic anions that can help diagnose and treat disease, promote health through prevention and enhance wellness. Synthetic LDH systems with positively charged brucite type layers of mixed metal hydroxides and positive charge located in interlayer spaces provide adjustable confinement for biochemically active anions. Selected advances in synthesis, exchange technology and associated biochemistry will be highlighted and discussed in terms of future applications for important human conditions where survivability, designed structure and controlled release of these materials are advantageous.

9:00 AM
Designing Layered Double Hydroxides for Targeted Applications: *Jeanne Hossenlopp*[1]; [1]Marquette University

Layered double hydroxides (LDHs), and other similar nanodimensional layered metal hydroxides, offer promise for a number of applications ranging from controlled release of bio-active compounds to polymer fire retardant additives. Tailoring LDHs for controlled release or adsorbant applications requires an understanding of the kinetics and thermodynamics of anion release or analyte uptake. Recent work in our laboratory on the effects of systematic alteration of the metal hydroxide layer and/or anion structure will be discussed. The composition of the metal hydroxide layer provides wide tunability in reactivity for controlled release or anion exchange reactions. Anion polarity and hydrogen bonding capability can be utilized to vary the extent and rates of exchange reactions. Similar approaches to LDH structural alterations are applied to the design of potential polymer fire retardant additives. The effect of metal hydroxide layer composition and anion structure and packing influences the morphology of LDH-polymer (nanocomposites) and their thermal/fire properties.

9:20 AM
Electrochemical Synthesis of Layer Double Hydroxides, Its Characterization, and Performance Study for Removal of Nitrate and Arsenic: Md Haider[1]; *Jewel Gomes*[1]; Kevin Urbanczyk[2]; David Cocke[1]; Hylton McWhinney[3]; George Irwin[1]; Paul Bernazzani[1]; [1]Lamar University; [2]Sul Ross State University; [3] Praire View A&M University

Green rust (GR) is an important intermediate Layered Double Hydroxides (LDHs) which exist in oxidative transformation of iron(II) phase. Anionic and cationic species can replace their corresponding parts in the layered structure, and different species can also be accumulated in between the layers. GR can play an important role in wastewater remediation, such as reduction and removal of toxic compounds. An afford was made to synthesize LDH electrochemically, and to characterize it by Mössbauer, x-ray diffraction, scanning electron microscopy/energy dispersive x-ray analysis, x-ray photoelectron spectroscopy, and Fourier transform infrared spectroscopic techniques. GR was used to remove nitrate and arsenic from wastewater. The optimized conditions for removal of these water pollutants were also investigated. The resistance against oxidation of GR was increased using dopents, such as magnesium and aluminum, so that it can be used for water treatment in remote areas.

9:40 AM
Enhanced Removal of Various Phosphates over Ca Based Fe-lLyered Double Hydroxide (LDH): *Guangren Qian*[1]; Ji Zhi Zhou[1]; Zhi Ping Xu[2]; Yunfeng Xu[1]; Jianyong Liu[1]; [1]Shanghai University; [2]The University of Queensland

Ca-Al-layered double hydroxide (LDH) has exhibited its efficient removal capacity to aqueous anions such as SeO42-, AsO42- though corresponding Ca-precipitate formation. Despite the similar structure to Ca-Al-LDH, Ca-Fe-LDH is barely investigated for anionic pollutants removal. In current work, the removal of various phosphates such as PO43-, pyrophosphate (P2O74-, PP) and triphosphate (P3O105-, TPP) was performed on Ca-Fe-LDH. Our research indicates that the dissolution-precipitation played an important role on the phosphates removal due to the Ca-P precipitate formed. In particular, the PO43- and P2O74- removal was enhanced as the adsorption of phosphate on CaxFe(OH)(3+2x) which was the hydrolyzed Ca-Fe-LDH. Such enhancement was not observed in the case of P3O105- as the formation of highly soluble Ca-TPP complex. Moreover, the introduction of Mg into Ca-Fe-LDH enabled a Mg0.5Ca1.5Fe-LDH to take up higher amount of TPP than that on Ca-Fe-LDH. It is due to the combination of adsorption/intercalation and dissolution-precipitation.

10:00 AM
Removal of Direct Red and Orange II Azo Dye from Synthetic Textile Water Using Electrochemically Produced Fe-LDH: *Sadia Jame*[1]; Jewel Gomes[1]; David Cocke[1]; [1]Lamar University

Layered double hydroxides are produced as an intermediate phase during in-situ electrochemical coagulation technique using iron sacrificial electrode. Its structure consists of cationic layers, Fe(OH)2n+, alternating with anionic layers stacked in a six-layer repeating sequence, giving rise to a hexagonal or pseudohexagonal symmetry. This Fe-LDH has also the ability to trap organic impurities in the interlayers when it is mixed with wastewater. This hypothesis was verified using dye molecules, such as Direct Red and Orange II. Generally, textile industries use various kinds of chemicals including dyestuffs and pigments during dyeing and finishing processes. Their effluent is extremely toxic and environmentally hazardous. Fe-LDH was found to remove dye molecules with satisfactory efficiency. Optimum conditions were explored by changing current density, dye concentration, conductivity and pH during the LDH generation process. The floc was characterized using SEM/EDS, XRD and FTIR.

10:15 AM Break

10:30 AM Invited
Charge Density and Counter ion Effects on Synthesis and Thermal Decomposition Character of Hydrotalcites: *Gary Beall*[1]; David Cocke[2]; Sergio Crosby[1]; Andrew Gomes[2]; Doanh Tran[2]; [1]Texas State University; [2]Lamar University

A series of hydrotalcites have been synthesized with exchange capacities ranging from 100 to 500 meq/100 g at temperatures ranging from room temperature up to 180 oC. These hydrotacite have been characterized by x-ray diffraction, scanning electron microscopy, and by thermal decomposition techniques. The temperature of synthesis has the largest effect upon crystallinity and the unit cell parameters are sensitive to charge density. The thermal decomposition of the hydrotalcites has been followed by thermal gravimetric analysis coupled with off gas analysis of the decomposition products. The off gas analysis yields very distinct decomposition profiles that are very dependant upon both charge density and counter anion. The mechanisms of decomposition will be discussed in detail.

10:55 AM
Microwave Synthesis and Vibrational Spectroscopy of Chemically Substituted Layered Double Hydroxides with Carbonate, Chloride and Sulfate Ions: *Anderson Dias*[1]; Andiara Vieira[1]; Lumena Cunha[1]; [1]UFOP

A hybrid material based on the intercalation of carbonate, chloride, and sulphate anions has been synthesized at mild temperatures through microwave-assisted hydrothermal synthesis. Chemically substituted layered double hydroxides were produced by changing both bivalent (Ni, Zn, Mn, Co, Mg) and trivalent cations (Al, Fe) into the structure. Powder X-ray diffraction patterns showed pure layered double hydroxide phases having crystallite size around 50 nm. Raman scattering measurements exhibit shifting of bands with changing of both divalent or trivalent metal ion type for all samples with carbonate, chloride or sulphate anions. Differential scanning calorimetry and thermogravimetry analysis exhibit the three stages of thermal degradation, which is characteristic behavior of hydrotalcites. Investigations carried out through transmission electron microscope showed a characteristic platelet morphology with the platelets stacked one above the other. Detailed discussion on the processing conditions and the final morphology and vibrational features is presented.

11:15 AM
Removal of Arsenic Using Green Rust and Other Electrochemically Generated Floc: *Md Rahman*[1]; Jewel Gomes[1]; Kevin Urbanczyk; David Cocke[1]; [1]Lamar University

Arsenic contamination from groundwater is a worldwide problem. It is considered as one of the toxic materials being controlled by Environmental Protection Agencies in several developed and developing countries. The most common form of inorganic arsenic in natural water system is arsenate and arsenite. Arsenite (As(III)) is more toxic than Arsenate (As(V)) and it is more abundant in anaerobic condition such as in groundwater. Removal of arsenic from synthetic wastewater was carried out by using green rust floc which belongs to the layered double hydroxide (LDH) family and it was produced in-situ during electrocoagulation procedure using iron sacrificial electrode. Other electrochemically generated flocs using copper and aluminum electrodes were also used for the removal of arsenic from synthetic wastewater. The maximum arsenic removal efficiency was recorded as 99.9%. The sludge produced during electrocoagulation was assessed for semi conductive property with diffuse reflectance UV-Vis spectroscopy.

11:30 AM
Formation of Layered Double Hydroxides in Self-Purification of Polynary Metal Electroplating Wastewaters for Effective Removal of Anionic Dye: *Jizhi Zhou*[1]; Guangren Qian[1]; Zhi Ping Xu[2]; Yueying Wu[1]; [1]Shanghai University; [2]The University of Queensland

The synchronous formation of layered double hydroxide (LDH) precipitates was performed for the self purification of wastewaters containing Ni2+, Zn2+, and Cr3+. With ~99% of metal ions removed, a pure Ni-Zn-Cr-bearing LDH was formed by accelerated carbonation process. The obtained LDH were characterized by XRD, FT-IR, SEM and BET surface area techniques. Moreover, the removal of a dye, Acid Scarlet GR (GR), from aqueous solution on the LDH was studied under varying conditions of pH, adsorbent dose and contact time. It is observed that Ni-Zn-Cr-LDH could effectively remove GR from aqueous solutions and the removal capacity increased with rising temperature. The final solution after dye removal exhibited rare heavy metal was dissolved. These results suggest a strategy to treat heavy metal wastewater efficiently and propose Ni-Zn-Cr-LDHs as an environmental friendly adsorbent for anionic dye removal.

11:45 AM
Characterization and Chemical Modification of Electrochemically Produced Layered Double Hydroxides as Nanomaterials: *Md Islam*[1]; Jewel Gomes[1]; Paul Bernazzani[1]; [1]Lamar University

Electrocoagulation (EC) is one of the most effective electrochemical techniques for the removal of trace amount of metal contaminants from waste water. The intermediate step of this process using sacrificial iron electrode is generation of layered double hydroxides generally known as green rust. When trace copper is removed using EC, the produced EC floc contains mostly iron and lesser proportion of copper incorporated in it. Instead of disposing the EC-floc as waste, it was further treated to produce important nanomaterials. The EC floc was chemically treated to convert nanowire of iron. The different proportion of copper was incorpoated into iron floc to see the effect of the change of the ratio of iron to copper in the structure, size, and shape of the nanowires. Copper was recaptured both chemically and electrochemically, and converted to nanorods. These nanomaterials were characterized using SEM, EDX, XRD, FTIR and TG-DSC.

Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Physical Property Effects and Responses to Current

8:30 AM Invited
Critical Studies to Evaluate the Events Controlling TMF Reliability of Sn-Ag Solder Joints: Stephanie Bergman[1]; Andre Lee[1]; *K.N. Subramanian*[1]; [1]Michigan State University

In order to gain a better understanding of the events controlling the solder joint reliability under thermomechanical fatigue thermal excursions with varying temperature differences in different temperature ranges were imposed on the joints. Such studies were focused on the very early stages of thermal excursions. Specimens were first subjected to limited number cycles of a chosen thermal profile were subsequently subjected to additional number of cycles of different thermal profile. Residual shear strength of the joints subjected to various combinations of these thermal profiles is used to evaluate the roles of critical microstructural events that control the thermomechanical fatigue reliability of solder joints.

8:55 AM
In-Situ Mechanical Assessment of Thermomechanically Fatigued POSS-Added Pb-Free Nanocomposite Solder Joints: Stephanie Bergman[1]; *Andre Lee*[1]; K.N. Subramanian[1]; [1]Michigan State University

Silanol of polyhedral oligomeric silsesquioxane (POSS-silanol) when incorporated in Pb-free, electronic solders increase the residual shear strength and reliability of thermomechanically fatigued (TMF) solder joints. Such enhanced TMF reliability has been attributed to the strongly bonded inert POSS-silanol at the boundaries of various microstructural entities in solder joints. Depending on the service temperature, presence of POSS-silanol can either increase the stress needed to cause decohesion or reduce the sliding motion between different entities. Recently a dynamic mechanical method has been used for TMF induced damage assessment in Pb-free solder joints by imposing temperature and frequency sweeps. The small shear strain amplitudes used in such evaluation does not cause additional damage. Hence, it is an ideal in-situ assessment method for monitoring the progression of TMF induced damages in the same solder joint. This presentation compares the findings on joints made with various Pb-free solder alloys, with and without POSS additions.

9:15 AM
Experimental and CPFEM Investigation of Stress Distribution in Shear Tests and Thermal Cycling in Lead-Free Solder Joints: *Payam Darbandi*[1]; Bite Zhou[1]; Farhang Pourboghrat[1]; Thomas Bieler[1]; Tae Kyu Lee[1]; Kuo Chuan Liu[1]; [1]MSU

A set of crystal plasticity analyses was used to evaluate stress, strain and shape change resulting from shear experiments on single lap shear specimens with different known crystal orientations. Phenomenological flow models for ten systems were estimated based upon semi-quantitative information available the literature and new experiments, along with known anisotropic elastic information. Optimization of material parameters is done to match prior experimental results where slip sytems activity has been quantified. This is also used to assist analysis of elastic strains measured in single crystal joints identified using synchrotron X-ray diffraction patterns during -situ solidification studies and subsequent thermal cycling between 0°C-100°C strains from CPFE simulations are used to compute changes in d-spacings to be compared with measured d-spacings in order to provide comparisons between model and simulation that will assist in improving the model and gaining quantitative understanding of strain evolution.

9:35 AM
Thermal and Mechanical Characterization of Cu/ Cu-In Solder Joints for Thermal Interface and Interconnect Applications: Effects of Interfacial Layers: *Jia Liu*[1]; Praveen Kumar[1]; Indranath Dutta[1]; Rajen Sidhu[2]; [1]Washington State University; [2]Intel Corporation

Cu-In composites, for thermal interface and interconnect applications, were prepared using liquid phase sintering. Two Cu pieces were joined using optimized Cu-In composite solder, having ~2.5 times higher thermal and electrical conductivities, and ~30% lower yield strength than commercial (Sn, Ag, Cu)-based solders. Mechanical properties in shear, and thermal and electrical resistance of these joints were measured as functions of inter-layer between solder and Cu, joint thickness and thermo-mechanical history. The joints showed higher shear compliance as compared to similar joints prepared using Sn-3.0%Ag-0.5%Cu and higher thermal and electrical conductivity as compared to those prepared using In and Sn-3.0%Ag-0.5%Cu. Minimizing interfacial contact-resistance is desired, especially for small joint thicknesses, and hence interfacial engineering is conducted based on the role of different interfacial layers. A nanometer thick Au layer coating on Cu-substrate reduces the contact-resistance by an order of magnitude. Structure-property relationship will be discussed in detail.

9:55 AM Break

10:05 AM
Wetting Behavior and Interfacial Reaction between New Electrolytic Ni-Pd Surface Finish/Sn-3.0Ag-0.5Cu Solder Joints: *Cheng Ying Ho*[1]; Jenq Gong Duh[1]; [1]National Tsing Hua University

ENEPIG, a new substrate surface finish in electronic package, was expected to take place of traditional ENIG substrate because of its low consumption, good reliability, and free "black-pad". However, the popularity of ENEPIG was restricted by complicated process and ultra-high cost. In this study, single Ni-2wt%Pd alloy electroplating process without gold layer was designed to be a replacement. Wetting behavior with molten Sn-3.0Ag-0.5Cu (SAC305) solder and the formation of metallic oxide under 150°C aging were analyzed. The Pd dopant tends to enhance the surface wettability, and the possible mechanism will be discussed. Furthermore, interfacial reaction between substrate and SAC305 under various aging time is studied. Growth mechanism of IMC and influence of Pd dopant in solder joints will be also evaluated.

10:25 AM
Analytical Modeling of Diffusion and Growth Processes in Sn-Ag Alloy Systems: *Sri Chaitra Chavali*[1]; Ganesh Subbarayan[1]; Mysore Dayananda[1]; [1]Purdue University

SnAg and SnAgCu solder alloys are common in microelectronic assemblies. These evolve in their mechanical behavior and microstructure due to environmental conditions. The dispersed Ag3Sn microscopic precipitates are an example of interface mediated shape evolution that evolve into needle-like structures during the course of static aging. In this paper, we develop an analytical model based on Zener's diffusion model to describe the kinetics of particles during the aging process. The ultimate goal is to develop a refined kinetics and thermodynamics based sidewise growth model for Ag3Sn precipitates in beta-Sn matrix. Aging experiments were carried out (ranging 298-398K for 1, 5, 15, 30 and 90 days) to induce microstructural evolution and quantitative metallographic characterization of the evolving microstructure. From the microstructural information obtained on growth of the particles, we derive the interdiffusion parameters at homologous temperatures of 05-0.7Tm (that are usually experienced in Microelectronic industry for SnAgCu systems).

10:45 AM
Effect of Solder Thickness on Electromigration in Sn2.5Ag Solder Joints: *Woei haw Khew*[1]; Chih Chen[1]; [1]Department of Materials Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan 30010, Republic of China

As the solder bump size becoming smaller, electromigration failure is a critical reliability issue. As 3D-IC will become an important packaging technology for high performance devices, the bump height will decrease to 10 to 20 micron. In this research, the effect of different solder thickness of electromigration is investigated. The solder joint consists 10 µm Sn2.5Ag solder joint with 3 µm electrical Ni on the chip side and 5 µm electroless Ni on the substrate side. The current density was about 5×10^3 A/cm^2 and the testing temperature at 150^{o}C controlled by using micro-thermal sensor. The result indicates that void and intermetallic compound formation was easily observed at higher solder thickness. Back stress may play an important role in electromigration of solder joints with a smaller bump height. We will investigate whether there is a critical thickness, below which there is no electromigration damage due to the back stress effect.

11:05 AM
Relationship between Reliability and Effect of Solid Solution Hardening at Solder Joints: *Minoru Ueshima*[1]; [1]Senju Metal Industry

The change of the microstructure causes the decrease in the fracture strength. On the other hands, the strength of Sn-Ag-Cu system alloys contained Sb and Bi, doesn't decrease very much after annealing at 125C. The reliabilities of the solder joints at the alloys contained Sb and Bi are investigated by measuring the shear strength of solder joints at the big chip resister (6.4 × 3.2 mm) and the small one (3.2×1.6 mm) after every 1000 cycles between -55 and 125°C. The lives of solder joints at the new alloys become twice more than at Sn-3Ag-0.5Cu alloy. Furthermore, addition of Bi is effective on improving the reliability at thermal fatigue tests between -55 and 150°C. The effect of solid solution hardening of Bi never disappears at 200°C.

11:25 AM
Current-Induced Phase Transformation Study of Ni-Sn Intermetallic Compounds in 18 \149; m Microbumps in Three-Dimensional Integrated-Circuit Packaging Using Kelvin Bump Structure: *Yuan-Wei Chang*[1]; Chih Chen[1]; [1]National Chiao Tung University

The electromigration behavior is investigated in 20 µm SnAg microbumps with Cu/Ni under-bump-metallization (UBM) at 150 □. A Kelvin bump structure was designed and fabricated in these samples to measure the bump resistance of only one bump, and the different stages (initial stage, 5% resistance increase, and 20% resistance increase) were in-situ monitored. The monitored bump resistance increased abruptly right after the current stressing by 4.6 x 104 A/cm2, but the resistance rose much slower after a certain period of time. Microstructural analysis indicates that the formation of the high-resistivity Ni3Sn4 intermetallic compounds (IMCs) is responsible for the abrupt resistance increase in the beginning of current stressing. The whole solder joint can be transformed into IMC joint in a short time, which has a higher electromigration resistance than the original SnAg solder and results in a much slow increase in resistance afterwards. The electromigration failure mechanism is also examined.

Recent Developments in Biological, Electronic, Functional and Structural Thin Films and Coatings: Applications to Bio, Energy and Electronic Systems

8:35 AM
Multilayer Roll Bonded Sandwich: Processing, Mechanical Performance and Bioactive Behavior: *Adele Carradò*[1]; Heinz Palkowski[2]; [1]IPCMS, UMR 7504 UDS-CNRS; [2]Clausthal University of Technology

Multi functionality of the materials makes it necessary to use hybrid systems such as combination of metals with polymers. Their applications can be found in all areas where light weight and improved mechanical properties as well as high functionality are necessary. Moreover adapted types of hybrids can be interesting for biomedical applications as under specific condition they show for e.g. good strength combined with high elasticity. The present study shows preliminary tests on the biomimetic behaviour of 316L/polypropylene copolymer/316L sandwich. The autocatalytic and biomimetic coating routes were applied to induce calcium phosphate layer in a way similar to the process of natural bone formation. Knowledge of the formability of three-layered sandwich sheets and their biomedical application are presented.

9:05 AM
Effect of Multiple Quaternary Ammonium Ion Salts on the Performance of Heparin Ionic Complex Coating: *Narayana Garimella*[1]; Bartley Griffith[1]; Zhongjun Wu[1]; [1]University of Maryland School of Medicine

Dissolved quaternary ammonium salts are excellent surfactants and can effectively coat numerous substrate materials and also form ionic complexes with negatively charged enzymes. Chemical constitution and dissolution of the salts in polar and non-polar solvents governs the substrate binding and retaining characteristics, whereas forming a precipitate of ionic complex along with heparin enzyme governs the applicability of bioactive coating. In this current study, effect of multiple quaternary ammonium salts on the performance of heparin ionic complex coating is studied from the view point of surface modification to polymeric hollow fiber membranes of artificial lung. Pre and post coating characteristics of the surfaces are evaluated in contact with normal saline, ringer's lactate and 1mol/L NaCl solutions to determine stability of coating. Immobilized enzyme activity was confirmed using biochemical and chemical assay methods. In-vitro blood compatibility experiments proved coating's ability to prevent platelet adhesion.

9:35 AM

Bio-Inspired Organic/Inorganic Multi-Layer Coating Synthesized by RF-Magnetron Sputtering and Pulse Laser Deposition: Yu-Chen Chan[1]; Hsien-Wei Chen[1]; Li-Wei Ho[1]; Jyh-Wei Lee[1]; *Po-Yu Chen*[1]; Jenq-Gong Duh[1]; [1]National Tsing Hua University

Abalone shell is a natural composite of 95 wt% stacked CaCO3 tiles and 5 wt% organic layers of chitin and protein hierarchically organized into a "brick-and-mortar" microstructure, which leads to exceptional mechanical properties. In this study, abalone-inspired organic/inorganic multilayer coatings were synthesized by combining RF-magnetron sputtering (inorganic) and pulse laser deposition (organic) in a single chamber. Selected inorganic nitrides and organic polymers were used. SEM and TEM images showed uniform polymeric layers (10-50 nm) sandwiched between ceramic layers (~0.5 µm). The microstructure and organic/inorganic thickness ratio were fine controlled to be the same as those in abalone shell. Additionally, organic/inorganic multilayers with increasing interfacial roughness were made to mimic the nano-sized asperities and mineral bridges observed in abalone. Nano-indentation and nano-scratch tests were performed on the synthetic multilayer coatings and abalone shell followed by SEM and AFM characterization. Mechanical properties and toughening mechanisms were discussed and comparisons were made.

10:05 AM

Nanomechanical Properties of Polyethylene Glycol Coatings on Flat Gold Substrates: *Frank DelRio*[1]; Gheorghe Stan[1]; Robert MacCuspie[1]; Robert Cook[1]; [1]National Institute of Standards and Technology

Medical devices have long utilized both gold and polyethylene glycol (PEG) as inert, biocompatible, and safe surfaces. A necessary step in advancing the use of PEG coatings is to provide direct and reliable nanoscale property characterization. In this work, atomic force microscopy (AFM) and atomic force spectroscopy (AFS) were used to study the morphology and mechanical properties of thiol-functionalized PEG coatings on flat gold substrates in solution and in air. AFM was used to investigate the morphology of PEG coatings as a function of concentration and molecular weight; the commonly-observed coverage was in the form of sparse brush-like islands. AFS was used to study the mechanical properties of PEG coatings in compression and tension as a function of molecular weight. Together, the various models were used to map a number of mechanical properties over individual PEG islands, which enabled a statistical approach for assessing the heterogeneity of PEG properties.

10:35 AM Break

10:50 AM

Doping and Co-Doping of Bandgap-Engineered ZnO Films for Solar Driven Hydrogen Production: *Sudhakar Shet*[1]; Nuggehalli Ravindra[2]; Yanfa Yan[1]; Mowafak Al-Jassim[1]; [1]National Renewable Energy Laboratory; [2]New Jersey Institute of Technology

The co-doped ZnO:(Al,N) and ZnO:(Ga,N) films were deposited by co-sputtering using radio-frequency magnetron sputtering on F-doped tin-oxide-coated glass. We found that the ZnO:(Al,N) and ZnO:(Ga,N) films exhibited greatly enhanced crystallinity compared to ZnO:N films doped by pure N and grown at the same conditions. Furthermore, the ZnO:(Al,N) and ZnO:(Ga,N) films showed much higher N-incorporation than ZnO:N films grown with pure N doping. As a result, the ZnO:(Ga,N) films showed significantly higher photocurrents than ZnO:N doped only by N. The ZnO:(Cu,Ga) films were synthesized by RF magnetron sputtering in O2 gas ambient at room temperature and then annealed at 500□C in air for 2 hours. We found that the carrier concentration tuning does not significantly change the bandgap and crystallinity of the ZnO:Cu films. However, it can optimize the carrier concentration and thus dramatically enhance PEC response for the bandgap-reduced p-type ZnO thin films.

11:20 AM

Characterization of Thin Film Photovoltaic Microstructure and Correlation with Conversion Efficiency: *Matt Nowell*[1]; [1]EDAX-TSL

Thin film photovoltaic devices have become an increasingly viable option for solar power generation. The conversion efficiencies of CdTe and CIGS polycrystalline thin film devices are higher than their single crystal equivalents. This indicates that the microstructural features present in the polycrystalline films play a beneficial role in device performance. In this work, Electron Backscatter Diffraction (EBSD) has been used to characterize CdTe photovoltaic thin films deposited by magnetron sputtering. These films were examined in the as-deposited state, and after annealing. This annealing, with a CdCl2 solution, is a standard treatment used to produce high performance films. Investigation of the as-deposited films provides information on the growth mechanisms of the films while investigation of the annealed films allows for correlation of microstructure with final device performance. In these films, significant twinning occurs during annealing, and these twins provide beneficial properties to the final microstructure.

Magnetic Field Assisted Heterogeneous Device Assembly: *Vijay Kasisomayajula*[1]; Michael Booty[1]; Anthony Fiory[1]; Nuggehalli Ravindra[1]; [1]New Jersey Institute of Technology

Heterogeneous device assembly using magnetic fields is analyzed. Small cylindrical solenoids are used as sources for a controlled magnetic field. This paper investigates the theoretical and experimental lower limit using technology in extant on the dimension of the solenoids and the devices that can be assembled using magnetic field assisted assembly.

12:10 PM

Study on Organic Thermal Mode Photo-Resist for the Application of Nano-Lithography: *Der-Ray Huang*[1]; [1]NDHU

A new technology call thermal mode lithography which developing a new photoresist with temperature sensitive characteristic that can breakthrough optical diffraction limit[1]. There have the photo UV absorption and thermal properties are the important characteristics of thermal mode photoresists[2]. It can be control the submicron pattern size and resolution. The decomposition and gasification mechanism of the thermal photoresists are analyzed by the thermal properties such as melting temperature(Tm) and cracking temperature (Td). The surface morphology of nano pattern can be controlled by using different laser power exposure on thermal photoresists.

Solid-State Interfaces II: Toward an Atomistic-Scale Understanding of Structure, Properties, and Behavior through Theory and Experiment: Interface Dynamics, Oxidation

Shrinking Island Grains: Mobilities and Driving Forces: David Olmsted[1]; *Mark Asta*[1]; Colin Ophus[2]; Tamara Radetic[3]; Ulrich Dahmen[2]; [1]University of California, Berkeley; [2]Lawrence Berkeley National Laboratory; [3]University of Belgrade

In this talk we will describe the results of molecular-dynamicssimulations examining processes related to the shrinking of island grains in Authin films. The island grains investigated in this work arebounded by<110> tilt grain boundaries with 90 degree misorientations,but varying grain-boundary inclinations. Our interest in this system ismotivated by parallel experimental investigations of the dynamics of the same type of islandgrains in mazed-bicrystal thin films, using in-situ electron-microscopy. We focus in this talk on analyses of thesimulation results designed to probe the magnitudes of thegrain-boundary interface stiffnesses and mobilities underlying the rateof grain shrinkage derived in the simulations. In addition, we analyzethe variations in these properties with grain-boundary inclination, anddiscuss the relationship between these anisotropies and the dynamicshape of the island grains. Comparison withexperimental observations obtained by in-situ microscopy will also be presented.

9:00 AM
The Dynamics of Shrinking Grains: Molecular-Dynamics Simulations and In-Situ Electron Microscopy Studies of Shrinkage, Shape, Rotation and Dislocation Production: *David Olmsted*[1]; Tamara Radetic[2]; Colin Ophus[3]; Ulrich Dahmen[3]; Mark Asta[4]; [1]University of California, Berkeley; [2]University of Belgrade; Lawrence Berkeley National Laboratory; [3]Lawrence Berkeley National Laboratory; [4]Lawrence Berkeley National Laboratory; University of California, Berkeley

Theoretical models and computer simulations of grain growth have shown that island grains may rotate as they shrink. This can result from shear-coupled boundary motion, or attraction to low-energy cusps. Here we study the dynamics of shrinking island grains for <110> 90 degree tilt boundaries in Au, which feature higher disorientations than have been studied previously. The experimental study is based on in-situ electron-microscopy of mazed bicrystal samples. Molecular-dynamics simulations of island grains with identical crystallography have been undertaken. The combination of experiment and simulation leads to detailed comparison of the rate of shrinkage, grain shape and rotation. In both experiment and simulation, dislocations may remain after the island grain is consumed. Possible sources of these dislocations are considered. This research is supported by the Director, Office of Science, Office of Basic Energy Sciences, Materials Science and Engineering Division, of the US Department of Energy, under contract no. DE-AC02-05CH11231.

9:20 AM
Coupled Motion of Interstitial-loaded Grain Boundaries in Bcc Tungsten as a Possible Radiation Damage Healing Mechanism under Fusion Reactor Conditions: *Valery Borovikov*[1]; Xian-Zhu Tang[1]; Danny Perez[1]; Xian-Ming Bai[2]; Blas Uberuaga[1]; Arthur Voter[1]; [1]LANL; [2]INL

As a potential first-wall fusion reactor material, tungsten will be subjected to high radiation flux and extreme mechanical stress. We propose that under these conditions, coupled grain boundary motion, and enhanced mobility of interstitial-loaded grain boundaries, can lead to a radiation-damage self-healing mechanism, in which a grain boundary absorbs interstitials produced in collision cascades, activating motion of the grain boundary, which sweeps up the less-mobile vacancies. We examine the stress-induced mobility characteristics of a number of grain boundaries in W to investigate the likelihood of this scenario.

9:40 AM
Calculation of Grain Boundary Mobility in Slow-Moving Nickel Bicrystals: *Shawn Coleman*[1]; Stephen Foiles[2]; Douglas Spearot[1]; [1]University of Arkansas; [2]Sandia National Laboratories

Different computational methods to determine grain boundary mobility are compared using synthetic driving force molecular dynamics simulations of nickel bicrystals. Grain boundaries with a wide range of mobility are selected in this study. Particular focus is placed on grain boundaries demonstrating mobility at the lower measurable limit within the timescale of molecular dynamics simulations. Slow moving grain boundaries are of interest because they play a limiting role in microstructure evolution, e.g., the kinetics of recrystallization or grain growth in polycrystalline materials. It is found that the level of consistency between different methods is dependent on the simulation temperature and synthetic driving force energy.

10:00 AM
The Mobility and Grain Boundaries Study of Austenite-Ferrite Interface in Pure Fe from Molecular Dynamics Simulations: *Huajing Song*[1]; Jeff Hoyt[1]; [1]McMaster University

A molecular dynamics (MD) method has been developed to simulate the austenite – ferrite transformation in pure iron. For low index FCC/BCC crystallographic orientations no interface motion is observed, but for slight misorientations steps are introduced at the interface and sufficient mobility is observed over MD time scales. The misorientation geometry generates a primary and secondary disconnection structure on the FCC/BCC interphase boundary and both defect arrays are necessary to activate interface motion. The effect of misorientation, dislocation and disconnection density on the interface mobility and activation energy will be discussed. In addition, a multi crystal simulation to observe the net effect of different FCC/BCC grain boundaries during the transformation is presented.

10:20 AM Break

10:25 AM
Thermally Activated Avalanches: Jamming and the Progression of Needle Domains: *Xiangdong Ding*[1]; E.K.H. Salje[2]; Turab Lookman[3]; Avadh Saxena[3]; [1]Xi'an Jiaotong University; [2]University of Cambridge; [3]Los Alamos National Laboratory

Interface pinning, depinning, doping, the formation of global interfacial patterns and 'glassy' states are important phenomena in metallurgy. Typical examples are the twin boundaries in ferroelectric/martensitic materials, conducting interfaces in an insulating matrix, and magnetic interfaces in ferromagnetic materials. The interfaces remain a coherent part of the crystal and can be moved under appropriate forcing (stress, thermal, electric or magnetic fields). The kinetic process of the wall movement can be smooth, jerky, or combine both aspects. It can also be athermal or thermally activated. However, it is not clear whether all jerks are defect-generated avalanches and whether athermal behavior is required to generate such avalanches. In this presentation, by means of atomistic simulations, we demonstrate that this is not necessarily the case.

At moderate temperatures we find jerky behavior which displays classic power-law exponents without any extrinsic defects, while jerks can be thermally activated at high temperatures.

10:45 AM
Atomic-Scale Modeling of the Mobility of Boundaries of Deformation Twins in Alpha-Iron: *Jinbo Yang*[1]; Yuri Osetsky[1]; Roger Stoller[1]; [1]ORNL

Twinning plays an important role in plastic deformation of alpha-iron at low temperatures, and it also occurs in association with martensitic transformation in steels. Twinning in bcc metals is a simple shear process which takes place by moving successive planes of {112} by a displacement <111>/6. The underlying mechanism can be attributed to the glide of partial dislocations <111>/6 or <111>/3. These partial dislocations will form non-coherent boundaries of twin embryos. However, the mobility of these non-coherent boundaries has not been systematically studied. The atomic-scale modeling has been performed here to simulate various non-coherent twinning boundaries in alpha-iron. The results provide a satisfactory rationale of many unexplained experimental observations, e.g. why the formed twin boundaries lose their mobility when the applied stress is reversed during twinning in alpha-iron.

11:05 AM
First Principles Study of Ti (10-12) Twin Boundary: Interactions with Oxygen Interstitials and Screw Dislocations: *Maryam Ghazisaeidi*[1]; Dallas Trinkle[1]; [1]University of Illinois at Urbana-Champaign

Interaction of twin boundaries with dislocations and oxygen interstitials influences the plastic deformation of titanium. We investigate the interactions of (10-12) twin boundary with oxygen from first principles. The energetics of four interstitial sites in the twin geometry is compared with the bulk octahedral site. We show that the sites located at the boundary are attractive while the others are repulsive compared to bulk. Also, we model a [1-210] screw dislocation in the twin boundary using interfacial flexible boundary conditions. The dislocation is placed at narrow and wide spacing sites at the boundary. In both cases, the cores are compact and trapped in the boundary without dissociation. Electronic density of states plots show the change in directional bonding of the Ti d electrons in the dislocation core region at the presence of the twin boundary. The results provide a better understanding of how twin boundaries change mechanical properties of Ti.

11:25 AM Invited
Insights into the Oxidation Behavior ofAlloys: Oxide/Metal Interfaces at the Atomic Scale: *Emmanuelle Marquis*[1]; [1]University of Michigan

The roles of solute and alloying elements in modifying the oxidation resistance of alloys can be complex. It is often speculated that interfacial segregation, preferential oxidation are responsible for the observed behavior. However, the lack of detailed chemical information on metal/oxide interfaces and the oxide microstructure is lacking to confirm the existing models. Such information would allow the efficient design of novel oxidation resistant alloys required for high temperature and power generation applications. It will be shown how the systematic use of high resolution microscopy and atom probe tomography in particular can provide unique insights into the mechanisms taking place during alloy oxidation both at the surface and along grain boundaries.

11:55 AM
HR-STEM Investigation of Cu/SnO_2 Interfaces in the Internal Oxidation Zone of a CuSn9 Alloy: *Xavier Sauvage*[1]; Megha Dubey[1]; Samuel Jouen[1]; Béatrice Hannoyer[1]; [1]University of Rouen, CNRS

A CuSn9 alloy was oxidized in air laboratory at 580°C during several hours leading to some surface oxidation but also to some internal oxidation of Sn. The internal oxidation layer is about 10 micrometers thick and contains a large density of elongated SnO_2 particles. The crystallographic structure and the orientation relationship with the matrix and the growth direction were determined by conventional and high resolution TEM. SnO_2 particles were also analyzed by STEM-EDS and EELS. Then, a special emphasis was given on Cu/SnO_2 interfaces thanks to HAADF atomic scale STEM. These experimental data seem to indicate that the interface is covered by an oxygen rich layer. It is assumed that this layer could be a fast diffusion path for oxygen atoms coming from the surface, leading to the peculiar growth of SnO_2 particles.

Titanium: Advances in Processing, Characterization and Properties: General Abstracts

8:30 AM
Efficient OxidationProtection of Ti- and TiAl-alloys by Fluorine Treatments: *Alexander Donchev*[1]; Michael Schütze[1]; Rossen Yankov[2]; Andreas Kolitsch[2]; [1]DECHEMA; [2]HZDR

Ti-alloys suffer from high oxidation rates and oxygen uptake during exposure in oxidizing environments at elevated temperatures above approximately 600°C. TiAl-alloys have the same problem due to the insufficient oxidation resistance at temperatures above 850°C. The use of these alloys is hence limited. The fluorine effect is a very promising way to improve the oxidation resistance of TiAl-alloys. Defined amounts of fluorine in the surface zone of TiAl-components change the oxidation mechanism. A protective alumina layer is formed which prevents further oxidation and subsequently allows the use of this new alloy family in several high temperature applications. The Al-content of standard Ti-alloys is not enough to get the fluorine effect to operate but after Al-enrichment of the surface zone a subsequent fluorination leads to the same results. In this paper results of oxidation tests of untreated and treated Ti- and TiAl-alloys will be presented and their behavior compared.

8:50 AM
Characteristics and Wear Performance of Nitrided Ti6Al7Nb: *Farid Siyahjani*[1]; [1]Istanbul Technical University

Samples of a Ti6Al7Nb were treated by gas nitriding for 3,5,7 and 12 h at 1120 °C. Gas nitriding provided formation of TiN layer whose hardness and thickness changed with respect to nitriding time. The titanium nitride layer exhibited excellent wear resistance along with a lower coefficient of friction against alumina ball under dry sliding conditions when compared to the as-received state.

9:10 AM
Characterization of Texture Development in Multi-Layered Ti-Al-Nb Sheets Processed by Accumulative Roll Bonding at Different Rolling Speeds: *Liming Zhou*[1]; Viola Acoff[1]; [1]The University of Alabama

The influence of rolling speed on texture development in multilayered Ti-Al-Nb processed by accumulative roll bonding (ARB) was studied in this paper. The process of ARB followed by annealing has proven to be a high efficiency method to manufacture gamma-based titanium aluminide sheet materials. Unlike thermal activities and kinetics associated with this process, heterogeneous distribution of the anisotropic texture characteristics is still unclear. In this investigation, the Ti layers in the as-cold rolled sheets were characterized using a layer by layer approach. Both bulk and microtexture analyses using X-ray diffraction, electron backscattered diffraction (EBSD) and TEM were employed to characterize the development of texture as a function of rolling speed. Results indicate that texture intensity variation not only exists for variation of rolling speed and deformation ratio but also suggests different dominant texture compared with conventional rolling results of Ti slab.

9:30 AM
Ti-TiAl$_3$ Metallic-Intermetallic Laminate Composites Processed Using Accumulative Roll Bonding: *Derrick Stokes*[1]; Xiu-Ren Bu[2]; Jennifer Conway[1]; Stan Jones[1]; Viola Acoff[1]; [1]The University of Alabama; [2]Clark Atlanta University

Metallic-Intermetallic Laminate Composites (MLCs) perform well in structural applications because they can withstand high tensile stresses when load is applied in the laminate direction. MLCs are commonly produced in industry, but there are issues with the current manufacturing process. In this study, MLCs are processed using accumulative roll bonding (ARB) of alternating layers of pure titanium and aluminum foils. After stacking, the foils are subjected to annealing. During annealing, the desired MLC is processed from the transformation that occurs from diffusion which promotes the transformation for pure titanium and aluminum to alternating layers of Ti and TiAl3. Since the Ti-TiAl3 MLCs made by this process are prime candidates for use in military applications, especially in the area of ballistics, they will be subjected to perforation testing using a method developed by researchers at The University of Alabama. This study will provide information that relates MLC structure to mechanical properties.

9:50 AM
Composition Analysis of Diffusion Bonded γ-TiAl Intermetallic:TiAlV Alloy Interface by Using STEM: *Sivagnanapalani P*[1]; Gouthama .[1]; M Sujata[2]; [1]IIT Kanpur; [2]National Aerospace Laboratories

Diffusion bonding occurs when two similar or dissimilar materials are brought together under the application of pressure and temperature for sufficient time. In the present study, diffusion bonding of γ-TiAl intermetallic with Ti-6Al-4V alloy is carried out in high vacuum. The diffusion bonding is performed at temperatures of 800°C and 850°C under the constant pressure of 40MPa and at varying time. The diffusion bonded region is analysed by Scanning transmission electron microscope (STEM). From the results obtained, the diffusion bonded region is found to be a fairly extended junction zone of few micrometers width. From EDS results obtained, some regions were rich in aluminium and some regions are rich in vanadium. The compositional variation across the interface is not gradual but rather abrupt. The observations are discussed in the light of the solid solubility of variation element in different phases, phase equilibria and phase transformation characteristics of the materials involved.

10:10 AM
Effect of Erbium Addition on Microstructre of As-Cast Ti-22Al-25Nb Alloy: *Jingru Dai*[1]; Huimin Lu[1]; Zhijin Cai[1]; [1]Beihang University

The rare earth metal erbium was added to ternary Ti-22Al-25Nb(at.%) alloys. This work investigated effects of erbium on the microstructure of Ti2AlNb based alloy and the morphologies of rare earth-rich phases by XRD, OM, SEM, TEM and EDS. It was found that the grain size of this orthorhombic intermetallic alloy can be greatly refined by Er additive; the grain size of Ti-22Al-25Nb was in the range of 250-1200μm, while the materials containing erbium consisted of grain size of as fine as approximately 40μm, and the grain size was more uniform; Adding Er to the Ti-22Al-25Nb alloy yields precipitates of rare earth-rich phases, which mainly distributed in grain boundaries in the shape of net, and some ellipsoids and clavate precipitates were also observed within the grains.

10:30 AM Break

10:40 AM
Titanium Coatings Using Cold Spray: *Phillip Leyman*[1]; Rob Hrabe[2]; Brian James[3]; Christian Widener[4]; [1]Army Research Laboratory; [2]H.F. Webster Inc.; [3]GS-12, Supervisor AF Engineering Technical Services; [4]South Dakota School of Mines and Technology

Department of Defense (DOD) aircraft have been experiencing a significant chaffing problem of titanium hydraulic tubing resulting in significant cost in maintenance man-hours and reduction in operational readiness rates. The U.S. Army Research Laboratory has developed a cold spray process that deposits a fully dense adherent titanium coating on titanium hydraulic tubing to either repair the already chaffed area or provide additional wear surface on new titanium tubing to extend the lifetime of the tubing. The deposition characteristics of titanium coatings deposited by cold spray process using helium gas were evaluated. The microstructure of the feedstock powders and deposited coatings were examined using optical and scanning electron microscopy. The characteristics of the cold spray titanium coatings were evaluated using density, hardness and bond strength measurements. Due to work hardening via plastic deformation induced by cold spraying, the titanium coatings have twice the hardness of wrought titanium.

11:00 AM
Novel Surface Coating Techniques for Titanium Alloys: *Mingxing Zhang*[1]; Shoumou Miao[1]; [1]The University of Queensland

Two novel surface coating techniques for titanium alloys have been developed aiming at effective improvement of the surface durability of Ti alloys. One is the refined packed powder diffusion coating (PPDC) approach, which is simple, reliable and low cost. The PPDC treatment leads to formation of composite coating with thickness varying from 100 μm to 1500 μm depending on the process. Compared with the substrate, the PPDC coating offers high wear resistance, high corrosion resistance and extremely high oxidation resistance at temperature up to 1000°C, which is comparable with Ni-based superalloys. Thus, the PPDC treatment makes it possible to partially replace the very expensive superalloys with coated Ti alloys in aeronautical industry. Another is a low coat nitriding process that produces up to 100 μm thick TiN layer on Ti alloy substrate, which significantly increases the wear resistance of the components by 3 to 4 order magnitude.

11:20 AM
Fracture Behaviors of TiN and TiN/Ti Multilayer Coatings on Ti Substrate during Nanoindentation
: *Yong Sun*[1]; Cheng Lu[1]; Anh Kiet Tieu[1]; Yue Zhao[1]; Hongtao Zhu[1]; Kuiyu Cheng[1]; Charlie Kong[2]; [1]University of Wollongong; [2]University of New South Wales

TiN monolayer and TiN/Ti multilayer thin films were deposited on commercially pure Ti substrates using a filtered arc deposition system (FADS). Surface topography and chemical composition have been characterized by atomic force microscopy (AFM) and X-ray diffraction (XRD), respectively. Fracture properties of coatings induced by nanoindentation have been investigated. Focused ion beam (FIB) and transmission electron microscopy (TEM) were used to identify the fracture modes. It was found that the TiN/Ti multilayer coating exhibited a higher pop-in force, which indicated good film ductility. Transmission electron microscope (TEM) observation showed that the small bending crack was the dominant crack in the TiN/Ti multilayer coating. The Ti layer shows that it could efficiently suppress the crack propagation, which was responsible for the improved ductility of the TiN/Ti multilayer coating.

11:40 AM
Deformation Mechanism in Nanoindentation of Ti63.375Fe34.125Sn2.5 Alloy: *Kuiyu Cheng*[1]; Cheng Lu[1]; Kiet Tieu[1]; Laichang Zhang[2]; Yong Sun[1]; [1]University of Wollongong; [2]The University of Western Australia

Ti63.375Fe34.125Sn2.5 alloy was fabricated by arc melting. In this study nanoindentation technology has been used to investigate the mechanical properties of the main component phases (TiFe and ß-Ti). It has been found that the ß-Ti and the TiFe phases have close values of Young modulus and hardness. The cross section beneath the indent was cut out by focus ion bean (FIB) and analysed by transmission electron microscopy (TEM). It was found that the high strength and limited plasticity of Ti63.375Fe34.125Sn2.5 alloy are related to the interaction between dislocation and phase boundary. Phase boundaries stop the dislocation movement in most simulations. Dislocation only can pass through phase interfaces when the conjoint ß-Ti and the TiFe phase are in particular orientation relationships.

8:30 AM
Characterization of Nanocrystalline SnO2:F Thin Films Prepared by the Spray Pyrolysis Technique: *Shadia Ikhmayies*[1]; [1]Al Isra University

Nanocrystalline fluorine-doped tin oxide SnO2:F thin films were prepared by the spray pyrolysis (SP) technique on glass substrates. The films were characterized by using X-ray diffraction (XRD), scanning electron microscope (SEM) observations, X-ray dispersive spectroscopy EDX and transmittance measurements. X-ray diffraction patterns revealed the nanocrystalline nature of the films where the grain size was estimated from Sherrer formula. SEM micrographs showed that the films are uniform and totally covered with the material and they confirmed the nanocrystalline nature of the films. The absorbance was deduced from the transmittance measurements and its first derivative was used to estimate the optical bandgap energy. Bandgaps larger than the bandgap of the bulk SnO2:F were obtained which is evidence on the presence of quantum dots. The hyperbolic band model was used to estimate the radii of the nanocrystallites. A comparison between the results from the different methods was performed.

8:50 AM
Characterization of the Orthotropic Elastic Constants of a Micronic Woven Wire Mesh through Experiments and Modeling: *Steven Kraft*[1]; Ali Gordon[1]; [1]University of Central Florida

Woven structures are steadily emerging as excellent reinforcing components in composite materials. Metallic woven wire mesh materials in particular display good ductility and relatively high strength and resilience. While use of this class of materials is rapidly expanding, a significant gap in property characterization still remains. Through the use of uniaxial tensile experiments, and 3D meso-scale finite element modeling, this research classifies the orthotropic material properties of a representative twill-dutch woven wire mesh. Digital Image Correlation (DIC) methods, along with the meso-scale model, are employed to investigate the relationship between local and global elastic stain accumulation, and evidence of significant elastic damage in this material is displayed.

9:10 AM
Complex Impedance Plots of CdS:In Thin Films Prepared by the Spray Pyrolysis Technique: *Shadia Ikhmayies*[1]; Riyad Ahmad-Bitar[2]; [1]Al Isra University; [2]University of Jordan

Cadmium sulfide thin films were prepared on glass substrates by the spray pyrolysis technique at a substrate temperature of Ts = 490 °C. Some of the films were etched by HCl in distilled water, others were heat treated in nitrogen atmosphere, and another set of films were first etched by HCl thin annealed. Room temperature impedance spectroscopy measurements on the films were performed using coplanar geometry in the dark and room light in the frequency range 20 Hz to 1 MHz. The experimental data was represented by the complex plane diagrams and showed one well-defined semicircle in the high frequency region. Hence the equivalent circuit that models the CdS:In thin films was found to be a single RC circuit, which indicates the bulk conduction through the grains. The influence of treatments on the electrical properties was investigated.

9:30 AM
Characterization of Mexico Magnetic Concentrate Samples for Trace Elements Ni, Cu, Zn, S and P: *Mingming Zhang*[1]; [1]ArcelorMittal Global R&D

Magnetic concentrate samples from Mexico were characterized by chemical, X-ray diffraction (XRD), optical microscopy (OM) and scanning electron microscopy (SEM) methods. The objective of this work is to investigate the occurrence of nickel, copper, zinc, sulfur and phosphorus in these samples and identify their origin and associations with iron minerals. The results indicated that magnetite is the major iron oxide mineral with hematite as a second phase based on the OM and XRD studies. Pyrite, chalcopyrite and bravoite are major sulfide minerals. Trace amounts of apatite, wardite, giniite and vivianite were identified by SEM and XRD. Microscopic studies also indicated that most of the sulfide grains in the mineral sample are present either as liberated fine particles (<10 microns) or as inclusions within the magnetite and hematite grains. XRD studies confirmed the microscopic findings. Copper, nickel, and zinc are mainly present as chalcopyrite, bravoite, and franklinite in trace amount, respectively.

9:50 AM Break

10:10 AM
Preparation and Characterization of High-Magnetization Microspheres of Fe3O4 Encapsulated with SiO2 and TiO2 Layers: *Nan Zhang*[1]; Gaifeng Zue[1]; Shangchao Liu[1]; Benquan Fu[1]; [1]Research and Development Center of Wuhan Iron & Steel Group Corp.

The high-magnetization Fe3O4@SiO2@TiO2 microspheres were prepared. They were characterized by FTIR spectroscopy, transmission electron microscopy and scanning electron microscopy. These high-magnetization microspheres could be readily dispersed by shaking while they could be fast separated from the aqueous solution simply by applying an external magnetic field. The two shells of SiO2 and TiO2 protected the iron oxide core well and the microspheres were stable in acid and base solution. Therefore, they have a good potential in applications such as phosphopeptides enrichment and photocatalytic activity.

10:30 AM
Characterization of Amorphous Vacuum-Evaporated SnO2 Thin Films: *Shadia Ikhmayies*[1]; [1]Al Isra University

Tin oxide (SnO2) thin films of thickness in the range 100-700 nm were prepared on glass substrates by vacuum evaporation at ambient temperature. The films were characterized by transmittance measurements, X-ray diffraction (XRD), scanning electron microscope (SEM) observations and energy dispersion X-ray analysis (EDX). It is found that the films have high transmittance and non sharp absorption edge. XRD diffractograms showed that the films are amorphous and the SEM micrographs showed that the surfaces are smooth, uniform and well covered with the material. The EDX analysis showed that the films are rich in oxygen. Indirect optical bandgap energy and Urbach tailing in the bandgap was observed and the width of the tail which is related with disorder and localized states was estimated.

10:50 AM
Preparation of ß-Diketone Modified Silica Gel and its Application to the Removal ofHeavy Metal Ions from Industrial Wastewater: *Nan Zhang*[1]; Gaifeng Xue[1]; Lei Zhang[1]; Pu Liu[1]; Lina Wang[1]; [1]Research and Development Center of Wuhan Iron & Steel Group Corp.

A novel ß-diketone modified silica gel was synthesized. The prepared material was characterized by diffuse reflectance FTIR spectroscopy and it was used for the adsorption of heavy metal ions in industrial wastewater.

The main parameters affecting the sorption of heavy metal ions, including pH, water flow rate and temperature, have been investigated in detail. Under the optimized operating conditions, most of the heavy metal ions could be removed. The material could be simply regenerated by acid. The method is rapid, selective, economical and applicable to the removal of heavy metal ions in industrial wastewater.

11:10 AM
Elastic Modulus and Density Dependence on the Diameter of Piassava Fibers: *Felipe Lopes*[1]; Alice Bevitori[2]; Isabela Silva[2]; Renan Carreiro[2]; Denise Nascimento[2]; Sergio Monteiro[2]; [1]IME; [2]UENF

Natural fibers obtained from plants have increasingly been used as reinforcement of polymeric composites in engineering applications. This is the case of the fiber extracted from the piassava palm tree, a native of the southeast region of South America and since long time used in simple items like brooms and brushes. Recently it was reported that the tensile strength of the piassava fiber varied inversely with the equivalent diameter. Following that previous work, it was investigated the elastic modulus and the density dependence on the diameter of stiffer piassava fibers of the Attalea funifera specie. Precise measurements with profile projector and Weibull analysis of the experimental results indicated that both the elastic modulus and the density of piassava fibers also follow an inverse correlation with the diameter. Scanning electron microscopy observation, of the microstructure and fracture surface showed that defects and participation of microfibrils are responsible for this correlation.

8:30 AM
Leaching of Lithium Cobalt Dioxide Using Citric-Thiosulfate Solutions: *Alejandro Alonso*[1]; Gretchen Lapidus-Lavine[1]; Lizeth Alvarado[1]; [1]Universidad Autonoma Metropolitana

Cobalt and lithium recovery from spent Li-ion secondary batteries is of great interest due to the high value of both metals and the low proven reserves for lithium. Up until now, the standard method uses first the deactivation and crushing of batteries; the spinel ($CoLiO_2$) from the battery cathode is then leached using a highly acid solution, such as 1.5 to 2.0M HCl or H_2SO_4, in a temperature range from 120ºC to 250ºC. Once the cobalt is separated by electrodeposition and lithium by precipitation, large amounts of carbonate are needed in order to precipitate lithium carbonate at alkaline pH values. In the present work, citric-thiosulfate solutions are used to leach the spinel at room temperature, by reducing the cobalt-lithium dioxide and stabilizing cobalt (II) as cobalt citrate and lithium (I) as Li^+ at pH 5, with recoveries of about 99% for both metals.

8:50 AM
Hydrometallurgical Purification from Leach Liquor of Printed Circuit Board with Cyanex 272: *Adriana Santanilla*[1]; Viviane Tavares de Moraes[1]; Jorge Alberto Soares Tenorio[1]; Denise Crocce Romano Espinosa[1]; [1]Polytechnic School of University of São Paulo

Increasing volumes of solid waste are generated worldwide, due to the continuous technological advances, the electronic scrap is part of these waste, requiring the study of recycling processes to stimulate this activity or the reuse of its components. The separation of nickel from sulphate leach solution, which also containing iron, zinc and aluminium was carried out using bis-(2,4,4-trimethylpentyl) phosphinic acid (Cyanex 272) as extractant, in order to determinate the effects of pH and temperature. The number of stages required for extraction was also assessed; the results showed that the ions metals extraction increased with the pH increasing, on the other hand, with the increasing temperature was found a behavior no favorable for all metals, however, under conditions used in this paper the purification of solution containing nickel was possible.

9:10 AM
Leaching of Chalcopyrite Concentrate with Organic Ligand Compounds: *Oscar Solis-Marcial*[1]; Gretchen Lapidus-Lavine[1]; [1]Universidad Autonoma Metropolitana-Iztapalapa

Oxidative dissolution of copper from refractory phases, such as chalcopyrite, represents a technological challenge that has occupied hydrometallurgists for more than half a century. Innumerable processes have been suggested, but the majority operates at high temperatures or employ corrosive media. Recent studies have revealed that the origin of this refractory nature is the formation of passivating phases of iron(III) or copper. One option is to add non-corrosive ligands that complex these metal ions, facilitating their dissolution. In the present work, the effect of acetone in sulfuric acid solutions was studied, first on chalcopyrite carbon paste electrodes using cyclic voltammetry, where greater reactivity was observed in its presence. Later, leaching tests with hydrogen peroxide, cupric sulfate, ozone and mixtures of these, as oxidants, were performed. High levels of extractions were achieved in three hours at 50°C. Solid residues contained the iron in the form of oxides (Fe_2O_3 and FeOOH).

9:30 AM
The Electrochemical Behavior of Electro-Deoxidation Process of Ilmenite Concentrate in Molten Salt: *Xuyang Liu*[1]; Meilong Hu[1]; Chenguang Bai[1]; Xuewei Lv[1]; [1]Chongqing University

The electro-deoxidation process of titanium concentrate in molten salt was studied by cycle voltammetry and AC impedance spectrum. The result of cycle voltammetry is consistent with AC impedance spectrum. The result showed that the electro-deoxidation process of titanium concentrate consists of two processes. One step is that Fe is firstly reduced from titanium concentrate. The second reaction is the decomposition of TiO_2. Intermediate product is $CaTiO_3$. In the low voltage, the electrochemical reaction is the main step. With the potential increasing, the diffusion of ion is the main rate control step of the electro-deoxidation of $FeTiO_3$.

9:50 AM Break

10:10 AM
Vanadium Extraction from High Calcium-Content Vanadium Slag by Calcification Roasting: *Hong-Yi Li*[1]; Ning Wang[1]; Bing Xie[1]; [1]Chongqing University

Compared to traditional sodium roasting, calcified roast inhibits chlorine pollution. Especially, vanadium extracting technique based on calcified roast is suitable to high silicon low vanadium slag. In this report, V_2O_5 was extracted from vanadium slag by calcified roast followed by acid leaching and hydrolysis precipitation. In optimized conditions, the high silicon low vanadium slag was roasted at 850°C for 2 hours without CaO addition. The roasted materials was leached with 35 % H_2SO_4 in solid-liquid ratio of 1:5 (g/mL) at 95°C for 4 hours. The leaching rate of vanadium was up to 97.66%. These results are instructive to V_2O_5 production in industry.

10:30 AM
The Kinetic Investigation of the Dissolution Of Powellite in Oxalic Acid Solutions: *Sedat Ilhan*[1]; Ahmet Kalpakli[1]; Cem Kahruman[1]; Ibrahim Yusufoglu[1]; [1]Istanbul University

In this study, the effects of oxalic acid concentration, temperature, stirring rate and particle size on the dissolution rate of synthetically prepared calcium molybdate and concentrated scheelite ore which includes powellite as contamination were investigated. Calcium molybdate dissolves in oxalic acid solutions as series – parallel type reaction. In the first reaction step, calcium aqua oxalato molybdate is formed as complex chelate intermadiate product. In the second reaction step, molybdic acid formed during the slow hydrolysis of calcium aqua oxalato molybdate reacts rapidly with oxalic acid by forming the polymeric hydrogen oxalate dimolybdate complex chelate as end product. The activation energies and frequency factors for both steps were calculated.

10:50 AM
Metallurgical Characterization of Waspaloy Presenting Variations on Chemical Composition, Grain Size, and Hardness: *Miguel Neri*[1]; Alberto Martinez -Villafañe[1]; Caleb Carreño[1]; Octavio Covarrubias-Alvarado[2]; Alma Gonzalez-Escarcega[1]; [1]CIMAV, S.C.; [2]FRISA AEROSPACE S.A. DE C.V.

Waspaloy is a super alloy used to manufacture some aeronautical parts subjected to high temperatures and stresses, during it thermo-mechanical processing cracks are generated, causing that some parts will be rejected during their processing. In order to determine the causes of these cracks, this alloy was characterized using techniques such as Chemical Analysis, Optical Microscopy, Scanning Electron Microscopy,and EDX analysis. Heterogeneous grain size on the microstructure causes a non- uniform strain distribution on these parts, and may originae cracks on zones with different grain sizes.

11:10 AM
Recent Trends in the Processing of Complex Sulphide Ores: *Sarveswara Rao Katragadda*[1]; [1](Retd.) IMMT (CSIR)

In view of increasing importance to process lean grade ores as potential future resources, efforts are made worldwide to develop suitable technologies for recovery of both nonferrous, base and precious metals. There are various types of lean grade ores and present in many countries. Gradually, the mineral reserves for production of the metals have undergone complex changes with regards to their grades and particularly the physical and chemical properties of minerals to be separated from each other. So, there is a need for upgrading the existing technologies to recover metal values from the ores that are otherwise unutilized. Accordingly, an overview of different existing types of mineral resources and economical processes based on ore horizons, consumption of energy and reagents and environmental concerns is made in this paper, along with a summary of metallurgical and engineering challenges to be overcome when implementing alternate technologies.

11:30 AM
Biosorption Characteristics of Pb(II) from Aqueous Solution onto Poplar Cotton: *Kai Huang*[1]; Shuanglong Du[1]; Ting Luo[1]; Tao Gui[1]; Yifan Xiu[1]; Hongmin Zhu[1]; [1]University of Science and Technology Beijing

Poplar cotton, a cellulosic material, was found to adsorb the metals ions effectively. In present study, the biosorption characteristics of Pb(II) onto poplar cotton, were evaluated as a function of pH, contact time, biomass dosage, initial concentration and temperature. Within the pH range investigated (1.0-6.0), the optimal pH value suitable for the uptaking of Pb(II) was determined. The maximum adsorption capacity obtained from the Langmuir model is around 0.52mol kg-1 for the poplar cotton sorbent. Equilibrium time is 60min for the studied concentrations. Above results suggest that the poplar cotton can be directly used as an effective and low-cost biosorbent for removal of Pb(II) from aqueous solution.

Ultrafine Grained Materials VII: Applications and Transitions

Exceptional Mechanical and Functional Properties of Ultrafine-Grained NbZr Biomedical Alloys: *Ibrahim Karaman*[1]; Hans Maier[2]; Gencaga Purcek[3]; Felix Rubitschek[2]; Thomas Niendorf[2]; [1]Texas A&M University; [2]University of Paderborn; [3]Karadeniz Technical University

Niobium–1-3 wt.% zirconium (NbZr) alloys demonstrate exceptional mechanical properties in UFG condition. In this talk, we will summarize the unconventional mechanical and functional properties of UFG NbZr samples that were processed using ECAP at room temperature. Monotonic tensile and low-cycle fatigue responses and the corrosion fatigue behavior in simulated body fluid (SBF) will be reported. The room temperature processing resulted in UFG microstructure, high density of high angle grain boundaries, a favorable combination of high strength and ductility with superior biocompatibility and excellent corrosion resistance. The corrosion resistance of UFG NbZr was similar to that of Ti-6Al-4V. High-cycle fatigue tests showed no alteration in the crack initiation behavior due to the SBF environment, and absence of pitting and corrosion products. Internal oxidation of UFG NbZr formed nano-ZrO2 precipitates on the surface, significantly intensified the surface hardness without deterioration of the surface quality, and thus remarkably improved the fatigue performance.

8:55 AM
Electrochemical Corrosion of Bulk Cryomilled UFG Al5083 in Contrast to its Coarse Grained Counterpart in Aerated 3.5wt% NaCl Solution: *Indranil Roy*[1]; John Meng[2]; Enrique Lavernia[3]; Farghalli Mohamed[4]; [1]Schlumberger; [2]Honeywell Corrosion Solutions; [3]University of California, Davis; [4]University of California, Irvine

In this study bulk cryomilled ultrafine-grain (UFG) Al5083 and its coarse grain polycrystalline (CGP) commercial counterpart were exposed to aerated 3.5-wt% NaCl solution at 120F for various holding times. To compare their electrochemical corrosion behavior(s) linear polarization resistance and cyclic potentiodynamic polarization experiments were also carried out in the same aerated solution. Deep pits were observed on the commercial Al5083 alloy in contrast to numerous microscopic pits manifested in the UFG-material. Uniaxial tensile tests performed on specimens of UFG-Al5083 exposed to the same neutral halide solution for various holding times exhibited far better performance in contrast to catastrophic failures of CGP Al5083. In line with recent publications[1,2] that nano-materials perform better than their CGP counterparts, our results affirm that grain refinement abets the corrosion performance in contrast to their CGP counterparts. 1. Mishra et al., Corros. Sci. 46, 3019-3029 (2004). 2. Qiu J., *Mater. Sci. Forum,* 437-438, 211-214 (2003).

9:10 AM
Microstructural Aspects of Enhancing Strength and Ductility of Ultra-Fine Grained Ti Rods Processed by ECAP-Conform: *Irina Semenova*[1]; Georgy Raab[1]; Alexander Polyakov[1]; Ruslan Valiev[1]; Terry Lowe[2]; [1]Ufa State Aviation Technical University; [2]Manhattan Scientifics

This work is focused on understanding the strength and ductility of the UFG titanium processed by ECAP-Conform with further drawing. UFG materials can have decreased ductility due to low strain hardening rate and strain localization. This resulted from the low dislocation storage efficiency associated with small grains and very high dislocation densities. By examining specific combinations of ECAP-Conform and drawing we have determined that size and shape of grains, substructure formation, and grain boundary state are the main microstructural parameters that determine the strength and ductility in UFG Ti. For example, for the UFG Ti Grade 4 the contribution to increase of uniform tensile elongation is made by equiaxed shape of grains with low density of lattice dislocations, high-angle misorientation of boundaries and grain-boundary segregations. The correlations of microstructure with high strength and ductility further allowed us to define the main requirements to increase the fatigue resistance of UFG titanium.

9:25 AM Invited
Potential of UFG Materials as High Performance Penetrator Materials: *Kyung-Tae Park*[1]; Lee Ju Park[2]; Hyung Won Kim[2]; Chong Soo Lee[3]; [1]Hanbat National University; [2]Agency for Defense Development; [3]POSTECH

UFG materials possess high potential as high performance penetrator materials. Shear localization, one of the main deformation characteristics of UFG materials at room temperature, enhances the self-sharpening effect which is essential to kinetic energy penetrators. High strain rate superplasticity of UFG materials is to be highly possible to improve metal jet formability of chemical energy penetrators. In this study, the effects of UFG morphology on shear formability of a 4130 steel were examined. A lamellar UFG structure exhibited better shear formability than the equiaxed UFG one. In addition, the metal jet formability of UFG OFHC Cu will be compared to that of coarse grained counterpart. The enhanced shear formability and metal jet formability of UFG materials are to be discussed in view of their microstructural characteristics. The present preliminary study may provide an informative guidance for early industrial application of bulk UFG materials.

9:45 AM
Study of a New SPD technique: High Pressure Tube Twisting (HPTT): *Roxane Arruffat*[1]; Mandana Arazaghi[2]; Arnaud Pougis[1]; Jean Jacques Fundenberger[1]; Laszlo Toth[1]; [1]University Paul Verlaine; [2]Institue PPRIME, UMR 6617 CNRS,

The new Severe Plastic Deformation (SPD) technique was invented in 2008. This process designated as High Pressure Tube Twisting (HPTT), is a continuous process for grain refinement in bulk metallic materials with tubular geometry. It consists of placing a mandrel into the tube before applying an axial compression directly on the tube confined on both sides to produce high hydrostatic pressure. The tube is then twisted by an external torque with the help of the friction force generated by the hydrostatic pressure.In the present study, experiments were conducted on Copper, Aluminium (commercially pure and AA6061) and IF Steel to the different amounts of shear deformation. The ultra-fine grained structures produced with HPTT are confirmed using transmission electron microscopy and their microstructure and mechanical properties were evaluated. Microstructural evolution is studied by electron backscattered diffraction and texture measurements were carried out using both X-ray and the EBSD technique.

10:00 AM
SPD Procedure and High Performance of Ultrafine-Grained Cu-Mg Alloy for Electrical Railway: *Ai-Bin Ma*[1]; Chengcheng Zhu[1]; Jinghua Jiang[1]; Dan Song[1]; Wenyong Xu[1]; [1]Hohai University

Continuous Con-form plus equal-channel angular pressing (EACP) was applied to produce ultrafine-grained Cu-Mg contact wire materials with high strength and good conductivity, aim to push back the catenary barrier of high-speed trains by maximizing the tension and improving the power delivery. Microstructure change and mechanical properties of Cu-Mg alloys after various severe-plastic-deformation (SPD) routes were investigated by microscopic analysis and tensile tests. The results show that the Cu-0.2wt% Mg samples after multi-pass ECAP at 473K obtain ultrafine grains with homogeneously distributed secondary phases, having obviously improved strength. The more passes of ECAP make the finer grains and the higher strength of Cu - 0.2 Mg alloy, but the strength increment of ECAPed alloys is appreciably lower with increasing ECAP temperature up to 673K. Grain refinement via continuous SPD procedures can endow Cu-Mg contact wire materials superior strength, high conductivity and anti-softening characteristics, which are advantageous to high-frequency electrification railway systems.

10:30 AM
Twenty-five Years of Severe Plastic Deformation: Recent Developments in Evaluating the Degree of Homogeneity through the Thickness of Disks Processed by High-Pressure Torsion: Megumi Kawasaki[1]; Roberto Figueiredo[2]; *Terence Langdon*[1]; [1]Univ of Southern California; [2]Federal Univ of Minas Gerais

The processing of disks by high-pressure torsion (HPT) leads to an inhomogeneous distribution in strain with a high strain around the perimeter of the disk and a zero strain in the center. Despite this apparent inhomogeneity, there are now many experiments showing that the hardness values on the surfaces of disks gradually evolve with increasing strain to give a high level of homogeneity. This report examines whether this high level of homogeneity extends also through the thickness of the disks or whether there are inhomogeneities within the vertical cross-sections. Results are presented for high-purity aluminum and a magnesium alloy as two representative materials showing different hardness characteristics.

10:45 AM
Anti-Corrosion Behavior of Ultrafine-Grained Al-26wt% Si Alloy Fabricated by ECAP: *Jinghua Jiang*[1]; Aibin Ma[2]; Dan Song[2]; Jun Shi[2]; Kaile Wang[2]; Donghui Yang[2]; Jianqing Chen[2]; [1]hohai university; [2]Hohai University

Grain refinement of hypereutectic Al-Si alloys, through severe plastic deformation (SPD), can endow its improved physicochemical properties and wider application in the automotive, aerospace and construction industries. Herein, Ultrafine-grained (UFG) Al-26wt.%Si alloy was achieved through multi-pass equal-channel angular pressing (EACP) procedure and subsequent tested in 3.5wt.%NaCl solution for electrochemical corrosion evaluation. The results show that the ECAPed alloy with more pressing passes obtains lower mass-loss ratios, nobler Ecorr and Epit, lower Icorr values and higher anode polarization. The increased corrosion resistance of the ECAPed alloy results from the homogeneous UFG structure with the breakage of brittle large primary silicon crystals, which is contributed to a higher pitting resistance. The oxidation product with improved adhesion force and protection efficacy can be formed more easily on UFG alloys, making UFG Al alloy from SPD more corrosion resistant.

11:00 AM
Ultrafine-Grained Thermoelectrics Processed by HPT Featuring Enhanced ZT Values: *Michael Zehetbauer*[1]; Gerda Rogl[1]; Peter Rogl[1]; Ernst Bauer[2]; Daria Setman[1]; Jelena Horky[1]; Erhard Schafler[1]; [1]University of Vienna; [2]Vienna University of Technology

This lecture reports on processing of nanocrystalline thermoelectric p- and n-type skutterudites by High Pressure Torsion (HPT). Ultrafine grained materials were achieved by introducing many defects like interfaces, dislocations or point defects, making use of HPT advantages such as sustaining the samples' dimensions during processing, and providing an enhanced hydrostatic pressure preventing cracks. Both p- and n-type skutterudites were deformed by HPT at pressures 2-4 GPa and temperatures till 500°C resulting in an oriented lamellar nano-grained structure with crystallites of 30 nm in size, amorphous aggregates and an enhanced dislocation density. In comparison with ball milled / hot pressed skutterudites, the HPT samples exhibited a 3x smaller grain size and an 100x larger dislocation density, resulting in an 40%-decrease of thermal conductivity. Although the electrical resistivity is markedly higher in parallel with an only slightly higher Seebeck coefficient, HPT proved to enhance ZT values up to 30%.

11:15 AM Invited
Application of High-Pressure Sliding for Bismuth-TellurideThermoelectric Materials: Kiyonari Tazoe[1]; Kanako Mitarai[1]; Takahiro Hayashi[2]; Shinji Munetoh[1]; *Zenji Horita*[1]; [1]Kyushu University; [2]Yamaha Corporation

High-pressure sliding (HPS) is a newly developed process of severe plastic deformation. This process is similar to high-pressure torsion (HPT) as it is operated under high pressure but the difference is that HPS uses samples having a rectangular sheet shape while HPT uses with a disk or ring shape. In this study, HPS is applied to bismuth-telluride thermoelectric materials. Samples with dimensions of 1.3×2.95×64 mm3 were subjected to HPS under a pressure of 1 GPa at 773 K for sliding distances of 5, 10 and 15 mm with a sliding speed of 0.2 mm/s. Measurements of Vickers microhardness, electrical resistivity, Seebeck coefficient and thermal conductivity were carried out including microstructural observation and X-ray diffraction analysis. It is shown that the HPS processing leads to an improvement of thermoelectric performance of the materials.

11:35 AM
Application of High-Pressure Torsion to Ceramic-Based Materials: *Kaveh Edalati*[1]; Zenji Horita[1]; [1]Kyushu University

Ceramics are generally brittle materials at room temperature because of strong ionic or covalent bonding which makes the dislocations motion very difficult through the crystalline structure. This study shows that intense plastic deformation is feasible in ceramic-based materials such as alumina, zirconia and tungsten carbide at room temperature using high-pressure torsion (HPT). Several interesting phenomena were observed following the HPT processing of ceramics: dislocations generation, nanograins formation, allotropic phase transformations and decreasing the sintering time and temperature even when compared to those for hot isostatic pressing (HIP).

11:50 AM
Microstructure and Mechanical Properties of Thixomolded Mg Alloys After Thermomechanical Processing: *Bilal Mansoor*[1]; Raymond Decker[2]; Sanjay Kulkarni[2]; Steve LeBeau[2]; Marwan Khraisheh[1]; [1]Masdar Institute of Science and Technology, Abu Dhabi, UAE; [2]Thixomat Inc.

Thixomolded Mg alloy sheets with fine grain size offer a favorable starting point to produce wrought Mg alloys with superior mechanical properties by severe deformation processing [1-2]. Following a similar approach a novel processing technique was developed by Thixomat Inc. to Thixomold then Thermomechanically Process (TTMP) to produce wrought Mg alloy sheets with ultrafine grain size, improved creep resistance and higher specific stiffness and strength [2]. In this work, a detailed characterization of microstructure is carried out by optical and electron microscopy. Additionally, mechanical properties of TTMP processed AZ Mg alloys are studied by hardness and tensile tests. The microstructure and mechanical properties of TTMP material is also compared with commercial Mg alloys. The significant improvement in mechanical properties achieved after thermomechanical processing opens several avenues of research related to these materials.

12:05 PM Invited
Development of Nanostructured Coating via Electro-Chemical Method: *Young Gun Ko*[1]; Dong Hyuk Shin[2]; [1]Yeungnam University; [2]Hanyang University

The application of nanocrystalline solids has long been facilitated by the wide range of cutting edge techniques such as sol-gel, vapor condensation, mechanical milling, and chemical anodizing. At present, the nanostructured coating utilizing high energy plasma has been shown to possess unique and often enhanced materials properties in comparison to the cermet coatings via current technology. Now, the behavior of nanostructured materials subjected to plasma electrochemical coating was rendered complex by the choice of factors such as electrolyte, electric parameters, and cell atmosphere. Thus, it is essential to optimize the processing design which could lead to the achievement of excellent materials performance heretofore unattainable via conventional coatings. The present paper is to offer a general overview of recent progress in the area of high performance nanostructured coatings, paying much attention to underlying fundamental issues.

12:25 PM
Equal Channel Angular Extrusion of GLIDCOP for use in High-Field Pulsed Magnet Applications: Ryan Need[1]; *David Mutnick*[1]; Adriana Tudela[1]; Weston Lee[1]; David Alexander[1]; Robert Field[1]; Charles Swenson[1]; [1]Los Alamos National Laboratory

High-field pulsed magnets are capable of producing fields of up to 96T. However, these fields create large mechanical and thermal stresses on the conducting wires. In this study, equal channel angular extrusion (ECAE) is evaluated as a potential processing route to create high strength, high conductivity materials for use in pulsed magnets. Alumina dispersion-strengthened copper alloys (tradename GLIDCOP) were subjected to 1 to 4 passes of ECAE by route BC. Mechanical properties were measured by means of quasi-static, uniaxial tensile testing. Electrical conductivity was quantified via the four point probe method. Microstructural evolution was evaluated by scanning electron microscopy (SEM) and electron backscatter diffraction (EBSD). Grain size refinement is posited as the primary mechanism for the observed changes in material properties. The performance of these materials is compared with other existing and proposed magnet conductors.

2:00 PM

Developing Cost-Effective Air Separation Plants for the Mining and Mineral Processing Industry: *Goutam Shahani*[1]; [1]Linde Engineering

Today, the mining and mineral processing sectors are being impacted by highly fluctuating supply – demand, extreme price volatility and tremendous market uncertainty on a world-wide basis. The market for many non-ferrous metals such as gold, nickel and copper has become very robust. This pattern is expected to continue for the foreseeable future. Mineral processing by smelting and various hydrometallurgical operations requires oxygen and oxygen enriched air. This provides greater thermal efficiency and improved emissions. While these processes can be based on air, the use of pure oxygen results in smaller equipment and more complete mineral recovery. Consumers of industrial gases (oxygen, nitrogen) in tonnage quantities have to make informed investment decisions in these uncertain economic times. Plant owners – operators need to carefully examine their current and future industrial gas needs in order to develop the most cost-effective industrial gas plant configuration.

2:15 PM

Effects of Sodium Salts-Modified Paigeite on Dephosphorization of High-Phosphorus Oolitic Hematite during ReductionHematite during Reduction: *Guanghui Li*[1]; Ting Lei[1]; Tao Jiang[1]; Mingjun Rao[1]; [1]School of Minerals Processing and Bioengineering, Central South University

With the rapid development of the iron and steel industry, the iron ore supply can not meet the current demand for iron and steel industry in China, although large reserves of oolitic hematite have been discovered but with low iron grade (30% ~ 45%) and high phosphorus content (0.4% ~ 1.8%). Traditional processes for utilization of this ore are characterized as either high production cost or inefficient dephosphorization. In this study, the sodium salts-burdened paigeite was prereduced as an additive firstly, and then the intensified reduction roasting of oolitic with addition of the previous additive followed by magnetic separation was carried out. The type of sodium salts, the amount of sodium salt, and the effects of the reduction time and reduction temperature were investigated. A magnetic concentrate with iron grade of 91.37% and phosphorus content of 0.084% was obtained under the optimal condition.

2:30 PM

Study of Certain Parameters in Laboratory-Scale Smelting of Sivrihisar Laterite Ores of Turkey: *Ender Keskinkilic*[1]; Saeid Pournaderi[2]; Ahmet Geveci[2]; Yavuz A. Topkaya[2]; [1]Atilim University; [2]Middle East Technical University

Conventional ferronickel smelting has five main steps: Drying, calcination, prereduction, smelting and refining. In the scope of the current work, smelting experiments were conducted using Sivrihisar laterite ores (1.26% Ni) of Turkey. The ore samples previously subjected to drying, calcination and prereduction stages were smelted in alumina crucibles in a laboratory-scale horizontal tube furnace under argon atmosphere. Smelting experiments were performed at 1500, 1550 and 1600 oC. The amount of excess coal used in prereduction step was another variable. Sivrihisar laterite ore is a limonitic one with low MgO composition. Therefore, MgO was added to the smelting charge as a flux. The effects of experimental variables on metal Ni content and slag composition were investigated.

2:45 PM

Dephosphorization Technology of High Phosphorus Oolitic Hematite in Rotary Hearch Furnace Direct Reducing Process: Hongliang Han[1]; *Dongping Duan*[1]; Jiwei Zhao[1]; [1]Institute of Process Engineering, Chinese Academy of Sciences

In this study, physical,chemical and microscopic characteristics of high phosphorus oolitic hematite were investigated firstly. Based on which, the reduction mechanism of apatite in high phosphorus hematite was discussed. And the experiments of high phosphorus hematite used in the 'solid state reduction by rotary hearth furnace + high-intensity magnetic separation' and iron bead by rotary hearth furnace direct reduction processes were studied. The experiment results showed that high temperature, low basicity and high carbon content is conducive for the apatite in iron ore to reduce into molten iron, but not conducive to the removal of phosphorus. Through optimization of process parameters, dephosphorization rate of high phosphorus hematite is more than 60% by 'Solid State Reduction Roasting+ High-intensity magnetic separation' process while that is up to 80% by iron bead process. This study can provide theoretical and technical basis on economical and rational use of high phosphorus oolitic hematite.

3:00 PM

Effect of Basicity and MgO on the Pelletzing of Specularite Concentrate: De Qing Zhu[1]; Jinliang Zhang[1]; Jian Pan[1]; *Zhao Qiang*; [1]Central South University

Burned-Magnesite and limestone were added to vary MgO contents and Basicity (CaO/SiO2 ratio) of pellets for investigating their influences on the specular hematite pellets quality. At fixed MgO content, the addition of limestone don't effect on the quality of green pellets significantly. Burded-Magnesite addition plays a very important role on the quality of green pellets, especially on the cracking temperature, without burned-magnesite addition the cracking temperatures are about 400°C, but when adding burned-magnesite, the cracking temperature will be increased obviously. For preheated pellets, when the magnesite is added, the compressive strength will be decreased. For roasted pellets, without burned-magnesite, the calcium additives can form binding phase of calcium-ferrite, and suitable liquid phase will improve recrystallization of hematite, but excessive liquid will destroy the structure of pellets, so the compressive strength of pellet increases firstly and then decreases, when adding burned-magnesite, the strength will increases as the Basicity increases.

3:15 PM

Effects of MHA Binder on Roasting Behaviors of Oxidized Pellets from Specularite Concentrate: Youlian Zhou[1]; *Yuanbo Zhang*[1]; Tao Jiang[1]; Guanghui Li[1]; Daoyuan Zhang[1]; [1]Central South University

Modified humic acid (MHA) has been developed by Central South University and authorized in China. It has reported that MHA is an effective binder for oxidized pellets prepared from specularite concentrates with poor hydrophilicity and ballability as well as bad high-temperature reactivity. In this study, effects of MHA binder on roasting behaviors of the specularite pellets are studied by chemical analysis, optical microscopy, XRD, etc. MHA is an organic binder, containing much carbon, hydrogen, oxygen, etc. During the roasting, MHA can provide heat because of combustion or decomposition, which is beneficial for the recrystallization form of Fe2O3 in the specularite oxidized pellets at high temperature. The original hematite is first reduced to magnetite, then, magnetite is oxidized into secondary hematite, which obviously improves the roasting performance of specularite pellets.

3:30 PM Break

3:40 PM

A Study of Carbon-Burdened and Cold-Bonded Pelletizing–Electrosmelting Process Disposing Low-Grade Manganese Ore: *Zhao Qiang*[1]; [1]Changsha Research Institute of Mining and Metallurgy

The carbon-burdened and cold-bonded pellets-electrosmelting process is used to dispose low-grade manganese, and the qualified rich-manganese slag is obtained. On the condition that reduction roasting temperature was 1000°C, reduction time was 45min, particle-size was -1mm, reductant dosage was 1.6%, basicity was 0.3, smelting temperature was 1410°C, smelting time was 60min, it had a good effect on the melting between slag and metallographic phase, the manganese content was 32.58%, manganese recovery was 92.16% in the slag; while the iron content was 94.40%, iron recovery was 95.32% in the metallographic phase. It was proved by the demonstration tests.

3:55 PM

The Characteristics of Roasting of Magnesium Pellets and Roasting Strengthening: *Xiaohui Fan*[1]; Luben Xie[1]; Min Gan[1]; Xuling Chen[1]; Lishun Yuan[1]; [1]Central South University

The effect of magnesium additives on roasting quality of iron ore oxidized pellets was studied. The result shows that no matter the major components of the pellets is magnetitic concentrate or hematite concentrete, the mechanical strength of roasted pellets decreases as the contents of MgO increased by adding magnesite, serpentine and MgO powder. The main reasons are that MgO dissolves in magnetite, and MgO promote hematite decomposing into magnetite. Adding calcium-containing or boron-containing materials to promote low melting point material generating can increase the strength of magnesium pellets. The results of microstructure test indicate that the generation of low melting point materials which contain calcium or boron can bring in suitable amount of liquid accelerating the diffusion of Fe^{3+} and Mg^{2+} , promoting the recrystallization of Fe_2O_3 which results in good pellets strength.

4:10 PM

Research on Dephosphorization of Complex and Refractory Oolite Hematite Ore: Chaoying Qi[1]; Tiejun Chun[1]; [1]Central South University

With the rapid development of iron and steel industry in China, a significant increase in the demand for iron ores has been occurring in the past few years, resulting in a high dependence on imported iron ores, which enhanced the developing of low grade and complicated iron ore resources, especially the oolite hematite ore in China. The mineralogical results demonstrate that the phosphorus of ROM (Run of mine) iron ore mainly occurs in the form of collophanite. The apatite aggregates are composed mainly of collophanite as phosphatic mineral with some kaolinite, illite, quartz, gypsum as gangue minerals. Some different ways of magnetic separation, flotation, roasting, aid leaching and microbiological leaching were used to treat the oolite hematite ore. The results show that the process of roasting-magnetic separation-reverse floatation is an effective way to treat the oolite and the phosphorus reduces from 0.85% to 0.18%.

4:25 PM

Separation of Iron from Zinc Calcine by Magnetic Roasting and Dressing: Ning Peng[1]; *Bing Peng*[1]; Liyuan Chai[1]; Mi Li[1]; Jiming Wang[1]; [1]Central South University

A novel technological routine for iron separation from high iron-bearing zinc calcine was proposed. The zinc ferrite ($ZnFe_2O_4$) in zinc calcine was decomposed to zinc oxide and magnetite under reduction atmosphere at temperature over 800°C. The magnetic dressing was carried out to separate magnetite from reduction roasting products. The effects of roasting temperature, roasting time and magnetic intensity on grade and recovery of iron were investigated and the results showed that roasting temperature had a significant impact on iron recovery. In addition, ultrasonic dispersion and mechanical milling were performed to break the structure of the magnetic phases and non magnetic phases before magnetic dressing. The results indicated that ultrasonic dispersion could improve the iron recovery while mechanical milling could increase the grade of iron in concentrates. More than 80% of iron was recovered by using the optimal magnetic roasting and dressing.

4:40 PM

Study on Mechanism of Limonite Granulation Gas-Based Roasting-Magnetic Separation Techniques: *Zhucheng Huang*[1]; Shiyou Tian[1]; Tao Jiang[1]; [1]Central South University

In connection with the refractory low-grade limonite, the granulation Gas-based Roasting-magnetic separation technological is used for experimental study. Optical microscope, XRD, and SEM detection is used to detect production's porosity changing, phase transformation and microstructure characteristics before and after roasting. Study results show that: on condition that the weak reducing atmosphere $CO:CO_2:N_2$ is 1:2:2 and the temperature is 650-750°C, roasting time is 10 minutes, and magnetic separation iron concentrate grade is 61.26% after ball milling and magnetic separation, at the same time recovery rate is 86.27%. Most of limonite phase are transformed into artificial magnetite; microscopic performance shows that after roasting iron minerals are uniformly reduced, iron phase uniform distributed. On the different test conditions artificial magnetite's micro-topography and features are differences.

Modeling Cathode Cooling Due to Power Interruption: *Marc Dupuis*[1]; Alton Tabereaux[2]; [1]GeniSim; [2]Consultant

Extended electrical power interruptions often result in the shutdown and cooling of cells which causes causes the formation of numerous cooling cracks on the surface of cathode blocks. New ANSYS® based thermal cooling models (2D+ full cell slice model, 3D full side slice model and a 3D full cell quarter) were developed to determine the cathode cooling rates, the differences in the temperature gradients and the resultant stress from cooling cathodes for 24 to 48 hours. The results indicate significant temperature gradients and corresponding stress develop during cooling to cause cracking of the cathode blocks. Reducing the aluminum metal level in cells during cooling was found to reduce the level of stress and thus reduce, if not eliminate the cathode surface cracks. Having no metal at all creates a completely new pattern of stresses that may produce cracks in the block edge instead of the block surface.

Modeling the Mass and Energy Balance of Different Aluminium Smelting Cell Technologies: Vanderlei Gusberti[1]; *Dagoberto Severo*[1]; Barry Welch[2]; Maria Skyllas-Kazacos[2]; [1]CAETE Engenharia - Brazil; [2]School of Chemical Engineering - UNSW - Australia

The modern primary aluminium industry is continuously aiming to reduce the cell energy consumption and the harmful cell emission rates. In order to optimize both aspects, a comprehensive understanding and prediction of the electrolysis cell mass and energy balance must be obtained. Traditionally, many cell heat balance models have presented limited considerations on the mass balance, reactions above the cavity crust and cell duct flow. The thermal balance model presented in this paper is entirely based on the first law of thermodynamics. The extended cell control volume that includes the hooded cell space is adopted. This new approach allows automatic accounting for important exothermic reactions and the study of the impact of duct gas flow rate on the energy balance.A user-friendly software tool for studying the cell energy balance was developed. The new modeling tool is applied to assess the mass and energy consumption rates of different cell technologies.

Current Efficiency Predictive Model and Its Calibration and Validation: *Zhiming Liu*[1]; Wangxing Li[2]; Qingjie Zhao[2]; Jiemin Zhou[1]; Yueyong Wang[2]; [1]School of Energy Science and Engineering Central South University; [2]Zhengzhou Research Institute CHALCO Ltd.

Current efficiency is one of the most important technical and economic parameters. Current efficiency loss is due to dissolved aluminum reacting with the anode bubbles by the back reaction, which is assumed to be responsible for the largest part of current efficiency loss in Hall-Héroult aluminum reduction cells. The magnetichydrodynamics flow in cells can be seen as a gas-liquid-liquid flow by neglecting the mina effect of alumina particles. An current efficiency predictive model(CEPM) was developed based on multiphase multicomponent flow. The model takes the flow in cells as a three-phase(the bath, the metal, and the anode bubbles) and multicomponent problem(the bath phase: bath species and dissolved al species; the anode-bubble phase:CO2 and CO), which is able to incorporate the mechanism of current efficiency loss in cells. The model was calibrated by a 160kA cell and validated by a 300kA cell. This study provides a new approach for predicting current efficiency of aluminum reduction cells.

Wireless and Non-Contacting Measurement of Individual Anode Currents in Hall-Héroult Pots; Experience and Benefits: *James Evans*[1]; Nobuo Urata[2]; [1]University of California, Berkeley & Wireless Industrial Technologies; [2]Alumilab and Wireless Industrial Technologies

Continuous measurement of individual anode currents in Hall-Héroult cells is now becoming practical. It has the advantage of early warning of anode effects and possibly improvements in current efficiency and operation (e.g. warning of anode burn-off). The paper describes the approach of Wireless Industrial Technologies which entails a "master-slave" arrangement with a slave measuring the magnetic field produced by the current in each anode rod each second and the masters wirelessly communicating the data to a computer. With this system there is no direct contact with the anode rods and thereby no interference with normal pot operations such as changing anodes. Such a system has been under test at a smelter in the USA since December, 2010. A second smelter will be conducting tests of the system by the time of the Orlando conference. Experience with this system is described and projections made concerning potential economic benefit.

Impacts of Anode Set on the Energy Re-distribution of PB Aluminum Smelting Cells: *Cheuk-Yi Cheung*[1]; Chris Menictas[1]; Jie Bao[1]; Maria Skyllas Kazacos[1]; Barry Welch[1]; [1]The University Of New South Wales

The routine work practice of anode setting has become a more critical operation as the anode sizes have increased at the expense of liquid bath volume, especially for low superheat operation. The spatial operating disturbances as each anode is changed in different parts of the cell alter the control envelope and decision making limits. This paper presents a dynamic thermal model that can simulate the impacts of anode setting on the local thermal balance and hence the overall operating condition, by incorporating individual anode current signals acquired from an operating prebaked reduction cell. By incorporating real plant data, the model can predict the local thermal conditions during the increase of current pick up of a newly replaced anode and the change in current distribution. This model can also be employed in an online fault diagnostic system to help isolating other disturbances, hence improve early detection of impending abnormal conditions.

Dimensional Analysis in Cold Water Model Experiments of New Cathode Structure Aluminum Cell: *Liu Yan*[1]; Zhang Ting'an[1]; Li Chong[1]; Zhao Qiuyue[1]; Wang Shuchan[1]; Feng Naixiang[1]; He Jicheng[1]; [1]Northeastern University

Compared with the traditional cathode structure cell, the new cathode structure cell can restrain the level fluctuations of aluminum liquid, effectively reduce polar distance and decrease cell voltage, it makes greatly electricity saving into reality. In this paper, using cold water model experiment basing on principle of similitude to study the level fluctuations by anode gas disturbance, and investigate the rules of level fluctuations in new cathode structure electrolytic cell. Numerical simulation of the anode structure with Fluent was also carried out. Simulation results are basically consistent with experimental results, which can verify possibilities of using Fluent to study fluctuations in the interface of cell. According to the analysis of experimental data, the empirical formula of amplitude are obtained by using dimensional analysis, which are associated to a variety of material factors, operating factors, equipment factors. After the theoretical analysis, Dimensionless equation is in good agreement with experimental results.

4:20 PM
Flow Field Comparison between Traditional Cell and New Structure Cell by Chaclo by CFD Method: Zhiming Liu[1]; *Fengqin Liu*[1]; Yueyong Wang[1]; [1]Zhengzhou Research Institute of Chalco

Energy saving receives more and more attention because of high energy price and environment requirement. The flow field and interface wave of new structure cell by Chaclo were studied by ANSYS and CFX combination. The results show that the maximum velocity of traditional cells is 26.74 cm/s and the maximum velocity of new structure cell is 21.22cm/s. The maximum velocity is reduced. The interface wave of traditional cells is between -2.19cm and 3.41cm and that of new structure cell is between -1.15cm and 2.50cm. The interface wave is weakened by 34.82%. The industrial practice shows that the anode-cathode distance of new structure cell can be reduced without current efficiency loss in comparison with traditional cells.

Bulk Metallic Glasses IX: Other Related Alloys and Properties

New Refractory High Entropy Alloys: *Oleg Senkov*[1]; Svetlana Senkova[1]; Daniel Miracle[1]; Christopher Woodward[1]; [1]Air Force Research Laboratory

Several new refractory high entropy alloys containing Cr, Hf, Mo, Nb, Ta, Ti, V, Zr and Al as principal alloying elements have recently been produced by vacuum arc melting. The as-solidified alloy samples have been hot isostatically pressed (HIPd) and homogenized prior to the microstructure/properties analysis. Some alloys have a single-phase, disordered BCC crystal structure, while other alloys contain several crystal phases among which a disordered BCC phase prevails (more than 50% by volume). The chemical composition of the phases has been identified using EDS and WDS analyses. The microstructure of these alloys has been studied using SEM and EBSD techniques. These results, together with the alloy properties such as density, microhardness, compression modulus, yield strength and ductility, will be reported and the relationships between the composition, microstructure and properties will be outlined for these new alloys. This work was conducted under the U.S. Air Force contract FA8650-10-D-5226.

2:20 PM

Disordered and Weakly-Ordered Solid-Solution Phases in the High-Entropy Alloy System of Al-Co-Cr-Cu-Fe-Ni: *Louis Santodonato*[1]; Zhi Tang[2]; Andrew Chuang[2]; Peter Liaw[2]; [1]ORNL and UT; [2]University of Tennessee

The high-entropy alloy system AlxCoCrCuFeNi is known to form solid-solutions with a face-centered-cubic phase (A1), dominating at low aluminum contents, and a body-centered-cubic phase (A2), dominating at higher aluminum contents. The A2 phase, however, separates into a modulated structure with ordered (B2) and disordered (A2') regions, possibly indicating the formation of intermetallic compounds. The present study examines the structural evolution of these phases, using neutron and X-ray diffraction at elevated temperatures up to 800 °C, and applies a semi-empirical model to interpret the results. It is shown that the A2 phase separates into the A2' (Al-Ni depleted solid-solution) and the B2 (Al-Ni rich, partially ordered solid-solution), which lowers the total free energy. It is also shown that the A1, A2' and B2 phases coexist in significant fractions throughout the wide temperature range of room temperature to at least 800 °C.

Properties Optimization of High-Entropy and Amorphous Alloys by Alloying and Multiple Processing: *Yong Zhang*[1]; [1]University of Science and Technology Beijing

A criterion for the solid-solution phase formation in the high-entropy alloys was proposed based on two parameters $\Omega>1.1$ and $\Delta<6.6\%$. The properties of several high-entropy alloys were optimized by alloying, and multiple processing, e.g., Bridgman solidification, cold rolling, annealing, water quenching. The low temperature properties of the high-entropy and amorphous alloys were studied, and an equation for predicting the low temperature strength of the amorphous alloys was proposed. The strengthening mechanism of the dendrite/amorphous alloy composite were analysied by using a two phase model.

High-Entropy Carbides Based on High-Entropy Alloys: Yu-An Yeh[1]; *Ming-Hung Tsai*[2]; Jien-Wei Yeh[1]; [1]National Tsing Hua University; [2]North Carolina State University

Based on the concept of high-entropy alloys, first high-entropy bulk carbide (Cr, Nb, Ti, V, W)50C50 with equal-mole transition metals has been synthesized through mechanical alloying and solid-state sintering. The sintered carbide is a thermally-stable NaCl-type FCC solid solution of five binary carbides. This simple FCC phase formation demonstrates that high entropy effect in enhancing solid solution in high-entropy alloys also works in this five-component carbide. Nano-powder prepared by ball milling is the key factor to realize the successful pressureless sintering at a low temperature around 0.56 of the melting point. The average nanohardness value is 32 ± 3 GPa which is higher than the mixture-rule hardness, 23 GPa, by around 40 %. This suggests that high-entropy carbides also exhibit large solution hardening effect.

Accumulation and Recovery Processes in a High-Entropy Alloy Irradiated with 2.5 MeV Electrons: *Yuri Petrusenko*[1]; Alexander Bakai[1]; Valeriy Borysenko[1]; Eduard Mayevsky[1]; Peter K. Liaw[2]; Gongyao Wang[2]; Jien-Wei Yeh[3]; [1]National Science Center - Kharkov Institute of Physics & Technology; [2]Department of Materials Science and Engineering, The University of Tennessee; [3]Department of Materials Science and Engineering, National Tsing Hua University

The accumulation and annealing characteristics of irradiation-induced defects in an Al-Co-Cr-Cu-Fe-Ni high-entropy alloy have been studied during low-temperature (80 K) irradiation with 2.5 MeV electrons and subsequent isochronous annealing. The data obtained are compared with the literature results on the point-defect generation and annealing behavior in crystalline Fe-Cr-Ni alloys and steels under electron irradiation. Qualitatively irradiation dose dependences of the electrical resistivity of both families of alloys are rather similar and can be interpreted using the basic parameter of a resistivity increase per Frenkel pair. The isochronous annealing behavior for the high-entropy alloy is also similar to that of the Fe-Cr-Ni system. The characteristic activation energy of the vacancy-annealing stage is estimated. It is concluded that the increase of the resistivity during electron irradiation is induced by the Frenkel pair generation. The observed resistivity changes during annealing are caused by vacancies and compositional ordering and disordering.

3:30 PM

Spark Plasma Sintering of Fe-Based Bulk Metallic Glasses: *Sandip Harimkar*[1]; Ashish Singh[1]; [1]Oklahoma State University

Amorphous alloys or bulk metallic glasses represent a new class of advanced materials exhibiting attractive combinations of properties such as high strength/hardness and excellent wear/corrosion resistance. While bulk processing of amorphous alloys using conventional casting processes is often difficult, micrometer-sized powders of the amorphous can be readily processed using gas atomization processes. The novel spark plasma sintering (SPS) presents tremendous potential for the bulk processing of these exciting alloys using starting atomized amorphous powder. In this presentation, our recent results on microstructure and properties of SPS processed Fe-based bulk amorphous alloys will be discussed.

Formation of HfW2 in Mechanically Alloyed W-Based Alloy Systems: *Laszlo Kecskes*[1]; Anthony Roberts[1]; Kristopher Darling[1]; [1]US Army Research Laboratory

The lethality of depleted uranium (DU) as a kinetic energy penetrator (KEP) is ascribed to its high density 18.95 g/cm3 and its ability to undergo adiabatic shearing. An alternative replacement, a tungsten (W)-based bulk metallic glass would inherently incorporate the necessary physical attributes for an ideal KEP. Several W-based binary systems may form the basis for a refractory, high-density glass composition. Phase diagrams for the binary systems W-Hafnium (Hf) and W-Zirconium (Zr) are similar, but equilibrium melting studies preclude the use of Hf, due to the formation of the HfW2 intermetallic. However, Hf remains advantageous as it has a relative density of 2 compared to Zr and thus will result in a higher density glass. The current investigation utilizes the non equilibrium method of high energy mechanical alloying, to investigate if the suppression of HfW2 formation could be accomplished in both the binary and higher-order amorphous alloy systems.

4:15 PM
Manifestation of Short-Range Order, Medium-Range Order, and Structure Defects in Bulk Metallic Glasses: *Yuri Petrusenko*[1]; Alexander Bakai[1]; Ivan Neklyudov[1]; Igor Mikhailovskij[1]; Sergij Bakai[1]; Peter K. Liaw[2]; Gongyao Wang[2]; Qingming Feng[2]; Tao Zhang[3]; Lu Huang Huang[3]; Zengqian Liu[3]; [1]National Science Center - Kharkov Institute of Physics & Technology; [2]Department of Materials Science and Engineering, The University of Tennessee; [3]School of Materials Science and Engineering, Beijing University of Aeronautics and Astronautics

The idea that bulk metallic glass (BMG) structures can be regarded as an ensemble of clusters is confirmed by direct and indirect observations. There is a finite set of the structure units, "perfect" (locally preferred) coordination polyhedra, specified by compositional and topological order. The clusters of poor order form structural defects. Field emission and transmission electron microscopy reveal regions of ~10 nm in size, which can be identified as locally ordered clusters separated by diffuse poorly ordered boundaries. In the defectless regions, the point defects, vacancies, and interstitials are stable. The most important extended defects of BMGs are intercluster boundaries. The revealed size dependence of the BMG strength, Kaiser Effect, and feature of the low- and high-frequency compression-compression fatigue are presented in this report. They are considered as manifestation of the shear transformation, sliding and creep in boundary layers. As result, shear bands and crack initiation and propagation takes place.

4:25 PM
Structural Relaxation in Zr-based BMGs Viewed from Potential Energy Landscape: *Osami Haruyama*[1]; Hiroyuki Sawada[1]; Yoshihiko Yokoyama[2]; Kohichi Tsuchiya[3]; Kazumasa Sugiyama[2]; [1]Tokyo University of Science; [2]Institute of Materials Research, Tohoku University; [3]National Institute of Materials Research

The structural relaxation in amorphous alloys has been classified into two categories. One is called the topological short range ordering (TSRO) process, which is manifested in accompanying with annihilation of quenched-in free volume under T_g. Another is the chemical short range ordering (CSRO) process whose characteristic is the reversible variation in physical properties during relaxation. The kinetics of both processes conforms to a stretched exponential relaxation function with an index β less than 1. The β of TSRO process is largely temperature-dependent, while the CSRO process has a constant value of β. Following the potential energy landscape, the structural relaxation in BMGs is regarded as a transition between local potential energy minimum locations on a multidimensional potential energy hyper-surface. In the present study, we examine the structural relaxation of BMGs in both high-temperature region (roughly T_g-60 K≤T≤T_g+10K), and low-temperature region (T_g-250 K≤T≤T_g-150K) based upon this model.

4:35 PM
Investigation of Porous Zr-Based Bulk Metallic Glass: *Junhua You*[1]; [1]Shenyang University of Technology

The Zr57Cu15.4Ni12.6Al10Nb5 porous bulk metallic glass with a diameter of 6mm was fabricated by melt infiltrating casting method. The porous cell morphology, structure, fracture surface and phase constituent of the porous material were investigated by scanning electron microscopy (SEM) and X-ray diffractometry (XRD), respectively. And the mechanical properties and cell structure were also discussed. The results show that a uniform distribution of porous cells with size of 0.2-0.8 mm forms by introducing CaC2 particles as space holders. The density and porosity of the porous bulk metallic glass are 3.57 g/cm3 and 47%, respectively. The largest yield strength of this porous material is 384 MPa and it gradually declines accompanied by serrated flow under compression. The final failure occurs at a strain of 18.6%, well in excess of monolithic amorphous alloys.

Controlled Nanocrystallization of a Bulk Metallic Glass in the Zr-Al-Cu-Ni-Co System – Structure, Properties and Ways to New Materials Design: *Rainer Wunderlich*[1]; Arnaud Caron[1]; Hans-Joerg Fecht[1]; [1]Universitaet Ulm

A controlled two-phase mixture of nanocrystalline and amorphous phases offers the possibility of tailoring the ductility and mechanical strength of BMG forming complex alloys. This has been investigated in the Zr-Al-CuNiCo alloy system as a function of the Al-concentration varied between 7 and 20 at% and of the Co-concentration between 2 and 8 at%. At the composition limit of glass formation different amorphous to crystalline phase ratios have been obtained by casting and investigated by XRD, SEM, atomic resolution TEM. Detailed recent AFAM measurements point to a phase separation in the initially amorphous and fully relaxed states. The phase contrast originates from the difference in elastic properties on the scale of a few hundred nanometers. Minor compositional variations result excellent glass forming ability and two widely separated crystallization. Controlled crystallization allows a wide variation of nanocrystalline / glassy microstructures and related properties and, thus, a new way of materials design.

2:20 PM
Magnetocaloric Effect of Fe-Based Amorphous Metals: *Anja Waske*[1]; Björn Schwarz[1]; Norbert Mattern[1]; Konstantin Skokov[1]; Jürgen Eckert[1]; [1]IFW Dresden

Magnetocaloric materials could one day be the basis of a new magnetic cooling concept for consumer use, replacing conventional refrigeration technology. However, currently known materials with high magnetic entropy changes are challenging to implement into devices for actual consumer use, since they contain either very expensive or toxic components or exhibit large magnetoelastic effects, which question their long-term stability. Here, we report on the magneto-caloric effect in Fe-based metallic glasses. Although exhibiting only moderate magnetic entropy changes, metallic glasses offer a range of qualities very well suited for application in a cooling device. Also, Fe-based alloys are among the cheapest compounds showing the magnetocaloric effect. We show tuning of Curie temperature upon doping Fe-based amorphous alloys with Nb. Furthermore, the influence of selected rare earth addition will be discussed. Differences between using bulk metallic glasses and amorphous ribbons for application in a test cooling device will be commented on.

2:30 PM Invited
Work Hardening of High Strength Nanocrystalline Ni-W Alloys: *Tohru Yamasaki*[1]; Kazutaka Fujita[2]; [1]University of Hyogo; [2]Ube National College of Technology

It is well known that nanocrystalline alloys exhibit very low ductility under tensile testing conditions. This may be due to the formation of highly localized shear bands because of their low work hardening ability. We have developed the nanocrystalline Ni-16.9 at. W alloy having grain size of about 5 nm by electrodeposition. This alloy exhibited high tensile strength of 2,900 MPa with large plastic strain of about 1.0 %. In this case, large work hardening was observed during plastic deformation. Many ductile dimples with a size of about 100 nm were observed at the fractured surface. By using the high-resolution SEM, local grain growth up to about 20 nm in diameter were observed near the fractured surface. It is suggested that the local grain growth near the fractured surface may be occurred by rapid heating during plastic deformation, resulting the hardening according to the inverse Hall-Petch strengthening law.

2:50 PM
Medium Range Order Correlations in Lliquid and As-Quenched Al-Tb System: *Eren Kalay*[1]; Matthew Kramer[2]; Tuba Demirtas[1]; Merve Genc[1]; Jinwoo Hwang[3]; Paul Voyles[4]; [1]METU; [2]Ames Laboratory US DOE; [3]University of California, Santa Barbara; [4]University of Wisconsin, Madison

We've investigated the glassy and the liquid states of Al-Tb alloys by a combined study of HEXRD, APT, FEM, molecular dynamics and RMC simulations. The experimental HEXRD indicated a pre-peak and side-peak in the total structure factor function in liquid and amorphous Al-Tb which is also confirmed by MD simulations at the corresponding temperatures. We believe that these extra reflections are resulted due to clustering of RE atoms at relatively longer length scales as compared to short-range ordering in liquid state. The APT and RMC clearly shows the compositional fluctuations in the amorphous states resulted in formation of a network structure of Al-depleted regions between which ~1 nm of isolated clusters of pure Al exist. Fluctuation electron microscopy results demonstrate that these Al rich and depleted regions tend to order themselves into MRO structure. The chemical and topological order in question will be discussed and presented during the talk.

3:00 PM Invited
Plasticity of BMG with Shear Bands-Sized Sample: *Scott Mao*[1]; [1]University of Pittsburgh

This talk will be based on publication of J. H. Luo, F. F. Wu, J.Y. Huang, J. Q. Wang, and S. X. Mao*, "Superelongation and Atomic Chain Formation in Nanosized Metallic Glass", PRL 104, 215503 (2010). Bulk metallic glasses are brittle and fail with no plastic strain at room temperature once shear bands propagate. How do metallic glasses deform when the size is less than that of shear bands? Here we show that Al90Fe5Ce5 metallic glass with a size <20 nm can be extremely elongated. Remarkably, even an atomic chain was formed after sample necking, which was never observed in metallic glasses. The unexpected ductility may originate from the fast surface diffusion and the absence of shear band formation, and may guide the development of ductile metallic glasses for engineering applications.

3:20 PM
Hydrogen Solubility and Permeatbility of Ni-Nb-Zr Amorphous Alloy: *Narendra Pal*[1]; Steve Paglieri[2]; Dhanesh Chandra[1]; Sang-Mun Kim[1]; Wen-Ming Chien[1]; Anjali Talekar[1]; Ted Flanagan[3]; Michael Dolan[4]; [1]University of Nevada, Reno; [2]TDA Research Inc.; [3]University of Vermont; [4]Commonwealth Scientific and Industrial Research Organisation

Hydrogen from coal gasification is one of the cheaper routes considered for hydrogen production on sustainable basis. Conventionally, Pd alloys have been used as filtration membranes for hydrogen permeation. The prospective alternative could be Ni-Nb-Zr amorphous alloys which can reduce the membrane cost drastically. The Ni42Nb28Zr30 amorphous alloy membrane was fabricated using melt-spinning and was coated with thin Pd layer (500nm) by sputtering. The P-C-T isotherms were obtained from solubility test in Sievert's apparatus at different temperatures (200-400°C). The solubility of Pd at 200°C was found to be 0.63, which matches with previous published data. The permeability of Ni42Nb28Zr30 was measured to be 1.2 x 10-8 mol m-1 s-1 Pa-0.5 at 400°C which is close to the permeability of Pd at this temperature. As Ni42Nb28Zr30 amorphous alloy shows permeability close to Pd, the solubility data of Pd at different temperatures would be compared with Ni42Nb28Zr30 in details.

Understanding Mechanical Properties of Bulk Metallic Glasses Using Nanoindentation Pop-In Experiment: *Hongbin Bei*[1]; Yanfei Gao[2]; [1]Oak Ridge National laboratory; [2]University of Tennessee/Oak Ridge National Laboratory

Pop-in events during nanoindentation have been used extensively to probe dislocation plasticity in crystalline metals. In amorphous metals (metallic glasses), dislocation-mediated plasticity is not possible because those materials lack long-range order. However, Pop-ins are also observed in bulk metallic glasses (BMGs) during spherical nanoindentation. The first pop-in marks the transition from perfectly elastic to plastic deformation, i.e., the onset of plastic flow (incipient plasticity) in BMGs. The dependence of pop-in on materials and loading conditions provides the unique information for the development of constitutive models for BMGs. We conduct many indentation experiments on the as-cast (in different cooling rate), annealed, deformed metallic glass samples to investigate effects of cooling rate, relaxation, pre-existing shear band on the onset of yielding of BMGs. Based on the experiment observation, a statistic model was used to explain the strength distribution and how they are affected by the processing.

4:05 PM
Sliding Wear Behavior of Cu50Hf41.5-xAl8.5Yx (x = 0, 2, 5, 8, 10 at. %) Bulk Metallic Glass: *Dharma Maddala*[1]; Rainer Hebert[1]; [1]University of Connecticut

The sliding wear behavior was investigated of Cu50Hf41.5-xAl8.5Yx (x = 0, 2, 5, 8, 10 at. %) bulk metallic glasses (BMG). Alloying with yttrium resulted in a gradual increase in hardness, but the notch toughness decreased. The wear resistance increased up to 5 at. % of Y addition, but deteriorated with further increase in the Y content. The results suggest that the hardness controls the wear behavior at small Y levels. At higher Y concentrations the toughness decrease outweighs the hardness in its effect on the wear behavior. The comparison with the wear behavior of a Cu50Hf41.5Al8.5 BMG shows the same trend in the wear behavior with changes in hardness and toughness for partially devitrified samples. While the processing conditions for optimal wear can be predicted approximately from the hardness and toughness data, a refined wear prediction has to consider the wear mechanisms and their changes with alloying or precipitation.

4:15 PM
Ultra-High Fracture Strength and Elongation to Failure of Submicron-Sized Metallic Glasses: *Lin Tian*[1]; Yong-Qiang Cheng[2]; Cheng-Cai Wang[1]; Zhi-Wei Shan[1]; Ju Li[3]; Xiao-Dong Han[4]; Jun Sun[1]; Evan Ma[2]; [1]CAMP-Nano, Xi'an Jiaotong University; [2]Department of Materials Science and Engineering, Johns Hopkins University; [3]Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, MIT; [4]Institute of Microstructure and Property of Advanced Materials, Beijing University of Technology

For the first time, the mechanical properties of submicron-sized metallic glasses (MGs) were studied through quantitative in situ tensile test inside a transmission electron microscope, which employs high-resolution measurements of the loading forces and accurate strain measurement with deposited markers on the gauge length. The quantitative experiment establishes that the small-volume MGs have fracture strength and elongation to failure reaching record high values of about 4 GPa and 6%, respectively. At the same time, the yield stress and elastic stain limit are found to be about twice as large as the already-high elastic limit observed in macroscopic samples, in line with model predictions of the intrinsic limit in the absence of heterogeneous shear band nucleation facilitated by extrinsic factors. The origin of the apparent "work hardening" seen in the tensile stress-strain curves will be also discussed in this talk.

4:25 PM
Smaller is Stronger in Amorphous Metals: *Chengcai Wang*[1]; Zhiwei Shan[1]; Jun Sun[1]; Ju Li[2]; Evan Ma[3]; [1]Xi'an Jiaotong University; [2]Massachusetts Institute of Technology; [3]Johns Hopkins University

The mechanical properties and deformation mechanisms of metallic glasses at the micro- and nano-scale are receiving much attention recently. However, in comparison with the well-accepted "smaller is stronger" trend in their crystalline counterparts, the size-dependent yield strength and deformation mode in metallic glasses is still under intense debate. Here we demonstrate the "smaller is stronger" trend in submicron-sized aluminum-based metallic glasses through quantitative in situ tension tests inside a TEM. In a 100-nm thick beam, the elastic strain could reach 3.8% and fracture strength is about 1.75 GPa, almost twice that of bulk samples of the same composition. Meanwhile, a tendency towards "homogeneous-like" distributed deformation is observed in compression studies of nanopillars, which is in line with earlier findings.

4:35 PM
The Correlation between Glass Formation and Hardness of the Amorphous Phase: *Zhitao Wang*[1]; Kaiyang Zeng[1]; Yi Li[1]; [1]National University of Singapore

We report a non-monotonous behavior of the hardness of amorphous Cu-Zr films as a function of composition, via applying a combinatorial deposition and nanoindentation method with unparalleled compositional resolution. Distinct peaks in hardness were found at particular compositions to match well with the previously reported density peaks. Our results not only provide a shortcut to search for new glass-formers, but also raise the possibility to develop bulk metallic glasses with enhanced plasticity and/or ductility for engineering applications.

4:45 PM
Atomic Packing and Its Correlation with Glass Transition in Metallic Glasses: *Xiong-Jun Liu*[1]; Zhao-Ping Lu[1]; Xidong Hui[1]; C. T. Liu[2]; [1]University of Science and Technology Beijing; [2]City University of Hong Kong

Deciphering the atomic structure of metallic glasses (MGs) is a longstanding scientific challenge. Despite considerable effort has been devoted to resolving this issue over the years, a general description of atomic packing for various MGs is still lacking at present. Moreover, the structural origin of the glass transition remains a great puzzle. In this paper, we will present a global feature to describe the atomic packing in MGs, and then correlate the structural parameter with the glass transition. By statistically analyzing the rule of peak positions in the pair distribution functions for a variety of MGs, we have revealed that the complex atomic configuration in MGs can be virtually characterized by a combination of the spherical-periodic order and local translational symmetry (LTS). By quantitatively exploring the evolution of LTS-order atoms during glass transition, we have identified the correlation of the glass transition event with the extent of the LTS order.

4:55 PM
Amorphous Phase Separation in a Bulk Metallic Glass of Negative Heat of Mixing: *Si Lan*[1]; Yeuk Lan Yip[1]; Man Tat Lau[1]; Hin Wing Kui[1]; [1]Chinese University of Hong Kong

Amorphous phase separation has been a controversial issue for many years in the field of metallic glass (including bulk metallic glass). For example, there are reports saying that amorphous phase separation occurs in Pd-Ni-P, which has a negative heat of mixing. On the other hand, there are as many reports claiming that phase separation is absent in amorphous Pd-Ni-P alloys. The difficulty is mainly due to a lack of direct experimental evidences. In this work, high resolution TEM techniques, including HREM and high-angle angular dark-field (HAADF) EDX spectrum mapping were employed for the purpose. It was found that amorphous Pd41.25Ni41.25P17.5 will undergo phase separation after an intermediate thermally annealing.

Characterization of Minerals, Metals, and Materials: Characterization of Ferrous Metals II

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Materials Characterization Committee
Program Organizers: Jiann-Yang Hwang, Michigan Technological University; Sergio Montero, State University of North Rio De Janeiro; Chenguang Bai, Chongqing University; John Carpenter, US Department of Energy; Donato Firrao, Politecnico di Torino; Byoung-Gon Kim, Korea Institute of Geoscience & Mineral Resources; Mingdong Cai, Schlumberger

Session Chairs: Mingming Zhang, ArcelorMittal Global R&D; Zhiwei Peng, Michigan Technological University

2:00 PM
Comparison of Creep Life Assessment between Tin-Based Lead-Free Solders and Lead Solders: *Kenji Monden*[1]; [1]Denki Kagaku Kogyo K.K.

The creep properties of tin-based lead-free solders, Sn3.0Ag0.5Cu and Sn0.7Cu0.1Ni, and lead solders, 10Sn-90Pb and 50Sn-50Pb, were investigated at temperatures between 298K and 398K. The creep rupture time decreases with increaseing the initial stress and the temperature. The analysis of creep curves of those solders apply the Omega method. The creep rate $d\varepsilon/dt$ is expressed by following formula : $\ln(d\varepsilon/dt) = \ln(d\varepsilon_0/dt) + \Omega\varepsilon$, where $d\varepsilon_0/dt$ and Ω are experimentally determined. The parameter $d\varepsilon_0/dt$ increases with increaseing the initial stress and the temperature. The activation energy for $d\varepsilon_0/dt$ is 108 kJ/mol at Sn3Ag0.5Cu and 85 kJ/mol at Sn0.7Cu0.1Ni. The energies suggest that the lattice diffusion of tin is dominant. The energy of 10Sn-90Pb is 37 kJ/mol and that of 50Sn-50Pb is 67 kJ/mol. The creep rupture time is calculated using the parameters, $d\varepsilon_0/dt$ and Ω. The calculated creep rupture time is good agreement with the measured creep rupture time.

2:15 PM
Correlationship between JIC and Equivalent Fracture Strain Determined by Small-Punch Test in JN1, JJ1 and JK2 Austenitic Stainless Steels: *Victor Lopez-Hirata*[1]; Maribel Saucedo-Muñoz[1]; Toshiyuki Hashida[2]; [1]Instituto Politecnico Nacional (ESIQIE); [2]Tohoku University

Small-punch tests and determination of fracture toughness JIC were conducted at 4 and77 K on new cryogenic JN1, JJ1 and JK2 austenitic stainless steels, after isothermal aging. Equivalent fracture strain was determined by measuring the reduction of thickness in the small-punch test specimen. A linear dependence of JIC on equivalent fracture strain was found in these new materials. Regression analysis of experimental data produced the following linear relation JIC = 1304.1 equivalent fracture strain + 8.09 [kJm-2]. An analysis of present work relation was pursued on the basis of material properties and evaluation method of JIC. Results showed that the slope value has a strong dependence on material yield strength and JIC evaluation method. This linear relation is useful for the evaluation of fracture toughness JIC, measuring the equivalent fracture strain by means of small-punch test.

2:30 PM
Effect of Heat Treatment on the Surface Characteristics of AISI D2 Steel Machined by Wire EDM: *Milind Dhobe*[1]; I Chopde[2]; Chandrashekhar Gogte[3]; [1]P.E.S. College of Engineering, Aurangabad; [2]Visvesvarya National Institute of Technology; [3]Marathwada Institute of Technology

The quality of machined surface is becoming more and more important to satisfy the increasing demand of components performance and its reliability. While machining any component, it is necessary to satisfy the surface integrity requirements. Heat treatment plays an important role in improving the characteristics of the material. In this research work it has been tried to investigate the effect of heat treatment on the surface characteristics of AISI D2 tool steel after Wire Electro Discharge Machining. The test specimens were prepared by hardening and tempering and then machined with Wire –Electro Discharge Machining (W-EDM) process. Optical and scanning electron microscopy, surface roughness and micro hardness tests were used to study the surface characteristics of the machined specimens.After analyzing the microstructure and test results, it is observed that the recast layer droplets are of smaller size with reduced white layer thickness resulting in higher hardness and lower surface roughness.

2:45 PM

Formability of Multilayered Steel Composites with Improved Strength-Ductility Combination: *Shoichi Nambu*[1]; Junya Inoue[1]; Toshihiko Koseki[1]; [1]The University of Tokyo

Authors developed a multilayered steel composites consisting of high-strength steel and ductile steel with improved strength-ductility combination (ultimate tensile strength above 1.3GPa and fracture elongation above 25%). In this study, the formability of the multilayered steel composites such as a forming limit diagram (FLD), a crash test, and an impact bending test was investigated. From the FLD result, the fracture elongation in plane strain is about 20%, and the good formability was demonstrated in spite of ultra-high strength. For the crash test and the impact bending test, 590DP steels were also prepared for comparison. The profiles of buckling after crash test were almost identical, while the amount of buckling of multilayered steel composites was smaller than that of 590DP steel. The similar phenomenon was also observed for the impact bending test. These results demonstrate that the multilayered steels composite has a good impact resistance in spite of ultra-high strength.

3:00 PM

Wear And Nanoindentation Study Of Hardfacing Dual Layer Clad Of Austenitic Stainless Steel And Tungsten Carbide-Cobalt Alloy: *Samar Kalita*[1]; [1]Advanced Engineered Materials Center - University of North Dakota

Many engineering applications demand surfaces with high wear and corrosion resistance for dynamic operating environments. Carbide metal matrix composites (MMC) are preferred choice for such critical applications. Here, tungsten carbide – cobalt (WC-Co) thick MMC coatings were developed thought direct metal laser deposition. As WC laser clads often has cracks and pores, an intermediate austenitic stainless steel clad was applied for corrosion protection. The clad integrity was examined by optical microscopy, while the microstructure and composition were analyzed by SEM and EDS techniques. The mechanical properties were evaluated in terms of hardness and reduced elastic modulus using Vickers hardness testing, and depth-sensing instrumented indentation using a Hysitron-TI950 Nanomechanical Tester. Wear resistance was evaluated according to ASTM F1978-00e1 using a Taber abrader. SEM and LSM analyzed worn surface morphologies. Hardness of WC-Co, austenitic stainless steel and AISI 1018 steel substrate were found to be 1100, 252 and 172 HV, respectively.

3:15 PM

Hot Deformation Study by Processing Maps of N Containing Microalloyed Steel: *Martina Dikovits*[1]; Cecilia Poletti[1]; Fernando Warchomicka[2]; Gajanan P. Chaudhari[3]; Vivek Pancholi[3]; [1]IWS, TU Graz; [2]IMST, TU Vienna; [3]IITR, Roorkee

The hot formability of a microalloyed steel with 0.16wt%C modified with N is studied by using processing maps. Compression tests of cylindrical samples are carried out using a Gleeble®3800 simulator in the range of temperature between 750-1000°C and strain rates between 0.01-100 s-1. For this alloy, an Ar3-temperature about 740°C is determined by means of dilatometry. Processing maps are calculated using the modified dynamic material model developed by Murty and Rao for different logarithmic strains. For the instability map, the parameter κj developed by the authors in previous works is used and compared with other instability values. Softening in the flow curves provoked by induced ferrite during deformation at low temperatures and low strain rates is reflected in the □-value. Light optical microscopy (LOM) and electron back scattered diffraction (EBSD) measurements are used to study the microstructure of the hot deformed samples to determine the deformation mechanisms active and to verify the processing maps.

3:30 PM

Influence of Annealing Treatment on Microstructure and Mechanical Properties of Cold-Rolled Sheet of Fe-36Ni Invar Alloy: *Xiang Jiang*[1]; Lijuan Li[1]; Xin Xia[1]; Junjun Huang[1]; Qijie Zhai[1]; [1]Shanghai University

Some experiments with different annealing temperatures (1173, 1223, and 1273K) and different holding times (3, 4, 5, 6min) were carried out on cold-rolled plate of Fe-36Ni invar alloy. The microstructure and the mechanical properties were observed and tested respectively, and the fracture morphology was observed by SEM. The results show that with increasing of the temperature and the annealing time, the austenite grains gradually grow up accompanied by a small amount of annealing twin crystals, meanwhile, its plasticity and toughness are improved, and it is typical ductile fracture under the condition of tensile failure. After annealed at 1223K, the invar alloy has better comprehensive properties than that at the other annealing temperatures, and the grains size is more uniform. Furthermore, when the annealing time is 4min, the invar alloy has the best comprehensive properties.

3:45 PM

Mechanical Properties of Friction Stir Welded Inconel 600/SS 400 Lap Joints: *Kuk Hyun Song*[1]; Won Yong Kim[1]; Kazuhiro Nakata[2]; [1]Korea Institute of Industrial Technology; [2]Joining and Welding Research Institute

The present study was carried out to evaluate the mechanical properties of friction stir welded Inconel 600/SS 400 lap joints. In this process, friction stir welding (FSW) was performed at a tool rotation speed of 200 rpm and welding speed of 100 mm/min, and argon gas was utilized to prevent surface oxidation during the welding. Application of FSW notably decreases the grain size of Inconel 600 alloy from 20 μm in the base material to 8 μm in the stir zone. However, the grain size of SS 400 in the weld zone was slightly coarsened, when compared to the base material. Also, the hooking in the advancing side and the intermetallic compounds (M7C3) in the weld interface between Inconel 600 and SS 400 were well formed. These intermetallic compounds and hooking were effective to increase in mechanical properties such as tensile and peel strengths.

4:00 PM

Thermodynamic Analysis and Observation on Precipitation of Inclusions in RE-253MA Heat Resistance Steel: *Zhou Cai*[1]; [1]Chongqing University of Science and Technology

The effect of Ce on modifying inclusions of 253MA Heat Resistance stainless steel was studied by metallographic examination, SEM and electron spectroscopy. Thermodynamic calculation was used to analyze the formation and transformation of RE inclusions in 253MA Heat Resistance stainless steel. The result shows that Al2O3 and MnS can be entirely replaced by Ce2O2S and CeS that are spherical.

Energy Nanomaterials: Catalysts and Photocatalysts

Computational Studies of Graphene-Supported Metal Nanoparticle Catalysts: *Ashwin Ramasubramaniam*[1]; Ioanna Fampiou[1]; [1]University of Massachusetts Amherst

The synthesis of well-dispersed, size-controlled metal nanoclusters on carbon supports is highly desirable in order to enhance catalytic activity and selectivity in a variety of chemical reactions. However, metal clusters interact rather weakly with defect-free carbon supports and coarsen over time leading to loss of surface area and thence catalytic activity. Defects in carbon supports play an important role in enhancing metal-carbon bonding, thereby reducing the propensity for cluster coalescence. Using a combination of density functional theory and empirical potential simulations, we examine the interaction of Pt clusters with point and line defects in graphene. We compare and contrast the binding energies and diffusivities of clusters bound at defects and on pristine graphene. We examine the influence of support-metal interactions on the morphology, electronic structure, and CO-tolerance of bound nanoparticles. Our results suggest possible avenues for controlling the dispersion and activity of catalyst nanoclusters on carbon supports via defect engineering.

2:30 PM

Oxygen Reduction Reaction (ORR) Activity and Electrochemical Stability of Thin-Film Bilayer Systems of Platinum on Niobium Oxide: *David Mitlin*[1]; Li Zhang[1]; Liya Wang[2]; Chris Holt[1]; Titichai Navessin[3]; Kourosh Malek[3]; Michael Eikerling[2]; [1]University of Alberta and NINT NRC; [2]Department of Chemistry, Simon Fraser University; [3]NRC Institute for Fuel Cell Innovation

We used electrochemical testing and theoretical calculations based on density functional theory to examine the oxygen reduction reaction (ORR) activity of platinum electrocatalyst supported on several forms of niobium oxide. Bi-layer electrocatalysts were synthesized in the form of 5 nm thick Pt layers (ca. 0.01 mg/cm2), deposited on 5 or 10 nm thick niobium oxide and backed by glassy carbon (GC) electrodes. The NbO and NbO2 supports enhance the specific electrochemical activity of Pt relative to the identically synthesized baseline system of Pt on GC, but have no positive effect on the mass activity. The electrochemical stability of the Pt/NbO2 bi-layer system was investigated by potential cycling with up to 2500 CV cycles. After 2500 cycles, data indicates minimal electrochemical area loss. Using DFT calculations, we have evaluated effects of oxygen incorporation on stability, electronic structure, and electrochemical activity of Pt|NbxOy systems.

2:50 PM

Development of Highly Active Titania-Based Nanoparticles for Composite Propellant Combustion: *David Reid*[1]; Kevin Kreitz[2]; Matthew Stephens[2]; Jessica King[1]; Ponnusamy Nachimuthu[3]; Eric Petersen[2]; Sudipta Seal[1]; [1]University of Central Florida; [2]Texas A&M University; [3]Pacific Northwest National Laboratory

Recent research in the field of energetic materials has focused on the development of nanostructured fuels and oxidizers to enhance performance and energy release rates. However, these nanoparticulates present serious challlenges due to their safety hazards, instability, and difficulty of manufacture. Our research focuses on an alternate route, the use of nanoscale metal-oxides to catalyze reactions between micrometer-scale energetic constituents. By tuning the physical and chemical properties of nano-TiO2 suspensions in polymer-matrix energetic composites, we have achieved an 81% increase in the combustion rate of HTPB-AP based composite solid propellants with a nanoparticle loading of 1 wt %. These findings make nano-TiO2 a viable material for advanced propulsion while avoiding the safety hazards and manufacturing difficulties of competing technologies.

Hierarchical Microporous Materials: Rational and Designable Heterogeneous Catalysts for Renewable Energy: *Wei Fan*[1]; [1]University of Massachusetts Amherst

One of the challenges for utilization of renewable biomass resources by biorefinery is the discovery and investigation of novel and efficient catalysts for the conversion of biomass into fuels and chemicals. It has been recognized that biorefinery require multi-step conversion from biomass to desired chemicals and biofuels. Cascade reactions achieved through integration of different active sites in the same catalyst could enable new one-pot processes. There is, thus, a persistent need for the synthesis of hybrid multi-functional microporous catalysts which are capable of performing multiple "primary" functions simultaneously or sequentially in time. In this talk, we will show how a wide range of the combination of different functions of microporous catalysts (zeolites) and/or with other functional materials can be realized by controlling the architecture of microporous catalysts at a nanoscale level with using a confined growth method.

Characterization of Chemistry of Nanomaterials by (Scanning) Transmission Electron Microscopy: *Masashi Watanabe*[1]; [1]Lehigh University

Nanoscale composition variations within particles can be an important factor in controlling their physical functionality. The chemistry of individual nanoparticles can in principle be analyzed by (scanning) transmission electron microscopy ((S)TEM) with X-ray energy dispersive spectrometry (XEDS) and electron energy-loss spectrometry (EELS). However, there are still several problems to overcome for characterization of nanomaterials: useful signals from individual nanoparticles are extremely weak because of the limited volume and the analysis is further complicated when the particles are in close proximity to other supported materials. In addition, if the elemental distribution fluctuates locally within a single particle, individual point analyses could miss such variations. Therefore, an elemental mapping approach is essential to characterize nanomaterials. The limited signals can be offset by applying spectrum imaging combined with multivariate statistical analysis (MSA). In this talk, several examples for characterization of the local chemistry variations in nanomaterials in combination with MSA will be presented.

4:25 PM

TiO2 Nanotube Arrays Grown in Ionic Liquids: High-Performance in Photocatalysis and Energy Storage: Huaqing Li[1]; *Jun Qu*[2]; Surendra Martha[2]; Qingzhou Cui[2]; Hanbing Xu[2]; Huimin Luo[2]; Miaofang Chi[2]; Roberta Meisner[1]; Nancy Dudney[2]; Wei Wang[2]; Sheng Dai[2]; [1]University of Tennessee; [2]Oak Ridge National Laboratory

This study overcomes the previously reported limitations in anodization potential (<10 V) and tube dimension (<600 nm) for synthesizing TiO2 nanotubes in ionic liquids (ILs). Several micrometers long, debris-free NTs were obtained under anodization voltages of 10-50 V in 1-butyl-3-methylimidazolium tetrafluoroborate with an optimized water content of ~2wt.%. IL electrolytes decompose at a lower rate and thus induce fewer contaminants to the TiO2 matrix due to their higher electrical conductivity compared to conventional organic electrolytes. As a result, NTs grown in ILs (IL-NTs) have no nano-cracks or tube wall separations, which are commonly observed in NTs fabricated in ethylene glycol-based electrolytes (EG-NTs) and are believed to cause deterioration in the NTs' photoelectrical properties. The ILs-NTs have demonstrated great potential in both photocatalysis and energy storage applications with much higher photocurrent in water splitting and substantially better capacity retention as the anode in a half-cell Li-ion battery cycling compared with EG-NTs.

4:45 PM

Solid State Reactions in TEA Precipitated Cr-ZnO Nanoparticles and Their Use in Photochemical Splitting of Water: *Octavio Dominguez*[1]; Luisa Flores[1]; Adriana Gaona[1]; Guadalupe Sanchez[1]; Roel Cruz[1]; [1]San Luis Potosi University

This work reports the preliminary results about solid state reactions of nanometric Cr-ZnO solid solutions and ZnCr2O4 particles obtained with triethanolamine (TEA). Different compositions were prepared: 0.65, 2.7, 8, 16 and 33.3 at% chromium, the last one corresponding to ZnCr2O4 spinel. Infrared Spectroscopy (FTRI) together with X-ray diffraction (XRD) peaks of the powders with Cr3+ between 0.65 and 16.0 at% were assigned to Cr-ZnO solid solution after treatment at 400 °C due to the only presence of ZnO structure. FTIR spectra indicating that Cr-O bonding exists even if there was no presence of ZnCr2O4. From Williamson-Hall and Rietveld methods the lattice dimensions were assigned to chromium incorporation in ZnO structure and the lattice contraction by particle size refinement. Cr-ZnO nanoparticles were tested for photoelectrochemical splitting of water under UV irradiation, showing some improvement as Cr3+ content was increased.

Energy Technologies and Carbon Dioxide Management: Waste Heat Recovery

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS Light Metals Division, TMS: Energy Committee

2:00 PM Introductory Comments

2:05 PM

Effect of Materials on the Autoignition of Cyclopentane: *Donna Guillen*[1]; [1]Idaho National Laboratory

Cyclopentane, a flammable hydrocarbon, is being considered as a working fluid for waste heat recovery applications. Experiments were conducted to determine the ignition delay time (IDT) of cyclopentane using an Ignition Quality Test (IQT) device. Two sets of experiments were conducted per ASTM D6890 (with exception to charge pressure and temperature) to determine ignition delay of the fuel at atmospheric pressure for normal air (~21% oxygen) and vitiated air (13.3% oxygen) at a temperature of 530oC. Operation of the IQT device at a much lower pressure (1 bar) than normal operation (21.1 bar) led to very rich conditions and wetting of the stainless steel chamber walls. Catalytic effects produced small IDTs. Experiments were repeated with a modified injector to prevent wall wetting, resulting in average IDTs that are substantially longer.

2:25 PM

Low Grade Waste Heat Driven Desalination and SO2 Scrubbing: *Srinivas Garimella*[1]; Donald Ziegler[1]; James Klausner[2]; [1]Alcoa; [2]University of Florida

By 2015, nearly half the world's population will live in "water stressed" areas. Production of fresh water utilizing waste heat from industrial processes has been identified globally as a research priority. About 15% of the electricity required to produce aluminum is lost as waste heat in the off-gas. However, the heat's low grade limits reuse. The off-gases contain 50-150 ppm SO2; tightening regulations coupled with increasing coke sulfur levels are motivating SO2 control, for which seawater scrubbing is attractive for smelters with suitable access. We describe a process that produces fresh water, utilizing the waste heat while scrubbing SO2. It uses direct contact between seawater and off-gas to humidify the off-gas. The vapor is subsequently condensed. In smelter trials, a unit treating a slip stream produced high quality water at anticipated levels, attaining over 95% SO2 scrubbing. Future work involves scaling the process to be economically attractive.

2:45 PM

Waste Heat Integration Potential Assessment through Exergy Analysis in an Aluminum Production Facility: *Cassandre Nowicki*[1]; Louis Gosselin[1]; Carl Duchesne[1]; [1]Aluminium Research Centre - REGAL, Laval University

Quebec's primary aluminium production industry consumes roughly 39 TWh of electricity per year and is accountable for roughly 7 million tons of CO2 equivalent. By tapping only a small portion of waste heat and integrating it inside the production facility itself, we can significantly reduce GHG emissions and energy consumption. Although the amount of thermal waste can be adequately estimated by applying an energy balance to production processes, this provides very little information on the quality of waste heat and its potential for integration. A measure of exergy is required. Waste heat streams characterized by high exergy content may generally offer valuable incentives for recovery and integration. More generally, exergy values constrain integration possibilities. An exergy analysis is provided for the aluminium electrolytic reduction process. This is meant to guide future heat recovery initiatives and energy efficiency measures.

Study on Drying Characteristics of Australian Brown Coal Using Superheated Steam: *Tsuyoshi Kiriyama*[1]; Shozo Kaneko[1]; Akira Hashimoto[1]; Masafumi Maeda[1]; [1]The University of Tokyo

Coal produces about 40% of the CO_2 emission in the world, and it is essential that it to be used more efficiently to prevent global warming. Victorian brown coal in Australia has over 60wt% moisture content and, when dried, it becomes highly reactive. Due to the difficulty in transporting it, brown coal is used as fuel for the thermal power stations near the mines. If a highly efficient drying system were developed, a dramatic increase in efficiency would be possible for these brown coal fired power stations. Moreover, brown coal can be easily gasified and converted to synthetic gaseous and liquid fuels or used in IGCC (Integrated coal Gasification Combined Cycle). This research focused on superheated steam drying, where the weight and temperature of variously sized single particles of brown coal were measured by this process, and the basic drying characteristics were investigated.

3:20 PM
Sustainability, Energy Efficiency and CO2 Elimination in Concentrate Drying: *Jyri Talja*[1]; Shaolong Chen[1]; Hannu Mansikkaviita[1]; [1]Kumera Corporation

Drying (water removal) prior to smelting is always economically feasible. Unnecessary heating of vapour can thus be eliminated resulting in savings of 5-15 MUSD every year. Thermodynamically removal of one ton of water out of copper concentrate at 100 °C requires some 3300 MJ/tH2O. This consists of water heating (377 MJ), concentrate heating (509 MJ) and water evaporation (2260 MJ). More heat is needed as higher temperature is practiced to enhance the drying performance and reduce the equipment size. However, major nominator in drying energy efficiency is amount of gases. Drying technologies based on direct heating with fossil fuels (high gas flow rate), require additional energy of 1400-1600 MJ/tH2O, compared to indirect modern drying at 250-400 MJ/tH2O. Significant energy benefits (900–1300 MJ/tH2O) with additional bonus profit of 2-4 MUSD/y year and full elimination of 40 000 tpy CO2 / smelter are available by selecting sustainable, energy efficient steam drying.

3:35 PM
COURSE50 Development of Heat Recovery System from Steelmaking Slag: *Yasutaka Ta*[1]; Hiroyuki Tobo[1]; Yuuki Hagio[1]; Michihiro Kuwayama[1]; [1]JFE Steel Corporation

The steel industry in Japan has been working on the projects of “Environmentally Harmonized Steelmaking Process Technology Development (COURSE50)”. COURSE50 aims at developing technologies to reduce CO2 emissions by approximately 30%. As one of the projects, JFE Steel Corporation has been developing sensible heat recovery process from steelmaking slag. Molten slag, which is also generated in steel plants, has high temperature, but its energy has not been harnessed. To recover the thermal energy from the slag and to apply to separation of CO2 are economical and environmental conscious ways because CO2 separation technology requires an enormous amount of energy. In our process, molten slag is solidified continuously on water-cooled roll and the solidified slag plates are charged into counter-current heat recovery equipment. In laboratory scale experiments, more than 30% heat recovery ratio was optimizing by controlling the thickness of slag. This research was carried out as NEDO project.

3:50 PM
Dry Granulation of Molten Blast Furnace Slag and Heat Recovery from Obtained Particles: *Qin Yuelin*[1]; Lv Xuewei[1]; Bai Chenguang[1]; Qiu Guibao[1]; [1]College of Materials Science & Engineering, Chongqing University

Blast furnace slag (BFS), is the main by-product in the ironmaking process, which contains large amounts of sensible heat. To recover the sensible heat, this paper described the hot experiments which were carried out in a rotary multi-holes cup atomizer, where the molten BFS was transformed into granules without water impingement; subsequently, a new method—pyrolysis the printed circuited board (PCB) with the hot BFS particle, was proposed for recovering the sensible heat in this study. The gaseous products were analyzed by gas analyzer. The residual of the PCB was analyzed by FT-IR and XRD respectively, and the obtained slag particles were analyzed by XRD. The results showed that it is a feasible process of pyrolyzing PCB powder with the hot BFS particle. The sensible heat of hot BF slag could be converted to chemical heat and a large amount of combustible gas could also be generated during the process.

4:05 PM
The Environment Load Assessment of Iron and Steel Producing BF-BOF and EAF Route Process: *Hongxu Li*[1]; Shengli Tao[1]; Hao Bai[1]; Daqiang Cang[1]; [1]University of Science and Technology

The life cycle inventory was compiled and assessment model based on Gabi software was established. Environmental impact of two different routes of BF-BOF and the EAF were analyzed respectively and intercompared. The results show that the EAF route is superior to the traditional BF-BOF route on almost all the environmental impact indexes, which including acidification potential, eutrification potential, global warming potential, ozone depletion potential, etc. In the whole life cycle of BF-BOF route in China, the transporting process ranks the biggest contribution to the overall global warming potential, which caused by fossil fuel burning of transporting vehicles during the long distance from Australia to China. Apart from transporting process, Coking, blast furnace and iron mining processes could induce great environmental problems, while for the EAF route, the electricity consumption is considerable, which causing large amount of CO2 emission indirectly. Based on the analysis, several further countermeasures were proposed.

4:20 PM
Aluminum Smelter Waste Heat Recovery Plant (Heat Exchangers Fouling and Corrosion-A Detailed Investigation): *Hadi Fanisalek*[1]; Mohsen Bashiri[1]; Reza Kamali[1]; [1]Hormozal

The main bottleneck for primary aluminum production industry is dealing with a huge amount of input energy. The fact is that part of provided energy to aluminum production smelters will be lost as waste heat and it never used for aluminum production. One part of waste heat is escaping from the potroom exhaust gases, which was studied for possible recovery in a desalination plant to produce distilled water and the paper was presented in 2011 TMS Annual Meeting. However, it was shown that waste heat recovery plant to produce distilled water is highly profitable but the main fact is that the exhaust gases from potroom are highly corrosive, abrasive and dusty. The main challenge for desalination plant construction, which is using aluminum smelter exhaust gases as the main heat source, is the highly corrosive environment that makes the situation difficult and complicated for equipments design and plant construction. In this paper, we are trying to study a detailed investigation regarding the heat exchangers fouling, corrosion in heat exchangers including heat exchangers' material, how often we need to shut down the plant for maintenance or cleaning, and plant thermal efficiency with considering fouling.

Magnesium Technology 2012: Energy and Biomedical / Primary Production

In-Vitro Corrosion Studies of Bioabsorbable Magnesium Alloys: *Puneet Gill*[1]; Norman Munroe[1]; [1]Florida International University

In this investigation, the electrochemical degradation of various cast manufactured binary, ternary and quaternary magnesium alloys were studied in accordance with (ASTM G 102-89) and by immersion test (ASTM G 31-72) in simulated body fluid (SBF) and SBF with amino acids at 37°C. Hydrogen evolution from each alloy was measured under simulated body conditions and the concentration of metal ions in the medium after each corrosion test was determined by inductive coupled plasma mass spectroscopy (ICP-MS). The change in surface morphologies, composition and the microstructure of the alloys were observed before and after corrosion tests by scanning electron microscopy (SEM), X ray diffraction (XRD) and transmission electron microscopy (TEM).

2:20 PM
High-Capacity Hydrogen-Based Green-Energy Storage Solutions for the Grid Balancing: *Fabrizio D'Errico*[1]; Adamo Screnci[2]; [1]Politecnico di Milano; [2]Mc Phy Energy SA

One of the current main challenges in green-power storage and smart grids is the lack of effective solutions for accommodating the unbalance between renewable energy sources, that offer intermittent electricity supply, and a variable electricity demand. Energy management systems have to be foreseen for the near future, while they still represent a major challenge. Integrating intermittent renewable energy sources, by safe and cost-effective energy storage systems based on solid state hydrogen is today achievable thanks to recently some technology breakthroughs. Optimized solid storage method made of magnesium-based hydrides guarantees a very rapid absorption and desorption kinetics. Coupled with electrolyzer technology, high-capacity storage of green-hydrogen is therefore paracticable. Besides these aspects,magnesium has been emerging as environmentally frend energy storage method to sustain integration, monitoring and control of large quantity of GWh from high capacity renewable generation in the EU.

2:40 PM
Reaction Sintering of Mg2Si Thermoelectric Materials by Microwave Irradiation
: *Zhou Cai*[1]; Bai Guang[2]; [1]Chongqing University of Science and Technology; [2]Chongqing University

In order to reduce the oxidizing and volatilizing caused by Mg element in the traditional methods for synthesizing Mg2Si compounds, solid state phase reaction at low temperature was introduced by microwave field. XRD was used to characterize the powders. At the same time, the influences of parameters during the synthesis processing were discussed. The results suggest that the heating profile is also dependent on the initial green density and higher green density provides lower heating rate while power setting are fixed and the oxidation of Mg can be rest rained by changing microwave heating programs. It was found that high purity Mg2Si intermetallic compound can be obtained with excessive content of 8at% Mg from the stoichiometric Mg2Si, 853K and 30 min.

3:00 PM
Charge-Discharge Mechanism of MgC Powders and Mg-Li Alloy Thin Film Materials: *Yen-Ting Chen*[1]; Fei-Yi Hung[2]; Truan-Sheng Lui[2]; Ren-Syuan Xiao[1]; Yi-Wei Tseng[1]; Chih-Hsien Wang[2]; [1]Institute of Nanotechnology and Microsystems Engineering, Center for Micro/ Nano Science and Technology, National Cheng Kung University, Tainan, TAIWAN 701.; [2]Department of Materials Science and Engineering, National Cheng Kung University, Tainan, TAIWAN 701.

Magnesium-carbon powders and Magnesium-lithium powders were used as the anode materials for lithium ion batteries to investigate the structure and electrochemical behavior in room temperature. The composition of Mg-C powders contained 1:1 and 9:1. The powders and the thermal evaporated films of Mg-10Li were compared with Mg-C systems. In addition, Mg-10Li thermal evaporated film was used as the experimental materials to process the annealing treatment. The results show that Mg-C powders system had the interface effect of a Cu foil to reduce the electrochemical reaction. With increasing the carbon powder content, the charge-discharge characteristics of Mg-C powders was raised. Notably, the Mg-10Li specimen had better cycling properties than that of Mg-50C (1:1). After annealing at 200°C for 1hr, Mg-10Li alloy film not only increased the capacity, but also improved the charge-discharge cyclability.

Control of Yttrium Diffusion Out of Yttria Stabilized Zirconia During SOM Electrolysis for Magnesium Production: *Eric Gratz*[1]; Soobhankar Pati[2]; Jarrod Milshtein[1]; Adam Powell[2]; Uday Pal[1]; [1]Boston University; [2]Metal Oxygen Separation Technologies

The solid oxide membrane (SOM) process has been used to produce magnesium by direct electrolysis of its oxide. In this process MgO is dissolved in a molten CaF2-MgF2 flux and an yttria-stabilized zirconia (YSZ) SOM membrane separates the cathode and the flux from the anode. YSZ membrane stability limits the operating life of the SOM electrolyzer. The YSZ membrane is known to degrade due to diffusion of yttrium into the flux. Yttrium diffusion can however be decreased by adding YF3 to the flux. This study investigates the long-term stability of the YSZ membrane. Yttrium composition profiles in the YSZ membrane were determined using WDS as a function of immersion time and YF3 content in the flux. An analytic solution to the diffusion equation was used to model the diffusion process. This study allows the determination of the optimum YF3 content needed in the flux to minimize yttrium diffusion and increase membrane stability to be determined.

4:00 PM
Study on the Thermodynamic and Experimental Carbothermic Reduction of Garnierite: *Tao Qu*[1]; Yang Tian[1]; Bin Yang[1]; Bao-Qiang Xu[1]; Da-Chun Liu[1]; Yong-Nian Dai[1]; [1]National Engineering Laboratory for Vacuum Metallurgy, Kunming University of Science and Technology

The overall utilization of magnesium and other metals should be systematically considered during the exploration of deficient garnierite. In this paper the thermodynamic analysis of the carbothermic reduction process for extracting metal magnesium from garnierite in vacuum was carried out to investigate its feasibility.The calculation results indicate that it is feasible technically that the carbothermic reduction process for extracting metal magnesium from garnierite in vacuum. Under the temperature of 1500°C and vacuum degree is less than 300Pa, metal magnesium was obtained. The Nickel content in residue is more than twice as garnierite ore.

4:20 PM
Mechanism of Carbothermic Reduction of Magnesia and Reverse Reaction: *Yang Tian*[1]; Tao Qu[1]; Bin Yang[1]; Hong-Xiang Liu[1]; Cheng-Bo Yang[1]; Yong-Nian Dai[1]; [1]Kunming University of Science and Technology

Abstract: In this paper, the mechanism of the carbothermic reduction process to extract magnesium from magnesia and the reversion reaction in vacuum were investigated. The carbon monoxide (CO) content of the gas, phases of the condensing product, surface morphology of the reduction slag and phase of the distillation product were measured by means of gas chromatography (GC), XRD, and SEM. The experimental results indicated that Mg is generated by magnesia and carbon at 1623K and 30~100Pa in the carbothermic reduction process.The main gas in carbothermic reduction process is carbon monoxide, no carbon dioxide occurred at any reaction time, the reduction reaction is MgO(s)+C(s)=Mg(g)+CO(g). The gas-phase reversion will commence as soon as a saturated gas mixture is cooled. The reversion reactions are favored below 1373K.The distillation product by vacuum distillation process produced a high purity metal magnesium product, it can be deduced that reversion reaction occured at low temperature and 30~100Pa during carbothermic reduction. Through the calculation of reversion reaction, the peak value of γ is less than 9%.

Magnesium Technology 2012: Processing-Microstructure-Property Relationships II

2:00 PM
Enhancement of Strength and Ductility of $Mg96Zn_2Y_2$ Rolled Sheet by Controlling Structure and Plastic Deformation: *Masafumi Noda*[1]; Yoshihito Kawamura[2]; Hiroshi Sakurai[2]; Kunio Funami[3]; [1]Chiba Institute of Technology; [2]Department of Materials Science, Kumamoto University; [3]Department of Mechanical Science and Engineering, Chiba Institute of Technology

Mg-Zn-Y alloys are well known that dramatically enhanced strength during plastic deformation because the kink bands formed in the LPSO phase. On the other hands, high strength Mg-Zn-RE alloy is achieved by an extrusion process it was difficult to know a development of LPSO and Alpha Mg Phases during processing. In this present study, the effect of fine dispersed LPSO and alpha Mg phase on development of high strength Mg-Zn-Y rolled sheet a few pass schedules and its mechanical properties and the thermal stability were investigated. The tensile yield strength and elongation of Mg-Zn-Y rolled sheets achieved to 360 MPa and 5 % at 673 K and 4 pass used by thermo-mechanical controlled processing, respectively. On the other hands, tensile yield strength decreases while elongation improves in 623K or more so that alpha Mg phase grain growth and kink bands induced LPSO phase recovere.

2:20 PM
Microstructural Characteristics of High Rate Plastic Deformation in Elektron WE43 Magnesium Alloys: *Joseph Hamilton*[1]; Sarah Brennan[1]; Yongho Sohn[1]; Brunce Davis[2]; Rick DeLorme[2]; Kyu Cho[3]; [1]University of Central Florida; [2]Magnesium Elektron North America; [3]US Army Research Laboratory

High strain rate deformation of WE43 magnesium alloy was carried out by high velocity impacts, and the characteristics and mechanisms of microstructural damage were examined. Six samples were subjected to a variety of high velocity impact loadings that resulted in both partial and full damage. Optical, scanning and transmission electron microscopy analyses were performed in order to identify regions of shear localization. These regions were used to map, both quantitatively and qualitatively, the effects of deformation on the microstructure. Shear localization was observed in every sample, and its depth was measured. Evidence of shear localization was observed to a greater extent in samples with partial damage while fracturing was observed more frequently in samples with full damage.

2:40 PM
Microstructure and Mechanical Properties of As-Extruded Mg-Sn-Al-Zn Alloys: *Sung Hyuk Park*[1]; Young Min Kim[1]; Chang Dong Yim[1]; Ha-Sik Kim[1]; Bong Sun You[1]; [1]Korea Institute of Materials Science

Mg-xSn-yAl-1Zn (x=5, 6, 7 and 8 wt.%, x+y=9 wt.%) alloys were subjected to indirect extrusion and the extruded bar was examined by scanning electron microscopy, transmission electron microscopy, electron backscatter diffraction (EBSD) and X-ray diffraction. Tensile and compressive tests at room temperature were performed parallel to extrusion direction to assess the tension-compression asymmetries in yield behavior. The results showed that the basal texture are basically similar, however, the grain size decreases and the amount of fine particles such as Mg2Sn phase increase with increasing the Sn content. Mg-8Sn-1Al-Zn alloy, which has a higher number of particles and smaller grain size, showed the highest yield strength due to the combined effects of grain boundary hardening and precipitation hardening. While, Mg-5Sn-4Al-1Zn alloy exhibited a lower degree of yield asymmetry because twinning was retarded during compression by fine particles of Mg17Al12 phases formed on the non-basal plane.

3:00 PM
Tensile Properties of Three Preform-Annealed Magnesium Alloy Sheets: *Junying Min*[1]; Jon Carter[2]; Ravi Verma[2]; [1]Tongji University; [2]GM R&D

Automotive structural application of magnesium alloy sheet has been hindered by the low room-temperature formability of typical sheets. One approach to effectively increase formability is to change the forming process from one which involves a single stamping hit to one which utilizes two hits plus an intermediate anneal (i.e., "preform anneal process"). In this paper, the preform annealing behavior of three rolled sheets was studied using uniaxial tensile tests. The sheets studied were: conventionally rolled (CR) AZ31B, CR ZEK100, and specially rolled (SPR) AZ31B. The preform annealing process was found to increase the total elongation of all three sheets compared to the elongation in the annealed O-temper. The CR ZEK100 with a thickness of 1.5 mm showed more attractive tensile properties than the 1.6 mm CR AZ31B. Although the SPR AZ31B has a thickness of only 0.7 mm, it still has elongation comparable to the 1.6 mm CR AZ31B.

3:20 PM
The Role of Intermetallics on Creep Behaviour of Extruded Magnesium Alloys: Michelle Fletcher[1]; Lukas Bichler[1]; *Dimitry Sediako*[2]; [1]UBC Okanagan; [2]NRC - CNRC

This study analyzed six extruded high performance magnesium alloys (AE33, AE42, AJ32, AX30, EZ33 and ZE10) developed for elevated temperature applications. In-Situ Neutron diffraction was used to determine alloy tensile and compressive creep behavior at 150 and 175°C in the radial as well as transverse directions to determine the effect of texture on creep performance. The aluminum containing alloys exhibited larger creep strains than the EZ and ZE alloys; the highest strain was seen by AE33 of 9.9% compared to 0.2% exhibited by ZE10. Microstructure analysis has shown that the distribution and composition of secondary phases is critical for creep resistance. The aluminum containing alloys have acicular and globular intermetallics, whereas the EZ and ZE alloys contain fine and irregular intermetallics which effectively pinned grains under high temperature stresses. Significant recrystallization was also apparent in the aluminum containing alloys but was not observed in the EZ and ZE alloys.

4:00 PM
High Performance Mg-System Alloys for Weight Saving Applications: First Year Results from the GREEN METALLURGY EU Project: *Fabrizio D'Errico*[1]; Gerardo Garces Plaza[2]; Markus Hofer[3]; Shae Kim[4]; [1]Politecnico di Milano; [2]Centro Nacional de Investigaciones Metalúrgicas; [3]Buhler AG; [4]Korea Institute of Industrial Technology

The GREEN METALLURGY Project, a LIFE+ project co-financed by the EU Commission, has just concluded its first year. The Project seeks to set manufacturing processes at a pre-industrial scale for nanostructured-based high-performance Mg-Zn(Y) magnesium alloys. The Project's goal is the reduction of specific energy consumed and the overall carbon-footprint produced in the cradle-to-exit gate phases. Preliminary results addressed potentialities of the upstream manufacturing process pathway. Two Mg-Zn(Y) system alloys with rapid solidifying powders have been produced and directly extruded for 100% densification. Examination of the mechanical properties showed that such materials exhibit strength and elongation comparable to several high performing aluminum alloys; 390 MPa and 440 MPa for the average UTS for two different system alloys, and 10% and 15% elongations for two system alloys. These results, together with the low-environmental impact targeted, make these novel Mg alloys competitive as lightweight high-performance materials for automotive components.

4:20 PM
Effect of Extrusion Conditions on Microstructure and Texture of Mg-1% Mn and Mg-1% Mn-1.6% Sr Alloys: *Hemant Borkar*[1]; Mihriban Pekguleryuz[1]; [1]McGill University

Mg-1% Mn (M1) and Mg-1% Mn-1.6% Sr alloys have been subjected to hot extrusion and the effect of extrusion conditions on the microstructure and texture has been investigated. Addition of Sr to M1 alloy refines the extruded microstructure. Two different ram speeds of 4 mm/s and 8 mm/s and two different temperatures of 300°C and 350°C have been used in the study. The extent of recrystallization increases with increasing ram speed. The texture of extruded M1 weakens with Sr addition. The mechanism of texture weakening is suggested to be PSN with formation of new grains having orientations different than that of parent grains.

4:40 PM
On the Deformed Microstructure of Rolled Mg-2.9Y: *Amir Farzadfar*[1]; Mehdi Sanjari[1]; In-Ho Jung[1]; Elhachmi Essadiqi[2]; Stephen Yue[1]; [1]McGill University; [2]CANMET

The hot and cold rolled microstructures of a Mg-2.9Y alloy were examined by means of metallography, X-ray texture measurement and EBSD technique. It is found that Y in solid solution suppresses dynamic recrystallization even at 450 °C. After rolling, a heterogeneous microstructure containing twins and bands is obtained. The bands were found to originate form double and compression twins, and are locations of high stored energy. The bulk texture of the rolled material consists of the typical basal component, and also a component from the ND towards the TD. The latter component results from the presence of parent grains with c-axis along the TD. The strain is accommodated in such parent grains by extension twinning and possibly prismatic slip. At all rolling temperatures, internal strain exhibits a relatively uniform distribution, indicating that all grains contributed to the deformation.

Materials and Fuels for the Current and Advanced Nuclear Reactors: Nuclear Fuels and Materials

2:00 PM
Neptunium Oxide Reduction Technique: *Leah Squires*[1]; Paul Lessing[1]; James Stuart[1]; Bryan Forsmann[2]; [1]Idaho National Laboratory; [2]Boise State University

A process to reduce neptunium oxide (NpO_2) to neptunium metal was developed. NpO_2 is combined with calcium and heated to temperatures between 650°C and 850°C under argon. Three successful trials were conducted to yield a total of approximately 20 g of neptunium with purity estimated greater than 97%. The metal is needed to determine important thermal and phase properties of binary neptunium systems as well as fresh metallic fuels that simulate the compositions of recycled fuel. The process development was necessary since most of the neptunium available is present as the oxide. Future efforts are planned for understanding the process parameters in relation to neptunium purity, and for purifying the metal produced.

2:20 PM
Enthalpy of gamma-delta Transition in Ternary U-Pu-Zr Fuel Alloys: *Cynthia Papesch*[1]; Thomas O'Holleran[1]; Robert Mariani[1]; Matthew Cromwell[2]; [1]Idaho National Laboratory; [2]University of Idaho

Several ternary nuclear fuel alloys were investigated using differential scanning calorimetry. The results were evaluated using a curve-fitting routine, and the enthalpies of individual phase transitions were determined. Individual transitions were assigned with reference to published ternary phase diagrams, and a compositional analysis for the partial transformations of each alloy allowed the first determination of the gamma-delta transition enthalpy for the ternary fuel alloys. These results agree with prior research for binary fuel alloys that found the enthalpy to be approximately 5 kJ per mole with some variation depending on the exact composition within the broad delta-UZr2 phase range. The comparable results suggest that the heat of solution for the zirconium in the ternary delta-phase is similar to that for zirconium in the binary delta-phase, which might be expected; however it is possible that the activities of Pu and Zr in the delta phase may be self-compensating.

2:40 PM
Microstructural Analysis of Ion-Implanted PyC/ß-SiC: *Rob Coward*[1]; Shyam Dwarknath[2]; Mitra Taheri[1]; [1]Drexel University; [2]University of Michigan

Common metallic fission products, such as Ag, diffuse through PyC/SiC to create precipitates in the SiC zinc blende structure. In this work, the effect of ion implantation of Ag on pyrolitic carbon (PyC) coated CVD ß-silicon carbide (SiC) was studied using X-ray photoelectron spectroscopy (XPS), electron backscatter detection (EBSD), Auger electron spectroscopy (AES), and transmission electron microscopy (TEM). The PyC coated ß-SiC samples were implanted with 400 keV

Ag at 22°C to a fluence of 1 x 1016 atoms/cm2, which corresponds to a peak of 1.25 atom % at a depth of approximately 170 nm into the PyC. The samples were then annealed at temperatures of 1600°C, 1300°C, 1100°C and examined using XPS, EBSD, AES, and TEM to verify the microstructural evolution and also to examine preferential segregation of the implanted Ag along specific grain boundaries.

3:00 PM
Role of Microstructure on Ag and Cs Diffusion in SiC: *Tyler Gerczak*[1]; Todd Allen[1]; [1]University of Wisconsin-Madison

TRIstructural-ISOtropic fuel has been identified as the fuel of choice for the very high temperature gas cooled reactor. In the fuel design the SiC layer is the main fission product barrier, however Ag and Cs fission products have been observed to release from intact particles resulting in safety and operational issues. The release has been suggested to be dictated by the SiC microstructure. To understand Ag and Cs diffusion in TRISO, we simulated diffusion via ion implantation diffusion couples exposed to elevated temperature. The effect of microstructure is understood by investigating diffusion in various SiC substrates, single crystal and polycrystalline SiC. Depth profiles measured by SIMS suggest grain boundary diffusion to be a fast diffusion pathway. The role of individual grain boundaries will be investigated by atom probe tomography to understand the contribution of grain boundary character on diffusion.

3:20 PM
Grain Size Dependence of Radiation Response in Silicon Carbide: *Laura Jamison*[1]; Peng Xu[1]; Kumar Sridharan[1]; Todd Allen[1]; [1]University of Wisconsin-Madison

Silicon carbide is of interest in nuclear systems as a structural material or as a diffusion barrier coating material in TRISO fuel particles because of its stability at high temperatures. Nanocrystalline silicon carbide (ncSiC) is of particular interest because the increased concentration of grain boundaries may cause the material to be more radiation resistant. The goal of this research is to compare the behavior of ncSiC and micron-scale grain size SiC under ion irradiation. To accomplish this, nanopowder SiC samples and bulk CVD SiC samples were irradiated with Kr+ ions in an in-situ irradiation experiment. Additionally, the synthesis of bulk ncSiC by spark plasma sintering SiC nanoparticles is being investigated. Results of experiments to achieve satisfactorily high bulk densities while maintaining nanometer-scale grains will be presented. This work is supported under a DOE-NEUP Graduate Fellowship, DOE-BES grant DE-FG02-08ER46493, and utilized NSF-supported shared facilities at the University of Wisconsin-Madison.

3:40 PM Break

3:50 PM
Silver Diffusion in PyC Coated ß-SiC: *Shyam Dwaraknath*[1]; Gary Was[1]; [1]University of Michigan

Understanding the mechanism and quantifying the rate by which silver diffuses through CVD ß-silicon carbide (SiC) is crucial to the success of the TRISO fuel design. The diffusion of Ag was studied using Rutherford backscattering spectrometry (RBS) on a novel specimen design. Thin (~300 nm) films of highly anisotropic pyrolitic carbon (PyC) were deposited on CVD ß-SiC specimen. The PyC films were subsequently implanted with 400 keV Ag at 22°C to a dose of 1 x 16 cm-2, which corresponds to a peak of 1.25 atom % at a depth of approximately 170 nm into the PyC layer. A 10 nm Mo cap was then deposited by electron beam evaporation to retain the implanted Ag in post-deposition annealing treatments. RBS was used to determine the Ag composition profiles as a function of annealing temperature: 1600°C, 1300°C, 1100°C, from which diffusion coefficients were calculated.

4:10 PM
Mechanism of Proton Irradiation-Induced Creep of Pyrolytic Carbon: *Anne Campbell*[1]; Gary Was[1]; [1]University of Michigan

Determining the mechanism of irradiation-induced creep of pyrolytic carbon is critical to predicting the integrity of the TRISO fuel particles for the Generation-IV Very High Temperature Reactor. Proton irradiation-induced creep experiments have been performed on graphite samples to provide a baseline for comparison of the pyrolytic carbon behavior. The experiments performed on graphite show a linear dependence on both applied stress and dose rate. The irradiation-induced creep behavior of the pyrolytic carbon will be presented and compared with the graphite behavior at similar stress, dose rate, and temperature ranges. Finally a mechanism will be proposed that describes the proton irradiation-induced behavior of pyrolytic carbon. The mechanism will be supported with analysis of the effect of irradiation-induced creep on the sample anisotropy, density, and Young's modulus.

4:30 PM
Gas Evolution from Lithium Hydride During X-Irradiation: *Carol Haertling*[1]; Joseph Tesmer[1]; Yongqiang Wang[1]; William McAlexander[1]; [1]Los Alamos National Laboratory

Lithium hydride (LiH) is a highly reactive solid that may be used in radiation environments, where ionizing radiation is present that can disrupt the structure of a material. This disruption creates defects and can produce gases, most obviously H2 gas; irradiation of LiH corrosion products may produce further gases. We have performed introductory experiments to determine the effects of radiolysis on LiH and its ubiquitous hydrolysis product, LiOH. Our experiments focus on x-ray irradiations. We have used a particle accelerator in the Ion Beam Materials Laboratory to produce characteristic x-rays at desired energies from metal targets. During irradiation, evolved gases were measured, particularly H2, and quantified. Our data allows prediction of concentrations that could be released over time.

4:50 PM
Study of MnO_2/Ag_2O Mixture for an Efficient Trapping of Hydrogen: *Kevin Galliez*[1]; Philippe Deniard[2]; David Lambertin[1]; Stephane Jobic[2]; Florence Bart[1]; [1]CEA; [2]CNRS

Management of explosion risk from hydrogen produced by radiolysis of organic compounds in waste packages is a major problem for the safety of radioactive wastes transportation. This risk can be minimized through the use of a hydrogen getter. Different getters exist to trap hydrogen: organic materials, recombiners, hydrides and mineral oxides. Among different mineral oxides MnO_2/Ag_2O mixture forming the so called getter has been selected. MnO_2 plays the role of a trap whereas Ag_2O that of the promoter. In the MnO_2 family the nsutite variety leads to the best efficiency when it is added to 13wt% of Ag_2O, tested under hydrogen/nitrogen atmosphere. Parameters, such as specific area and defects have been studied as well as the role of the promoter. From magnetism measurements the reduction of manganese IV+ to III+ has been clearly evidenced, highlighting a chemisorption process of hydrogen trapping.

5:10 PM
Novel Methods of Hydrogen Isotope Sequestration using Proton Conducting Ceramic Separation Membranes in Next Generation Nuclear Energy Systems: *Kyle Brinkman*[1]; [1]Savannah River National Laboratory (SRNL)

A technical hurdle to the use of high temperature heat from the exhaust produced in the next generation nuclear processes in commercial applications such as nuclear hydrogen production is the trace level of tritium present in the exhaust gas streams. Successful tritium sequestration in situ will make it possible to maximize the heat values available for hydrogen production and other commercial applications in NGNP systems. In addition, tritium collection and confinement is required from next generation fusion machines where a highly tritiated water (HTW) stream could be generated in such processes like vacuum vessel wall conditioning, and cryopump regeneration. This presentation outlines the synthesis and characterization of perovskite based (ABO3) proton conducting ceramic materials for use as hydrogen isotope gas separation membranes and high temperature solid oxide electrolysis cells.

Microstructural Characterization of Activated Materials with Neutron Diffraction: *Donald Brown*[1]; Thomas Sisneros[1]; Paula Mosbrucker[1]; Levente Balogh[1]; [1]Los Alamos National Lab

Diffraction is well suited to the characterization of microstructures. Neutron diffraction, in particular, has some undeniable advantages for studying activated samples. Neutrons penetrate millimeters into most materials, providing a statistically relevant probe of the microstructure in the bulk of the material. Moreover, little or no hazardous and costly sample preparation is necessary, which enables repeat tests on the same sample or even in-situ measurements under simulated operating conditions. Finally, neutron detectors are often insensitive to background gamma radiation emitted from activated samples.The SMARTS diffractometer at the Lujan Center was designed to study engineering materials under their operating conditions and, as such, has sophisticated sample environments enabling in-situ ND studies during deformation and at non-ambient temperatures. This talk will use the example of in-situ diffraction measurements during annealing and deformation of irradiated HT-9 steel to highlight the capabilities of the instrument, in particular, related to the study of activated materials.

2:30 PM

On the Influence of Proton and He Irradiation on Mechanical Properties and Microstructure of Intermetallic Strengthened Steels: *E. Stergar*[1]; Christina Hofer[2]; S. A. Maloy[3]; P. Hosemann[1]; [1]University of California-Berkeley; [2]University of Leoben; [3]Los Alamos National Laboratory

Proper heat treatment of specialized tool-steels (maraging-steels) leads to formation of coherent, nanometer-sized, fine dispersed intermetallic precipitates with a number density of 10^{23}-10^{24} m^{-3}. These number densities are comparable to those of nanostructured alloys which gain their radiation resistance from nanometer sized (oxides) precipitates. In contrast to nanostructured alloys were elaborate and complicated manufacturing processes (powder milling, hipping) are necessary intermetallic precipitates are formed by solution annealing and subsequent heat treatment. Although not suitable for very high temperature applications, recent investigations show promising mechanical properties and thermal stability in radiation environment up to 480\176C. In this work the concept of intermetallic precipitates acting as defect sinks and their evolution under irradiation is explored. For this study Ion beam irradiations were performed to cause radiation damage up to 2 dpa. High resolution post irradiation examination (nanoindentation, TEM, atom-probe) was used to link changes in materials properties and microstructure of different maraging-steels.

2:50 PM

Characterization of Ion Irradiation Effects on the Microstructure of 316 Austenitic Stainless Steel: *Alexandre Volgin*[1]; Bertrand Radiguet[2]; Philippe Pareige[2]; Marie-France Barthe[3]; Pierre Desgardin[3]; Brigitte Décamps[4]; Aurélie Gentils[4]; Cédric Pokor[5]; [1]EDF R&D MMC / GPM UMR CNRS 6634 - Université et INSA de Rouen; [2]GPM UMR CNRS 6634 - Université et INSA de Rouen; [3]CEMHTI CNRS UPR 3079; [4]CSNSM, CNRS-IN2P3, Université Paris-Sud; [5]EDF R&D MMC

Internal structures of Pressure Water Reactors (PWR) are maintained by bolts made of 316 austenitic stainless steel (SS). They are subjected to neutron irradiation, which can lead to the cracking of bolts by the complex phenomenon of Irradiation Assisted Stress Corrosion Cracking (IASCC). One of the origins of IASCC is the evolution of the steel microstructure during irradiation.In order to get a better understanding of irradiation effects on the microstructure of austenitic SS, model alloys (FeCrNi, FeCrNiSi) and 316 austenitic SS were ion irradiated at 200°C and 450°C, up to 5 displacements per atom (dpa). Complementary techniques were used to characterize the steel: Atom Probe Tomography to quantify local chemical changes, Transmission Electron Microscopy to get information about defects clusters (loops and cavities) and Positron Annihilation Spectroscopy to characterize vacancy type defects.The experimental results, obtained in the PERFORM60 European project, will be detailed and discussed in this talk.

3:10 PM

Irradiation Induced Phase Change and Microstructures in X-750 CANDU Spacer Materials: *Ken Zhang*[1]; Colin Judge[2]; Zhongwen Yao[1]; [1]Queen's University; [2]AECL – Chalk River Laboratories

Work on X-750 spacers removed from CANDU reactors has shown the development of many small cavities within the metal matrix and along grain boundaries. To simulate the neutron irradiation induced phase and microstructural changes, in-situ heavy ion irradiations under observation of an intermediate voltage electron microscope (IVEM) are carried out at various temperatures. Apart from dislocation loops, the irradiation damage consists mostly of stacking fault tetrahedra (SFTs), the remaining being unidentified defects. The size and fraction of SFTs appears to be independent of dose. The γ' precipitates were apparently disordered at very low dose (<0.2 dpa) when irradiated at temperature up to 400°C, but stable up to high doses (>6 dpa) at 500°C. Contrary to the evidence collected for ex-service spacers, no voids were observed at all doses and temperatures, indicating that the radiation damage rate and Helium production may influence the formation of cavities.

3:30 PM

Pair Distribution Function Analysis of Irradiated Cladding and Duct Reactor Materials: *Avishai Ofan*[1]; Simerjeet Gill[1]; Stuart Maloy[2]; Lars Ehm[1]; Lynne Ecker[1]; [1]BNL; [2]LANL

Ferritic-martensitic (F/M) steels have properties such as low swelling, low activation, resistance to embrittlement and hardening, and good corrosion resistance thus making them good candidates' materials for Generation IV reactors. To qualify candidate materials for nuclear structural materials for Generation IV reactors their response to long term irradiation to high doses at high temperatures should be investigated. Total scattering and pair distribution function (PDF) analysis are useful for atomic structure analysis of materials with high degree of disorder, thus making them promising techniques for studying phase transition and defects in irradiated steels. In this presentation we will discuss the microstructure of the F/M HT9 steel duct taken from representative locations of the ACO-3 duct of Fast Flux Test Facility (FFTF) after long term irradiation up to a dose of 147 dpa and temperatures from 416 to 504°C based on XRD and PDF analysis results.

3:50 PM Break

4:00 PM
Toward a Better Understanding of the Hydrogen Impact on the Radiation Induced Growth of Zirconium Alloys: *Lea Tournadre*[1]; Fabien Onimus[1]; Jean-Luc Bechade[1]; Didier Gilbon[1]; Jean-Marc Cloue[2]; Jean-Paul Mardon[2]; Xavier Feaugas[3]; Ovidiu Toader[4]; [1]CEA; [2]AREVA; [3]Laboratoire d'Etude des Matériaux en Milieux Agressifs (LEMMA); [4]Michigan Ion Beam Laboratory (MIBL)

Under neutron irradiation, recrystallized zirconium alloys, used as structural materials for Pressurized Water Reactor fuel assemblies, undergo stress-free growth which accelerates for high irradiation doses. This acceleration is correlated to the formation of c-component vacancy dislocation loops. Some feedbacks from neutron irradiations show that the in service hydrogen pick-up could influence the fuel assembly radiation-induced elongation. 2 MeV proton irradiations were performed on as received and pre-hydrided materials in M5® and recrystallized Zircaloy-4. The irradiations were conducted on a Tandem Accelerator (MIBL/University of Michigan) at 623K up to three doses. Observations by Transmission Electron Microscopy show, in some cases, a significant impact of the hydrogen content on densities and distributions of the c-component loop microstructures. For both grades, the c-component loops evolution with dose will be examined and compared to the neutron irradiated microstructures. Then, the role played by hydrogen in solid solution and as precipitated hydrides will be discussed.

4:20 PM
Influence of Copper Level on Neutron Irradiation Effects in Low Copper Pressurized Water Reactor Vessel Steels: *Hefei Huang*[1]; Bertrand Radiguet[1]; Patrick Todeschini[2]; François Clémendot[3]; Philippe Pareige[1]; [1]GPM UMR CNRS 6634 - Université et INSA du Rouen; [2]EDF R&D MMC; [3]EDF-CEIDRE

Neutron irradiation results in hardening and embrittlement of Reactor Pressure Vessel (RPV) steels. To guarantee safe operation of reactors, this embrittlement has to be conservatively evaluated. Since it is linked with the microstructure evolution of the steel (formation of solute clusters, point defects clusters …), microstructural data on irradiated steels bring information on the validity of the models used for embrittlement prediction. So different base metals from French RPV surveillance program (neutron irradiation in production reactor conditions) were characterised at atomic scale, by Atom Probe Tomography. The evolution of solute cluster characteristics as a function of neutron fluence (up to doses corresponding to 40 years of operation) were characterised. The comparison between results obtained on several French fleet RPV steels provides information about the effect of small variation of nominal copper level. Experimental results are compared with the latest correlation used for the embrittlement assessment of French RPV fleet.

4:40 PM
A Synchrotron X-ray Diffraction and Transmission Electron Microscopy Study of Ion-Implantation Induced Microstructure Evolution on the Nuclear-Grade Graphite: E-Wen Huang[1]; *Chang Chung-Kai*[2]; Shuo-Cheng Tsai[3]; Ji-Jung Kai[3]; [1]Department of Chemical & Materials Engineering and Center for Neutron Beam Applications, National Central University; [2]Cental University; [3]Department of Engineering and System Science, National Tsing-Hua University

We simulate the neutron-irradiation damage on nuclear-grade graphite by C2+ ion-implantation. The graphite was artificially irradiated with 3 MeV C2+ ion to mimic the fast neutron-radiation damage of the High Temperature Gas-cooled Reactor (HTGR) core environment. The irradiation temperature were controlled at 600°C and 900°C in a high vacuum environment of 10-7 torr, respedively. The irradiation effect induced the graphite damage and caused the undesirable change in internal engery, microstructure and physical property – called Wigner effect. We quantify the structural integrity of the graphite with/without iradiation via synchroton x-ray diffraction experiments and High-Resolution Transmission Electron Microscopy (HRTEM). The results reveal the microstructure development subjected to the combination of the irradiation and high temperature effects. We described the standard deviation of d-spacing changing from irradiation effect at different temperature as disorder coefficient of d-spacing to discuss the mechanism of deformation by synchrotron x-ray diffraction and High-Resolution Transmission Electron Microscopy.

5:00 PM
Investigating the Dissolution of Oxide Particles in ODS Steels under Irradiation: *Ceri Williams*[1]; Emmanuelle Marquis[2]; Paul Bagot[1]; George Smith[1]; [1]University of Oxford; [2]University of Michigan

Oxide-dispersion-strengthened ferritic steels are candidate materials for structural applications in fusion power plants. A dispersion of ~2nm oxide nanoclusters maintains strength at high temperatures (~650°C), and stabilises the microstructure under irradiation. The majority of research reports no significant change to the nanoclusters after irradiation however, Allen et. al. have shown a reduction in particle size after ion irradiation up to doses of 150 dpa at 500–700°C (Journal of Nuclear Materials 2008, vol.375 p.26-37). To clarify the effect of temperature on the stability of the oxide dispersion, we use Atom Probe Tomography (APT) and TEM to characterise a 14Cr-2W-0.3Ti ODS alloy after Fe2+ ion implantation (5dpa up to 500°C). A significant reduction in mean particle size is observed at low temperatures. The mechanisms of particle dissolution will be discussed, together with the validity of using ion implantation as an analogue for fusion reactor conditions.

5:20 PM
Effects of Neutron Irradiation on Select MAX Phases: *Darin Tallman*[1]; Elizabeth Hoffman[2]; Dennis Vinson[2]; Robert Sindelar[2]; Gordon Kohse[3]; Michel Barsoum[1]; [1]Drexel University; [2]Savannah River National Lab; [3]Massachusetts Institute of Technology

Gen IV nuclear reactors need materials that can withstand harsher environments than in current reactors. The Mn+1AXn (MAX) phases are a group of layered machinable ternary compounds, where M is an early transition metal, A is a group 13 to 16 element, and X is C and/or N. These compounds possess mechanical properties atypical for ceramics, notably thermal conductivity and plasticity at high temperatures. Data about their irradiated properties are required to fully realize their potential. Research is thus ongoing to characterize their irradiated properties. The post-irradiated characterization of samples irradiated to 0.1 dpa will be presented, including TEM analysis of microstructure, and electrical resistivity.

5:40 PM
TEM Analysis of the Microstructure Evolution in Ion Irradiated Austenitic Stainless Steels: *Alexandre Volgin*[1]; Cedric Pokor[1]; Brigitte Decamps[2]; Aurelie Gentils[2]; Bertrand Radiguet[3]; Philippe Pareige[3]; Abderrahim Al-Mazouzi[1]; [1]EDF R&D; [2]Centre de Spectrométrie Nucléaire et de Spectrométrie de Masse CNRS-IN2P3; [3]Groupe de Physique des Matériaux UMR CNRS 6634

Austenitic stainless steels are widely used in nuclear power plants as internal structures of PWR. These steels are subjected to severe irradiation and temperature conditions. Understanding of microstructural changes of austenitic steels due to these conditions is an important task for safety and life-extension reasons. Ni ion irradiation on thin foils and in bulk is done in CSNSM-Orsay on commercial purity 316L and model FeNiCr alloy to a dose of 5 dpa at 450°C. These conditions are representative of several operational years. A detailed defect analysis (dislocation loops, cavities, induced phases) is performed by TEM techniques combination and discussed in the two alloys. TEM studies are associated with APT, detailed in an other paper. A special attention is ported on the differences in defects accumulation between both type of irradiated samples (thin and bulk). This work is done as a part of the FP7 European Collaborative project Perform60.

Minerals, Metals and Materials under Pressure: New Materials and Properties

2:00 PM Invited
Pressure Stabilized Alkali Metal Polyhydrides: *Eva Zurek*[1]; [1]University at Buffalo, SUNY

Stabilization of solid phases with unusual stoichiometries and unexpected electronic structures may be achieved by applying external pressure. Theoretical work has predicted that LiH_6 and LiH_2 become particularly stable phases at about 100 GPa. NaH_9 is predicted to be the most stable combination of Na and H by 25 GPa. These hydrogen-rich materials with nontraditional stoichiometries are computed to undergo an insulator to metal transition at a pressure lower than that necessary to metalize hydrogen. The evolutionary algorithm XtalOpt has been employed to search for the most stable stoichiometries of the heavier alkali polyhydrides as well confirming that under pressure there is an increased tendency to form multicenter bonds.

2:30 PM
Polaron Hopping in LiFePO4 at Elevated Pressures and Temperatures: *Lisa Mauger*[1]; Sally Tracy[1]; Jorge Munoz[1]; Hongjin Tan[1]; Hillary Smith[1]; Brent Fultz[1]; [1]California Institute of Technology

LiFePO4 has high technological potential as a Li-ion battery cathode material but it suffers from low electrical conductivity resulting from a large electronic band gap. Electron conduction in LiFePO4 occurs via small polaron hopping between Fe sites. Synchrotron Mossbauer Spectroscopy (SMS) was used to measure the hyperfine fields of $Li_{x=0.6}FePO4$ at elevated temperatures and pressures in an externally heated diamond anvil cell. The polaron hopping frequency was studied by analyzing the lifetime effects evident in the quadrupole splitting signal of the various Fe valence states. The observed polaron hopping rate increases with temperature, but applied pressure suppresses the onset of this behavior. The polaron activation energy and activation volume are extracted by examining the temperature evolution of the SMS patterns at different pressures. The positive polaron activation volume in LiFePO4 will be discussed along with its implications for improving the electrical conductivity of this material.

2:50 PM
Effect of Pressure on the Critical Resolved Shear Stress of MgO Single Crystal: Insights from Numerical Modeling: *Philippe Carrez*[1]; Jonathan Amodeo[1]; Patrick Cordier[1]; [1]Lab. UMET CNRS-8207

The study of plastic properties of minerals is of primary importance to model the Earth's mantle rheology, responsible for plate tectonics. Numerical modeling provides an alternative to deformation experiments to address the behaviour of materials under exterme (P,T) conditions. In this study, we use a hierarchical multi-scale model to study the effect of high pressures (up to 100 GPa) on the critical resolved shear stresses (CRSS) of MgO (one of the main constituents of the Earth's mantle). Using a generalised Peierls-Nabarro model, we show that core structure of 1/2<110> screw dislocation is strongly sensitive to pressure, with an inversion of the easiest slip plane from {110} to {100} around 60 GPa. By applying kink pairs theory, we find that pressure increases CRSS and shifts athermal temperatures towards higher temperatures.Under high pressure, MgO is thus characterized by a significant lattice friction on both slip systems.

3:10 PM
High Pressure Study of the Effects of Vacancies on the Lattice Dynamics of B2 FeAl: *Matthew Lucas*[1]; [1]Air Force Research Laboratory

Ordered intermetallic B2 FeAl alloys are of technological interest as high-temperature structural materials due to their high resistance to corrosion, low density, and high strength. The usefulness of these alloys are hindered by their brittleness, which is due to a propensity to develop an abnormally high equilibrium vacancy concentration at high temperature. A combination of ambient pressure inelastic neutron scattering and high pressure elastic and inelastic scattering in a diamond anvil cell were used to probe the effect of vacancies on the lattice dynamics of B2 FeAl. It was observed that the effects of vacancies on the phonon spectrum were largely due to changes in volume and were generally consistent with the quasiharmonic approximation. Vacancies on the Fe site alter phonons by their effect on the specific volume of the crystal, where the decrease in volume leads to an increase in the phonon energies.

3:30 PM
Amorphization and Nanocrystallization in Boron Carbide and Silicon Carbide Impacted at High-Velocity: *Jerry LaSalvia*[1]; Eugene Shanholtz[1]; [1]U.S. Army Research Laboratory

Boron carbide and silicon carbide are common hard-face components in lightweight ballistic protection technologies. Ballistic impact involves the generation of transient, large amplitude, spatially and temporally varying stresses and deformations. Material responses can be complex, involving phenomena which span atomistic-to-macroscopic length-scales driven by hydrostatic, deviatoric, and principal stresses. In this investigation, a hot-pressed boron carbide and modified-CVD silicon carbide were ballistically impacted with cemented carbide spheres at high velocity. Recovered ceramics were sectioned through the impact site and polished to reveal sub-surface features. Beyond multi-scale cracking and fragmentation, evidence for solid-state amorphization and nanocrystallization was observed in both compressive and tensile stress regions. The discreteness of these features reflects the importance of shear stress and deformation on these phenomena. These features were subjected to SEM, EDS, micro-XRD, and micro-Raman spectroscopy in an effort to characterize them. Atomistic modeling results and thermodynamic-based considerations are presented which aide in explaining these findings.

Random Search - A Tool for Discovery at High Pressure: *Chris Pickard*[1]; [1]University College London

Much progress has been made in the prediction of structure from first principles. My approach - ab initio random structure searching (AIRSS) [1,2] is simple and powerful. Its lack of bias makes it particularly suitable for theoretical explorations leading to new and unexpected phenomena. I have uncovered ionic phases of ammonia[3], and structural richness at terapascal pressures in aluminium[4], iron[5] and carbon. In this talk I will focus on the hunt for novel physics, illustrated by the discovery of a new route to bulk magnetism in the elements[6]. [1] C.J. Pickard and R.J. Needs, *PRL,* 2006, 97, 45504 [2] C.J. Pickard and R.J. Needs, *JPCM,* 2011, 23, 053201 [3] C.J. Pickard and R.J. Needs, *Nature Materials,* 2008, 7, 775-779 [4] C.J. Pickard and R.J. Needs, *Nature Materials,* 2010, 9, 624-627 [5] C.J. Pickard and R.J. Needs, *JPCM,* 2009, 21, 452205[6] C.J. Pickard and R.J. Needs, *PRL,* 2011 (in press)

4:30 PM
Equation of State of Solid Solution $Mg_{2.4}Fe_{0.6}Al_2Si_3O_{12}$ Measured in Diamond Anvil Cell: *Shu Huang*[1]; Jiuhua Chen[1]; Bin Yang[1]; Vadym Drozd[1]; Andriy Durygin[1]; [1]Florida International University

The Pressure-Volume relation of synthetic pyrope-almandine garnet ($Mg_{2.4}Fe_{0.6}Al_2Si_3O_{12}$) was measured at ambient temperature and pressure up to 9.3 GPa in diamond anvil cell with synchrotron X-ray diffraction. The p-v data were fitted to a third order Birch–Murnaghan equation of state. With fixed values for the ambient cell volume (V_0 = 1511.4(4) Å^3) and the pressure derivative of the isothermal bulk modulus (K'_{T0} = 5.45), an isothermal bulk modulus of K_{T0} = 178(3)GPa was obtained. This data agrees well with previous measurements on almandine-pyrope garnets and fits in between the bulk modulus range of pyrope and almandine. This result shows that the bulk modulus of garnet along py-alm join is proportional to the almandine percentage in this binary solid solution.

4:50 PM
HPHT Synthesis of Phosphorus Doped Diamond from Triphenylphosphine and Graphite: *Bin Yang*[1]; Fangli Chi[1]; Ernesto Vallejo[1]; Jiuhua Chen[1]; [1]Florida International University

Phosphorus doped diamonds have attracted great attentions in recent decades because of their n-type semiconductor properties. Most of them can be successfully produced by chemical vapor deposition (CVD) method. However, at high pressure high temperature (HPHT) conditions, the P-doped diamonds only obtained from carbon solution in phosphorus melt. We explored a new route to synthesize P-doped diamond. The diamond has been synthesized at 19 GPa and 1800 °C for 1 min in a multi-anvil apparatus by using triphenylphosphine [$P(C_6H_5)_3$] and graphite as starting materials. The molar ratio of P to C was 1:100. The X-ray diffraction confirmed the existence of the diamond. The diamond crystallite size was determined to be about 14 nm. The Raman spectroscopy revealed a large shift in the diamond peak position between the sample (1326.9 cm^{-1}) and the pure diamond (1332 cm^{-1}). It may be caused by the phosphorus doping. The further studies are in progress.

5:10 PM
High Pressure X-ray Diffraction Studies for Piezoelectric Materials: *Lingping Kong*[1]; Zhenhai Yu[2]; Luhong Wang[2]; Haozhe Liu[3]; Wenge Yang[1]; Ho-kwang Mao[1]; [1]Carnegie Institution of Washington; [2]Argonne National Laboratory; [3]Harbin Institute of Technology

The structural stability of several piezoelectric materials under high pressure has been investigated through in situ high pressure angle dispersive X-ray diffraction experiments at room temperature. For the Pb(Yb1/2, Nb1/2)O3–PbTiO3 (PYNT) case, the crystal structure evolution up to 24.5 GPa was measured, which revealed a ferroelectric–paraelectric phase transition at about 8.0 GPa. The bulk moduli of ferroelectric and paraelectric phases were estimated as B0 = 99 (3) and 204(4) GPa, respectively. The structural stability of other piezoelectric materials, including Ca3TaGa3Si2O14 and La3Ga5SiO14, were studied as well. These experimental results will give us insight into the origins of piezoelectric properties, and provide input for the better design of this kind of materials with optimized structure-property relationship.

Production, Recovery and Recycling of Rare Earth Metals: Session I

2:00 PM Introductory Comments

2:05 PM
Recycling of Rare Earth Metals: A Review: *Lifeng Zhang*[1]; [1]Missouri University of Science and Technology

Over 100 literature papers on the recycling of rare earth metals are reviewed. The benefits and the main technologies for the recycling of rare earth metals were summarized.

2:35 PM
Hydrogen Processing – a Novel Route for the Recycling of Sintered Nd-Fe-B Magnets: *Oliver Gutfleisch*[1]; Konrad Güth[1]; [1]IFW Dresden

There is an increasing demand for permanent magnets based on Nd-Fe-B in HEV and wind turbine applications. These magnets contain a significant amount of rare earth elements, generally for excellent magnetic performance (light RE) and then to ensure appropriate thermal stability in these specific applications (heavy RE) [1]. Some of them, Dy and Tb are indeed rare; all of them have seen drastic price increases. Sustainable usage of such resources is pivotal and the recycling of advanced magnets will become increasingly important. We investigate the feasibility of recycling scrap sintered Nd-Fe-B by hydrogen processing. A combination of HD and HDDR is used to recover magnetically anisotropic powder, suitable for the subsequent production of polymer bonded highly textured magnets. Microstructure and magnetic properties were studied by SEM/EBSD and magnetometry. Comparable properties to those of non-recycled polymer bonded magnets were obtained. [1] Gutfleisch et al. Adv. Mat. 23 (2011) 821.

3:05 PM
Electrochemical Behaviour of Neodymium in Aqueous Electrolytes: *Ralph Sueptitz*[1]; Kristina Tschulik[1]; Margitta Uhlemann[1]; Ludwig Schultz[1]; Annett Gebert[1]; [1]IFW Dresden

The rare earth metals are essential for highly energy-efficient technologies with many applications. The electrochemical behaviour, especially the material degradation by corrosion, is crucial for a long lifetime of electromagnetic devices. While the corrosion properties of some compounds containing these metals (e.g. NdFeB permanent magnets) have been characterized, the electrochemical behaviour of the pure metals is scarcely investigated. However, to understand the electrochemical behaviour of the alloys and compounds it is necessary to know the electrochemical behaviour of the pure elements. This will then allow developing corrosion protection strategies to ensure a low loss of efficiency during the lifetime of an electromagnetic device. Here, an electrochemical characterization of Neodymium in various aqueous electrolytes is presented. The corrosion properties and passive film formation are summarized and the local breakdown of passivity due to aggressive anions in the solution is shown. Furthermore, an abnormal hydrogen evolution under anodic polarization conditions is discussed.

3:35 PM
Recovery of Rare Earth Metals via Liquid Metal Extraction: *Ryan Ott*[1]; Dan Cavanaugh[2]; Warren Straszheim[2]; Matthew Kramer[2]; Larry Jones[2]; [1]Ames Laboratory (USDOE); [2]Ames Laboratory (USDOE)

With the increased demand for rare earth (RE) metals in critical technologies coupled with supply concerns, recycling of RE metals has become increasingly more important. Here we describe utilizing liquid Mg to extract RE metals from magnetic scrap material. By utilizing induction melting of liquid Mg followed by vacuum distillation, we were able to recover >98% pure RE metal. From the recovered RE metals, we synthesized $RE_2Fe_{14}B_1$-type magnetic alloys for comparison with alloys synthesized from pure RE metals. The magnetic properties and the microstructure of the alloys prepared from the two different starting materials are discussed. Lastly, we discuss the extraction of RE metals from oxidized samples.

4:05 PM Break

4:15 PM
Rapid Separation of Rare Earth Elements with Interstitial Polymer Network Ion Exchange Columns: *Richard Hammen*[1]; John Hammen[1]; Anupam Goyal[1]; [1]IntelliMet LLC

Rare earth element (REE) production is essential for much of 21st Century technology. Current methods of producing purified REE metals require multi-stage solvent extractions that are expensive due to high capital, operational, and environmental costs. We describe a new generation of ion exchange columns that are effective for REE separation. The columns are manufactured with beds of silica particles that have thinly cross-linked polymer networks crossing the interstitial spaces between the particles. These interstitial polymer networks (Spiderwebs) suspended between silica particles have enhanced rates of equilibration with solutions flowing through the Spiderweb. When the Spiderweb-like polymer networks are modified with REE-selective chelating agents, the columns are able to rapidly separate RE ions from mixtures. We report the separation of cerium and lanthanum from RE mixtures to give highly purified metal salts. In addition, we describe the separation of praseodymium and neodymium in one pass through a Spiderweb column.

4:45 PM
Selective Extraction of Neodymium from Nd-Fe-B alloys Using Magnesium: *Taek-Soo Kim*[1]; Hongjun Chae[1]; Ryan Ott[1]; [1]Korea Institute of Industrial Technology (KITECH)

This study is to investigate a selective diffusivity of Nd to Mg from Nd-Fe-B, a typical permanent magnet composition. The process will be an invironmental friendly recycling process, compared with the conventional chemical method. The effects of the holding time on the reactivity in the high frequency vacuum induction melting (VIM) were analyzed using Scanning-electron microscopy (SEM), X-ray diffraction (XRD) and Energy-dispersive spectrum (EDS). Microstructural and compositional change happened during the reaction was also examined. The experimental results showed that the Nd initiated to diffuse into Mg as the Nd-Fe-B specimen contacted with Mg melt, and form a dendritic Mg-Nd eutectic phases. Diffusivity was found to vary with holding time.

5:15 PM
Effect of Tellurium Reduction and Thermoelectric Properties on Thermoelectric Materials Produced by Rapid Solidification Processes and Hot Extrusion.: Hyo-Seob Kim[1]; Taek-Soo Kim[2]; *Soon-Jik Hong*[1]; [1]Kongju National University; [2]Korea Institute of Industrial Technology(KITECH)

Due to their potential application in power generation and cooling devices along with their advantages, Tellurium-based thermoelectric(TE) materials have attracted much interest and attention. However, a severe issue that ought to be faced is the low reserves of the scarce element tellurium and its rapidly increasing usage in industries. New tellurium-free or low-tellurium bearing materials to replace traditional commercial Tellurium-based TE materials need to be explored. Recently, it has been reported that the TE properties can be increased with low-tellurium bearing TE materials, using rapid solidification process. In this study, we investigated the effect of Tellurium reduction on the TE properties of TE materials by introducing a new rapid solidification (Gas-Atomization) method, followed by hot extrusion under different conditions(ratio: 10:1~25:1, temperature: 350~500°C). The structure, morphology, mechanical and TE properties of these materials are investigated by means of different techniques including electron microscopy(SEM), X-ray diffraction(XRD), micro Vickers hardness and TE measurements.

5:45 PM
Study on the Cerium Oxide Prepared by Pyrolysis of Cerium Chloride Solution: *Bian Xue*[1]; Wu Wenyuan[1]; [1]Northeastern University

This paper aims to explore a kind of process for the preparation of cerium oxide (CeO2) which is CeO2 preparated by CeCl3 solution direct pyrolysis. The optimal condition of Roasting temperature for 950°C. Material liquid concentration for 270g/L and feeding speed for 0.23ml/s is obtain by orthogonal regression equation. In the optimal condition, conversion rate of CeO2 is 99.9%, and the grain size is about 500nm.

2:05 PM
Morphologies in Polycrystalline Film Growth: *Ramanathan Krishnamurthy*[1]; Mikko Haataja[2]; [1]Purdue University; [2]Princeton University

Polycrystalline films are commonly used in materials applications; however,growth models rarely include time-dependent lateral grain size effects. We employ a thermodynamics-based method to effectively handle grain grooving / lateral grain growth and film growth. Previously, we exercised the model to successfully predict experimental features related to polydisperse-sized film annealing (zero deposition flux) including ghost lines, groove asymmetry and their relation to annealing kinetics, and the non-monotonous time-variation of film roughness. Here we examine film growth (non-zero deposition flux). For large, spatially uniform deposition fluxes, the accompanying greater chemical potential driving grooving produces enhanced grooving / impeded grain growth. When deposition fluxes vary spatially as in diffusion limited processes (e.g. electrodeposition), the ratio of the length scale characteristic of the deposition process and grain size critically affects growth morphologies, and different features such as impeded grain growth, and characteristic non-equilibrium grain surface morphologies are found for different values of this ratio.

2:35 PM
Nitrogen Doped ZnO (ZnO:N) Thin Films Deposited by Reactive RF Magnetron Sputtering for PEC Application: *Sudhakar Shet*[1]; Kwang-Soon Ahn[2]; Nuggehalli Ravindra[3]; Yanfa Yan[1]; Mowafak Al-Jassim[1]; [1]National Renewable Energy Laboratory; [2]School of Display and Chemical Engineering; [3]New Jersey Institute of Technology

ZnO:N films were deposited by reactive RF magnetron sputtering on F-doped tin oxide coated glass in mixed N2 and O2 gas ambient. Their PEC properties were measured and compared with those of as-grown and annealed ZnO films. The ZnO:N films exhibit photoresponse in the visible-light region, yielding higher total photocurrents than ZnO thin films. With combined ultraviolet/infrared and color filtering, our data indicate that the main contribution to the high photocurrent is from the absorption of light in long-wavelength regions.

3:05 PM
Hydrothermal Synthesis of Zinc Oxide Thin Film for Printed Electronics: *Ruihong Zhang*[1]; Carol Handwerker[1]; [1]Purdue University

Hydrothermally synthesized zinc oxide is a promising semiconductor for printed electronics due to its higher mobility than the organic semiconductors and its simple and environmentally benign processing route for thin film formation. In this study, the rapid, low-temperature synthesis of dense and continuous ZnO thin films from 70 nm nanoparticle seed layers was examined using aqueous solutions with the initial pH ~5 at 90oC for times ranging from 0.25 h to 2 h. The effects of counter ions, complexing agents, pH, and solution concentration on film growth, morphology and texture were characterized using SEM and x-ray diffraction. The mobilities of the ZnO thin films measured by the Hall Effect are correlated to the thin film microstructures observed by high resolution transmission electron microscopy (HR-TEM), thereby establishing the relationship between the morphology and the mobility of the films.

3:25 PM
Spin-Coated Erbium-Doped Silica Sol-Gel Films on Silicon: *Sufian Abedrabbo*[1]; Bashar Lahlouh[1]; Sudhakar Shet[2]; Anthony Fiory[3]; Nuggehalli Ravindra[3]; [1]University of Jordan; [2]National Renewable Energy Laboratory; [3]New Jersey Institute of Technology

This work reports optical functionality contained in, as well as and produced by, thin film coatings. A sol-gel process, formulated with precursor active ingredients of erbium oxide and tetraethylorthosilicate (TEOS), was used to produce by spin-coating thin (~130 nm) erbium-doped (~6 at. %) silica films on single-crystal silicon. Annealed films produce infrared emission in the 1.5-micron band from erbium ions in the film, as well as greatly enhancing (> 100X) band-gap emission from the underlying silicon. The distinctly different mechanisms for the two modes of optical activity are interpreted in terms of optical emission theory and modeling; prospects for opto-electronic applications are discussed.

Influence of Annealing on the Martensitic Transformation and Magnetocaloric Effect in $Ni_{49}Mn_{39}Sn_{12}$ Ribbons: *Dianzhen Wu*[1]; Sichuang Xue[1]; Hongxing Zheng[1]; Qijie Zhai[1]; [1]Shanghai University

Magnetocaloric effect associated with martensitic transformation (MT) can be induced in $Ni_{49}Mn_{39}Sn_{12}$ alloy. The influence of annealing on the martensitic transition and magnetocaloric effect in metamagnetic polycrystalline $Ni_{49}Mn_{39}Sn_{12}$ ribbons produced using melt spinning technique was investigated systemically based on the results of vibrating specimen magnetometer (VSM) measurements. Ribbons were annealed at 1273K for 4h, followed by water quenching or furnace cooling to room temperature. Magnetic-field induced reverse MT from paramagnetic martensite phase to ferromagnetic austenite phase together with large magnetization change is evident in thermal-magnetic curves, thus entropy change appears. The magnetic entropy change enhances strikingly for all annealed ribbons in comparison of melt-spun ribbons. The magnetic refrigerant parameters for ribbon water quenched exhibits optimum values, of potential extensive application in practical refrigerant cycles.

4:30 PM
Metal Diaphragm Based Magnetic Field Sensor: *Asahel Banobre*[1]; Ivan Padron[1]; Anthony T. Fiory[1]; Nuggehalli M. Ravindra[1]; [1]NJIT

A diaphragm based magnetic field sensor is designed and fabricated. A thin metal diaphragm is used as a sensing element and it responds to an external magnetic field. Deformation of the diaphragm due to the pressure produced from the interaction between the magnetic field and the metal surface can be detected electronically through a Wheatstone bridge placed over the diaphragm. Analytical and experimental analyses are used to study the precision and accuracy of devices for sensing magnetic field flux.

4:50 PM
Optical and Electronic Properties of III-V Nitrides: *Chiranjivi Lamsal*[1]; Nuggehalli Ravindra[1]; [1]New Jersey Institute of Technology

The optical properties of III-V binary and ternary nitrides have been analyzed in this study. The analysis takes into account the optical properties such as the reflectance and transmittance of these nitrides. The related optical properties such as the energy dependent dielectric function, refractive index, extinction coefficient and absorption coefficient are evaluated utilizing Kramers-Kronig relation. Model calculations based on those of Penn and Wemple-Didomineco are deployed to interpret the peaks in the reflectivity spectra. Temperature and pressure dependence of the energy gap and the refractive index and their nature have been analyzed. Influence of substrates on the optical properties of these nitrides is discussed.

5:10 PM
Application of Expanding Thermal Plasma for Deposition of Hydrogenated Diamond like Carbon Thin Films on Rubber Seals: *Ali Reza Eivani*[1]; Yutao Pei[1]; Jeff Th.M. De Hosson[2]; Teodor Zaharia[1]; Richard M.C.M. Van de Sanden[3]; [1]Materials Innovation Institute (M2i); [2]University of Groningen; [3]Eindhoven University of Technology

Hydrogenated diamond-like carbon (DLC) thin films were deposited on nitrile butadiene rubber (NBR) using expanding thermal plasma (ETP) apparatus in a C_2H_2 / Ar plasma. Effect of arc current on the tribological behavior of the coated rubber is investigated with ball-on-disc tribology test under dry sliding condition against 100Cr6 ball. Coefficient of friction (CoF) of the coated rubber decreases significantly by reducing arc current due to the changes occurred in the plasma chemistry and consequently deposition of a softer film. High resolution scanning electron microscopy (SEM) is used for characterization of the surface morphology of coated rubbers to correlate microstructure to CoF. Wear scar of the counterpart, i.e., 100Cr6 steel ball, has also been investigated and its wear morphology is discussed in correlation with SEM micrographs and CoF measurements.

2012 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: Poster Session

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Nanomaterials Committee

Program Organizers: Jiyoung Kim, University of Texas; David Stollberg, Georgia Tech Research Institute; Seong Jin Koh, University of Texas at Arlington; Nitin Chopra, The University of Alabama; Terry Xu, UNC Charlotte

Monday PM — Room: Atlantic Hall
March 12, 2012 — Location: Dolphin Resort

U-1: A Facile, One Pot and Completely 'Green' Synthesis of Sugar-Reduced Silver Nanoparticles: Lucwaba Yolisa[1]; Vulyewa Ncapayi[1]; Odey Akpa[1]; Sandile Songca[1]; *Oluwafemi Oluwatobi*[1]; [1]Walter Sisulu University

We herein report the synthesis of highly monodispersed water soluble silver nanoparticles (Ag-NPs), via an eco-friendly, completely green method in a natural polymeric media. The method involves the use of silver nitrate, gelatine and maltose as the silver precursor, stabilising agent and reducing agent respectively in aqueous solution. By varying the reaction time, we monitored the optical and structural properties of the colloidal Ag-NPs. The nanoparticles were characterised using UV-vis absorption spectroscopy, Fourier transform infrared spectroscopy (FTIR), x-ray diffraction (XRD), transmission electron spectroscopy (TEM), high resolution electron transmission microscopy (HRTEM) and energy dispersive spectroscopy (EDS). The absorption maxima of the as-synthesised materials were blue-shifted as the reaction time increases indicating decrease in particle size. The TEM images showed well-defined monodispersed, spherical particles with average particle diameter of less than 4 nm at higher reaction time and are in agreement with the absorption analysis.

U-2: Analysis of RTS Noise Characteristics in Fin-Type Silicon-Oxide-High-k-Oxide-Silicon (SOHOS) Flash Memory: *Seung Dong Yang*[1]; Sang Youl Lee[2]; Ho Jin Yun[2]; Kwang Seok Jeong[2]; Yu Mi Kim[2]; Jae Sub Oh[3]; Hi-Deok Lee[2]; Ga Won Lee[2]; [1]Chungnam University; [2]Chungnam university; [3]National Nanofab Center

This paper discusses the Random Telegraph Signal (RTS) noise in Fin-type Silicon-Oxide-High-k-Oxide-Silicon (SOHOS) flash memory. As the device dimensions continue to shrink with each new generation of flash memory, the so called RTS noise, characterized by discrete switching events of the channel current, have often been observed and attributed to the trapping and de-trapping of conduction carriers by individual interfacial defects. In flash memory, RTS noise is one of major reason for problem of threshold voltage shift which causes performance errors. Fin-type SOHOS device using HfO2 trapping layer shows superior Program/Erase speed. However, the data retention properties are degraded. To find out the causes, we carried out the RTS noise analysis in fabricated a SOHOS flash memory and distribution of traps is looking for the cause of poor data retention characteristics.

U-3: Atmospheric-Pressure Plasma Sintering of Silver Nanopaste Screen-Printed on PI: *Kwang-Seok Kim*[1]; Woo-Ram Myung[1]; Seung-Boo Jung[1]; [1]Sungkyunkwan University

Recently, the field of printed electronics has gradually matured. Numerous researches have proposed feasible applications such as interconnections for micro-circuitry on a printed circuit board, and electrodes for thin film transistor circuits. Heat treatment is inevitably required because direct printing technology is based on an additive manufacturing method. However, conventional heating is not compatible with common polymer substrates that have a relatively low glass transition temperature. Therefore, we suggest atmospheric-pressure plasma (APP) sintering. The microstructure and electrical resistivity were investigated with a FE-SEM and a 4-point probe station, respectively. Argon and helium were used for APP sintering. As experimental results, the selective sintering of Ag nanopaste was achievable by APP without affecting a polyimide substrate. Also, the electrical resistivity was achieved less than one order of magnitude higher than that of bulk Ag. The mechanism of these phenomena will be deeply discussed in the conference site and full manuscript.

U-4: Effects of Calcination Conditions on Particle Size and Morphology of NiFe2O4 Nanoparticles Synthesized by Solid-State Reaction: *Zhigang Zhang*[1]; Yihan Liu[1]; Guangchun Yao[1]; Di Wu[1]; Junfei Ma[1]; [1]Northeastern University

Nickel ferrite (NiFe2O4) nanoparticles were synthesized via low temperature solid-state reaction. The precursors prepared by grinding the mixture of FeSO4•7H2O, NiSO4•6H2O, NaOH and dispersant (NaCl) sufficiently at room temperature were calcined under various calcination conditions to obtain NiFe2O4 spinel nanoparticles. The effects of the calcination conditions, namely calcination temperature and heat preservation time, on particle size and morphology have been investigated in detail. X-ray diffraction (XRD) and transmission electron microscopy (TEM) were employed to characterize the as-synthesized particles. The results indicate that particle size and morphology can be controlled by calcination conditions. The low temperature solid-state reaction technique is a convenient, inexpensive and effective preparation method of NiFe2O4 in high yield.

U-5: Electrical Characterization in Pillar Type Silicon-Oxide-Nitride-Oxide-Silicon Flash Memory Using Bandgap Engineering Method: *Sang Youl Lee*[1]; Seung Dong Yang[1]; Jae Sub Oh[2]; Ho Jin Yun[1]; Kwang Seok Jeong[1]; Yu Mi Kim[1]; Hi Deok Lee[1]; Ga Won Lee[1]; [1]ChungNam University; [2]National Nanofab Center

Continued scaling down of flash memory device causes reliability problems such as increasing leakage current and changing a operate voltage due to thinner tunnel oxide. Thinner tunnel oxide is easily degraded when a lot of program and erase process are repeated. To solve these problems, many researchers have studied new memory structures such as Nano Floating Gate Memory (NFGM), 3D structures and Silicon-Oxide-Nitride-Oxide-Silicon (SONOS). However, the SONOS structure is recently focusing as the next generation memory device due to a better scale down characteristics than previous flash memory devices. Band Engineering (BE) method that is adding a thin layer in a tunneling oxide is also well known as a process to improve data retention and charge writing/erasing characteristics. Therefore, we fabricated the conventional pillar type SONOS and BE-SONOS flash memory devices. Through these devices, it is found out that the BE device has better reliability characteristics.

U-6: Electrical Characterization of TiO_2 Thin Films Prepared by Atomic Layer Deposition: *Antonio Lucero*[1]; Mingun Lee[1]; Jiyoung Kim[1]; [1]University of Texas at Dallas

Titanium dioxide has received considerable interest in the study of nanomaterials. The material has been proposed for use in a variety of applications ranging from chemical sensors to dye sensitized solar cells. Titanium dioxide nanotubes, nanoparticles and porous films are frequently tested in these roles. This work attempts to characterize the properties of nanoscale TiO_2 by looking at thin films deposited by atomic layer deposition (ALD). Thin films can be patterned with traditional lithography techniques. Their reproducibility is one advantage over materials such as nanotubes, which are often produced with a random distribution of sizes. Electrical characteristics are studied as a function of both film thickness and length, and the effects of temperature and gas environment are observed.

U-7: Electrospinning of the Dendritic Polymer (Acrylonitrile /Acrylic Acid) and the Properties of Fibers: *Elahe Helmi*[1]; [1]Engineering Faculty

To produce a dendritic structure, CA has been used as a generation by divergent synthetic route for the synthesis of a dendritic polymer on the surface of (Acrylonitrile /Acrylic acid) base copolymer. Nanofiber mats of the synthesized dendritic structure were fabricated by electrospinning method. The effects of the dendritic structure generation on the nanofiber formation and their diameter were studied. Morphology and diameter of the nanofibers were studied using optical and scanning electron microscope. The results showed that increase in dendritic generation increases the average of nanofiber diameter. Results were discussed on the base of the change in solution shear viscosity and dendrimer structure.

U-8: Fabrication of Bulk Al-Fe-V-Si Nanocrystalline Alloy by Mechanical Alloying and Hot Pressing: *M.H. Enayati*[1]; H. Ashrafi[1]; R. Emadi[1]; [1]Isfahan University of Technology

In this study, bulk nanocrystalline Al-Fe-V-Si alloy was produced by mechanical alloying and hot pressing. The elemental powders of Al, Fe, V and Si were milled in a planetary ball mill for 60 h to obtain a nanocrystalline Al solid solution. The milled powders were hot pressed in a uniaxial die at 550°C under pressure of 300 MPa for 0.5 h to acquire a bulk nanostructured alloy. The microstructure of consolidated sample consisted of Al12(Fe,V)3Si in nanocrystalline Al matrix with a grain size of 55nm. The consolidated sample had a hardness value of about 280 HV.

U-9: Implementation of Parylene as a Low- κ Gate Dielectric Material for Graphene Field Effect Transistors (GFETs): *Greg Mordi*[1]; Srikar Jandhyala[1]; Jiyoung Kim[1]; [1]University of Texas at Dallas

Graphene, a two-dimensional (2D) hexagonal carbon lattice has been used as the conducting channel for field effect transistors because of its exceptional electrical properties. For a top gated FET, the graphene-dielectric interface play an important role in the FET behavior and mobility degradation mainly due to carrier scattering after the dielectric deposition process has been reported. In this work, we report on the fabrication and characterization of top gated graphene field effect transistors using a thin layer of parylene-C as gate dielectric. Parylene C excellent bulk properties such as its moisture barrier, high mechanical strength, thermal stability, phenyl structure and electrical insulation make it an ideal candidate as a top gate dielectric material for graphene devices. The thickness of the parylene and surface morphology was characterized by ellipsomerty and AFM techniques. Electrical measurements reveal excellent characteristics with room temperature mobility in excess of 4000cm2/Vs.

U-10: Mechanical Properties of WC-10wt.%Co Hard Materials Prepared by SPS Process for FSW Tool Application: Hyun-Kuk Park[1]; *Hee-Jun Youn*[1]; Ik-Hyun Oh[1]; [1]KITECH / Automotive Components Center

Using the spark plasma sintering method, WC–10wt.%Co hard materials were densified using an ultra fine WC–Co powder. The WC–Co was almost completely dense with a relative density of up to 100 % after the simultaneous application of a pressure of 60 MPa and an electric current for 12 minutes without any significant change in the grain size. The average grain size of WC that was produced through SPS was about 730 nm. Also, it was found that the Vickers hardness and fracture toughness of WC-Co sintered body were 2068.38 kg/mm2 and 10.21 MPa.m½, respectively.

U-11: Nanotechnology Coating of Buildings with Sol–Gel Method: *Aref Sadeghi Nik*[1]; Ali Bahari[2]; MohammadH. Khalilpasha[3]; Adel Sadeghi Nik[1]; [1]Young Researchers Club, Jouybar Branch, Islamic Azad University, Jouybar, Iran; [2]Department of Physics, University of Mazandaran, Babolsar, Iran; [3]Dept. of Civil Engineering, Islamic Azad University, Jouybar branch, Jouybar, Iran

The hydrophilic nature of the coating causes water that comes into contact with it to form an exterior building layer, thereby allowing the dust and dirt that have accumulated on the surface to be washed away. In fact, hydrophilic property can also allow stains to cover the exterior surfaces. This point of the coating in the present work has been done with using different percent of Zycosil (1:20, 1:15, 1:10 and 1:5 and noting to ASTM C642 standard procedure. With this coating technology, the surface building maintenance, especially for skyscrapers, since they reduce the need for costly surface cleaning. Moreover, the obtained results which have been obtained with sol – gel method and AFM (Atomic Force Microscopy) indicate that it reduces the frequency of washes and correspondingly, drive down the coast of building maintenance.

U-12: PHB Nanocomposite Microcapsules with Brazilian Smectitic Clays: Francisco Valenzuela-Diaz[1]; *Maria da Silva-Valenzuela*[1]; Wang Shu Hui[1]; Helio Wiebeck[1]; [1]Universidade de Sao Paulo

The search for better materials has placed the polymer/clay nanocomposites in the centre of attention. Biopolymer-based nanocomposites as polyhydroxybutyrate (PHB), due to the current concern over environmental problems and biomedical use, can be a good alternative to produce microcapsules with application in drug delivery systems. In this work, we describe for the first time, from our knowledge, the preparation of microcapsules from two PHB nanocomposite systems: a) PHB/OMMT (Cloisite 20A), (PHB1) and b) PHB/montmorilonite (MMT), natural Brazilian green policationic clay, (PHB2). The microcapsules PHB/OMMT and PHB/MMT nanocomposite were prepared by solvent evaporation technique. The XRD of films and microcapsules do not show d(001) peak, evidencing an exfoliated structure in the nanocomposites. The films have shown by SEM a homogeneous distribution of the clay mineral particles spread uniformly in the PHB film matrix. By SEM the microcapsules revealed spherical particles with a porous surface structure very similar to a “hydrangea”.

U-13: Raman Spectroscopy of Graphene and Plasma Treated Graphene under High Pressure: *Ali Hadjikhani*[1]; Jiuhua Chen[1]; Santanu Das[1]; Won-bong Choi[1]; [1]FIU

Due to its exceptional mechanical and electrical properties, graphene (one layer sheet of carbon atoms) has attracted a lot of attention since its discovery in 2004. The purpose of this research is to compare the Raman spectra of graphene with plasma treated graphene sheets which have been treated by changing the different parameters affecting the plasma treatment like gas flow, power, pressure and treatment time. We report a Raman spectroscopy study of graphene on copper substrate at high pressures. A diamond anvil cell (DAC) was used to generate pressure. In situ Raman spectra were collected at pressures up to 10 GPa. The result indicates that the G band of graphene shifts with pressure significantly (about 5 cm-1/GPa) whereas the 2D band changes very little.

U-14: Research on Preparation of Anisotropic Sm2Co17 Nano-flakes by Ball Milling under Magnetic Field: *Ying Chang*[1]; Jian Zhao[1]; Xiaodong Li; Zhiyong Wei[1]; Minggang Zhu[2]; Zhaohui Guo[2]; Wei Li[2]; [1]Dalian University of Technology; [2]China Iron & Steel Research Institute Group

High anisotropy magnetic nanoparticle materials have drawn great attention for their potential applications in anisotropic nanocomposite magnets. Surfactant assisted ball milling has already been proven to be an effective way to prepare high anisotropy magnetic nanoparticle materials such as Nd2Fe14B, SmCo5 flakes. In this study, a new preparation method of Sm2Co17 flakes was investigated. Nanocrystalline hard magnetic Sm2Co17 flakes with 20-100nm thickness were obtained by milling in heptanes and oleic acid under 1T magnetic field for 3~6 hours. It was shown that the magnetic anisotropy of the prepared Sm2Co17 flakes after aligned at 1.5 T magnetic field could be further enhanced. The best (BH)m of 16MGOe was obtained for the magnetic anisotropic Sm2Co17 nano-flakes.

U-15: Room-Temperature Synthesis of Spherical and Flowerlike Ag Nanostructures in Different Solvent: *Guoliang Li*[1]; Bing Peng[2]; Liyuan Chai[2]; Lei Jiang[2]; Liyuan Zhang[2]; [1]Central South University ; [2]Central South University

Nano Ag particles with different morphologies are synthesized by mixing silver nitrate and para-phenylenediamine (PPD) in different solvent at room temperature. The characterizations of the as-synthesized Ag particles are performed using SEM, EDS, UV-Vis spectra and XRD. It is found that the type of solvent has a significant effect on the formation and growth of these novel nanostructures. The possible formation mechanism of Ag nanostructure is also discussed.

U-16: Scaling Down High-k Gate Dielectrics for Graphene-Based Device Applications: *Srikar Jandhyala*[1]; Greg Mordi[1]; Jiyoung Kim[1]; [1]University of Texas at Dallas

In order to realize graphene-based field-effect-devices, one of the foremost requirements is the ability to deposit high-quality, high- dielectrics on graphene for effectively modulating the gate potential. But, being just one atom thick and having an inert surface, it poses a challenge to develop a top-gate dielectric process for graphene which preserves its pristine properties. Here, we will present our approach based on atomic layer deposition through ozone functionalization to deposit high- dielectrics (such as Al2O3) with physical thicknesses in sub (=) 5nm regime. In this study we have investigated the effect of ozone dose on Al2O3 coverage using HOPG (Highly Oriented Pyrolytic Graphite) and single-layer graphene. Electrical characteristics of dual-gated graphene field-effect transistors (GFETs) fabricated with single-layer graphene and Al2O3 as top-gate dielectric will be discussed.

U-17: Selective Area Atomic Layer Deposition (ALD) with E-Beam Lithography (EBL) on Self-Assembled Monolayers (SAM): *Jie Huang*[1]; Mingun Lee[1]; Jiyoung Kim[1]; [1]University of Texas at Dallas

In this study, nano-line patterns are defined by electron beam lithography (EBL) on octadecyltrichlorosilane (OTS) SAMs modified Si/SiO2 substrates. During the EBL process, SAMs on solid substrates can be damaged or removed to generate discernible patterns. A thin film of titanium oxide (TiO2) is deposited by atomic layer deposition (ALD), of which deposition mechanism is a self-limiting surface reaction, selectively on the e-beam patterned nano-lines. To control the width of the metal oxide patterns, we have optimized the conditions of both EBL and ALD. As characterized by scanning electron microscope (SEM), atomic force microscope (AFM) and high resolution transmission electron microscope (HRTEM), selectively deposited TiO2 line patterns with sub-30 nm in width and 50 nm in pitch were achieved with e-beam voltage of 2 kV and line dose of 10 nC/cm. Proximity effect prevent dense line to be patterned closer than 50 nm in pitch.

U-18: Sensitive Colorimetric Detection of Cysteine in the Presence of Glutathione Using Gold Nanoparticles Aggregation: *Ensieh Seyedhosseini*[1]; M.Reza Hormozi-Nezhad[2]; [1]Chemistry Department , Sharif University of Technology; [2]Institute for Nanoscience and Nanotechnology(INST),Sharif University of Technology

Low-molecular-mass aminothiols such as cysteine (Cys), homocysteine (Hcy) and glutathione (GSH) play a critical role in many biochemical pathways . Their level in biological fluids such as human plasma and urine are important for clinical diagnostics of a variety of diseases. A fast, easy and very sensitive way to monitor plasma aminothiols is needed to constantly monitor levels as a diagnostic tool for biological concern. We report here in the development of a highly sensitive colorimetric method for detection of cysteine using citrate capped gold nanoparticles (Au-NPs) .This assay relies upon the distance-dependent of gold nanoparticles surface plasmonic resonance band of gold nanoparticles. By controlling ionic strength, pH and Au-NPs concentration, the ratio intensities of absorbance at longer wavelength (640 nm) to original wavelength (521 nm) allow us to develop a simple colorimetric method for determination of cysteine in the presence large amounts of glutathione in biological samples.

U-19: Study on Liquid Sodium with Suspended Nanoparticles-(1) Fabrication and Dispersion of Nanoparticles: *Koichi Fukunaga*[1]; Masahiko Nagai[2]; Kuniaki Ara[3]; Jun-ichi Saito[3]; [1]Mitsubishi Heavy Industries, Ltd.; [2]Mitsubishi Heavy Industries, Ltd..; [3]Japan Atomic Energy Agency

Although liquid sodium has an excellent thermal property as a coolant of the fast breeder reactor, it has disadvantage due to the high chemical reactivity with water and oxygen. The purpose of this study is the development of the technology to suppress the chemical activity of sodium by the dispersion of the nanoparticle in liquid sodium. In this paper, fabrication technology and dispersion technology of nanoparticles are reported. The conditions to suspend the nanoparticle into sodium stably are approximately 10nm in diameter and non-oxidation surface. So the evaporation method was used to produce nanoparticles. It became clear that the cooling rate of metallic vapor was a key factor to control the diameter of nanoparticle. The morphology of nanoparticles in sodium was observed by TEM. The diameter of nanoparticles did not grow in liquid sodium at elevated temperature. These results mean that nanoparticles were suspended stably in liquid sodium.

U-20: Study on Liquid Sodium with Suspended Nanoparticles-(2) Atomic Interaction and Characteristics of Liquid Sodium with Suspended Nanoparticles-: *Jun-ichi Saito*[1]; Keiichi Nagai[1]; Kuniaki Ara[1]; [1]Japan Atomic Energy Agency

Liquid sodium has superior thermal properties as a coolant of the fast reactor. However it has high chemical reactivity with water and oxygen. The purpose of this study is to suppress the high chemical reactivity by dispersing nanoparticles into liquid sodium. An idea of this study is to use an atomic interaction between the nanoparticle and sodium to suppress the chemical reactivity. The theoretical calculation showed the atomic bonding between nanoparticle and sodium was stronger than that between sodium atoms. It is expected that the fundamental and reaction properties change by the atomic interaction. Evaporation rate and surface tension of sodium with suspended nanoparticles changed. It is caused by the atomic interaction. Also the reaction behavior with water or oxygen of sodium with suspended nanoparticles was suppressed. It means that there is the possibility of suppression of reactivity of liquid sodium by the atomic interaction.

U-21: Study on Microstructure Control and Atmospheric Corrosion of Micro-alloying Heavy Rail Steel: *Wang Xiao Li*[1]; [1]University of Science and Technology Beijing

Atmospheric corrosion of steel is a universal and serious problem that caused great damage every year. There are advantages in mechanical properties for micro-alloying heavy rail steel.If improved the steel corrosion resistance, it can be obtained good mechanical properties and corrosion resistance. In this paper, the effects of alloying elements on atmospheric corrosion of Micro-alloying heavy rail steel were studied by accelerated corrosion in laboratory. This provides a feasible technical route for development of a corrosion resistant high strength heavy rail steel.

U-23: The Post-Annealing Effects of N-Doped ZnO Films Deposited by the Atomic Layer Deposition: *Kwang Seok Jeong*[1]; Yu Mi Kim[1]; Ho Jin Yun[1]; Seung Dong Yang[1]; Sang Youl Lee[1]; Young Su Kim[2]; Hi Deok Lee[1]; Ga Won Lee[1]; [1]Chungnam National University; [2]Nanofab Center

ZnO-based optical devices are expected to be efficient and practical due to wide band gap(~3.4 eV) and the large exiton binding energy (~60 meV). However, the ZnO film suffers from the difficulty with p-type film formation due to the drawbacks of the ZnO film itself. N doped ZnO films of 15 at% are deposited to form the p-type film on Si3N4/Si substrate of 150 °C by the atomic layer deposition process and then the post-annealing process is carried out from 300 °C to 700 °C under N2 ambient. From XRD analysis, as-grown and post-annealed N-doped ZnO films show larger FWHM values of the (002) peaks, compared with those of as-grown ZnO films, which means that N atoms and/or N–H complexes are

POSTERS

incorporated on O sites or in the ZnO lattice. Afterwards, through Hall effect measurement, it is found out that P-type ZnO films is successfully formed at 500 °C.

U-24: Thermo-mechanical properties investigation of PMMA nanocomposites using functionalized zirconia nanoparticles: *Muhammad Sajjad*[1]; [1]Vienna University of Technology

PMMA-ZrO2 nano-composites were prepared by in-situ polymerization of zirconia dispersions in methyl methacrylate (MMA). Zirconia nanoparticles in two different size ranges, one in the low nanometer range (about 10 nm) and other in the high nanometer range (about 50 nm) were modified with two types of organo-phosphorus coupling agents, one with short alkyl chain (C2) and other with long alkyl chain spacer (C10). SAXS (small angle x-ray spectroscopy) and TEM (transmission electron microscopy) investigations revealed homogeneous dispersion of the modified zirconia nanoparticles in PMMA. Thermo-mechanical characterization of the prepared nano-composites films showed significant positive effect on the properties of PMMA with both types of modified nano-particles. PMMA nano-composites exhibited improvements in glass transition temperature, storage modulus, micro-hardness and thermal stability. Positive effects on properties are attributed to coupling agents responsible for creating strong interaction between the organic polymer phase and modified interface of nano-particles.

Alumina and Bauxite: Poster Session

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee
Program Organizer: Benny Raahauge, FLSmidth

Monday PM — Room: Atlantic Hall
March 12, 2012 — Location: Dolphin Resort

M-1: Acid Cleaning of Titanium Based Scales Formed on Preheaters in the Bayer Process: *Ibrahim Akpinar*[1]; Yasemin Guldogan[2]; Oktay Uysal[2]; Gökhan Demir[3]; Meral Baygul[3]; Yücel Sahin[4]; [1]Entekno industrial, technological and nano materials ltd.; [2]Entekno Industrial, Technological and Nano Materials Ltd.; [3]Eti Aluminyum A.S; [4]Anadolu University

The titanium impurity in the bauxite leads to titanium based scale formation on the preheater units at the Bayer process. Scale formation leads to decreased heat transfer coefficient, increased energy consumption and higher maintenance costs. For these reasons, periodical cleaning of the scale is essential for alumina plants. Acid cleaning is used whenever other methods of cleaning are not effective. For different kinds of scale the effect of acid types differs considerably. While H2SO4 and HCl acids are affective for cleaning sodium aluminosilicate type scales they are not affective for cleaning titanium containing scales. In this work, effects of types of acids on the cleaning performance of titanium based scales in the Bayer process were investigated with respect to time and thickness of the scale by using dynamic and static conditions at room temperature. This paper reports an acid formulation which is best suited for titanium based scales.

M-2: Extracting Alumina from Coal Fly Ash with Ammonium Sulfate Sintering Process: *Laishi Li*[1]; Xinqin Liao[1]; Yusheng Wu[2]; Yingying Liu[1]; [1]Shenyang Aluminum & Magnesium Engineering & Research Institute Co., Ltd.; [2]School of Materials Science and Engineering, Shenyang University of Technology

The whole process of extracting alumina from coal fly ash was gotten by experiments. Alumina was prepared with sintering, leaching, separating, precipitation with ammonia water and calcination units. The effects of the sintering temperature and the sintering time, molar ratio of ammonium sulfate and alumina in fly ash and the size of fly ash on the extracting efficiency of alumina in fly ash were studied. The extracting efficiency of alumina can reach 95% under the optimum conditions.

M-3: Study on Absorption of Low-Concentration SO2 with Basic Slag Intensified by Ultrasonic Wave: *Nan Xiangli*[1]; Zhang Ting'an[1]; Zhang Lu[1]; Liu Yan[1]; Lv Guozhi[1]; Zhao Qiuyue[1]; [1]Northeastern University

In this paper, it focuses on the absorption of low-concentration SO2 with red mud to eliminate the harm of both the low-concentration SO2 and Bayer red mud to the environment. It studies on the absorption experiments intensified by ultrasonic wave of 20 kHz at different ultrasonic power. It also investigates the effects of experimental conditions on desulfurization and dealkalization processes, which are different liquid-solid ratio, stirring speed of impeller, gas flow, temperature and ultrasonic power. Through the single factor experiment and orthogonal test, the results were analyzed by the chemical and XRD analysis technology. The conclusion shows that the desulfurization and dealkalization processes can be intensified by ultrasonic wave. The optimal conditions are: liquid-solid ratio is 9:1; stirring speed of impeller is 250 rpm; gas flow is 0.1 m3/h; the ultrasonic power is 550 W. The amount of desulfurization reaches 36.7 ml/g at 25°C.

Aluminum Alloys: Fabrication, Characterization and Applications: Poster Session

L-1: A Study of Microstructural Stability of Friction Stir Welded Joints of Al-Mg Alloys during Subsequent Thermal Exposure: *Chun-Yi Lin*[1]; Truan-Sheng Lui[1]; Li-Hui Chen[1]; [1]National Cheng Kung University

Al-Mg wrought alloys such as Al-2.6Mg, Al-4.6Mg and Al-4.6Mg-1Si were friction stir welded and a subsequent thermal exposure was carried out in this study. The effects of elements addition and exposure temperature on the microstructural stability of welded zone were investigated. A grain refinement was found in the weld zone of each alloy and the average grain size of friction stir welded Al-2.6Mg, Al-4.6Mg and Al-4.6Mg-1Si was 10.1, 7.4 and 4.7μm, respectively. Thermal exposure caused drastic coarsening of grains in the stirred zone and abnormal grain growth initiated at some preferred sites such as upper surface and bottom. The volume fraction of coarsening grains increased with increasing exposure temperature; however an unexpected decrease in grain size was found at 550°C in compare to 500°C. Besides, the addition of Mg and Si deteriorated the thermal stability of grain structure in stirred zone.

L-2: Characterization of the Compressive Behaviour of an Al Foam by X-Ray Computerized Tomography: *Girolamo Costanza*[1]; F. Mantineo[2]; Severino Missori[1]; Maria Elisa Tata[1]; Andrea Sili[2]; [1]University of Rome "Tor vergata"; [2]Università di Messina

Al metal foams manufactured by the powder-method have been investigated. Compression tests were performed on the same sample at increasing deformation steps: at each stage the sample was observed by X-ray computerized tomography. A geometric evaluation of porosity on many sections was performed by calculating, for each pore, its area, equivalent diameter, perimeter and circularity. During compression tests at first deformation occurs in the weakest zones of the samples, leading to cells collapse and densification that progressively propagates in a wide region until final densification. Going on compression, cells reduce progressively their dimensions: at each compression step it can be observed the disappearance of cells with the greatest equivalent diameter and the increasing of the number of cells with the smallest diameter. In particular at the last step the reduction of the total cells number occurs.

L-3: Computer Aided Cooling Curve Thermal Analysis of Al-Si-Cu-Mg Alloys: First and Second Derivative Curves: *Saeed Farahany*[1]; Ali Ourdjini[1]; Mohd Hasbullah Idris[1]; [1]Universiti Teknologi Malaysia

Since industrial alloys behave far from ideality and equilibrium, computer aided cooling curve thermal analysis (CA-CCTA) is more practical compare to DTA, DSC and TGA. Determining critical characteristic parameters is crucial to control the quality of melt in terms of level of grain refinement, Si modification and impurity. Due to the small amount of heat evolved of some phase transformation, first derivative curve is used to reveal characteristic temperatures. However, there are contradicting views about the application of second derivative curve. The intention of this study is to establish a relationship between those curves. Two slope-tangents cross technique was used to measure TN based on the first derivative curve. However, in this research, a turning point at the second derivative curve was considered the precise moment when the dT/dt shifts upwards. Moreover, second derivative curve was introduced as a criterion for determining dendrite coherency point (DCP) based on one thermocouple technique.

L-4: Effect of Co on the Microstructure of Al-20Si-5Fe Alloys: O. Uzun[1]; M.F. Kilicaslan[2]; F. Yilmaz[3]; *Soon-Jik Hong*[4]; [1]Gaziosmanpasa University; [2]Kastamonu University; [3]Gaziosmanpa University; [4]Kongju National University

Al-20Si-5Fe-XCo (X=0, 3) alloys were produced by both conventional sand casting and melt-spinning at 20m/s disc velocity. The microstructures of the alloys were investigated using XRD, OM, and SEM. Vickers microhardness tester was used to see changing tendency of hardness with the effect of Co. Results of measurments showed that the microstructure of cast alloys consisted of a- Al, coarse intermettallic compounds and Si particles, and fine lamellar ternary eutectic microstructure. Co had little effect on both primary and eutectic Si in cast alloys. With addition the Co, the morphology of d-intermetallic compound was changed from acicular to rod-like. In the case of the melt-spun ribbons, the addition of Co brought about changing of the microstructure drastically. The melt-spun ribbons had finer microstructure compared to the cast alloys. There was an increase in hardness values of both the cast and the melt-spun alloys parallel to the addition of Co.

L-5: Effect of Pin Tool Pass on the Quality of Friction Stir Weldment: An Experimental Evaluation: *Abdelrahman Shuaib*[1]; Fadi Al Bedour[1]; Nesar Merah[1]; Abdulaziz Bazoune[1]; [1]King Fahd University of Petroleum & Minerals

Most of the current applications of friction stir welding of aluminum parts involve the conventional butt, corner,edge,lap, and tee joints in which the pin-tool travels along a straight line. There are increasing efforts in introducing friction stir welding in relatively more complex contoured welding applications such as end joining of small diametr pipes and joining tubes to tubesheets in heat exchangers. This paper presents the results of an experimental investigation on the effect of the tool path on the weld quality of a 600 alumium grade. A fully instrumented experimental RM-1 Friction Stir Welding machine manufaured by Manufacturing Technolgies, Inc. (MTI) with a CNC controller is used to produce two types of weldments: a straight butt weld, and a contoured weld simulating the pass of tube-tubesheet joint.The results of the tests are used to identify the porcess pramaetrs that are influnced by the changes in weld geometry.

L-6: Energy Absorption of Aluminum Foam-Filled Tubes under Quasi-Static Axial Loading: *Huan Liu*[1]; Guangchun Yao[2]; Zhuokun Cao[2]; [1]Northeastern University ; [2]Northeastern University

Closed aluminum foams fitted thin-walled circular tubes was investigated for its energy absorption characteristics. Compression test was carried out to obtain the representative quasi-static stress-strain curves. The deformation characteristic (foam, tube and their combination) was analysed. The results indicated that the plateau region of the stress-strain curve exhibited a marked fluctuant serration which was related to the formation of folds and cracks. The foam–tube configuration absorbed more energy than the sum of foam and tube due to the interaction between tube and filler which contains friction, extrusion, crack formation and growth. In addition, the energy absorption of foam–tube configuration was 4.5 times of aluminum foams. The experiment results reflected that the foam–tube configuration was a potential energy absorber candidate for car industry and transportation cask.

L-7: Fabrication and Characterization Al-SiC Composite Foam: *Geo Harrison*[1]; Ganapathy Subramanian[2]; Vinoth Kambli[2]; Pradeep Kumar[2]; [1]COLLEGE OF ENGINEERING GUINDY, ANNA UNIVERSITY; [2]College of Engineering Guindy, Anna University

Metal matrix composite foams have very low density, high stiffness and good impact resistance. These properties enable them to be used in various automotive and structural components. Al-SiC composite foams are prepared by dispersion of fine Silicon carbide powder in molten aluminum, followed by blowing of an inert gas and simultaneous stirring. The well dispersed inert gas bubbles form numerous micro-voids during solidification of the composite. A fine Al-SiC composite foam with homogeneous micro-structure is manufactured by this process. The impact resistance, stiffness and the mechanical behavior of the Al-SiC are analyzed subsequently.

L-8: Friction Stir Welding of Aluminum Alloys: *Jaehyung Cho*[1]; Chang Gil Lee[1]; [1]Korea Institute of Materials Science

Microstructure and mechanical properties of friction stirred aluminum alloys, AA5xxx (solid solution alloys), and AA6xxx (aging alloys) were investigated. Microstructural feature and texturing according to various welding conditions were examined. AA5xxx alloys had comparatively narrower welding zone than AA6xxx. Strength of the welded zone of AA5xxx was almost similar to that of the base materials. While, AA6xxx had lowered strength near the weld and HAZ, comparing with the base materials. The weld zone is wider than the diameter of the tool probe. In both alloys, fined and recrystallized grains were mainly observed near the weld zone. Elongated and curved grains from the base to the weld zone clearly disclosed the typical metal flow during welding. Various shear texturing was also observed with position and the equi-axed grain shapes reflected that they were fully-recrystallized due to high heat generation during welding process.

L-9: Mechanical and Microstructural Characterization of a 2618 Aluminum Alloy under Compression Tests: *Adriana Salas Zamarripa*[1]; Edgar Fragoso[1]; Ana Macias[1]; Martha Guerrero Mata[1]; [1]Universidad Autonoma de Nuevo Leon

Identification and quantification of microstructural heterogeneities in a 2618 aluminum alloy under three different heat treatment routes, such as second phase particles, inter- and trans- granular quenched precipitates and precipitate free zones, were done during this investigation. The relationship between these heterogeneities, specially the second phase particles (FeNiAl9), and the mechanical performance under compression was evaluated. Scanning Electron Microscopy (SEM) and image analysis were employed to identify and quantify the FeNiAl9 particles. This analysis was done before and after the compression tests. The compression tests were done under three different rates and under high temperature to emulate forging conditions. The results showed differences in amount, size, and shape factor of the FeNiAl9 particles and these characteristics had an effect in the compression behavior of this material.

L-10: Optimization of Process Parameters of Preparing Foamed A1-Si Alloy Based on Ga-Based Bp Neural Network: *Jingbo Xu*[1]; Huimin Lu[1]; Qiang Li[1]; [1]Beihang University

This paper analyses the dependence of the structures of foamed Al-Si alloy on the process parameters. It takes the aid of back propagation (BP) neural network theory to build the nonlinear mapping relations between the crucial process variables and the quality of pores. Then by the integrating BP neural network and genetic algorithm (GA), the optimized process parameters for high porosity of foamed Al-Si alloy can be searched. The comparisons between experiment results and neural network simulation results show that GA-based on BP method can predict the porosity with

POSTERS

higher prediction accuracy. The effects of viscosity and cooling conditions on the foamability are also important. The mechanism of thickening agent has been analyzed theoretically. The suitable solidification method of the melt is good for promoting uniformity of the pore structure of the alloy foams.

Biological Materials Science Symposium: Poster Session

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division, TMS: Biomaterials Committee
Program Organizers: Nima Rahbar, University of Massachusetts Dartmouth; Candan Tamerler, University of Washington; Po-Yu Chen, University of California, San Diego; Molly Gentleman , Texas A&M University

Monday PM — Room: Atlantic Hall
March 12, 2012 — Location: Dolphin Resort

G-1: Aging Heat Treatment and Phase Transformations in Ti-Nb-Sn Alloys: Eder Lopes[1]; Alessandra Cremasco[1]; Rodrigo Contieri[1]; *Rubens Caram*[1]; [1]University of Campinas

Application of titanium in the orthopedic biomaterials field is ever growing. Research has recently focused on the β Ti alloys, that can be produced from non toxic elements and depending on composition and processing routes applied, can present low elastic modulus, enhanced biocompatibility, high corrosion resistance and high strength-to-weight ratio. Mechanical behavior of β titanium alloys depends on microstructural features and it can be improved by tailoring the microstructure through the control of their phase transformations. The objective of this investigation is to discuss phase transformations during aging heat treatment of β Ti-Nb-Sn alloys and to correlate microstructure and mechanical behavior. The results obtained from high temperature XRD experiments showed decomposition of orthorhombic a" phase, which is followed by β and α phases precipitations. The mechanical behavior of Ti-Nb-Sn alloys was found to be very sensitive to the microstructural changes caused by addition of Sn and heat treatments.

G-2: Corrosion Behavior under Biological Environment of $Zr_{61}Ti_2Cu_{25}Al_{12}$ Amorphous Alloy: *Ling Shi*[1]; Xu Zhao[1]; Qiang He[1]; Jian Xu[1]; [1]Institute of Metal Research, Chinese Academy of Sciences

Electrochemical behavior of $Zr_{61}Ti_2Cu_{25}Al_{12}$ (ZT1) amorphous alloy in PBS and artificial saliva with NaF addition simulating the fluoride contents in commercial toothpastes was investigated. The corrosion resistant i.e. a decrease in the corrosion rate and anodic current density and an increase in the pitting potential decreased with increasing NaF concentration. The equivalent circuits from EIS test were proposed. Mott–Schottky analysis showed the passive film is n-type semiconductor and the donor density increased sharply with 0.5% NaF addition. A change from a high field-controlled layer growth to a diffusion-controlled oxide layer formation with increasing NaF was observed. XPS analysis indicated the outmost surface was predominantly composed of Zr^{4+} and Al^{3+} species. Compared with Ti-6Al-4V, ZT1 exhibits a lower penetration rate (CPR) with NaF=0.01% and then a higher CPR with NaF=0.1%. This indicates the presence of fluoride ions was detrimental to the protective ability of the ZrO_2-based film on ZT1.

G-3: Effect of Heat Treatment on Oxidation Behavior and Brightness of Oxide Film Formed on Ti-Nb-Ta-Zr Alloy: *Eri Miura-Fujiwara*[1]; Soichiro Yamada[2]; Yoshimi Watanabe[2]; Toshihiro Kasuga[2]; Mitsuo Niinomi[3]; Tohru Yamasaki[1]; [1]University of Hyogo; [2]Nagoya Institute of Technology; [3]Tohoku University

Metallic materials for dentistry have excellent mechanical properties as a load bearing material, however, they are inferior in point of esthetic."White metal", which has excellent mechanical properties like metal with white color top has been long awaited. Now, we have found oxide film on Ti-29Nb-13Ta-4.6Zr alloy formed at high temperature has a white color and high exfoliation strength. In this study, the oxide film formation behavior and effect of heat treatment condition on brightness of oxidized surface were investigated. Dense white-colored oxide film was formed by heat treatment in air, and it was found by a x-ray diffraction and a x-ray photoemission spectroscopy that oxidation film was consisted of rutile and Ti(Nb, Ta)2O7. Brightness of the oxidized surface increased with increasing oxidation time, since thickness of the oxide layer increased with increasing. Optimum oxidized condition without exfoliation was determined.

G-4: Effects of Nitrogen Addition on Mechanical Properties of Hot-Forged Biomedical Co–Cr–Mo Alloys with Ultrafine–Grained Microstructures: *Kenta Yamanaka*[1]; Manami Mori[2]; Akihiko Chiba[1]; [1]Tohoku University; [2]NISSAN ARC, LTD.

The ultrafine-grained (UFG) microstructures of Ni-free Co–29Cr–6Mo (wt.%) alloys, which are designed for biomedical applications, have been successively fabricated by conventional hot forging process. The mean grain size of 0.8 µm was obtained by hot forging reduction of 83% (true strain of 1.8), which is much smaller than those in so-called severe plastic deformation. Significant grain refinement drastically enhanced tensile strength, while the elongation was limited to a few percent in Co–Cr–Mo ternary alloys. We have revealed that the addition of nitrogen, as is known to be one of the non-toxic phase (fcc) stabilizer, improves the elongation remarkably. The excellent ductility of the UFG alloys with N doping should be involved in constituent phase and strain-induced martensitic transformation. The present method characterized by ultragrain refinement with nitrogen addition to stabilize the phase can provide a potent strategy to obtain superior mechanical properties.

G-5: Evaluation of Properties of TiO2 Ceramic Dental Block Fabricated by Magnetic Pulsed Compaction (MPC): Hyo-Young Park[1]; Jin-Sung Choi[1]; Hyo-Seob Kim[1]; Uk-Hyon Joo[2]; Jar-Myung Koo[1]; *Soon-Jik Hong*[1]; [1]Kongju National University; [2]BioMaterials Korea Inc

TiO2 is well known for its excellent properties and dental application, such as biocompatibility, good fracture resistance, high fracture toughness and hardness. However, commercially available bulks still lack good mechanical properties. In this study, to improve the mechanical properties, TiO2 bulk was fabricated using TiO2 powders with addition of Ti and P-25 (Degussa) by magnetic pulsed compaction (MPC). In order to evaluate the effect of Ti and P25, MPC pressure (0.5~2GPa) and sintering temperature (800~1450°C, 2h) on TiO2 bulk, various mixing conditions has been investigated (Ti: 2wt%, P-25: 0~8wt%). Results suggest that all of the samples' density and mechanical properties are improved with increased MPC pressure and sintering temperature. In addition, density and hardness of bulks decrease with addition of P-25 powder whereas fracture toughness and hardness increase with addition of Ti on the sintered bulks.

G-6: In Vito Osteogenic Capability of Rat-Derived Mesenchymal Cells Cultured on Biomimetic Hydroxyapatite: *Mina Khorami*[1]; Saeed Hesaraki[1]; Sajad Farhangdoust[1]; Ali Zamanian[1]; Hamid Nazarian[1]; [1]materials and energy research center

Nanostructured-carbonated hydroxyapatite (n-CHA) was prepared utilizing hydraulic conversion of calcium phosphates and characterized using TEM/SEM, XRD and FTIR. Rat-derived Mesenchymal stem cells (MSCs) were seeded on n-CHA in osteogenic agent-free medium. The MSCs/scaffold constructs were cultured up to 14 days and proliferation, alkaline phosphatase activity and morphology of MSCs were determined. Osteogenic differentiation of seeded MSCs was assayed by alizarin Red staining as well as ALP, Osteopontin and osteocalcin expression which was further confirmed by Real-time PCR analysis as osteogenic differentiation markers. The results confirmed that n-CHA comprised needlelike crystals of carbonated-apatite with thick diameter ranging 20-30 nm. It was observed that MSCs attached and spread well on n-CHA scaffold with enhanced proliferation and ALP activity. Interestingly, the

POSTERS

osteogenic differentiation of MSCs was confirmed by the expression of bone specific proteins including osteocalcin, osteopontin and alkaline phosphatase. Overall, the osteoconductive bone-like n-CHA apatite may also serve as an osteoinductive materials.

G-7: Mechanical Behavior and Corrosion Resistance of Nanostructured $Ti_{67.79}Fe_{28.36}Sn_{3.85}$ and $Ti_{53}Nb_{35}Zr_{7}Ta_{5}$ Alloys for Biomedical Applications: *Anna Hynowska*[1]; Jordina Fornell[1]; Eva Pellicer[1]; Sergio González[1]; Nele Van Steenberge[1]; Santiago Suriñach[1]; Maria Dolors Baró[1]; Jürgen Eckert[1]; Jordi Sort[1]; [1]Universitat AUtonoma de Barcelona

The mechanical behavior and corrosion resistance, in simulated body fluid, of nanostructured $Ti_{67.79}Fe_{28.36}Sn_{3.85}$ and $Ti_{53}Nb_{35}Zr_{7}Ta_{5}$ alloys are compared to those of commercial Ti-Al6-V4. The as-cast $Ti_{67.79}Fe_{28.36}Sn_{3.85}$ rods consist of few β -Ti (Im3m) dendrites embedded in a β -Ti/FeTi (Pm3m) nanoeuctectic matrix. The $Ti_{53}Nb_{35}Zr_{7}Ta_{5}$ alloy shows a composite-like microstructure consisting of several β -Ti phases with different amounts of Nb, Zr and Ta. Nanoindentation experiments reveal that the $Ti_{67.79}Fe_{28.36}Sn_{3.85}$ rods exhibit very large hardness (˜ 8 GPa) and high Young's modulus. In turn, the $Ti_{53}Nb_{35}Zr_{7}Ta_{5}$ alloy shows rather low Young's modulus (˜ 88 GPa), which is advantageous in terms of biomechanical compatibility with bone. All the samples show a rather similar corrosion potential, E_{corr} around -20 mV vs Ag/AgCl, but differ in the corrosion current density values, j_{corr}. The $Ti_{53}Nb_{35}Zr_{7}Ta_{5}$ system has low j_{corr}, very close to that of commercial Ti-Al6-V4, whilst the $Ti_{67.79}Fe_{28.36}Sn_{3.85}$ shows a much larger value.

G-8: Nature's Inspiration: How Do Quills Protect Porcupines?: *Wen Yang*[1]; Ekaterina Novitskaya[1]; Sara Bodde[1]; Zherrina Manilay[2]; Christy Chao[3]; Joanna Mckittrick[1]; [1]Materials Science and Engineering Program,Univerisity of California, San Diego; [2]Department of Mechanical and Aerospace Engineering, Univerisity of California, San Diego; [3]Brown University

African and American porcupine quills were examined using microscopic methods and tested in compression and flexure. Quills are light-weight, composed of alpha-keratin and protect the animal from predators. The African porcupine quills are larger than the American ones and have longitudinal stiffeners (ribs) that extend from the cortex to the center, with foam that fills the remaining volume. This is in contrast to the American quills, which are only filled with foam. The cortex of quill has similar compressive strength to that of the whole quill whereas the foam has a much lower strength but a larger strain to failure, indicating that the cortex functions to resist deformation while the foam functions as buffer that absorbs energy. Deformation mechanisms and structure-mechanical property relationships are evaluated and discussed. This research is supported by the NSF, DMR, Ceramics Program Grant 1006931.

G-9: Nitinol Commercialization Accelerator – Ohio Third Frontier: *Janet Gbur*[1]; JR Lewandowski[1]; H Lavvafi[1]; M Young[2]; D Schwam[1]; JD McGuffin-Cawley[1]; MV Nathal[3]; S Padula[3]; JJ Lewandowski[1]; [1]Case Western Reserve University; [2]Cleveland Clinic; [3]NASA Glenn Research Center

The Ohio Third Frontier Wright Projects Program recently funded a collaborative effort between the Cleveland Clinic, CWRU, University of Toledo, NASA Glenn Research Center, and Norman Noble, Inc. in order to develop a better understanding of the metallurgical processing and mechanical characterization of nitinol for use in biomedical and aerospace applications. Biomedical applications range from orthodontia to implantable devices while higher temperature shape memory alloys are of interest for aerospace. The collaboration is designed to create synergy amongst collaborators in the research and development of nitinol products. CWRU is developing a facility wherein the effects of composition changes on mechanical performance can be determined. The CWRU facility includes a vacuum arc melter and heat treatment system, high temperature DSC, laboratory extrusion press, and various fatigue testers. Capabilities and preliminary fatigue data will be provided.

G-10: Parametric Study of Fibroblast Attachment Kinetics on Fibronectin-Coated Polystyrene Tissue Culture Plates: *Shawn Regis*[1]; Sina Youssefian[1]; Nima Rahbar[1]; Sankha Bhowmick[1]; [1]UMass Dartmouth

Cell adhesion is mediated by specific interaction between receptors and ligands. This research presents the results of a numerical and experimental study on cellular attachment to fibronectin-coated 24-well polystyrene plates. This process relies on the interaction between the a5ß1 integrin and fibronectin ligands. This project focuses on the generation of insightful models to accurately represent fibroblast ability to attach to fibronectin. Based on existing literature and experimental parameters, a dynamical model of fibroblast attachment kinetics on fibronectin coated tissue culture plates was developed. This was accomplished using a phase plane analysis of a system of nonlinear ordinary differential equations, which govern the changes in free receptor density and bond density within the contact area with time. Furthermore, experimental data of receptor-ligand bond density was used to analyze the accuracy of the devised model.

G-11: Peptide-Enabled Control of Metal Nanoparticle Biomineralization: *Marketa Hnilova*[1]; Dmitriy Khatayevitch[1]; Hanson Fong[1]; Candan Tamerler[1]; Mehmet Sarikaya[1]; [1]University of Washington

Peptide mediated synthesis of metallic nanostructures is biocompatible and non-toxic alternative to conventional chemical methods. Here we examine formation mechanism, kinetics and morphology of nanoparticles (NPs) produced by combinatorially selected Au binding peptides (AuBP). We produced AuBPs in linear and cyclic forms to determine effect of molecular constraints on peptides' catalytic activities. Both AuBPs catalyze gold formation in aqueous solution under ambient conditions resulting in stable peptide-capped AuNPs. By varying reaction conditions, we tailor NP morphology by controlling the nucleation and growth rates during the biomineralization process. The synthesis is controlled such that NPs in the size range of 2 nm to >100 nm can be produced with fairly uniform distribution. Peptide-based biomimetic syntheses have implications in a wide range of applications including nanobiophotonic and biosensing platforms. Research is supported by NSF-IRES, -BioMat (DMR 0706655) and -MRSEC Programs through the University of Washington GEMSEC (DMR 0520567).

G-12: Processing and In Vivo Evaluation of Spark Plasma Sintered Al2O3-YSZ-TiO2 Composites: Ipek Akin[1]; Viorica Simon[2]; Simona Cavalu[3]; *Gultekin Goller*[1]; [1]Istanbul Technical University; [2]Babes-Bolyai University; [3]University of Oradea

In this study, Al2O3, and Al2O3/YSZ composites with 3 and 5 wt% TiO2 were prepared by spark plasma sintering at 1400°C for 300 s under 40 MPa. Adult rats from the Wisthar-Furth lineage were used for in vivo evaluations. They were kept in a proper environment under natural lighting and temperature. A 0.75cm x 1.5cm bone defect was created on the body of each mandible in animals using a low RPM Sorensen 7.5 spherical burr. The defects were filled with granular Al2O3-based composites containing YSZ and TiO2, and blood plasma harvested from each animal prior to surgery. A collagen film was placed on the top of the filled defect in order to improve the biocompatibility of the implanted material. The histopathological tests of the surrounding tissue and specimens containing the junction between the implanted material and natural bone were characterized by using a scanning electron microscope.

G-13: Strong Fiber Reinforced Hydrogel Composite: Animesh Agrawal[1]; Sina Youssefian[1]; *Nima Rahbar*[1]; Paul Calvert[1]; [1]University of Massachusetts Dartmouth

This work is focused on designing a new class of hydrogels, based on fiber reinforced composites technique with a cartilage-like structure. In analogy to the spinning of a spider web, a pultrusion system is developed to spin micron-diameter fibers from polymer solution in order to build three dimensional patterned fibrous structures. Impregnating the fibrous construct with epoxy-amine hydrogel forms fiber-reinforced hydrogel composites. The fibrous construct improves the strength, modulus and toughness of the hydrogel and also constrains the swelling. By altering the construct geometry and studying the effect on mechanical properties we will develop the understanding needed to design strong hydrogels for biomedical devices and soft machines. Also experimental results were compared with hyper-elastic and poro-elastic theories in order to predict the mechanical behavior of composite hydrogels.

G-14: Strontium Releasing And Physicochemical Properties of Novel Calcium Sulfate Bone Substitute Materials: Saeed Hesaraki[1]; *Sajad Farhangdoust*[2]; Hadis Bandegani[2]; Mina Khorami[2]; Ali Zamanian[2]; [1]materials and energy research center; [2]Materials and Energy Research Center

This paper describes strontium-releasing, physicochemical and cellular properties of gypsum bioceramics doped with 0.19 – 2.23 wt. % of strontium ions. Strontium-doped gypsum (gypsum:Sr) was obtained by mixing calcium sulfate hemi-hydrate powder and solutions of strontium nitrate. Gypsum was the only phase found in the composition of both pure and gypsum:Sr, with slight right-shift in XRD peaks of latter. The compressive strength of pure gypsum was ~ 28 MPa which was reached to ~ 42 MPa by incorporating 2.23 wt% of Sr. Microstructure of all specimens consisted of rod-like crystals entangled to each other with more elongation and higher thickness in the case of gypsum:Sr. Continuous release of strontium ions was observed from gypsum:Sr during soaking in simulated body fluid. Compared to pure gypsum, gypsum:Sr showed better proliferation rate and higher alkaline phosphatase activity of osteoblasts. The results predict better in vitro performance of strontium-doped gypsum compared to pure one.

G-15: Sulfate- Reducing Bacteria Biofilm Corrosion Behavior of High Strength Steel (API-5L X80) Weldment: *Faisal Al-Abbas*[1]; Tony Kakpovbia[1]; David Olson[2]; Brajendra Mishra[2]; John Spear[2]; [1]Saudi Aramco; [2]Colorado school of Mines

The utilization of high strength carbon steels in the oil and gas transporting systems has been increased recently. This work investigates microbiologically influenced corrosion (MIC) of API 5L X80 linepipe steel weldment by Sulfate Reducing Bacteria (SRB), Desulfovibrio africanus sp. The biofilm and pit morphology that developed with time were characterized by using scanning field emission scanning electron microscopy (FESEM). Electrochemical Impedance Spectroscopy (EIS), linear polarization resistance (Rp) and open circuit potential (OCP) were used to analyze the corrosion behavior. Through circuit modeling, EIS results were used to interpret the physicoelctric interactions between the electrode, biofilm and solution interfaces. These results confirmed that corrosion activity of Desulfovibrio africanus sp is due to the formed biofilm and a porous iron sulfide layers on the metal surface developed over time. Corrosion products were characterized by X-ray diffraction (XRD) which identified the presence of different sulfide and oxide constituents.

G-16: Weibull Analysis of the Behavior on Tensile Strength of Bamboo Fiber of the Specimen Dendrocalmus Giganteu: *Lucas Martins*[1]; Nathalia Rosa[1]; Sergio Monteiro[1]; [1]UENF

The fibers extracted from the stem of the bamboo plant have been investigated as possible reinforcement composites due to their relatively high tensile strength. However no work was conducted to dimensional characterize the distribution and the effect of diameter on the mechanical resistance of bamboo fiber of the specimen dendrocalmus giganteus. The aim of the present work was to statistically characterize the distribution of the diameter of a lot of bamboo fibers of that specimen. Based on this characterization, diameter intervals were set and the dependence of the tensile strength of theses fibers with a corresponding diameter was analyzed by the Weibull Method. The results indicated an inverse dependence between the diameter and the resistance of that fiber that was adjusted with a hyperbolic equation. An analysis of the microstructure by means of scanning eletron microscope revealed possible mechanism for this correlation.

G-17: Wet Chemical Synthesis of Hydroxyapatite from Egg Shells: *Muhammad Aftab Akram*[1]; Rafaqat Hussain[2]; Mohammad Islam[1]; [1]National University of Sciences and Technology Pakistan; [2]University Teknologi Malaysia, 81310 UTM Skudai, Johor Darul Ta'zim, Malaysia.

Hydroxyapatite is well known bioceramic that possess excellent in-vivo and in-vitro properties due its chemical and structural similarity with mineral part of bone and is widely used as bone graft material in orthopedic surgery and dental implants. In this research a simple green chemistry and environment friendly wet precipitation rout was adopted for synthesis of micro crystalline hydroxyapatite from egg shells by using phosphoric acid as phosphorus precursor. Resulting powder was characterized using TGA/DTA for thermal stability, XRD for structural analysis which proved phase purity and SEM for morphological evaluation which showed spherical particles. FTIR and particle size analysis was also performed. Dielectric studies were also performed at varying temperatures to evaluate trends of relative permittivity, dielectric loss and AC conductivity for its potential sintering in microwave furnace.

C-1: A Kinetic Study of the Leaching of Germanium Dust and Fume by Sulfuric Acid: *Wankun Wang*[1]; Jinhui Peng[1]; Zebiao Zhang[1]; Lijuan Chu[1]; Guodong Lai[1]; [1]Kunming University of Science and Technology

A kinetic study of the leaching of germanium dust and fume by sulphuric acid has been investigated. The effects of (a) acid concentration ranging from 3.15 to 9.45mol/L and (b) temperature ranging from 60 to 80°C on germanium dissolution are reported. The dissolution rates are significantly influenced by the temperature and concentration of the sulphuric acid solutions. The experimental data for the dissolution rates of germanium have been analyzed with the shrinking-core model for reaction control. The observed effects of the relevant operating variables on the dissolution rates are consistent with a kinetic model for diffusion control. The apparent activation energy for the dissolution of germanium has been evaluated using the Arrhenius expression. Moreover, the apparent reaction order and the kinetic equation for the dissolution of germanium were obtained.

C-2: Continuous Modeling of Microstructure Evolution Coupled with Plastic Activity: *Maeva Cottura*[1]; Yann Le Bouar[1]; Alphonse Finel[1]; Benoît Appolaire[1]; Samuel Forest[2]; [1]Laboratoire d'Etude des Microstructures, CNRS/ONERA; [2]Mines ParisTech, Centre des Materiaux CNRS UMR 7633

Plastic activity is often involved during microstructure evolution. The Phase Field Method (PFM) is the most powerful technic to understand microstructure evolution during phase transformations at mesoscale. In this work, a model able to describe both microstructure evolution and plastic activity is derived by coupling a phase field model with a continuous viscoplasticity model. In a heterogeneous material, it is well known that, when the domains are small enough (below typically 1 micron), the plastic behavior of each domain depends on its size. In a continuous modeling, this effect can only be accounted for using a scale dependent plasticity model. Our approach follows a second gradient theory from generalized continuum mechanics. We will present this model and apply it to the study of microstructural evolutions in Ni-based superalloys under creep loading.

C-3: Convex Projection to Estimate Heat Content of Cold Charges in Peirce-Smith Converting: *Alessandro Navarra*[1]; Anna-Maria Pubill Melsió[2]; Joël Kapusta[3]; [1]Universidad Católica del Norte; [2]Air Liquide; [3]BBA Inc.

Peirce-Smith converting (PSC) is applied in over half of the primary production of copper and nickel. PSC generally follows a continuous smelting process, leads a sequence of batch operations, and can thus be a natural bottleneck in copper and nickel production. The main feed for a Peirce-Smith converter is molten matte. Additionally, there are several cold streams that are fed into the converter, which can be mixtures of matte, recycled slag or flue dust. The current work focuses on a technique to estimate the heat content of these cold streams. The heat balance between the hot matte and the cold charges is a major operational constraint that has implications throughout the metal production process. The heat estimation technique is based on geometrical projections in the chemical phase space, and has been conveniently implemented as a function within Microsoft Excel□.

C-4: Effects of Sub-Surface He Bubbles on Tungsten Surface Evolution: *Faiza Sefta*[1]; Karl Hammond[2]; Niklas Juslin[2]; Brian Wirth[2]; [1]UC Berkeley; [2]University of Tennessee

Tungsten is a leading candidate material for the diverter in ITER and other future nuclear fusion reactors. However, helium plasma bombardment experiments have demonstrated that surface defects and bubbles form even at modest ion energies, and in some cases "fuzz" and "coral" like surface features exist after a few hours of exposure. We investigate the formation mechanisms behind these surface features using atomistic molecular dynamics. Sub-surface helium bubbles, in particular, are found to leave behind relatively stable surface defects after they burst. Assuming sub-surface bubbles are in an equilibrium helium density state, we investigate how surface evolutions leading to a thinning of the tungsten layer above the sub surface bubble can lead to bubble bursting and subsequent surface deformation. Under these conditions, we quantify the conditions in which equilibrium and above equilibrium helium bubbles burst as a function of temperature, surface crystallography, bubble depth and tungsten surface deformations.

C-5: Establishment and Analysis of the Composite Key Stratum Model Layer on the Winkler Foundation: *HongYu Pan*[1]; Shu-Gang Li[1]; Peng-Xiang Zhao[1]; [1]Xi'an University of Science and Technology

With the depth and intensity of exploitation increase, some proximal hard rock appeared composite effect, the resulting of rock press appearance poses new challenges to safety in coal seam. The Composite Key Stratum Model Layer on the Winkler Foundation was established by using composite material structural mechanics theory and Key Stratum theory, which was used to analyze Composite Key Stratum's force theoretically and detrude Winkler foundation Composite Key Stratum's interval. Composite Key Stratum flexure formed advance pressure on the near under stratum. Making use of its transfer, spreading and attenuation, the advance pressure and the width of limit equilibrium zone under the Composite Key Stratum were analyzed. Provided theoretical basis for determining working face's cross-off pace and support lectotype in the condition of Composite Key Stratum.

C-6: First-Principles-Based Phase Diagram for $(Mo_xNb_{(1-x)})Si_2$ Pseudobinary Alloys: *Koretaka Yuge*[1]; Yuichiro Koizumi[2]; Koji Hagihara[3]; Takayoshi Nakano[4]; Kyosuke Kishida[1]; Haruyuki Inui[1]; [1]Department of Materials Science and Engineering, Kyoto Univ.; [2]Institute for Materials Research, Tohoku University; [3]Department of Adaptive Machine Systems, Graduate School of Engineering, Osaka University; [4]Division of Materials & Manufacturing Science, Graduate School of Engineering, Osaka University

$MoSi_2/NbSi_2$ duplex silicide is one of the most promising structural materials at ultra-high temperature for improving gas turbine engine performance in power generation systems. It was confirmed [T. Nakano et al., Intermetallics 6 (1998) 715.] that fine lamellae composed of $C11_b$ and C40 phases are formed at $(Mo_{0.85}Nb_{0.15})Si_2$, improving high-temperature strength. However, its phase stability is assessed for limited portion by experiment or is not fundamentally well-understood by theory, which should be significant information for understanding and controlling formation of the lamellae. In this study, we employ first-principles calculation with cluster expansion to quantitatively investigate the phase stability in $(Mo_xNb_{(1-x)})Si_2$ pseudobinary alloys. We find that (i) there is no stable intermediate structure between $MoSi_2$ and $NbSi_2$, (ii) complete miscibility cannot be achieved below melting temperatures, (iii) C40 phase exhibit around ten times larger solubility than $C11_b$, and (iv) temperature-dependence of solubility in C40 is much stronger than that in $C11_b$.

C-7: Gaseous Nitriding Process Control: Application of Customized Lehrer Diagrams: *Mei Yang*[1]; Richard Sisson[1]; [1]WPI

The experimental Lehrer diagram for pure iron is widely used in industry to specify the nitriding potential for nitriding process. However, applying the pure iron Lehrer diagram for alloy steels can lead to incorrect results because of phase stabilities in alloy steels. A customized Lehrer diagram for AISI4140 has been developed by using CALPHAD approach to predict the relationship between the nitriding potential and the phase development as a function of temperature. The prediction is in excellent agreement with the experimental investigation and this proves the utility of using thermodynamic database to calculate the customized Lehrer diagrams for alloy steels. In the present work, series of Lehrer diagrams are developed to analyze the effects of elements such as carbon and manganese for the nitriding process. These diagrams can not only provide the nitriding process parameters for specified alloys but also pave a way for computational materials design to nitriding alloys.

C-8: Intelligent Heat Treating: Simulation of Carburization Process: *Lei Zhang*[1]; Yingying Wei[1]; Liang He[1]; Richard D Sisson[1]; [1]WPI

An effective simulation software CarbTool is developed to predict the carburization performance of a variety of steels. The software is needed not only to predict the carbon profile but also to optimize the process in terms of the cycle time and the cost. It can meet these needs for both gas and vacuum carburization. In this paper, CarbTool predictions were used to provide recipes for the carburization of four types of steels, heat treated by both gas and vacuum carburizing processes. With the industrial experimental results, the simulation parameters are verified. Based on the excellent agreement of model predictions and experimental results, CarbTool may be used to predict the carbon concentration profile for a variety of alloys in both gas and vacuum carburizing processes.

C-9: Molecular Dynamics Simulation Study of the Alloying Reactions of Nanostructured Al/Ni Clad Particles System under Thermal Loading: *Shijin Zhao*[1]; [1]Shanghai University

We present molecular dynamics simulations of the alloying reaction process of nanostructured Al/Ni clad particles under thermal loading. The calculations indicate that the properties of nanostructured Al/Ni clad particles depend strongly on their nanostructures and combustion parameters such as particle size and mass density. With the particle size increasing, both the adbatic temperature and pressure of system rise but the propagation velocity of reaction front decreases. However, when either mass density or ignition temperature increases, the adiabatic combustion temperature, the pressure of the system, and the propagation velocity of

POSTERS

the reaction front increase. The cracking of nickel layer, governing the contact surface and mass diffusion of aluminums and nickels, plays a key role in the propagation process of Al/Ni clad particles.

C-10: Numerical Simulation of Directionally Solidified Structure of Ti-47Al-2Cr-2Nb Alloy Based on CA Method: Jixiang Xu[1]; Qingyan Xu[1]; Jin Cheng[1]; Hu Zhang[2]; Baicheng Liu[1]; [1]Tsinghua University; [2]Beihang University

Physical and mathematical models for microstructure evolution of Ti-47Al-2Cr-2Nb (atomic fraction, %) alloy during directional solidification process were developed based on CA method, considering peritectic reaction. Growth of peritectic phase during directional solidification was simulated. Simulated results show that a phase nucleates on the interface of liquid and ß below the peritectic temperature and grows into the ß phase and the liquid. Competitive growth of columnar grains was simulated to investigate the influence of different preferred growth orientations on the morphologies of columnar dendrites. Microstructure was simulated at the withdrawal rates of 1.2mm/min, 5mm/min and 10mm/min, which shows that directional growth zone is composed mainly of columnar grains of primary ß phase and a small volume fraction of peritectic a phase can be observed in the interdendritic regions of ß phase. Primary dendrite arm spacing of columnar grains decreases with the increasing withdrawal rate, which agrees well with experimental results.

C-11: Phase Diagram Determination for Several Fe-Based and Ni-Based Ternary Systems: *Siwei Cao*[1]; Ji-Cheng Zhao[1]; [1]The Ohio State University

A diffusion multiple was made by assembling finely-polished Ni, Fe, Co, Cr, and Mo metal pieces, followed by a hot-isostatic-pressing (HIP) treatment. Long-term heat treatment was performed at both 1200 °C and 1000 °C. Electron probe microanalysis (EPMA) are performed to obtain local equilibrium information at the phase interfaces to construct isothermal sections for some of the following ternary systems: Fe-Co-Ni, Fe-Mo-Ni, Fe-Cr-Ni, Mo-Cr-Ni, Mo-Co-Ni, Mo-Cr-Fe, Mo-Cr-Co, and Co-Cr-Fe. These phase diagrams will be important input data for thermodynamic modeling of these systems, especially related to the topologically close packed (TCP) phases. Lower temperature heat treatment is also planned to assess the stability of the R-phase in some of these ternary systems.

C-12: Reactivity of the Faying Surface in Al-Mg2Si Metal Matrix Composite/Magnesium Alloy Bonds: *Mehdi Mazar Atabaki*[1]; Andrew Mullis[1]; [1]University of Leeds

A model of dissolution and isothermal solidification during low temperature-partial transient liquid phase bonding process of Al/Mg2Si metal matrix composite to AZ91D joints using Al interlayer is presented. It was found that the lower temperature gradient resulted in increase of isothermal solidification. It is showed that kinetics of the bonding process significantly accelerated in presence of reinforcement (Mg2Si). This acceleration is attributed to the increased solute diffusivity through grain boundaries of the metal matrix composite. The numerical model estimates the fraction of wafer layer, formed at the surface of the substrates. Results suggest that Si and Mg contained in the interlayer favours the partial disruption of the aluminium oxide film, making easier the bonding process. However, the diffusion of Mg and its component to the grain boundary of the Al metal matrix composite was the main controlling factor in the bonding process.

C-13: Study on Blowing Nitrogen Alloying of Stainless Steel AISI410 with LF Refining: *Zhou Cai*[1]; [1]Chongqing University of Science and Technology

The effect of nitrogen blowing time, nitrogen rate and liquid temperature in normal atmosphere condition on nitrogen content has been tested and studied by using 40tLF for refining stainless steel AISI410 and the control model of nitrogen alloying during LF refining has been established. The experimental results show that with increasing nitrogen blowing time and nitrogen rate the nitrogen content in steel increases, the nitrogen content in liquid is more than 0.05% as nitrogen blowing for 10 min in normal atmosphere, with increasing nitrogen rate the time that come to saturated nitrogen in liquid decreases and with decreasing temperature of liquid the solubility of nitrogen increase. The analysis on nitrogen absorption is carried out by thermodynamic model and the calculated nitrogen content is in good agreement with the measured one, which provides reference for controlling nitrogen content by blowing nitrogen gas in LF refining stainless steel

C-14: Understanding H Induced Failure Mechanisms in Metallic Alloys: The Role of Attractive H-H Interactions in Nano-Precipitate Formation: *Johann von Pezold*[1]; Alexander Udyansky[1]; Ugur Aydin[1]; Tilmann Hickel[1]; Joerg Neugebauer[1]; [1]Max-Planck-Institut für Eisenforschung GmbH

Attractive H-H interactions have recently been shown to induce the formation of local hydride precipitates even in non-hydride forming matrices, such as Ni [1]. The formation of these nano-hydrides in the strain field of extended lattice defects has been correlated to the long-standing problem of hydrogen embrittlement in these metals. In this study we systematically investigate H-H interactions in a range of fcc matrices, including Ca, Mn, Fe, Co, Ni, Al and Pd, using density functional theory. While the interaction between H atoms in nearest neighbour interstitial sites is generally attractive, the nature of this interaction is strongly system and site dependent. Hence, the interaction between octahedral sites is predominantly of elastic nature, while interactions between tetrahedral sites exhibit a significant chemical contribution. Based on our results we discuss the possibility of nano-hydride formation in fcc metals. [1] J. von Pezold et al., Acta Mat. 59, 2969 (2011).

Deformation, Damage, and Fracture of Light Metals and Alloys: Poster Session

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Light Metals Division, TMS/ASM: Mechanical Behavior of Materials Committee
Program Organizers: Qizhen Li, University of Nevada, Reno; Fuqian Yang, Univ. of Kentucky; Ke An, Oak Ridge National Laboratory

Monday PM — Room: Atlantic Hall
March 12, 2012 — Location: Dolphin Resort

N-1: Correlation between Melt Quality and Fatigue Properties of 2024, 6063 and 7075: *Engin Tan*[1]; Ali Tarakcilar[1]; Derya Dispinar[2]; [1]Pamukkale University; [2]University of Istanbul

Extruded 2024, 6065 and 7075 alloys were subjected to Strain Induced Melt Activated (SIMA) process and average of 80 µm spherical grains were obtained. T6 solution heat treatment was carried out to all alloys. In addition to the typical water quenching at 20°C, temperature controlled bath was used where the water was set to 80°C and some samples were quenched in that water. High mean stress values were selected (0.9, 0.8 and 0.7 µm) and load stress ratio (R) was selected to be 0.1. The fatigue test results were analyzed by Weibull and the distributions were compared with metal quality. SEM analysis was carried out on the fracture surface. A good correlation was found between bifilm index and the fatigue properties; as the quality was lowered, the scatter of the test results was increased.

K-1: Characteristics of ß' Phase in an Aged Mg-10Gd-3Y-0.5Zr Alloy: *Dejiang Li*[1]; [1]Shanghai Jiao Tong University

The precipitation behavior at 225°C of Mg-10Gd-3Y-0.5Zr (GW103K) alloy was studied by transmission electron microscope. Particular attention was paid on the characteristics of meta-stable phase ß'. The crystal structure, chemical composition and habit precipitation plane of ß' were identified by TEM and EDS, which are as same as that studied by others in GW series alloys. However, the shape of ß' at early stages during precipitation was significantly different with that reported by previous studies. Plate-shaped rather than globular-shaped ß' phase was recognized with the plate diameter of about 10nm and thickness of several atomic layers along c-axes of Mg in the alloy after aged for 2h. With time prolonged to peak aging condition of 16h, ß' phase gradually changed to convex lens-shaped though simultaneously growing along [10-10] and [0001] direction. Based on the microstructure observation, the coarsening mechanism of ß' phase during isothermal aging treatment was discussed.

K-2: Coherency Strain and Interfacial Energy of Mg3–Rare Earth D019 Precipitates from First-Principles: *Ahmed Issa*[1]; James Saal[1]; Chris Wolverton[1]; [1]Northwestern University

The potential to greatly strengthen magnesium alloys has driven current research, with a recent focus on strengthening precipitates, particularly involving rare earth (RE) dopants. The morphology of these precipitates dictates their effect on the strength of the alloy, and quantifying the coherency strain and interfacial energies between the precipitates and the Mg matrix is key to determining the morphology of the precipitate. We apply density functional theory (DFT) to systematically predict the formation energies as well as interfacial energies and coherency strain energies of D019 precipitates in Mg-RE systems along several crystallographic directions. In particular, we look for D019 precipitates that will favorably form plate-shaped morphologies along non-basal planes, as this morphology should be effective obstacles to plastic deformation. These Mg-RE systems also provide an interesting testing ground for the accuracy of DFT methods for intermetallic compounds containing f- electrons.

K-3: Combination of Cooling Curve and Micro-Chemical Phase Analysis of Rapidly Quenched Magnesium AM60 Alloy: *Paul Marchwica*[1]; Jerry Sokolowski[1]; Adam Gesing[2]; John Jekl[3]; Carsten Blawert[4]; Richard Berkmortel[3]; [1]University of Windsor; [2]Gesing Consultants Inc.; [3]Meridian Technologies Inc.; [4]GKSS Forschungszentrum Geesthacht GmbH

Universal Metallurgical Simulator and Analyzer (UMSA) Technology Platform macro test samples of magnesium alloys AM60 and AE44 were melted and quenched at maximum instantaneous cooling rates ranging from 5°C/s to 250°C/s and the resultant cooling curves were analyzed. Characteristic reactions on these curves corresponding to the nucleated phases were identified with the aid of known data as well as metallographic analysis. The results indicate that the relative proportion of fraction solid of phases in the alloys shift with relation to the cooling rate. These higher cooling rates are typical of real industrial solidification processes such as die-casting. These findings can be used to improve future computer models of magnesium (and other alloys) casting solidification processes.

K-4: Corrosion Behavior of Pure Mg Extrudate: *Chang Dong Yim*[1]; Young Min Kim[1]; Sung Hyuk Park[1]; Ha-Sik Kim[1]; Byoung-Gi Moon[1]; Bong Sun You[1]; [1]Korea Institute of Materials Science

The effect of grain size on corrosion behavior of pure Mg extrudate was evaluated via various method. The pure Mg extrudates with different grain size were prepared by indirect extrusion followed by heat treatment. With increase of average grain size, current density was slightly increased. No obvious feature was not observed on the surface of specimen during cathodic polarization. In the case of specimen with small and homogeneous grain size, corrosion occurred uniformly on the surface of specimen. But in the case of specimen with large and inhomogeneous grain size, corrosion occurred locally. It was concluded that the corrosion behavior of pure Mg extrudate was strongly dependent on grain size and smaller and more homogeneous grain size was more favorable to higher corrosion resistance of pure Mg.

K-5: Critical Grain Size for Change in Tensile Deformation Behavior and Transition in Tension- Compression Asymmetry in a Magnesium Alloy: *S. K. Panigrahi*[1]; K. Kandasamy[1]; N. Kumar[1]; R. S. Mishra[1]; R. DeLorme[1]; B Davis[1]; R.A. Howell[1]; K Cho[1]; [1]Centre for Friction Stir Welding and Material science and Engineering

In polycrystalline materials, tensile deformation behavior is dependent on grain size. The influence of grain size on deformation behavior of fcc and bcc metals and alloys in the grain size range from nano to micrometer has been widely studied. However, similar work on hcp materials such as on magnesium alloys, has not been systematically investigated. Magnesium alloys often develop deformation texture during processing which results in tension-compression yield asymmetry. The tension-compression yield asymmetry in magnesium alloys restricts its use for structural applications. In the present work, the effect of grain size and texture on mechanical properties and yield asymmetry in a Mg-Y-RE alloy was studied. A critical grain size for transition in deformation behavior from strain hardening to strain softening during tensile testing has been identified. Below the critical grain size, no yield asymmetry was observed.

K-6: Doping Effect on the Formation Energy of the Basal-Plane Stacking Faults in Binary Mg-X Alloys: First-Principles Calculations: *William Yi Wang*[1]; Shun Li Shang[1]; Zhi Gang Mei[1]; Yi Wang[1]; Suveen Nigel Mathaudhu[2]; Xi Dong Hui[3]; Zi-Kui Liu[1]; [1]Pennsylvania State University; [2]US Army Research Office; [3]University of Science and Technology Beijing

Three kinds of low-energy intrinsic and extrinsic basal-plane stacking faults in the Mg, such as growing fault, deformation fault and external fault, are investigated via the first-principles calculations. Additionally, the doping effect of the favorable and unfavorable elements in the binary Mg-X alloys on the formation energy of these structures are reported, the variation tendency of which has the potential application to design the advanced Mg alloys with good mechanical properties, especially the ductility and creep resistance.

K-7: Ductility Improvement in Equal Channel Angular Processed AZ31 Magnesium Alloy: *Sonia Modarres-Razavi*[1]; David Foley[1]; Ibrahim Karaman[1]; Karl T. Hartwig[1]; Laszlo Kecskes[2]; Suveen Mathaudhu[2]; Vincent Hammond[2]; [1]Texas A&M University; [2]U.S. Army Research Laboratory

A commercial AZ31 magnesium alloy has been processed using a multiple-temperature equal channel angular processing (ECAP) to enhance its mechanical properties by introducing ultra-fine grained structure with grain size of about 400 nm. A total of six to eight passes were applied starting at 200 °C for the first four passes to get advantage of softening through dynamic recrystallization (DRX) and then conducting additional passes at lower temperatures down to 125 °C following a combination of routes A and C, to suppress DRX and grain growth. Tension experiments in the flow direction of the processed sample demonstrated high strength levels up to 385 MPa in yield and 460 MPa in ultimate strength with elongation-to-failure of 14%. In order to improve the ductility, the samples were annealed shortly followed by ECAE. This promising technique enhanced the ductility appreciably without much sacrifice in strength.

K-8: Effect of CaO on Creep Behavior of Magnesium Alloys: *Hyun Kyu Lim*[1]; Shae K. Kim[1]; [1]KITECH

Magnesium alloys offer the opportunity for significant weight reductions in automotive components due to their low density. Nevertheless, there are strong needs for magnesium alloys with improved high temperature mechanical properties to apply to power train parts in vehicles. In this study, two magnesium alloys were investigated; one is modified MRI153 alloy, where Ca and Sr were replaced with CaO and the other is 1.5 wt.% CaO added AM60 alloy. Test specimens of three alloys (modified MRI153, CaO added AM60, and conventional MRI153 (for comparison) alloys) were prepared by re-melting and casting into steel mold with ingots and machining. The mechanical properties and the creep behavior of these specimens were determined and their microstructures were characterized using OM and SEM. In addition, fluidity test were carried out with spiral mold. It is proposed that replacement of CaO or adding CaO is beneficial to the creep resistance at elevated temperature.

K-9: Effect of Gadolinium and Yttrium Content on Microstructure and Strength of Mg-Li Alloys: *Min Li*[1]; Guangchun Yao[1]; Guoyin Zu[1]; Mengxiao Chen[1]; Jun Cheng[1]; Qingyan Zhu[1]; [1]Northeastern University

Effect of gadolinium and yttrium addition on strength of Mg-Li alloy was investigated using the metallographic observation, scanning electron microscope (SEM) and X-ray diffraction (XRD). The results indicate that the strengths were greatly improved with gadolinium and yttrium additions, in which the tensile strength was 209 MPa and the elongation was 18.4%, respectively. Through comparing with the Mg-Li alloy, the increments of tensile strength was 57 MPa, respectively. The improved strength was mainly correlated to the grain refining effect, the strengthening effect of the Mg5Gd phases and also the hardening effect of the solutioned gadolinium and yttrium atoms.

K-10: Effect of Grain Refinement and Texture Changes Induced by Burnishing on Corrosion Resistance of Magnesium Alloy for Biomedical Applications: Z. Pu[1]; *S. Yang*[1]; G.-L. Song[2]; O.W. Dillon, Jr.[1]; D. A. Puleo[1]; I.S. Jawahir[1]; [1]University of Kentucky; [2]General Motors

Magnesium alloys are emerging as an attractive candidate material for biodegradable implants including orthopedic implants and vascular stents. However, premature failure may occur due to their low corrosion resistance in physiological environments. In this study, the surface of AZ31B was burnished with a custom made tool under dry and liquid nitrogen spraying conditions. It was found that significant grain refinement occurred near the surface when using both burnishing conditions due to dynamic recrystallization induced by severe plastic deformation. In addition, a strong crystallographic basal texture was generated on the burnished surface. While the burnished surface was reported to have improved corrosion resistance in a corrosive NaCl solution by using hydrogen evolution method and electrochemical methods, contradictory results on corrosion performance were found in a simulated body fluid by the two methods. The possible causes of the disagreement are briefly discussed.

K-11: Effect of Heat Input on Microstructure and Mechanical Properties of Pulsed TIG Welded AZ31 Magnesium Alloys: *Alireza Amirkhani*[1]; Alireza Ebrahimi[1]; Rasool Azari Khosroshahi[1]; [1]Sahand University of Technology

The process of pulsed TIG welding was used for joining Magnesium Alloy AZ31 using alternating current and the effect of heat input was investigated over the microstructure and mechanical properties of the welded joint. For this reason, the heat input was manually increased from 80.2 J/mm to 157J/mm and, simultaneously, the heat input was measured using a wet calorimeter. Results of microstructure observations showed that by approaching the fusion zone, grains gradually changed in to equiaxed form and in the center of fusion zone fine equiaxed grains together with lots of brittle precipitated particles of ß-Mg17Al12 were formed. In addition, ultimate tensile strength (UTS) of the welded joint increased by increasing the heat input, but too much increasing of the heat input led to decrease in UTS. In this case, decrease in microhardness due to increasing of the heat input, slowed down while too much heat input was applied.

K-12: Effect of Zn Concentration on the Microstructures and Mechanical Properties of Extruded Mg–Y–Gd–Zr Alloys: *Jian Meng*[1]; Ke Liu[1]; Xin Qiu[1]; Deping Zhang[1]; Yangde Li[2]; [1]Changchun Institute of Applied Chemistry, Chinese Academy of Sciences; [2]Dongguan e-ande Co. Ltd

In this article, Microstructures and mechanical properties of the Mg–7Y–4Gd–xZn–0.4Zr (x = 0.5, 1.5, 3, and 5 wt.%) alloys in the as-cast, as-extruded, and peak-aged conditions have been investigated by using optical microscopy, scanning electron microscope, X-ray diffraction, and transmission electron microscopy. It is found that the peak-aged Mg–7Y–4Gd–1.5Zn–0.4Zr alloys have the highest strength after aging at 220°C. The highest ultimate tensile strength and yield tensile strength are 418 and 320 MPa, respectively. The addition of 1.5 wt.% Zn to the based alloys results in a greater aging effect and better mechanical properties at both room and elevated temperatures. The improved mechanical properties are mainly ascribed to both a fine ß' phase and a long periodic stacking-ordered structure, which coexist together in the peak-aged alloys.

K-13: Effects of Friction Stir Process on the Tensile Properties of AZ61 Magnesium Alloy at Room Temperature to 200□: *Hsiang-Ching Chen*[1]; Truan-Sheng Lui[1]; Li-Hui Chen[1]; Fei-Yi Hung[1]; [1]National Cheng Kung University

Effect of friction stir process (FSP) on the microstructural evolution and tensile mechanical properties of AZ61-O magnesium alloy was investigated in this study. The tensile test was carried out from room temperature to 200°C. Experimental results show the metal flow microstructure, which includes both fine and coarse grains, was observed in the stir zone. The AZ61-FSP specimen possesses higher total elongation than AZ61-O at room temperature and 50°C. However, the AZ61-FSP specimen possesses lower total elongation than AZ61-O at 100 and 200 °C. The ultimate tensile strength and yield strength performance of the AZ61-O and AZ61-FSP specimens were decreased with increasing deformation temperature. In comparison, the strength of the AZ61-FSP specimen was all inferior to the AZ61-O specimen.

K-14: Enhanced Corrosion Resistance of AE42 Magnesium Alloy Achieved by SPD: *Peter Minárik*[1]; Robert Král[1]; Miloš Janecek[1]; [1]Charles University in Prague

The effect of refinement of microstructure on corrosion of AE42 magnesium alloy was investigated. Electrochemical impedance spectroscopy in normal salinity solution (0.1 M NaCl) showed a substantially higher charge transfer resistance in the fine-grained samples processed by equal channel angular pressing (ECAP) as compared to as-extruded material. The corrosion layers developed on the samples were investigated by SEM and differences between samples were found. The layer created on the ECAPed sample was more stable and physical processes behind this were investigated.

K-15: Eutectic Formation in Binary Alloys: *Morteza Amoorezaei*[1]; Rameez Ashraf[1]; David Montiel[1]; Nikolas Provatas[1]; [1]McMaster University

We experimentally and computationally explore the formation and distribution of eutectic phases in binary alloys of magnesium. The criterion for the eutectic nucleation is obtained based on local solute concentration and undercooling within the melt, as determined from the complex solid-liquid topology determined from phase field simulations. The resulting morphology will be compared to experiments in organic metal analogues as well as experiments on magnesium alloys.

K-16: Finite Element Analysis of the Evolution of Damage during Equal Channel Angular Pressing of a Mg–3Al–1Zn Alloy: *Feng Kang*[1]; Jing Tao Wang[2]; Chao Hong Zhang[1]; Ping Cheng[1]; Hai Ying Wu[1]; [1]Jinxi Axle Co., LTD; [2]Nanjing University of Science and Technology

Finite element analysis was used to simulate the evolution of damage in an Mg–3Al–1Zn alloy processed by equal channel angular pressing (ECAP). Oyane criterion for damage was selected to evaluate the fracture characteristic. Finite element modeling was used with experimental data obtained from tension and compression testing. The results show that initial crack may form in severe flow localization (i.e. in the inner corner) and these cracks may propagate leading to billet segmentation. The flow grid in simulation result is similar with previously experimental result.

K-17: High Strength Magnesium Alloys as Light Weight Advanced Structural Materials for Automotive and Aerospace Applications: *Ankit Gupta*[1]; [1]Assistant Manager, Materials Department, Tata Motors Limited, Pantnagar Works, INDIA

Vehicle weight reduction is one of the major means available to improve automotive fuel efficiency. Magnesium is a promising material for automotive use, primarily because of its light weight, ease of fabrication and the highest strength-to-weight ratio of all structural metals when alloyed.Conventional magnesium alloys are strength-competitive, not only with aluminum alloys, but also with steels and titanium alloys. Magnesium alloys with aluminum characterizes good mechanical properties, corrosion resistance and castability after sand and die casting. Magnesium Matrix Composites reinforced with ceramics and graphite fibers or particles present a new class of ultralightweight structural materials joined by brazing.The use of magnesium alloys in car design is expanding, and now includes ultralightweight matrix composites. The objective of this study is to review the classification of magnesium alloys and evaluate their applications in automotive and aerospace industry that can significantly contribute to greater fuel economy and environmental conservation.

K-18: Hot and Cold Deformation of Twin Roll Cast AZ31 Magnesium Alloy: Modeling and Experiments: *Hesamaldin Askari*[1]; John Young[1]; Hussein Zbib[1]; David Field[1]; Ghassan Kridli[2]; Mohammed Khaleel[3]; [1]Washington State University; [2]Texas A&M University at Qatar; [3]Pacific Northwest National Laboratory

Among all the manufacturing processing techniques, the twin roll casting process is of particular importance since it yields a microstructure with enhanced superplastic properties. However, superplastic deformation could be a relatively slow process, but the process can be accelarted by controlling certain microstructural features, such as grain size, and forming parameters, such as strain rate path. The objective of this study is to establish a physically-based constitutive model that integrates the effects of the underlying microstructure (grain boundaries, twinning, and dislocations) with other continuum properties. The modeling approach is by use of a self consistent viscoplastic model based on crystal plasticity to study hot and cold deformation behavior and microstructure evolution in AZ31 magnesium alloy at different strain rates. The material response and evolving microstructure obtained by the model are then compared to experiments and EBSD analyses.

K-19: Improved Sintering of Mg Powder Metallurgy Compacts by Thermal Pretreatment: *Paul Burke*[1]; Florian Saint-Lebes[2]; Georges Kipouros[3]; [1]Massachusetts Institute of Technology; [2]ICAM; [3]Dalhousie University

Magnesium and its alloys are attractive materials for use in automotive and aerospace applications because of the low density and good mechanical properties. Powder metallurgy (P/M) can be used to alleviate the formability problem through near-net-shape processing and also allows unique chemical compositions that can lead to new alloys with novel properties. However, the surface layer formed on the Mg powders during processing acts as a barrier to diffusion and sintering is problematic. The layer contains oxides, hydroxides, and carbonates of magnesium formed by reactions with the atmosphere. Magnesium hydroxide and carbonate are both unstable at temperatures well below the sintering temperature and can be decomposed, creating cracks in the remaining oxide layer. These cracks are pathways for unimpeded diffusion and interparticle bonding. To take advantage of this phenomenon a thermal pretreatment under vacuum prior to compaction was tested to assess the effect on sintered density, apparent hardness and microstructure.

K-20: Influence of Section Thickness on Microstructure and Mechanical Properties of Squeeze Cast Magnesium Alloy AM60: *Xuezhi Zhang*[1]; Meng Wang[1]; Zhizhong Sun[1]; Henry Hu[1]; [1]University of Windsor

Squeeze cast light alloys has been approved for advanced engineering design of light integrity automotive applications. An understanding of the effect of section thicknesses on mechanical properties of squeeze cast magnesium alloys is essential for proper design of different applications. The present work studied the tensile properties of magnesium alloy AM60 with different section thickness of 6, 10 and 20mm squeeze cast under an applied pressure of 30MPa. The results of tensile testing indicate that the yield strength (YS), ultimate tensile strength (UTS) and elongation (Ef) increase with a decreasing in section thicknesses of squeeze cast AM60. The microstructure analysis shows that the improvement in the tensile properties of squeeze cast AM60 is mainly attributed to the low level of gas porosity and the high content of eutectic phases and fine grain structure which resulted from high solidification rates taking place in the thin section.

K-21: Influence of Zinc-Yttrium Ratio and Cerium on the Mechanical Properties of Hot Rolled and Friction Stir Processed Mg-Zn-Y Alloys: *Arun Mohan*[1]; Rajiv Mishra[1]; Ravi Verma[1]; [1]Missouri University of Science and Technology

Four different alloys with Zn-Y weight % ratio ranging from 0.2 to 0.71 with a total alloying content similar to AZ31 alloy were hot rolled. Two different levels of Cerium were used. Cerium has been reported to increase ductility and decrease anisotropy. In order to maximize the impact of alloying addition, aging studies were conducted at 160°C, 190°C and 220°C for duration up to 8 days. An optimum aging condition was chosen based on peak hardness values. In the current work, microstructure and tensile properties of the as rolled, rolled+aged, friction stir processed (FSP) and FSP+aged sheets were evaluated and correlated with texture and alloy chemistry. Finally, mechanical properties of Mg-Zn-Y sheets were compared with direct chill cast and twin roll cast AZ31 sheets to establish the levels of reduction in anisotropy and improvements in strength and ductility.

K-22: Insights into the Nucleation of Extension Twins in Mg Alloys: *Ali Khosravani*[1]; Raja Mishra[2]; Brent Adams[1]; David Fullwood[1]; [1]Brigham Young University; [2]General Motors

This work presents an investigation of the correlation between extension twin nucleation and dislocation densities in AZ31 magnesium alloys using high resolution electron backscatter diffraction (HR-EBSD). Strongly textured fine grain size sheet samples and randomly oriented large grain billet samples are deformed to small strains in tension and compression and examined by HR-EBSD to determine local dislocation densities from lattice curvature measurements. To activate different twin variants in the textured sample, tensile and compression tests along both RD and TD direction of the sheet are performed. Together with the data obtained from Mg-Ce alloy samples, it is shown that twin nucleation not only happens at the grain boundaries but also at the highly mis-oriented areas inside the grain where local dislocation pile-ups are detected by HR-EBSD. Quantitative measurement of dislocation density required for activation of different twin variants in different microstructures will be discussed.

K-23: In Situ Quantitative Tension and Compression Study on Twinning and Detwinning in Submicron-Sized Mg Crystals inside a Transmission Electron Microscopy: *Boyu Liu*[1]; Zhiwei Shan[1]; Xiyan Zhang[2]; Jun Sun[1]; Evan Ma[3]; [1]Xi'an Jiaotong University; [2]Chongqing University; [3]The Johns Hopkins University

Quantitative testing on submicron-sized Mg single crystals have been conducted both in tension and compression mode inside a transmission electron microscope (TEM), for tensile loading along the c-axis and subsequent compressive loading perpendicular to the (new) c-axis. Comparing to conventional testing approaches on bulk scale samples, in which initial grown-in twins might exist, this in-situ TEM quantitative testing conducted on a submicron-sized single crystal is more advanced and visualized. This work directly observes the {10-12} twinning which instantly reorients the crystal by nearly 90° and detwinning which gradually recovers the twinned sample. The {10-12} twinning deformation remains predominant at a certain loading direction when sample size is reduced to ~200 nm, with the twinning stress far exceed that known for bulk Mg. The twinning stress is lower than the stress that is required to drive detwinning propagation during compressive loading perpendicular to the (new) c-direction.

K-24: Investigation of Mechanical Properties of AZ31 Mg Alloys Coated by Plasma Electrolytic Oxidation: *Ahmet Ucisik*[1]; Salih Durdu; [1]Bogazici University

In this study, AZ31 Mg alloy produced by twin roll casting was coated by a plasma electrolytic oxidation (PEO) in solution, consisting of Na2SiO3.5H2O + KOH electrolyte at 0,085 A/cm2 current density for 15, 30, 45 and 60 minutes. Thickness of the coated layer, surface morphology, phase structure, hardness and adhesion strength of the layer were analyzed by an eddy current, SEM, XRD, Vickers hardness and micro scratch tester, respectively. The average coating thickness ranged from 17 to 56 µm. A number of pores were formed on the coated layer. XRD revealed that Mg2SiO4 (Forsterite) and MgO (Periclase) phases were formed on the surface of the magnesium alloy. Average coating hardness was measured as 660 HV, while the hardness of the magnesium alloy was 72 HV. Adhesion strength of coatings was increased by increasing duration time.

K-25: Investigation of the Corrosion for Mg–Li-xGd–yY (x=7, 8, 9, 10, 11 wt%;y=1, 2, 3, 4, 5 wt%) Alloys: *Min Li*[1]; Guangchun Yao[1]; Guoyin Zu[1]; Jun Cheng[1]; Qingyun Liu[1]; Liping Zhou[1]; [1]Northeastern University

The corrosion behaviors of Mg-Li-xGd-yY(x=7, 8, 9, 10, 11 wt%;y=1, 2, 3, 4, 5 wt%) alloys in 3.5 wt.% NaCl aqueous solutions have been investigated by immersion test and polarization curve method.The corrosion products and their morphologies formed in the solution have been analyzed by SEM and XRD. It was found that the morphologies of the film of corrosion products varied with different elements.The results shows that the denser corrosion film of Mg-Li alloy was formatted due to the addition of gadolinium and yttrium, which can increase the corrosion potential alloy.

K-26: Magnesium Recycling of Partially Oxidized, Mixed Magnesium-Aluminum Scrap through Combined Electrorefining and Solid Oxide Membrane (SOM) Electrolysis Processes: *Xiaofei Guan*[1]; Peter Zink[1]; Uday Pal[1]; [1]Boston University

Pure magnesium (Mg) is recycled from 19g of partially oxidized 50.5wt.%Mg-Aluminum (Al) alloy. During the refining process, potentiodynamic scans (PDS) were performed to determine the electrorefining potential for magnesium. The PDS show that the electrorefining potential increases over time as the Mg content inside the Mg-Al scrap decreases. Up to 100% percent of magnesium is refined from the Mg-Al scrap by a novel refining process of dissolving magnesium and its oxide into a flux followed by vapor phase removal of dissolved magnesium and subsequently condensing the magnesium vapors in a separate condenser. The solid oxide membrane (SOM) electrolysis process is employed in the refining system to enable additional recycling of magnesium from magnesium oxide (MgO) in the partially oxidized Mg-Al scrap. The combination of the refining and SOM processes yields 7.4g of pure magnesium; could not collect and weigh all of the magnesium recovered.

K-27: Measuring Heat Transfer during Twin Roll Casting of Metals: *Pedram Mehraram*[1]; Mary Wells[1]; [1]University of Waterloo

Accurate knowledge of the heat transfer coefficient during casting (between a molten material and the mold) is critical to develop representative mathematical models for casting process such as Twin Roll Casting. In this project, an experimental apparatus was developed to enable to measurement of the interfacial heat transfer coefficient at the interface between a liquid metal and a chill. The experimental apparatus consists of a cylinder surrounded by a heater to melt the metal samples and a number of sensors to monitor temperature in both the molten metal and chill part. The interfacial heat transfer was calculated using an inverse heat conduction method in conjunction with the known thermo-physical properties of the chill and solidifying metal. The apparatus was tested successfully by using AZ31 and Sn-7.5%Sb-3.5%Cu alloy as the casting metal solidifying against H13 chill block. The effect of chill surface texture was investigated on the heat transfer coefficient.

K-28: Mg-Rich Region of the Mg-Gd-Al and Mg-Gd-Sn Ternary Phase Diagrams: *John Kuper*[1]; J.-C. Zhao[1]; [1]The Ohio State University

Mg alloys containing Gd are currently being explored for potential automotive applications to reduce the weight of vehicles. The strength of Mg-Gd alloys is a result of precipitation strengthening from interlocking, plate-shape precipitates of Mg5Gd (Mg46Gd9). To further increase the strength and balance the properties of these alloys, Al and Sn are considered as additional alloying elements for solid solution strengthening. To help understand the phase stability and alloying behavior of these alloys, diffusion multiples of Mg, Mg-25at%Gd, Mg-33%Sn and Al were made to map the Mg-rich corner of both the Mg-Gd-Al and Mg-Gd-Sn ternary systems at 400 °C and 300 °C. The phase stability results will be presented in this talk.

K-29: Microstructure and Mechanical Properties of Mg-5Sn-5Zn-xCa Alloys: *Liu Bin*[1]; [1]Shenyang University of Technology

Mg-5Sn-5Zn-xCa(x=0.5, 1, 2) alloys were meleted by the vacuum melting furnace. The microstructures and phase compositions were analyzed by the scanning electron microscope (SEM) and X-ray diffraction (XRD). The mechanical properties were tested by the electronic universal test machine. The fracture surface were observed by scanning electron microscope (SEM). The results indicate that the microstructures of Mg-5Zn-5Sn-xCa alloys are composed of CaMgSn phases, layer MgZn2 phases and Mg2Sn phases. Matrix precipitates onset Mg2Ca phase, when the content of Ca is 2 wt%. With the increasing of the Ca content, the needle CaMgSn phases gradually become rods, the layer MgZn2 phases and plate Mg2Sn phases become continuous, ultimate tensile strength decrease. Mg-5Zn-5Sn-0.5Ca alloy obtains the ultimate tensile strength 184Mpa.

K-30: Microstructure and Mechanical Properties of Nanocrystalline Pure Mg via Cryomilling, Spark Plasma Sintering and Extrusion: *Baolong Zheng*[1]; Troy Topping[1]; Yuhong Xiong[1]; Yizhang Zhou[1]; Suveen Mathaudhu[2]; Enrique Lavernia[1]; [1]University of California, Davis; [2]U.S. Army Research Office

Nanocrystalline (NC) Mg alloys are of interest due to their high specific strength, but most show a marked ductility decrease with grain refinement. In order to explore the mechanical response of Mg with grain refinement to the nanoscale, pure Mg powder with an average grain size of 67 nm was synthesized via a cryomilling (mechanical milling under cryogenic temperature) in liquid argon for 8 hours, and subsequently consolidated using spark plasma sintering (SPS) and extrusion. The microstructure evolution after each processing step was characterized with XRD, SEM and TEM/HRTEM. The mechanical properties and micro-hardness of consolidated bulk NC pure Mg were evaluated at room temperature. The influence of materials processing on microstructure evolution and resultant mechanical response are discussed in an effort to provide insight into understanding of fundamental deformation phenomena in NC pure Mg.

K-31: Microstructures and Mechanical Properties of Rapidly Solidified Mg-RE Base Alloy Powder Produced by Using LME Method: *Hong Jun Chae*[1]; Sun Woo Nam[1]; Tae Bum Kim[1]; Taek-Soo Kim[1]; [1]Korea Institute of Industrial Technology

Recently, the effect of addition of rare-earth elements (REE) on the mechanical properties and corrosion resistance of Mg alloys have been investigated by many researchers, and small addition of REE could improve the properties of Mg alloys effectively. However, systematic studies on the relationships between crystal structures and macroscopic properties in this Mg-RE alloy system are still necessary. Addition of Nd element to Mg alloy can increase high-temperature strengths and corrosion resistance of Mg alloy. However, the applications of Mg-Nd alloy are very limited due to expensive cost. In this study, the master alloys of Mg-Nd were produced by liquid metal extraction (LME) method from waste Nd-Fe-B scrap by using molten Mg. Also, The Mg-Nd base alloy powders were fabricated by gas atomization, and consolidated by the severe plastic deformation (SPD) method. The effects of process parameters on the homogeneity and the property of specimens were presented and discussed.

K-32: Microstructure and Texture Effects on the Deformation Behaviors of the Statically Recrystallized Mg-Zn-MM Alloy Sheets: *Heon Kang*[1]; SeEun Shin[1]; DongHyun Bae[1]; [1]Yonsei University

The Mg-Zn-MM alloy sheets produced by warm rolling processes were annealed at two different temperatures and mechanical properties and texture effect were evaluated. Few grains were observed in as-rolled sheets and the different grains size and orientations were analyzed in annealed sheets at 220°C, 380°C for 5min by electron back scattering diffraction. The heat treated sheet at 220°C showed the grain size of 4 um. The heat treated sheets at 220°C exhibited superior elongations to failure at room temperatures and the values of elongation to failure in the range of 100°C up to 350°C were found to around 2 times higher than those of commercially used AZ31 alloy sheet without the loss of tensile strength. The enhanced ductility was mainly stemming from the statistically recrystallized small grains which were initially developed and low recrystallized temperature. The details of deformation behavior of the alloy will be also presented.

K-33: Modeling of Deformation Behavior of Multiphase Wrought Magnesium: *Dongsheng Li*[1]; Curt Lavender[1]; Eric Lavender[1]; Xin Sun[1]; Mohammed Khaleel[1]; [1]Pacific Northwest National Laboratory

Synthetic microstructure of multiphase wrought magnesium was reconstructed from experimental data from OM, SEM and XRD. The synthetic microstructure is statistically stable with high resolution and enough components to represent the local and global structure. Simulated behavior from this synthetic microstructure is stable and accurate, comparing with simulation using microstructure information obtained by discrete chemical imaging modality. Correlation function and other statistical representation functions are used in microstructure reconstruction. Efficiency and accuracy in microstructure representation and property prediction were investigated.

K-34: Nanostructure Formation in a Quenched Mg Alloy: *Wanqiang Xu*[1]; Michael Ferry[1]; [1]University of New South Wales

Mg alloy has superior stiffness-to-weight ratio, generates potential application in aerospace and aircraft structures as well as structural components in ultra-light weight communication systems, but is low in strength. In this paper, the quenched microstructure of a bulk Mg alloy was investigated by TEM, atom probe and high resolution XRD. Results show a large amount of nano sized grains (~20-40nm) are formed by the decomposition of its high temperature phase during quenching process. These nano grains keep coherent with the remained high temperature phase in room temperature, resulting in a significant increase in hardness and strength.

K-35: One-Step Approach to Enhance Corrosion Resistance of Coating Layer on AZ91 Mg Alloy via Plasma Electrolytic Oxidation in Electrolyte Containing Ammonium Vanadate: You Chan Jung[1]; *Kang Min Lee*[1]; Sang Il Yoon[1]; Young Gun Ko[2]; Dong Hyuk Shin[1]; [1]Hanyang University; [2]Yeungnam University

The main purpose of this work is made to investigate the formation of anti-corrosive coating layer on AZ91 Mg alloy produced via plasma electrolytic oxidation (PEO) in the electrolyte containing ammonium vanadate. The PEO coatings were carried out as a function of ammonium vanadate under AC condition with current density of 100 mA/cm2 for 150 sec. In terms of the microstructure, the average pore size on the surface was decreased and the coating layer with vanadium oxide was much denser, followed by the addition of the ammonium vanadate due to complicated electrochemical process i.e., electrochemical reactions, diffusion and ion exchange. According to X-ray photoelectron spectroscopy analysis, the vanadium compound was here existed to be V2O3 and V2O5 compounds in the coating layer. Overall, it is obviously demonstrated that those vanadium oxides enhanced the corrosion resistance properties of the coating layer, confirmed by electrochemical corrosion tests.

K-36: Phase Dissolution of γ-Mg17Al12 during Homogenization of As-Cast AZ80 Magnesium Alloy and Its Effect on Room Temperature Mechanical Properties: *Rahul Kulkarni*[1]; Nityanand Prabhu[1]; Peter Hodgson[2]; Bhagwati Kashyap[1]; [1]Indian Institute of Technology Bombay; [2]Deakin University, Australia

The phase proportions and their sizes in as–cast AZ80 magnesium alloy were studied by using optical microscopy, X-ray diffraction, scanning electron microscopy. Differential scanning calorimetry reveals endothermic peaks at 439° and 453°C. Microstructure evolution during homogenization was investigated as a function of time for 0.5 to 100 h and over the temperature range of 400°- 453°C. This alloy contains α-Mg; partially and fully divorce eutectic of α and γ (Mg17Al12), and lamellar eutectic of α and γ phases. With increasing homogenization time, dissolution of lamellar eutectic occurs first which is sequentially followed by dissolution of fully divorce eutectic and partially divorce eutectic. The kinetics and mechanisms of dissolution of γ phase was analyzed. Micro-hardness of individual phases, macro-hardness and tensile properties were measured at room temperature as a function of homogenization time and temperature, and their contributions were evaluated to bring out the effect of progress in phase changes.

K-37: Precipitation Formation and Grain Refinement of Mg-Al-Sn Alloy during Hot Deformation: *Abu Syed Humaun Kabir*[1]; Jing Su[1]; Phuong Vo[1]; In-Ho Jung[1]; Stephen Yue[1]; [1]McGill University

Magnesium alloys are very popular in the automobile industry due to its high strength to weight ratio. However, the use of commercial magnesium alloys as sheet is limited by room temperature ductility. One way to improve the ductility may be to form precipitates during hot rolling. These may delay dynamic recrystallization, possibly leading to grain refinement, which is known to improve ductility. Equilibrium diagrams obtained from thermodynamic modeling software FactSage were used to design Mg-3Al-2Sn alloy, which should form Mg2Sn precipitates during hot rolling temperatures around 300 °C. To investigate this prediction, the alloy was cast in a copper mould and precipitates formation characteristics were studied by using optical microscope (OM), scanning electron microscope (SEM) equipped with an energy-dispersive X-ray spectroscopy (EDS).

K-38: Production of Mg-Ni Alloy by Consumable Cathode Molten Salt Electrolysis: *Bian Xue*[1]; Wu Wenyuan[1]; [1]Northeastern University

In producing process of Mg-Ni alloy, the low melting point and density caused the loss of Mg. In order to solve this problem, the production of Mg-Ni was studied by consumable Molten Salt Electrolysis in this paper. Using MgO as starting material, 60%cryolite-40%NaCl as electrolyte, Ni bar as cathode, graphite as anode, Mg-Ni alloy was produced, when temperature was 950°C. The current efficiency increased with increasing of temperature and primary current density. When temperature was 1000, primary current density of cathode and anode was 5 A•cm^2 and 1

POSTERS

A•cm[2] respectively, the current efficiency is 79.4%. The testing results of SEM, EDS and XRD were shown that MgO and Al_2O_3 of cryolite were reduced at the surface of Ni bar, and the fusion alloy produced. The phases composition were $MgNi_2$, Al_3Ni_2 and Al_3Ni.

K-39: Quasi-Static and Dynamic Compressive Mechanical Behavior of Coarse Grained and Ultrafine Grained Mg-Y-RE Alloy: *Nilesh Kumar*[1]; S. Panigrahi[1]; R. Mishra[1]; R. DeLorme[2]; B. Davis[2]; R. Howell[3]; K. Cho[3]; [1]Missouri University of Science & Technology; [2]Magnesium Elektron North America Inc.; [3]Weapons and Materials Research Directorate

Quasi-static and dynamic compression tests were carried out to study the deformation behavior of wrought Mg-Y-RE alloy at strain rates between 10^{-4} to 10^{4} s^{-1}. The alloy was tested in two different microstructural states – (a) coarse grained (20 µm), and (b) ultrafine grained (0.5 µm) – selected on the basis of their strength-ductility combination. In both the cases the alloy was tested in peak aged condition. The high strain rate (HSR) compression tests were carried out using split-Hopkinson pressure bar. Microstructural evolution during HSR deformation and dependence of deformation behavior were investigated. The deformed microstructure was characterized using electron backscatter diffraction and transmission electron microscope.

K-40: Secondary Ion Mass Spectrometry for Mg Tracer Diffusion: Issues and Solutions: *Jay Tuggle*[1]; Jerry Hunter[1]; Nagraj Kulkarni[2]; Yongho Sohn[3]; [1]VT; [2]Oak Ridge National Laboratory; [3]University of Central Florida

Historically, tracer diffusion studies have been performed using radioactive isotopes as tracers. Handling these radioactive isotopes demands a significant increase in safety requirements over non-radioactive isotopes resulting in increased cost and effort. In this study we have used Secondary Ion Mass Spectrometry (SIMS) to measure tracer diffusion of stable Mg isotopes avoiding the need for radio tracers. SIMS analysis of magnesium is subject to a number of artifacts that will lead to a significant loss of depth resolution resulting in a significant error in the measured diffusion coefficient. Methods to minimize these errors will be discussed. Additionally, a method to measure long (>20 um) diffusions will be presented and compared to the more traditional top-down profiling methods. Research sponsored by the U. S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Vehicle Technologies Program, under contract DE-AC05-00OR22725 with UT-Battelle, LLC.

K-41: Semisolid Joining of Magnesium AZ91 Alloy by Partial Remelting and Mechanical Stirring: *Hossein Aashuri*[1]; Vahid Hosseini[1]; [1]Sharif University

A technique to achieve the globular weld structure of magnesium AZ91 alloy using stirring a localized semisolid zone during butt-joining is developed. A gas heating system was used for heating the joint up to the required temperature. A dried and free oxygen gas was prepared when a stream of gas could pass closely around a hot element. Hot and pure gas flow through a precise ceramic nozzle was used to create a localized semisolid pool. At this stage a fine stirrer was introduced into the weld seam in order to mix the two sides into a single uniform joint. Substrates were moved in direction of joint line by a small trolley to avoid the deviation of nozzle from the joint line and its distance and angle from the substrate. A fixture system was used to hold two substrates together on the trolley.

K-42: Severe Plastic Deformation of Magnesium Alloys by Machining: *Saurabh Basu*[1]; M. Ravi Shankar[1]; [1]University of Pittsburgh

The microstructural consequences of severe plastic deformation of a prototypical Mg alloy –AZ31, during chip formation in machining are presented. Here, a plane-strain machining setup was utilized to examine the strain, strain-rate and temperatures in the deformation zone using high-speed imaging and infrared thermography. Subsequently, the microstructural consequences were elucidated in the chip and on the machined surface using X-ray and electron backscattered diffraction analysis. It is shown that chip formation in machining leads to a refinement of the microstructure in the chip and on the surface and that the shear deformation also offers a more favorable modulation of the crystallographic texture. The implications of these observations for enhancing the mechanical and functional properties of Mg alloys are discussed.

K-43: Slip and Twin Behavior of Magnesium Single Crystals: *Ming Zhe Bian*[1]; Kwang Seon Shin[1]; [1]Magnesium Technology Innovation Center, Seoul National University

The deformation behavior of magnesium single crystals was investigated using compression tests parallel to the c-axis at room temperature to 623K. The {10-12} tensile twin and the {10-11} compression twin, as well as the {10-11}-{10-12} double twin, were observed in compression tests. In the case of the {10-11} twin, new fine grains were formed due to dynamic recrystallization (DRX), indicating that sufficient energy was accumulated in the compressive twin region for recrystallization. The {10-13} twin and the {10-13}-{10-12} double twin were found to form at a compressive strain of only 2% at 473K. The dislocation and twin structures were systematically examined by TEM under various diffraction conditions.

K-44: Stress Corrosion Cracking Susceptibility of Ultrafine Grained AZ31: *Gaurav Argade*[1]; Wei Yuan[1]; Kumar Kandasamy[1]; Rajiv Mishra[1]; [1]Missouri University of Science and Technology

Stress corrosion cracking (SCC) behavior of AZ31 was studied using slow strain rate testing (SSRT) technique in 3.5 wt% NaCl solution. Friction stir processing was employed to obtain grain size in micron and sub-micron range. The samples for SSRT were extracted from processed region and were tested in air and solution at an initial strain rate of 10-6 s-1. Lower time to failure was observed for processed samples. Parent material as well as processed samples showed susceptibility towards SCC, with processed samples showing higher susceptibility as compared to parent material.

K-45: The Effect of Precipitation on the Mechanical Properties of Extruded AZ80: *Ran Liu*[1]; Jing Wang[1]; De Yin[1]; [1]Nanjing University of Sci & Tech

The effect of aging temperature and time on precipitates in AZ80 magnesium alloy was studied by optical microscope to investigate the change on mechanical properties. The results show that precipitation distributed as band along the extruded direction with no twinning. After aging, precipitation dispersed. When ageing at 150°C, discontinues precipitated phase could increase the yield and tensile strength but not good to the ductility of the material. Ageing at 300°C, with the increase the aging time, static ductility increase first and then decrease. That means recrystallization induced by continuous precipitation is benefit to the strength and ductility. However, the effect of ageing hardening under 300°C is not better than 150°C. And twinning also activated in compression much more than in tensile samples, that's the same as in AZ31 alloy.

K-46: The Investigation of Twin Interface Structure in AZ31 Magnesium Alloys: *Daisuke Ando*[1]; Yuji Sutou[1]; Junichi Koike[1]; [1]Tohoku Univercity

Deformation twinning is an important factor for deformation and fracture mechanisms in magnesium. We reported that {10-11}-{10-12} double twins are crack initiation sites and {10-12} twins tend to be crack propagation sites. However, it is not clear why only {10-12} twin interfaces tend to be crack initiation sites among other twin types. In the past studies, the twin interface structure has been reported only in the {10-12} type in pure Mg, but not in other twin types. So in this work, the twin interface structure of AZ31 was investigated by HRTEM. Results indicated that the twin interface structure of {10-12} in AZ31 is the same as in pure Mg. The (10-12) twin interface is composed of a (10-12) plane and a zigzagged step structure formed by (0001)twin/(1-100)matrix planes. Based on the obtained results, that the step structure of the (0001) twin/(1-100)matrix planes is the most likely sites for crack propagation.

Q-1: A Physical Model for Growth of Graphene Layers from Metallic Melts: *Shaahin Amini*[1]; Haamun Kalaantari[2]; Reza Abbaschian[2]; [1]University of California Riverside ; [2]University of California Riverside

Recently growth of graphene nanocrystals from metal-carbon melts was introduced by present authors. In this process, dissolved carbon in metallic melts consisting of Ni or Cu was found to grow as graphene or graphite layers on the surface of the melt along with graphite growing in the interior of the melt with morphologies including thick flakes or spheres. A comprehensive model is presented here to examine the effect of processing parameters on graphite growth morphologies. The model relates the solid-liquid interfacial kinetics in basal and prism directions to melt supercooling and cooling rates. It is found that at low supercoolings, the faceted basal plane lags behind the prismatic face, resulting in the formation of flakes. At increased supercoolings, however, basal plane becomes kinetically roughened with growth rate comparable to that of prismatic face, thus altering the morphology into bulky spheres. The analytical results are finally compared to experimental observations.

Q-2: A Way to Control Distortion of Metal Parts during Heat Treatment Process: Yuan Lu[1]; *Jin-wu Kang*[1]; [1]Tsinghua Univ

The distortion of metal parts during heat treatment process is one of the main obstacles in industry to ensure high-quality work and less or no machining allowance, especially for large but thin steel castings such as heavy turbine blades. In the paper, a method is proposed to control the distortion by adjusting heat transfer coefficient of metal parts during heat treatment process. Required heat transfer coefficients can be realized by getting the metal parts into contact with various media such as water spray, insulation felt or materials with different heat conductivity. The control method based on this idea is set up and achieved. By using insulation felt and water spray to change the heat transfer coefficient during the stages of heat treatment process, the results indicate that the proper control time and vary with materials.

Q-3: Analysis of Open Forging of Cylindrical Blanks between Two Flat Die Surfaces: *Ahmed Elkholy*[1]; Dhari Almutairi[1]; [1]Kuwait University

The successful and efficient execution of a forging process is dependent upon the correct analysis of loading and metal flow of blanks. This paper investigates the Upper Bound Technique (UBT) and its application in the analysis of open forging process when a possibility of blank bulging exists. In this regards, the kinematically admissible velocity field is obtained by minimizing the total forging energy rate. The significant advantages of this method is the speed of execution while maintaining a fairly high degree of accuracy. The information from this analysis is useful for the design of forging processes and dies. Results for the prediction of forging loads and stresses, metal flow and surface profiles with the assured benefits in terms of press selection and blank preform design are outlined in some detail. The predictions compared well with results obtained experimentally with a maximum error of no more than 14%.

Q-4: Effects of Tempering on the Microstructure and Hardness of a Spray-Formed Hot Work Tool Steel: *Wang Cunlong*[1]; [1]Guangdong University of Technology

Spray forming is a new way to produce high property materials. This paper was based on spray-formed hot working tool steel; a non-conventional heat treatment of the material was carried out, by doing so, the hardness of the material reached more higher than conventional. And OM, SEM, EDS and XRD were used to study the microstructure of the steels and different phase formation in the heat treatment process.

Q-5: Hot Deformation Behavior of Nb Microalloyed Coiled Tubing Steel: *Zhendong Zhang*[1]; Haitao Zhou[2]; Xianghua Liu[1]; Sijun Li[3]; Guofei Si[1]; Bingyu Zhang[1]; [1]Northeastern University; [2]Central South University; [3]Laiwu Iron and Steel Corp

Hot compression test of Nb microalloyed coiled tubing steel is performed on Gleeble3500 at 1123K—1373K and strain rate from 0.001 to 5s-1. It is found that flow softening occurs and the flow curves exhibit a peak with a characteristic of dynamic recrystallization (DRX) and change with temperature and strain rate significantly. The peak stress and peak strain are dependent on Zener-Hollomon relationship with activation energy of 390 KJ/mol. On the basis of Avrami equation and the Zener-Hollomon parameter, it is obtained that the dynamic recrystallization kinetics equation with which the calculated and measured recrystallization fraction is very close. On the results of hot compression test, the Nb microalloyed coiled tubing steel is rolled by Thermo-Mechanical-Control-Processing (TMCP), and it is obtained that the yield strength and tensile strength of Nb microalloyed coiled tubing steel are 565MPa and 685MPa respectively, and the elongation percentage is 30.1%.

Q-6: Investigation of the Relationship of the Melt Structures and Solidification Behaviors of Cu-Sb70 Alloy Explored by Electrical Resistivity Method: Yun Xi[1]; Jin Yu[1]; Li-Na Mao[1]; *Fang-Qiu Zu*[1]; [1]Hefei University of Technology

According to the behaviors of resistivity-temperature of Cu-Sb70 melt, which suggests a partly reversible temperature induced liquid structure transitions (LST) could occur in this alloy, in this paper, we investigated the dependence of solidification on the liquid state. Both resistivity and temperature were measured to track solidification process. The results show that the nucleating undercooling of the melt which experienced the LST increased and the solidified time decreased. Meanwhile, the solidified microstructures refined evidently, with the microscopic pattern of primary phase changes from disordered pillarlike dendrites into homotaxic ones. Moreover, it is verified that the microstructures would be different if the reversible part of the LST was restrained. The new phenomena and results reflected in this paper suggest that grasping the rules of melt structure change with temperature before material processing will give help for controlling the solidification more effectively and finally resulting in more ideal microstructures.

Q-7: Microstructure of Al2O3/YAG/ZrO2 Eutectic In Situ Composite Prepared by Laser Floating Zone Melting: Kan Song[1]; *Jun Zhang*[2]; Xiaojiao Jia[2]; Haijun Su[2]; Lin Liu[2]; Hengzhi Fu[2]; [1]Northwestern Polytechnical university ; [2]Northwestern Polytechnical university

Al2O3/YAG/ZrO2 eutectic in situ composite has now been regarded as new generation of high temperature structural material due to its excellent performance even close to its melting point. The directionally solidified Al2O3/YAG/ZrO2 eutectic ceramics are prepared by recently developed Laser Floating Zone Melting (LFZM) apparatus in which a splitter mirror is used to obtain two beams with the same quality from one CO2 laser. With the two laser beams irradiate the sample from opposite directions, the sample is zone melted. The apparatus configuration and the solidification processing are described in detail. The solid/liquid interface morphology is studied and the mechanism of microstructure formation especially the characteristic of eutectic cellular is discussed. It is shown that YAG and ZrO2 phases play a leading role during the ternary eutectic growth. Meanwhile, the relationship between the solidification microstructure and the processing parameters are investigated.

Q-8: Net Shape Manufacturing of a Novel Cermet Using Self-Propagating High Temperature Synthesis: *Atefeh Nabavi*[1]; Alexander Capozzi[1]; Sam Goroshin[1]; David Frost[1]; Francois Barthelat[1]; [1]McGill University

In this study, a novel chromium–chromium sulfide cermet was produced by self-propagating high-temperature synthesis (SHS). Conventional techniques for manufacturing metal sulfides are complex, environmentally harmful, and not suitable for producing complex-shape articles. To overcome these disadvantages, a new method for the preparation of the precursor charge in metal-sulfur by SHS is proposed which can be described as reactive casting. Cermet samples that are synthesized at atmospheric pressure have a porous structure which leads to low mechanical strength. The possible sources of porosity were investigated. The porosity was reduced from 40% to 12% by applying a vacuum during melting of the precursor mixture, varying the mixture stoichiometry, and carrying out the synthesis under high ambient pressure of an inert gas. Finally, the mechanism of flame propagation was studied by determining the influence of mixture properties on the critical flame quenching distance.

Q-9: Response Surface Methodology for the Optimization of the Dehydration Curve of Scheelite Concentrate by Microwave Heating: Lei Guo[1]; *Libo Zhang*[1]; Jinhui Peng[1]; Xinhui Duan[1]; Xin Wang[1]; [1]Key Laboratory of Unconventional Metallurgy, Kunming University of Science and Technology

Response surface methodology is applied for the process optimization of microwave drying scheelite concentrate, influences of process conditions such as drying temperature, drying time and material weight on the relative dehydration rates are investigated. Each predictor variable was tested at three levels with conditions of material temperature for 80°C,95°C,110°C, drying time for 70s,125s,180 s and material quality for 80g,190g,300g. The results indicated that with the increase of material temperature and drying time, the relative dehydration rates also increased, and the increasing of material weight, the relative dehydration rate decreased.

Q-10: Study on Inclusions in 65Mn Thin Slabs Produced by a CSP Process: Yi Tan[1]; *Huigai Li*[1]; [1]Shanghai University, Shanghai,China.

Abstract: The influence of superheat degree on the distribution and volume content of inclusions were studied in 65Mn thin slab produced by CSP, The results showed that the diameters of inclusions are mainly less than 5μm. Most of the inclusions gathered at the 1/4 thickness direction for the thin slab of 27°C superheat degree, compared with the center position for that of 37°C. There are more inclusions larger than 50μm in the low superheat samples, which is caused by the short floating time. In addition, the inclusions were observed and analyzed by metallurgical microscope, SEM and EDS in order to ensure their composition, type and further find their source. It was find that the types of these inclusions mainly are Al_2O_3, SiO_2, CaO and their composites, a few of them are TiN and MnS.

Q-11: The Optimization of Copper Utilization during Decoppering of Technical Lead: *Ahmet Haxhiaj*[1]; Izet Zeqiri[1]; Bajram Haxhiaj[1]; Mursel Rama[1]; [1]University of Pristina

In order to have increased utilization of copper during the decoppering process of technical lead in lead refinery in Trepça two samples have been analyzed with the same chemical composition. Furthermore, identical parameters have been used for both samples which are: the quantity of technical lead, the process temperature, the quantity of brimstone loaded, the mixing time and the time of removal of schlicker, and the dismantle of rings formed in the walls of caldron for refinery.After the removal of brimstone schlicker and chemical analyses one calculates the balance of melting phases and decoppering and the scale of copper utilization. The majority of copper is removed from technical lead with the oxide schlicker, one part with the liquation and remaining part by decoppering with brimstone. The paper reflects on increasing utilization of copper in the decoppering of technical lead which is achieved with effective engagement of human factor.

Materials Research in Microgravity: Poster Session

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS Extraction and Processing Division, TMS: Process Technology and Modeling Committee, TMS: Solidification Committee
Program Organizers: Robert Hyers, University of Massachusetts; Hani Henein, University of Alberta; Valdis Bojarevics, University of Greenwich; James Downey, NASA; Douglas Matson, Tufts University; Achim Seidel, Astrium; Daniela Voss, ESA

Monday PM	Room: Atlantic Hall
March 12, 2012	Location: Dolphin Resort

B-1: Advanced Optical Systems for Materials Science Experiments under Microgravity: *Martin Naegele*[1]; Michael Baumgarten[1]; Wolfgang Soellner[2]; Achim Seidel[2]; [1]OptoPrecision GmbH; [2]Astrium

Since materials science experiments under microgravity are often performed with highly reactive metals and alloys which are processed above and below their melting temperatures the use of non-contact diagnostics techniques is essential. This applies in particular to temperature and dimensional measurements of the samples under investigation. Dedicated optical systems are therefore employed in various experimental set-ups. While their specific design is tailored to the intended application they all have to comply with stringent optical, mechanical and environmental requirements. Solutions range from systems made up of sapphire and tungsten components for observations close to heated zones within a vacuum furnace (FMF) to combined camera/pyrometer systems for monitoring of Electromagnetic Levitator (EML) samples, which involve features like beam splitting into visual and near-infrared wavelength ranges, high spatial resolution using telecentric lenses, and objectives that are switchable into distinct measurement modes.

B-2: Containerless Processing on ISS: Ground Support Program for EML: Stefan Schneider[1]; Rainer Willnecker[1]; Angelika Diefenbach[1]; [1]DLR MUSC

EML is an electromagnetic levitation facility planned for the ISS aiming at processing liquid metals or conductive semiconductors by using electromagnetic levitation technique under microgravity and reduced electromagnetic field and convection conditions. Its diagnostics and processing methods allow to measure thermophysical properties and to investigate solidification phenomena. The EML project is a common effort of ESA and the German Space Agency DLR. The Microgravity User Support Center MUSC at Cologne, Germany, has been assigned the responsibility for EML operations. For the EML experiment preparation a ground support program is established at MUSC, providing scientific and technical services in the preparation, performance and evaluation of the experiments. Its final output is the transcription of the scientific goals and requirements into validated facility control parameters. The presentation will outline the extensive scientific support programme and provide insights into the results obtained so far.

B-3: Directional Solidification Experiments on Board the ISS Using MSL: *Daniela Voss*[1]; [1]ESA

TBA

B-4: EML - A Multi-User Electromagnetic Levitation Facility for Containerless Processing Experiments Onboard the ISS: *Achim Seidel*[1]; Wolfgang Soellner[1]; Christian Stenzel[1]; [1]Astrium

Electromagnetic levitation under microgravity is a powerful technique for containerless processing of electrically conducting samples such as metals and semiconductors. Based on the long and successfully heritage of the TEMPUS program which included parabolic flights, sounding rocket flights, and Spacelab missions a multi-user facility for electromagnetic levitation experiments onboard the International Space Station is currently being developed by EADS Astrium under contracts to ESA and DLR. During its 5 year operation the EML payload can process up to 180 samples in 10 batches, accommodating a wide range of experiments of nucleation phenomena or phase formation as well as the measurement of a range of thermophysical properties both above the melting temperature and in the undercooled regime. Upgrades of the basic configuration are under development, in particular instruments to precisely determine the electrical conductivity of the samples and to measure and control the residual oxygen content of the process atmosphere.

B-5: EML Experiments on Board the ISS: *Daniela Voss*[1]; [1]ESA

TBA

B-6: Fluid Flow in Phase Selection Experiments Using Electromagnetic and Electrostatic Levitation: *Briana Tomboulian*[1]; Robert Hyers[1]; Douglas Matson[2]; [1]University of Massachusetts; [2]Tufts University

Understanding and predicting internal flow in levitated samples is critical to designing the experiments and processing the samples successfully. Previous work demonstrated that the solidification path of some alloys is strongly affected by the flow velocity of the molten phase during solidification, yet many ranges in velocity have not been explored due to experimental limitations. We have developed simulations of spherical samples in electromagnetic levitation (EML) and electrostatic levitation (ESL). Flow is induced during EML by electromagnetic field body forces, while in ESL it is driven by a temperature gradient. Both models have been validated using cases with known analytical solutions and previous results from the literature. These simulations predict the flow velocities within a liquid drop, from which it may be possible to determine the solidification path, and provide an explanation for the microstructure. Estimates of the flow velocity within a sample can also be used to design experiments.

B-7: FMF: An MSL Furnace Insert for Float-zone Crystal Growth on the ISS: Adam Hess[1]; *Arne Cröll*[1]; Jan Zähringer[1]; Christian Stenzel[2]; Dirk Bräuer[3]; Harald Sauermann[3]; Volker Uhlig[3]; [1]Albert-Ludwigs University Freiburg; [2]Astrium; [3]Technische Bergakademie Freiberg

A laboratory model of a Floating Zone Furnace with Rotating Magnetic Field (FMF) for float-zone crystal growth experiments of Germanium-Silicon with process temperatures of up to 1500°C has been realised and tested. A flight version of this furnace is intended to be implemented as a further insert to the Materials Science Laboratory on the ISS. Under microgravity convection phenomena and their impact on segregation effects can be examined apart from the buoyancy driven ones. The FMF is a precisely temperature controlled 7 zone resistance furnace that provides thermal stability (+/- 0.05 K) and a variable temperature gradient (5-50 K/cm) at the phase boundary. In addition it allows visual observation in order to control the zone height and the interface, which until now was only possible in mirror furnaces. A rotating magnetic field was introduced to influence and control the melt flow during crystal growth.

B-8: High-Precision Temperature Control of a Crystal Growth Furnace at 1500°C: *Christian Stenzel*[1]; Arne Croell[2]; Adam Hess[2]; Dirk Bräuer[3]; Hartmut Sauermann[3]; [1]Astrium; [2]University of Freiburg; [3]Technical University Freiberg

For crystal growth of semiconductor materials a short-term temperature stability of 0.1°C at 1500°C is one of the essential parameters to be addressed for achieving high-quality crystals. Hence, for temperature monitoring and control with high precision in a floating zone furnace two sets of thermo-sensors, type S thermocouples and optical fibre thermometers, have been implemented and successfully operated in the furnace for more than 2000 h. The optical fibre thermometers consist of an optical system made of sapphire (two fibres plus a prism for deflection) and transmit the infra-red radiation of the heater to the outside of the hot core of the furnace for pyrometric temperature measurement. A dedicated control algorithm has been set up which controlled the power settings to the individual heaters. But sensor types showed no degradation after this period and yielded a short-term stability at 1200°C of 0.05°C (optical fibre thermometers), respectively 0.08°C (thermocouples).

B-9: Inductive Measurement Device for Microgravity Electromagnetic Levitator: Georg Lohoefer[1]; *Juergen Brillo*[1]; [1]German Aerospace Center, DLR

For the containerless processing of high temperature metallic melts the electromagnetic levitation technique, which utilizes high frequency alternating magnetic fields for the contactless, inductive positioning and heating of electrically conducting samples, is well established. The existence of alternating magnetic fields in electromagnetic levitation facilities suggests to use inductive methods also for the non-contact detection of liquid metal properties. Not only the electrical resistivity but also the shape change during the damped oscillation of an electromagnetically levitated liquid metal droplet, which is determined by its surface tension and viscosity, can be detected inductively. This contribution presents a measurement device designed and constructed by DLR, which utilizes the high frequency magnetic dipole fields of the microgravity electromagnetic levitation facilities TEMPUS, applied for parabolic flights, and EML, applied on board of the space station ISS, simultaneously also for an inductive determination of thermophysical properties of levitated metallic melts.

B-10: In-Situ Observation of Directional Solidification Processes in Transparent Materials on the ISS: *Daniela Voss*[1]; [1]ESA

TBA

B-11: Investigation of Thermocapillary Convection of High Prandtl Number Fluid under Microgravity: *Ruquan Liang*[1]; [1]Northeastern University

The flow and thermal fields of the thermocapillary flows in floating zone crystal growth configurations under microgravity has been investigated numerically. The Navier-Stokes equations coupled with the energy conservation equation are solved on a staggered grid. The new mass conserving level set approach is used to capture the free surface deformation of the liquid bridge, while the existing numerical simulations for liquid bridges adopted simplified models without considering the dynamic free surface deformation. The numerical results show that two vortexes are generated due to the thermocapillary convection in the liquid bridge initially, and then the vertex centers move toward the free surface. The recirculating flow generates a radial convection, which tends to make the bulk fluid temperature distribution rather uniform near the free surface. Therefore, the temperature gradient in the hot corner decreases, while the temperature gradient in the cold corner increases.

B-12: Modeling for ISS Experiments on Transient Nucleation in Glass- and Quasicrystal-Forming Melts: *Xiao Ye*[1]; Kenneth Kelton[2]; Robert Hyers[1]; [1]University of Massachusetts; [2]Washington University

Testing the theory of coupled nucleation in glass- and quasicrystal-forming metals requires that the diffusion fields around nuclei be left to grow unaffected by convection. Because the nuclei are so small, they follow the flow exactly and are not affected by the magnitude of the velocity. However, the gradient in velocity, which is the shear rate, can cause the diffusion fields to overlap. Magnetohydrodynamic calculations show the range of parameters that will permit the experiment to proceed without convective contamination.

B-13: Real Time In-Situ Observations of Equiaxed Dendrite Coherency in Al-Cu Alloys Using High Brilliance 3rd Generation Synchrotron Sources: *Andrew Murphy*[1]; David Browne[1]; Wajira Mirihanage[2]; Ragnvald Mathiesen[2]; [1]University College Dublin; [2]Norwegian University of Science and Technology

In the last decade synchrotron X-ray sources have fast become the tool of choice for performing high resolution imaging in materials science, particularly in alloy solidification. This paper presents the results of an experimental campaign carried out at the European Synchrotron

POSTERS

Radiation Facility, using a Bridgman furnace, to monitor phenomena during solidification of Al-Cu alloys - specifically the onset of equiaxed dendrite coherency. Conventional experimental methods for determining coherency involve measuring the change in viscosity or measuring the change in thermal conductivity across the solidifying melt. Conflicts arise when comparing the results of these experimental techniques to find a relationship between cooling rate and coherency fraction. It has been shown that the ratio of average velocity to the average grain diameter has an inversely proportional relationship to coherency fraction. In-situ observation therefore makes it possible to measure these values directly from acquired images sequences and make comparisons with published results.

B-14: Surface Tension and Viscosity of Ni-Al Catalytic Precursor Alloys Measured by the Oscillating Drop Method on Different Microgravity Platforms: *Rainer Wunderlich*[1]; Hans-Joerg Fecht[1]; [1]Universitaet Ulm

The surface tension and the viscosity of a variety of catalytic precursor Ni-Al alloys including Raney-NiAl haven been measured by the oscillating drop method in an electromagnetic levitation device under reduced gravity conditions on board parabolic and in a TEXUS sounding rocket flight. Surface tension values such obtained agree very well with values obtained in ground based em-levitation providing a verification of the Cummings and Blackburn correction of the shift of the surface oscillation frequency due to the magnetic pressure of the levitation field with a confidence level better \149; 2%. The good agreement of viscosity values obtained in the microgravity experiments with values obtained from the oscillating cup method under 1-g gives support to the application of the oscillating drop method in an electromagnetic levitation device with a confidence level of \149; 20%. Experimental results obtained are compared with the predictions of several semiempirical thermodynamic models.

B-15: Truncated Dual Cap Nucleation Site Development: *Douglas Matson*[1]; Paul Sander[1]; [1]Tufts University

During heterogeneous nucleation within a metastable mushy-zone, several geometries for nucleation site development must be considered. Traditional spherical cap and dual cap models are compared to a truncated dual cap to determine the activation energy and critical cluster growth kinetics in ternary Fe-Cr-Ni steel and Fe-Co magnetic alloys.

B-16: XRMON Modules on Sounding Rockets: *Daniela Voss*[1]; [1]ESA

A-1: Atomistic Prediction of Precipitate Strengthening in Nanoscale Metallic Multilayers: *Niaz Abdolrahim*[1]; Ioannis Mastorakos[1]; Hussein Zbib[1]; [1]Washington State University

Nanoscale metallic multilayer's (NMM) can play a leading role in the future micromechanical devices due to their high structural stability, mechanical strength, high ductility, toughness and resistance to fracture and fatigue. The design of better NMMs can be achieved by properly tailoring the nanostructure using appropriate materials-by-design algorithms. However, before those materials are put into service in any significant applications, many important fundamental issues remain to be understood. Among them, the role of the second phase particles on the strengthening properties of the nanocomposite materials. The purpose of this work is to address the question if the second phase particles can strengthen the nanoscale materials in the same manner as in bulk crystalline solids. In this view, Cu/Nb thinfilms with spherical Nb particles inside the Cu layer were examined using molecular dynamics simulations and show to exhibit a significant improvement on their mechanical behavior, compared to similar structures without particles.

A-2: Atomistic Simulations of the Adhesion of Alumina/epoxy Interfaces Using ReaxFF: *Fidel Valega Mackenzie*[1]; Barend Thijsse[1]; [1]Delft University of Technology

Alumina/epoxy interfaces are of great importance in many engineering environments. Not only due to aging but also because of temperature, moisture, shearing and mechanical loading they are subjected to failure. In order to understand how it occurs, reliable inter-atomic potentials need to be developed. Here we introduce the Reactive Force Field (ReaxFF) for alumina/epoxy interfaces, which describes the possible interactions between both of this surfaces. By making use of ReaxFF the polymer and the metal oxide were built and different interfaces were then created varying the roughness of the alumina surface by introducing the presence of defect-islands. The work of adhesion between this rough metal oxide surfaces and the epoxy is calculated, as well as its dependence with temperature. The effect of shearing parallel to the interface is also examined and discussed, presenting possible ways in which this interfaces may undergo failure.

A-3: Characterization of Coherency Limits in Si/Ge Core-Shell Nanowires Using Molecular Dynamics: *Yumi Park*[1]; Alejandro Strachan[1]; [1]Purdue University

We use molecular dynamics simulation with Stillinger-Weber potential to characterize how surface roughness and core diameter affect strain relaxation and coherency limit of Si/Ge core-shell nanowires. To this end, we vary core diameter and surface roughness, but keep the shell thickness and the wavelength of the roughness as constants proportional to the core diameter for all cases. After the coherency is lost, a significant strain relaxation is observed especially in the core. Interestingly, defect nucleation does not affect the axial strain for the wires with small roughness; only wires with significant roughness exhibit axial strain relaxation. Surface roughness also affects the coherency limits of the wires. For 20 nm diameter wires the instability limit decreases with increasing roughness; however, for smaller diameter wires (10 nm) we observe little dependence of the coherency limit with roughness. We also identify and quantify the defects responsible for the strain relaxation in the nanowires.

A-4: Controlling the Lithiation Induced Strain and Charging Rate in Nanowire Electrodes by Coating: *Liqiang Zhang*[1]; Xiaohua Liu[2]; Yang Liu[2]; Shan Huang[3]; Ting Zhu[3]; Liangjin Gui[4]; Scott X. Mao[1]; Zhizhen Ye[5]; Chongmin Wang[6]; John P. Sullivan[2]; Jianyu Huang[2]; [1]University of Pittsburgh; [2]Sandia National Laboratories; [3]Georgia Institute of Technology; [4]Tsinghua University; [5]Zhejiang University; [6]Pacific Northwest National Laboratory

Lithium ion batteries (LIBs)are presently the best advanced battery system, but they cannot meet requirements for more demanding applications due to limitations in capacity, charging rate and cyclability. One leading cause of those limitations is the lithiation-induced-strain (LIS) in electrodes that can result in high stress, fracture and capacity loss. Here we report that by utilizing the coating strategy, both the charging rate and LIS of SnO2 nanowire electrodes can be altered dramatically. The SnO2 nanowires coated with carbon, aluminum, or copper can be charged about 10 times faster than the non-coated ones. Intriguingly, the radial expansion of the coated nanowires was completely suppressed, resulting in enormously reduced tensile stress at the reaction front, as evidenced by the lack of formation of dislocations. Our work demonstrates that nanoengineering the coating enables the simultaneous control of electrical and mechanical behaviors of electrodes, pointing to a promising route for building better LIBs.

A-5: Dislocation-Interface Interaction Mechanisms in Nanoscale Laminates with Enhanced Interface Models: *Firas Akasheh*[1]; S. M. Yead Jewel[1]; [1]Tuskegee University

Nanoscale metallic laminates consist of alternating layers of two metals with individual layer thickness is on the order of nanometers. Recently, these structures have been receiving a great deal of attention due to their exceptional properties, including ultrahigh strength beyond the prediction of the rule-of-mixtures, and high ductility. Although such properties are attributed to the nature of dislocation interactions in confined nanoscale regions and, more so, to dislocation-interface interactions, a detailed understanding is still missing. In this work, we follow up on our previous studies on dislocation mechanisms in (001) epitaxial nanolaminates by including a new model of interface resistance in coherent systems and incoherent systems. We also include cross slip and the effect of Koehler image forces. We show the mechanism by which intersecting dislocations interactions lead to the breakdown on the interface as a barrier along with the corresponding hardening effect over the basic obstacle-free yield strength.

A-6: Effect of Hydrogen on Subsurface Deformation during Indentation of Pipeline Steel: *Moo Young Seok*[1]; In-Chul Choi[1]; Yong-Jae Kim[1]; Dong-Woo Suh[2]; Jae-il Jang[1]; [1]Hanyang university; [2]GIFT, POSTECH

To prepare the up-coming era of so-called 'hydrogen economy', many researches focused on the related topics are actively conducted all round the world. With a viewpoint of industrial field applications, one of the important topics being studied is hydrogen transmission (more specifically, 'hydrogen pipeline'). So, the development of advanced high-pressure hydrogen pipelines is highly desirable. As a good starting point for the purpose, one might wonder whether conventional pipeline steels (designed for oil and natural gas transmission) can be used as the hydrogen pipeline materials or not. To answer the question, we attempted to systematically analyze the influence of hydrogen on the mechanical performance of API linepipe steels. As a first step, here we examined the subsurface deformation produced during macroscopic indentation of the API X70 steel samples (before and after hydrogen charging) prepared by interface-bonding technique.

A-7: Effects of Focused-Ion-Beam Irradiation and Prestraining on the Mechanical Properties of FCC Au Microparticles on a Sapphire Substrate: *Seok-Woo Lee*[1]; Dan Mordehai[2]; Eugen Rabkin[2]; William Nix[1]; [1]Stanford University; [2]Technion-Israel Institute of Technology

We have studied the effects of focused-ion-beam (FIB) irradiation and prestraining on the mechanical properties of nearly defect-free Au microparticles on a sapphire substrate. The Au microparticles, which were produced by a solid-state diffusion dewetting technique, were FIB-irradiated and/or prestrained, the latter using a nanoindenter with a flat ended punch operating under a nanohammering mode. Also, the prestrained Au microparticles were exposed to FIB to examine the effects of ion-beam damage on the properties of crystals containing mobile dislocations. We found that both FIB irradiation and prestraining reduced the yield strength of pristine Au microparticles significantly and made the stress–strain curves jerky. However, FIB irradiation does not affect the mechanical properties of prestrained Au microparticles very significantly. Once a microparticle contains mobile dislocations, its mechanical properties are not influenced much by the defects generated by FIB irradiation, even at the submicrometer scale.

A-8: Effects of Ti on Electronic Structure and Mechanical Property of Uranium: a First-Principles Study: *Jianbo Qi*[1]; Jieyu Zhang[1]; [1]Shanghai University

In order to improve the tensile strength and elastic modulus properties of a-U, first principles plane wave pseudopotential method based on density functional theory (DFT) was utilized to calculate electronic structure, ground state energy and elastic constant of uranium-0.75 wt.% titanium alloy. Optimization structures of equilibrium phase (a-U) and metastable phase (martensite a´-U) are firstly calculated. Then calculation of the tensile test is preformed to predict mechanical properties and chemical bonding nature from density of state (DOS) and Mulliken population analysis are used to illuminate the calculation results. Finally, the macroscopic stiffness properties of a-U and a´-U, such as Young's, shear and bulk modulus, are determined by the elastic constants. Our results show that after Ti addition, tensile strengths of a-U and a´-U increase from 464MPa to 1162MPa while elastic moduli are 175GPa and 190GPa, respectively. These conclusions are in good agreement with our experimental results.

A-9: Investigation of the Crystal Structure on the Nanomechanical Properties of Pulsed Laser Deposited NbN Thin Films: *Cody Wright*[1]; M Mamun[1]; A Farha[1]; Y Ufuktepe[2]; H Elsayed-Ali[1]; A. Elmustafa[1]; [1]Old Dominion University; [2]Cukurova University

The nanomechanical properties of NbN/Nb deposited by pulsed laser deposition (PLD) were investigated as a function of the film/substrate crystal structure. In addition to the ß-Nb2N phase, the X-ray diffraction shows peaks correspond to d-NbN cubic and d´-NbN hexagonal phases. Several samples were tested of varied crystal structure between dominant cubic to dominant hexagonal. X-ray diffraction analysis, scanning electron microscopy, atomic force microscopy were employed to characterize their phases, microstructure, and surface morphology. Nanoindentation was used to investigate the nanomechanical properties of the films. A Nanoindenter XP equipped with a DCM II head was used in conjunction with the continuous stiffness method (CSM) in depth and load control modes to evaluate the hardness and modulus of the NbN thin films as a function of the crystal structure. The results show that there are clear effects of the crystal structure on the elastic modulus of the PLD-grown NbN films.

A-10: Investigation of the Indentation Size Effect in FCC Metals Using Activation Volume Analysis: *David Stegall*[1]; A Elmustafa[1]; [1]Old Dominion University

The activation volumes for plastic deformation for different FCC pure metals and alloys were measured using nanoindentation. The indentation size effect in FCC metals is examined using the rate effects characterized by the sensitivity of the hardness and the effective strain gradient beneath the indenter. The hardness was measured using a XP nanoindenter with a high load attachment capable of producing loads up to 10 N using a single Berkovich tip. The materials included pure polycrystalline aluminum, nickel, silver, and alloys; 70/30 copper zinc (alpha-brass), 7075 aluminum (aluminum zinc), 70/30 nickel copper, and 90/10 platinum rhodium. The activation volume, (9KbT/□H/□lneeff) is referred to as a measure of the Burger's vector (b) times the area swept out by dislocations during the process of thermal activation, the so-called "activation area" or . H is the hardness and eeff is the effective strain rate beneath the indenter.

A-11: Laser Compression of Nanocrystalline Tantalum: *Chia-Hui Lu*[1]; Brian Maddox[2]; Bruce Remington[2]; Eduardo Bringa[3]; Megumi Kawasaki[4]; Terence Langdon[4]; Hye-Sook Park[2]; Bimal Kad[1]; Marc Meyers[1]; [1]University of California, San Diego; [2]LLNL; [3]Conicet & ICB, U. N. Cuyo; [4]University of Southern California

Nanocrystlline tantalum was prepared by HPT (High Pressure Torsion) from monocrystalline [100] stock yielding a grain size of 70 nm. It was subjected to laser driven compression at energy levels of ~ 350 J to ~ 850 J in the Omega facility (LLE, U. of Rochester) yielding pressures as high as ~ 180 GPa. The laser beam created a crater of significant depth (~ 100μm). Transmission electron microscopy (TEM) revealed dislocations in the grains but no twins in contrast with monocrystalline tantalum. Hardness measurements were conducted and show the same trend as monocrystalline tantalum. The grain size was found to increase close to the energy deposition surface. The experimentally measured dislocation densities are compared with predictions using an analysis based on the constitutive response and the similarities and differences are discussed in terms of the mechanisms of defect generation.

A-12: Lithiation Induced Embrittlement of Multi-Walled Carbon Nanotubes: *Yang Liu*[1]; He Zheng[2]; Xiaohua Liu[1]; Shan Huang[3]; Ting Zhu[3]; Jiang Wei Wang[2]; Akihiro Kushima[4]; Nicholas Hudak[1]; Xu Huang[5]; Sulin Zhang[5]; Scott Mao[2]; Xiao Feng Qian[6]; Ju Li[4]; Jian Yu Huang[1]; [1]Sandia National Laboratories; [2]University of Pittsburgh; [3]Georgia Institute of Technology; [4]University of Pennsylvania; [5]Pennsylvania State University; [6]Massachusetts Institute of Technology

Lithiation of individual multi-walled carbon nanotubes (MWCNTs) was conducted in-situ inside a transmission electron microscope. Upon lithiation, the intertube spacing increased from 3.4 to 3.6 Å, corresponding to about 5.9% radial and circumferential expansions and ~50 GPa tensile hoop stress on the outermost tube wall. In-situ compression and tension tests show that the lithiated MWCNTs were brittle with sharp fracture edges. The lithiation-induced embrittlement is attributed to the mechanical effect of a "point-force" action posed by the intertubular lithium that induces the stretch of carbon-carbon bonds additional to that by applied strain, as well as the chemical effect of electron transfer from lithium to the antibonding p orbital that weakens the carbon-carbon bond. The combined mechanical and chemical weakening leads to a considerable decrease of fracture strain in MWCNTs. Our results provide direct evidence and understanding of the degradation mechanism of carbonaceous anodes in lithium ion batteries.

A-13: Mechanical Anisotropy and Texture in Caliber Rolled Twinning-Induced Plasticity Steels: *Young Soo Chun*[1]; Junmo Lee[1]; You-Hwan Lee[2]; Kyung-Tae Park[3]; Chong Soo Lee[1]; [1]POSTECH; [2]POSCO; [3]Hanbat Nat'l Univ.

A study was made to investigate the yield anisotropy in caliber rolled 18Mn-0.6C-1.5Al twinning-induced plasticity (TWIP) steel with the variation of reduction area (RA). As-received hot-rolled sheets with 10□ grain size were cold rolled by use of caliber rolling machine from 31 to 82% RA. Electron back scattered diffraction and transmission electron microscopy were conducted to analyze the microstructure. In order to investigate anisotropic deformation behavior, compression test was conducted on the specimens of which loading axes were aligned to have L and C axis of a caliber rolled rod, respectively. The results showed that with the increase of RA, the {111} and {100} textures were progressively developed parallel to L axis, resulting in the greater yield anisotropy in the L and C axis. Detailed mechanisms responsible for such anisotropy were discussed based on the texture analysis and microstructural evolution during the deformation.

A-14: Mechanical Behavior and Thermal Stability of Differently Oriented Nanotwinned Ag Films: *Daniel Bufford*[1]; Xinghang Zhang[1]; Haiyan Wang[1]; [1]Texas A&M University

Epitaxial nanotwinned Ag films with (111) and (110) orientation were deposited by magnetron sputtering. The twin boundary spacing in the as-deposited films is 9 nm in Ag (111) and 42 nm in Ag (110), with the twin boundaries normal to the growth direction in the (111) films and at an angle in the (110) films. Size dependent strengthening is observed in Ag films and related mechanisms are discussed. Thermal stability of films was investigated via isothermal annealing in argon up to 800°C. The evolution of microstructure and mechanical behavior of films will be presented.

A-15: Mechanical Behavior for Different Cutting Directions on Copper and Rhodium Single Crystals: *Seisuke Kano*[1]; Atsushi Korenaga[1]; [1]National Institute of Science and Technology (AIST)

Mechanical behavior on the metal surface is strongly related on the surface fracture by a mechanical cutting especially shaper type cutting to apply ultra-fine optics manufacturing and several nan-technologies. To realize the ultra-fine cutting, the crystallographic interface physics is quite important to control the surface fracture behavior. In this study, the surface fracture behavior evaluated using copper and rhodium single crystals cut on the (100) plane for several directions. As results of the cutting, the shapes of the cutting groves were different with the cutting direction between [010] direction and the others. The reason of this result was considered that the cutting tool moved along the slip plane belongs to [111] direction or not. In the case of shallow cutting under 1 \149; m, the spring back behavior was observed for the cutting directions. The mechanisms would be connected to the interface among the slip plane fracture by the cutting tool.

A-16: Mechanical Properties and Deformation Mechanism of Nanostructured Two-Phase $Fe_{30}Ni_{20}Mn_{20}Al_{30}$ Alloy: *Xiaolan Wu*[1]; I. Baker[1]; [1]Dartmouth College

This presentation will discuss the deformation mechanisms that control the strength of nanostructured, two-phase $Fe_{30}Ni_{20}Mn_{20}Al_{30}$. Two different microstructures of $Fe_{30}Ni_{20}Mn_{20}Al_{30}$ were studied: the ultrafine (wavelength of ~ 8 nm), as-cast modulated $B2/L2_1$ microstructure, possibly formed by spinodal decomposition; and the <100>-aligned two-phase (phase width of ~ 25 nm) $B2/L2_1$ microstructure, produced by a 72 h anneal at 823K. The alloy was mechanically tested over a range of temperatures and strain rates. The annealed alloy showed a lower brittle-to-ductile transition temperature (~ 573 K) than the as-cast material (~ 673 K). Dislocation analyses, based both on post-mortem and in-situ straining TEM, were performed in order to understand the deformation mechanisms of this alloy

A-17: Mechanical Properties of Nanostructured TiAlN Based Coatings: Sai Pramod Pemmasani[1]; *Koteswararao Rajulapati*[1]; Ramakrishna M[2]; Krishna Valleti[2]; Ravi Chandra Gundakaram[2]; Shrikant V Joshi[2]; [1]University of Hyderabad; [2]International Advanced Research Centre for Powder Metallurgy and New Materials

Transition metal nitrides are being used in novel configurations such as multilayers, nanolayers, superlattices and nanocomposites. In the present study, nitride coatings were deposited on tool steel substrates by cathodic arc evaporation under varied processing conditions. As-deposited coatings were characterized by XRD, SEM, FIB milling, TEM, nanoindentation, nano-scratch and wear testing. Nanoindentation was performed on both the surface and cross-section of the coatings followed by imaging of the indents and a qualitative determination of toughness. Post-scratch and post-wear imaging was used to determine the scratch and wear depths. The effect of processing induced microstructural changes on the coating hardness, modulus and adhesion was studied. The effect of multilayering and composition on the coating properties was also explored. A combination of electron microscopy along with nanoindentation and scratch testing was used to arrive at correlations between the coating microstructure and properties and these will be presented.

A-18: Mechanics of Individual Amorphous Carbon Nanoparticles from Experiment and Simulation: *Eric Bucholz*[1]; Susan Sinnott[1]; [1]University of Florida

In situ transmission electron microscopy experiments can be used to visualize and manipulate individual amorphous carbon (aC) nanoparticles which facilitate determination of their mechanical responses to external forces, which is critical for optimizing their use as lubricating additives to base oils in tribological applications. Complementary molecular dynamics simulations are used to characterize the behavior of aC nanoparticles at an interface during compression. In particular, their response as a function of particle diameter and normal load are quantified based, in part, on the ratio of sp2:sp3 carbon atoms. The simulations predict that the transition from elastic to plastic deformation is triggered by an increase in the percentage of sp3 carbon atoms with the mechanical response being independent of nanoparticle size over the range of diameters considered (2 – 5 nm). This work is supported by the Office of Naval Research.

A-19: Micromechanical Testing of Nanocrystalline BCC Metals: *Jonathan Ligda*[1]; Brian Schuster[2]; Qiuming Wei[1]; [1]UNC Charlotte; [2]Army Research Laboratory

High pressure torsion (HPT) processing has been utilized to refine the grain size of body centered cubic metals into the ultra-fine-grained and nanocrystalline regime. Because of the limited bulk specimen dimensions and the gradient in structure and properties in a single HPT disk, site-specific nanoindentation and focused ion beam based mechanical testing has been applied to systematically examine the effect of grain size on the strength and deformation mode. In-situ tensile testing within a scanning electron microscope employs a customer built test stage consisting of piezoelectric positioners, a high resolution linear actuator for load application and a strain gage based load cell. The system is controlled with a data acquisition program and strains are calculated using digital image correlation. Application of the above to nanocrystalline tantalum has shown a distinct transition in deformation mode from homogeneous to localized plastic deformation across the HPT disk.

A-20: Microstructural Changes Across Shear Bands in Nanotwinned Cu Foils Deformed at Room Temperature and 77K: *Timothy Furnish*[1]; Andrea Hodge[1]; [1]University of Southern California

Copper samples containing highly aligned nanotwins (mean spacing approx. 40nm) were tested in tension at both room temperature and 77K. The initial Cu samples present 500-800 nm grain width, medium twin density (3.0×10^6 m^2/m^3), high strength (540 to 690 MPa), low initial dislocation density and little to almost no strain hardening. The formation of shear bands appeared to be a dominant deformation mechanism and an increase in ductility at 77K compared to room temperature was observed. A higher number of shear bands formed in the samples tested at 77K, which is thought to be a contributing factor to the enhanced localized ductility. In this presentation, the microstructure of the as-prepared and tested samples will be discussed with emphasis on the changes within and across the shear bands in each of the samples.

A-21: Nano-Compression Testing of Freestanding Tetragonal Ni3Al Particles: *Bin Gan*[1]; Robert Maaß[2]; Julia R. Greer[2]; Sammy Tin[1]; [1]Illinois Institute of Technology; [2]California Institute of Technology

Recent advances in nano-compression testing techniques have enabled the development of powerful characterization tools that enable quantification of location specific mechanical properties within the microstructure of various classes of engineering materials. Tetragonal Ni3Al precipitates with edge lengths varying from 200 to 600 nm were electro-chemically extracted from a Ni-based single crystal superalloy. The freestanding, tetragonal particles possess plane normals that are oriented along the <100> directions and an aspect ratio bigger than 1.5. By carefully selecting and manipulating individual tetragonal precipitates, the response of individual freestanding Ni3Al particles to uniaxial compression was measured. Results from in-situ observations that detail the dynamic deformation response of these precipitates in both a Transmission Electron Microscope and a Scanning Electron Microscope will be presented and discussed.

A-22: Nanoindentation Investigation of VO2 Films Synthesized by Reactive Bias Target Ion Beam Deposition (RBTIBD): *Cody Wright*[1]; M. A. Mamun[1]; D. Nminibapiel[1]; Wei Cao[1]; D. Gu[1]; H. Baumgart[1]; Jiwei Lu[1]; H. Elsayed-Ali[1]; [1]Old Dominion University

Vanadium dioxide has a metal–semiconductor transition at 340 K, just above ambient temperature. For this reason the material has attracted a lot of attention as a potential candidate for novel phase transition switching and sensor applications based on electrically driven transitions. The low-temperature semiconducting phase has a monoclinic crystal structure, while the metallic phase has a rutile structure above the transition temperature. The objective of this study is to investigate and to understand the nanomechanical properties of the VO2 films. To this end we have performed nanoindentation experiments using a Nanoindenter XP with a DCM II head. The VO2 films were synthesized by both Pulsed Laser Deposition and Reactive Bias Target Ion Beam Deposition. The PLD experimental settings and the influence of the oxygen partial pressure on the stoichiometry is described. Physical analysis by X-ray diffraction and SEM and TEM was applied in order to characterize the PLD VO2 films.

A-23: Nanomechanical Behavior of Teflon-MWCNT Bilayer Films: *Rachel Schoeppner*[1]; Anqi Qiu[1]; Douglas Stauffer[2]; Ryan Major[2]; Jack Skinner[3]; Thomas Zifer[3]; Greg O'Bryan[3]; Andrew Vance[3]; William Gerberich[4]; David Bahr[1]; Neville Moody[3]; [1]Washington State University; [2]Hysitron Inc.; [3]Sandia National Laboratories; [4]University of Minnesota

Teflon MWCNT suspensions have the potential for creating conductive coatings on insulating films for static dissipation. However, there are few studies on polymer MWCNT suspension properties and even fewer that use Teflon. To define mechanical and electrical property relationships in this film system, we created bilayer Teflon AF MWCNT films with differing concentrations of functionalized and nonfunctionalized MWCNTs. Nanoindentation revealed that addition of MWCNTs increased modulus while hardness remained constant. Conducting indentation showed that films with 8 w/o MWCNT exhibited uniform stable conductance once indentation depth exceeded several hundred nanometers. Films with lower concentrations of MWCNTs were insulating. In this presentation, the results will be used to show that the two techniques provide a unique description of structure property relationships in this suspension film system. This work was supported by Sandia National Laboratories, a Lockheed Martin Company for the USDOE NNSA under contract DE-AC04 94AL85000.

A-24: Nanomechanical Properties of Atomic Layer Deposition Sb2Te3 Thin Films: *Cody Wright*[1]; M Mamun[1]; D Gu[1]; D Nminibapiel[1]; H Baumgart[1]; H Robinson[2]; V Kochergin[3]; A. Elmustafa[1]; [1]Old Dominion University; [2]Virginia Tech University; [3]MicroXact

The nanomechanical and structural properties of Antimony Telluride (Sb2Te3) thin films deposited by atomic layer deposition were investigated and reported. X-ray diffraction analysis, scanning electron microscopy (SEM) with energy dispersive x-ray spectroscopy analysis (EDS), atomic force microscopy (AFM), spectroscopic ellipsometry and high resolution transmission electron microscopy (HRTEM) were employed to characterize the Sb2Te3 single film composition and layered nanocomposites. Nanoindentation was used to investigate the nanomechanical properties of the films. A Nanoindenter XP equipped with a DCM II head was used in conjunction with the continuous stiffness method (CSM) in depth and load control modes to evaluate the hardness and modulus of the Sb2Te3 thin films. In addition the influence of the ALD fabrication parameters and post deposition anneal processes on the mechanical and structural properties are reported. The stoichiometry of the ALD synthesized Sb2Te3 thin films were investigated by secondary ion mass spectroscopy (SIMS) and Rutherford Backscattering (RBS).

A-25: NanoMechanical Properties of Hydrogen Implanted AlN for Layer Transfer by Ion-Induced Splitting: *Cody Wright*[1]; M Mamun[1]; K Tapily[1]; O Moutanabbir[2]; D Gu[1]; H Baumgart[1]; A. Elmustafa[1]; [1]Old Dominion University; [2]Max-Plank Institute

The nanomechanical and structural properties of epitaxially grown AlN were investigated as a function of different H-fluences and thermal evolution by nanoindentation, x-ray diffraction, atomic force microscopy, and high resolution transmission electron microscopy. A 2µm thick AlN layer was epitaxially grown on sapphire. The nanomechanical properties were measured using nanoindentation. The AlN samples were implanted with hydrogen ions at 50 keV with various fluences ranging from 0.5 x1017cm-2 to 3 x1017 cm-2. The modulus and hardness were carefully determined for each sample. A virgin non-implanted AlN sample was also used as benchmarking. The samples were then annealed in air at temperatures ranging from 300oC to 600oC for 5 min to study the influence of pre-layer splitting treatments on the nanomechanical properties. Once the H implantation was introduced, the hardness increased from 18 GPa for the virgin sample to ~25 GPa for the highest fluence of 3x1017 H cm-2.

A-26: Phase Field Dislocation Dynamics in Confined Volumes: *Lei Lei*[1]; Marisol Koslowski[1]; [1]Purdue University

When the material characteristic size or certain characteristic length, such as grain size or sample dimensions, approaches the nanometer range, metals display a strong size dependency given by an increase in the yield stress as the characteristic size decreases. The change in yield stress due to the interaction of dislocations with stress free surfaces has implications not only in micron and submicron size single crystals but also in void growth

POSTERS

in solids undergoing plastic straining and is potentially important to the understanding of ductile fracture. We will present a phase field dislocation dynamics model that includes the interaction of dislocations with stress free surfaces in single crystals. Stress free surfaces are modeled using Eshelby's eigenstrain approach, which enables the simulation of arbitrary geometries. The effect of stress free surfaces, crystal size and geometry, and the initial dislocation density on the strength of Nickel in small dimensions is examined.

A-27: Processing of ta-C Protective Films on Mold for Glass Lens: Seungkeun Oh[1]; *Youngman Kim*[1]; [1]Chonnam National University

Recently aspheric lenses are widely used for superpricision optical instruments, such as cellular phone camera modules, digital cameras and optical communication modules. The aspherical lenses are processed using mold core under high temperature compressive forming pressure. It is imperative to develop superhard protective films for the life extension of lens forming mold core. Especially ta-C films with higher sp3 fractions receive attentions for the life extension of lens forming mold and, in turn, the cost reduction of lenses due to their superior high temperature stability, high hardness and smooth surfaces. In this study ta-C films were processed on WC mold as a function of substrate bias voltage using FVA(Filtered Vacuum Arc) method. The processed films were characterized by Raman spectroscopy and nano-indentation to investigate bonding nature and hardness, respectively. The film with maximum 87% of sp3 fraction was obtained at the substrate bias voltage of -60V, which was closest to ta-C film. ta-C films showed better high temperature stability by sustaining relatively high fraction of sp3 bonding even after 2,000 glass lens forming applications.

A-28: Size and Asperity Height Effect on the Contact Hardness in Nanoscale Metallic Asperities Contact : Molecular Dynamics Study: *Hojin Kim*[1]; Alejandro Strachan[1]; [1]Purdue University

The macroscopic mechanical response of contacts between surfaces of interest in microsystems is dominated by the geometry and local properties of nanoscale asperities present in them. If the local stress experienced a given asperity is greater than its hardness, plastic deformation will permanently change its shape and increase the effective contact area between the two surfaces. We use large-scale molecular dynamics to study the hardness of nanoscale metal-metal contacts as a function of their size and shape. Two platinum slabs with different-sized asperities are compressed at a rate of 20MPa/20ps closing rate. We find the hardness of the asperities shows to increase with decreasing contact size. However, asperities with low aspect ratios (thin and tall) exhibit a strongest size and their hardness decreases for sizes below this critical value. We provide an atomic picture of the mechanisms responsible for these complex size effects.

A-29: Size Dependence of Mechanical Properties of Refractory Carbides: *Sara Kiani*[1]; Suneel Kodambaka[1]; Jenn-Ming Yang[1]; [1]UCLA

Ultra-high temperature ceramics (UHTC), such as refractory transition-metal and Si-based carbides, are promising class of materials for applications in aerospace industry owing to their excellent high-temperature oxidation-, ablation-, and erosion- resistance, and high-strength as well as toughness. Improvement in their thermal, chemical, and mechanical properties is desirable for the construction of next generation space vehicles and hypersonic flights. This requires a thorough understanding of the factors influencing the thermochemical and thermomechanical properties of UHTCs. As a first step, we focused on understanding the role of size on the mechanical properties of single-crystalline SiC(0001) and ZrC(100). We carried out compression tests on one-dimensional cylindrical pillars (about 20 µm long and 6-3 µm in diameter), prepared via focused ion beam milling. From the load-displacement measurements, we found that the ultimate compression strengths at 10% strain of both SiC and ZrC increased with decreasing pillar diameter and are higher than their bulk counterparts.

A-30: Size Effects of Single-Crystal Magnesium: Microcompression Experiments and Modeling: *Cynthia Byer*[1]; KT Ramesh[1]; [1]Johns Hopkins University

The increasing amount of literature on microcompression experiments suggests that for some materials, decreasing the diameters of these micro-scale pillars increases their yield stresses and amount of strain hardening. However, we still lack a complete understanding of size effects, especially for hexagonal close packed (hcp) materials, which have lower crystallographic symmetry than their more common face centered cubic (fcc) and body centered cubic (bcc) counterparts. In this study, we focus on the dependence of orientation and initial dislocation density on the deformation mechanisms, mechanical response, and size effects of single-crystal magnesium. We conduct microcompression experiments on micropillars that range from approximately 600 nanometers to 10 micrometers in diameter, and we use these experimental results, along with an adapted stochastic-based model that considers the available dislocations in the specimen, to obtain a better understanding of size effects in magnesium.

A-31: Strong Sample-Dimension Dependence of Submicro-Sized Single Crystal Mo Pillars: *Ling Huang*[1]; Qingjie Li[1]; Zhiwei Shan[1]; Ju Li[2]; Jun Sun[1]; Evan Ma[3]; [1]Xi'an Jiaotong University; [2]Massachusetts Institute of Technology; [3]Johns Hopkins University

In situ TEM compression tests were carried out to investigate the mechanical behavior of single crystal molybdenum pillars with diameters ranged from 75 nm to 1200 nm. There exists a critical size (~ 200 nm for Mo at room-temperature) below which the strengthening exponent in Hall-Petch like regression increases dramatically, from ~ 0.3 to ~ 1. Thus, a new regime for size effects in BCC is discovered that converges to that of FCC, revealing deep connection in the dislocation dynamics of the two systems. In addition, we demonstrate that with the pillar diameter decreasing to hundreds of nanometers, significant mechanical annealing (significant drop in stored dislocation density in response to applied stress) does occur in BCC Mo like previous observation in FCC metals. We attribute the observed phenomena to the diminishing mobility difference between screw and edge dislocations at high stresses.

A-32: Temperature Effect on Displacement Burst of Iron Nano-Particles: *Qing-Jie Li*[1]; Ling Huang[1]; Christopher R. Weinberger[2]; Zhi-Wei Shan[1]; Ju Li[3]; Jun Sun[1]; Evan Ma[4]; [1]Center for Advancing Materials Performance from the Nanoscale (CAMP-Nano) & Hysitron Applied Research Center in China (HARCC), State Key Laboratory for Mechanical Behavior of Materials, Xi'an Jiaotong University; [2]Sandia National Laboratories; [3]Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, MIT; [4]Department of Materials Science and Engineering, Johns Hopkins University

Recent experiments conducted at CAMP-Nano showed dramatic displacement burst of iron nano-particles during in situ compression test. Based on the experimental observations, molecular dynamics(MD) simulations on compression of iron nano-particles were performed to study the temperature effect on displacement burst. Simulations under isothermal condition with different temperature showed different yield load and different initial burst displacement but similar displacement burst size, while simulations under adiabatic condition revealed a significant temperature rise during the collapse/burst process. This indicates that temperature field during the burst process is crucially important. The temperature shock would have different spatial-temporal characteristics from the incipient dislocation plasticity shock. This indicates that there could be a critical length scale above/below which temperature field variation is important/unimportant.

A-33: The Role of Stacking Fault Energy and Deformation Twinning on the Indentation Size Effect of FCC Pure Metals and Alloys: *David Stegall*[1]; A Elmustafa[1]; [1]Old Dominion University

The effect of inter-facial phenomena including the stacking fault energy (SFE) and twinnability, on the magnitude of indentation size effect of several FCC metals was investigated using nanoindentation and electron backscattered diffraction (EBSD). The hardness was measured using a XP nanoindenter with a high load attachment capable of producing loads up to 1 N using a single Berkovich tip. The materials included pure polycrystalline aluminum, nickel, silver, and alloys; 70/30 copper zinc (alpha-brass), 7075 aluminum (aluminum zinc), 70/30 nickel copper, and 90/10 platinum rhodium. The plastic deformation of FCC metals is influenced by two competing mechanisms, dislocation slip and deformation twinning. The SFE is an important inter-facial characteristic and affects the deformation of FCC metals due to its influence on dislocation cross slip and dynamic recovery. The influence of deformation twinning is thought to affect the ISE given a twin boundary can disrupt the movement of dislocations.

A-34: Time-Dependent Mechanical Behavior of Indium Nanopillars: *In-Chul Choi*[1]; Yong-Jae Kim[1]; Moo-Young Seok[1]; Ting Y. Tsui[2]; Jae-Il Jang[1]; [1]Hanyang University; [2]University of Waterloo

To apply novel nanoelectronic devices, it is necessary to predict lifetime and reliability of nano-scale materials (especially, low-melting-temperature materials that can creep even at room temperature) that have many important applications. In this regard, here we performed compression test for indium nanopillars fabricated by electron beam lithography and electroplating, and attempted to analyze the time-dependent mechanical behavior of the materials and its size dependence.

Mechanical Behavior Related to Interface Physics: Poster Session

E-1: Delamination Characterization of Bonded Interface Using Surface Based Cohesive Model: Manivannan Ramamurthi[1]; *Young Suk Kim*[1]; [1]Kyungpook National University, Daegu, South Korea.

Element based Cohesive zone model(ECZM) is employed widely in studying delamination (or) decohesion of interface surface in adhesively bonded materials using finite element method(FEM). This paper uses surface based cohesive model(SCZM) available in commercial finite element Analysis(FEA) code in the place of ECZM by considering similarities between both models when interface thickness is zero for the advantages of less input parameters, easy modeling, reduced computational time. Mode I fracture study with 90 degree peel test experiment and simulation are done in polymer coated steel for this analysis. Results are compared with ECZM. Surface based cohesive model predicts delamination well and results are closer to ECZM. Cohesive model requires fine meshing in FEM to predict delamination closely. To verify the feasibility of using it in coarse meshes, same simulations are done with Coarse meshes. The results reveal that coarse mesh simulations also predicts delamination closer to fine meshes with reasonable accuracy.

E-2: First-Principles Investigation of Grain Boundary Cohesion by Magnesium in Aluminum: *Shengjun Zhang*[1]; Oleg Kontsevoi[1]; Arthur Freeman[1]; Gregory Olson[1]; [1]Northwestern University

Despite extensive experimental and theoretical investigations, whether magnesium segregation into the aluminum grain boundaries (GBs) leads to stress corrosion cracking (SCC) is still controversial. To understand the mechanism of magnesium-induced SCC at the electronic level, we provides a comprehensive investigation of magnesium on GB cohesion in aluminum by means of first-principles calculations with the highly-precise full-potential linearized augmented plane-wave method. We found: (i) Mg has a large driving force to segregate from Al bulk to the symmetrical GB core site; (ii) The calculated embrittling potency indicates that magnesium is a cohesion enhancer; (iii) Both atomic size effect and charge transfer effect have influence on the GB cohesion. A net result of these two competing effects combined increases the strength of the GB, which indicates that charge transfer effect plays a dominant role. This work establishes that Mg segregation does not contribute to SCC in Al alloys.

E-3: In-Situ Fracture Toughness Studies in Magnesium Aluminate Spinel: *Wanjun Cao*[1]; Animesh Kundu[1]; Mark McLean[1]; Martin Harmer[1]; Richard Vinci[1]; [1]Lehigh University

Micro-size Focused Ion Beam (FIB) machined pre-notched cantilevers were fabricated in magnesium aluminate ($MgAl_2O_4$) spinel specimens. They were tested to failure using a SEM based nano-mechanical testing system. Young's modulus, fracture stress and fracture toughness values were determined by the micro-cantilever deflection technique. It was verified that the Young's modulus and fracture toughness results of single crystal spinel obtained from the micro-scale beam deflection tests are in good agreement with values obtained from conventional mechanical tests. The in-situ cantilever deflection testing technique was successfully employed to obtain fracture toughness values of bicrystal interface. Fracture toughness results of both doped and undoped magnesium aluminate spinel bi-crystal interfaces are compared and discussed.

E-4: Plasticity in Al/Nb Nanoscale Multilayered Materials: Effects of Interface Shear Strength: *Arief Budiman*[1]; Youbin Kim[2]; Kevin Baldwin[1]; Nathan Mara[1]; Amit Misra[1]; Seungmin Han[2]; [1]Los Alamos National Laboratory (LANL); [2]KAIST

Microcompression tests were performed on the nanoscale Al-Nb multilayers with bi-layer thicknesses of 5nm and 50nm. The Al-Nb multilayers showed increase in strength as the bi-layer thickness was reduced; the average 5% flow stress of the 5nm and 50nm specimens were determined to be 2.1GPa and 1.4GPa, respectively. Comparison with the previous report on nanoscale Cu-Nb multilayers indicates that Al-Nb nanolayers have lower flow stress. Al-Nb with negative heat of mixing has higher degree of intermixing and thus would likely have a "stronger interface in shear" that would result in lower barrier to slip transmission as compared to Cu-Nb which interface is weak in shear and thus is a strong trap for glide dislocations via core spreading in the interface plane. This could lead to easier transmission of dislocations across the interface and therefore lower flow stresses for Al-Nb when compared to the case for the Cu-Nb multilayers.

E-5: Slip Transfer Across a Cu Bicrystal Interface: *Alankar Alankar*[1]; Niraj Gupta[2]; Shivraj Karewar[2]; Ricardo Lebensohn[1]; Alfredo Caro[1]; [1]Los Alamos National Laboratory; [2]University of North Texas

The current work examines the slip transfer across grain boundary in a Cu bicrystal. The experimental observations from the literature are compared with predictions of dislocation density based crystal plasticity model and a molecular dynamics simulation. The orientation images acquired from EBSD during interrupted channel die deformations of a Cu bicrystal show crystallite fragmentation near the grain boundary. The grain reorientation measurement also shows a strong influence of non-local slip activity and grain boundary character. The microstructure sensitive crystal plasticity model is able to show, to some degree of success, reorientation of crystallites and correct slip system activity. However, due to local nature of the constitutive behavior employed in the CPFE model, it is not able to account for the non-local effect via grain boundary. The molecular dynamics simulation shows the occurrence of slip transmissivity and co-operative slip activity. These results are used for setting up a slip transfer criterion.

E-6: The Effects of Aspect Ratios in Liquid Bridge on Surface Driven Flow under Microgravity JEMISS: *Shinichi Yoda*[1]; Satoshi Matsumoto[1]; Atsushi Komiya[2]; [1]JAXA; [2]Touhoku University

The surface tension driven flow (Marangoni) experiments were carried out by using liquid bridge of Silicones oil with 50mm diam. under microgravity condition on Japanese Experiment Module on International Space Station. The parameters in these experiments were liquid bridge length being corresponded to aspect ratio, which is defined as liquid length/liquid diam., and temperature difference between hot and cold disks, which sustains the liquid bridge. Observing the movement of the particles by three CCD cameras, we can determine the flow behavior of Marangoni with different temperature as 3 dimension flow. The critical Marangoni numbers that the transition from laminar to oscillatory flow was dependent on aspect ratios. The smaller aspect ratio around showed smaller critical Marangoni numbers, whereas the lager those were larger the numbers. This relationships are good agreement with numerical simulation results.

E-7: The In-situ Intrinsic Stress Measurements of Cu and Al Thin Films: Jun Young Yu[1]; *Youngman Kim*[1]; [1]Chonnam National University

We observed the in-situ stress evolution of Cu and Al thin films during deposition on (111) Si wafers using a thermal evaporation method in terms of deposition rates. Cu and Al films were deposited at rates ranging from 0.5 to 1.5Å for Cu and for Al. In-situ stress values in the growing films were obtained using multi-beam curvature measurement system installed in the chamber of thermal evaporator. For the copper films the in-situ intrinsic stress showed a typical three step behavior of initial compressive, tensile and gradual compressive stresses. For the aluminuim films the in-situ intrinsic stress showed rather unstable behavior without highly reliable repeatability.

V-1: Formation of Carbides in the Aluminum Matrix Composites Reinforced by Multi-Walled Carbon Nanotubes: *Seeun Shin*[1]; Heon Kang[1]; Donghyun Bae[1]; [1]Yonsei University

Enormous work has been conducted on the strengthening behavior of aluminum- multi-walled carbon nanotubes(MWCNTs) composites by powder metallurgy. Generally,MWCNTs are individually dispersed and mechanically interlocked in the aluminum matrix of Al/MWCNT composites and they thermally diffuse to form aluminum carbides from aluminum matrix during hot process. However,the process of the formation of carbides has not well attended. This study clearly explores the formation of carbides during heat treatment for the samples which damaged MWCNTs which thermally diffused more actively using argon containing 3% hydrogen atmosphere. While Al/MWCNT composite annealed at 500°C, the aluminum atoms decomposed from aluminum matrix and they diffused to individually dispersed MWCNTs to form aluminum carbides, then they occupied the interstitial sites of MWCNTs as a sphere. The hardness decreases when the composites are annealed for up to 3 h, and it gradually increases up to 24 h, significantly decreases as annealing time up to 72 h.

V-2: Impact Resistance of Nanostructured Partially Stabilized Zirconia Reinforced Porcelains: *Emmi Ngo*[1]; Hanry Yang[1]; Ricardo Castro[1]; [1]University of California, Davis

Partially stabilized zirconia(PSZ) is a heavily studied ceramic due to its unique properties. Most notable is PSZ's ability to undergo a phase transformation when placed under an applied stress. This transformation toughening relies on the relative stability of each of the polymorphs, which is dependent on the particle size. This creates the possibility of further improving the transformation toughening by exploiting nanostructured phases. In this study, we analyzed the mechanical properties of PSZ and fully stabilized zirconia(FSZ) reinforced porcelains. We focused on the effect of the particle sizes by systematically evaluating the improvement of mechanical properties when replacing kaolin in the porcelain composition by nano or microsized particles. In addition to the expected improved mechanical properties caused by the introduced nanoparticles, the phase transition in the PSZ is observed to provide improved features when compared to FSZ nanoparticles. The results are discussed based on the interface energetics and microstructure analysis.

V-3: Influence of the Type of Clay on the Morphology of Nanocomposites: *André Rodrigues*[1]; Maria Brasileiro[1]; Tomas Melo[2]; Edcleide Araujo[2]; Ariosvaldo Sobrinho[2]; Mucio Nobrega[1]; [1]UFC; [2]UFCG

In this work, polypropylene/bentonite and polypropylene/compatibilizer/bentonite nanocomposites were prepared by melt intercalation method using a modular co-rotational twin screw extruder and a counter rotating twin screw extruder. Initially, bentonitic clays were organophilized with ionic and non-ionic surfactants with the aim of obtaining organophilic clays. The XRD results showed that the ionic and non-ionic surfactants were incorporated into the clay, confirming the organophilization. Subsequently, the organophilic bentonitic clays were incorporated into PP and PP/PP-g-MA. From the results obtained through XRD, OM, SEM, TEM analyses, the method used and the processing conditions, it may be concluded that it is possible to develop nanocomposites with mixed structure (agglomerates, tactoids and exfoliated particles) with predominance of an intercalated structure. The processing conditions (screw type, feeding rate and screw speed), matrix viscosity, concentration and type of the bentonite clay and PP-g-MA concentration had little effect on the nanocomposite obtention and on its properties, in general.

V-4: Mechanical Properties of Fe-Based Nanocomposites with Dispersed Multi-Walled Carbon Nanotubes: *Ji-Yeon Suh*[1]; Jaehyuck Shin[1]; Donghyun Bae[1]; [1]Department of Materials Science and Engineering, Yonsei University

Multi-walled carbon nanotubes (MWCNTs) are favorable reinforcement with outstanding mechanical properties. However, it has been difficult to reveal the remarkable properties of MWCNTs in metal matrix composites (MMCs) due to poor interfacial bonding with metals. The present study deliberates to disperse MWCNTs uniformly in the Fe matrix in which cohesive energy between them is relatively high. High-energy ball milling under an argon atmosphere is carried out for homogeneous dispersion of MWCNTs in Fe powders. MWCNTs are dispersed through deformation of the powders to transform from flake-like shape to sphere during milling process. The ball-milled powders are consolidated during the hot-pressing. Yield stress increases with increasing the volume fraction of MWCNTs, and the composites containing 4 vol. % MWCNTs exhibits superior yield stress of 2.3 GPa under compression by interfacial bonding between MWCNTs and Fe matrix. The detailed fabrication process and mechanical properties will be presented.

V-5: Modeling Elastic Behaviors of Peptide Reinforced Hydrogel Nanocomposites: *Jingjing Qiu*[1]; [1]Texas Tech University

A novel mathematical model based on Eshelby equivalent tensor is developed to analyze the elastic properties of peptide reinforced hydrogel nanocomposites. The model takes into account the effect of small size

POSTERS

of reinforcement phase and stochastic distribution of peptide into the formulation. The overall effective elastic modulus is predicted using micromechanics. The effect of interfacial bonding on the overall effective elastic modulus is also investigated.

V-6: Modification of the Temperatures of Phase Transformations of Alumina by the Insertion of MgO and ZrO2: *Deise Cristina Rosário*[1]; Douglas Gouvêa[1]; [1]University of São Paulo

Due to the stability and diversity of different polymorphs of alumina, this becomes a very interesting material for the study of stability in accordance with changes in surface energy. This study aims at understanding the phenomena that change transformation amorphous-gamma phase temperature by inserting additives, MgO and ZrO2, taking into account the effects of Thermodynamic. Powders synthesized by Pechini's method were characterized by DSC, XRD, BET and FTIR. The results showed an increase in the stability for the amorphous phase for the doped samples, which showed the formation of solid solution and surface segregation independently of the doping concentrations. Although a second phase formation was not observed, it noted a change in the chemistry surface to samples.

V-7: Role of Nano-Silica on Alkali-Silica Reactivity of Concrete: *Mohammad Islam*[1]; [1]UBC

Past research investigations revealed that the ASR-induced expansion decreased with an increase in the silica content of the cementitious materials. The main objective of this study was to suppress the excessive expansion of concrete caused by alkali-silica reactivity with the use of nano-silica having 99.99% SiO2 by weight. The experimental program consisted of four highly reactive aggregates, nano-silica and superplasticizer. The mortar bar specimens were prepared with each trial aggregate and three dosages of nano-silica, 3, 6, and 9% by weight of cement replacement. The required dosages of superplasticizer, a percentage of the weight of the cementitious materials, which produced a uniform flow with no bleeding or segregation, were also adjusted depending on the amount of nano-silica. Mortar bars without nano-silica were also used as control specimens. The ASR-induced expansions of the test mortar bars were also evaluated based on the failure criteria of the mortar bars at the immersion ages of 14, 28, 56 days. The study showed that the expansion of the test mortar bars decreased with an increase in the nano-silica content. The results of the study concluded that, for the most trial aggregates, the mortar bars containing 9% nano-silica was not capable of reducing the ASR-induced expansions below the expansion limits of ASTM C 1260 at the above-mentioned three immersion ages.

V-8: Thermal Properties of Mg-Nanocomposites Reinforced by CNT in Relation to Pure-Mg: *Sardar Iqbal*[1]; [1]Southern Illinois Univ, Carbondale

Thermal properties, of Mg-nanocomposites were measured from 25-500°C to determine thermal diffusivity, thermal expansion coefficient and specific heat capacity. The Mg and Mg-CNT nanocomposites (0.5, 1, 2 and 5 %) were prepared with powder metallurgy method by cold press followed by sintering at 620°C. Density of pure Mg decreased with increasing CNTs whereas porosity increased. Thermal diffusivity and heat capacity of 1%CNT-Mg nanocomposites showed the highest value. The thermal conductivity calculated for Mg nanocomposites (1%CNT) was the highest with temperature. The results show that thermal properties of Mg improved significantly with the addition of CNTs. The microstructure was characterized by polarized light microscopy and SEM, and structure by TEM and X-ray diffraction patterns.

Neutron and X-Ray Studies of Advanced Materials V: Centennial: Poster Session

F-1: An Investigation of the Tempering Kinetics and Residual Stress States of a Cryogenically Treated and High Magnetic Field Processed Steel via Neutron Scattering Experiments: *Orlando Rios*[1]; Tom Watkins[1]; Ling Yang[1]; Alexandru Stocia[1]; Ben Shassere[1]; Don Nicholoson[1]; Gerry Ludtka[1]; Gail Ludtka[1]; [1]Oak Ridge National Laboratory

Commercial steel and heat-treating operations have been plagued with costly conventional processing steps (e.g., cryogenic treatments, long double-temper cycles) to reduce the amount of retained austenite (RA). Research at ORNL is investigating the application of high magnet fields to destabilize retained austenite and reduce residual stresses. Neutron scattering experiments were performed at the Spallation Neutron Source on the VULCAN instrument to investigate the residual stress state and tempering kinetics in a steel sample processed under extreme conditions (9 Tesla) alongside cryogenically processed materials. The neutron scattering experiments revealed a structural rearrangement in the tetragonal phase at temperatures below 100C and indicated that the massive transformation was complete at much lower temperatures than expected. First principles calculations help identify alternative arrangements of interstitial carbon and their relationship to residual strain. Additionally, the residual stress state was examined and correlated to the structural relaxation of the metastable phases. Study funded by DOE-ITP-EERE.

F-2: The Study of Structural Stability for TiSi2 under High Pressure: *Chunyu Li*[1]; Zhenhai Yu[2]; Jinggeng Zhao[1]; Luhong Wang[2]; Tianquan Lü[3]; Haozhe Liu[2]; [1]Brookhaven National Laboratory; [2]Argonne National Laboratory; [3]Harbin Institute of Technology

Over the past decades, metallic silicides have attracted considerable interest because of their special properties for engineering uses in hostile environment of extreme temperature and pressure. In this paper, the in situ high-pressure angle dispersive X-ray diffraction experiment on TiSi2 (for C54 phase, space group:Fddd) has been performed using a diamond anvil cell with synchrotron radiation at room temperature. The diffraction patterns of C54 phase TiSi2 were gathered and its high-pressure structural stability was systematically analyzed. The lattice constants were refined using Rietveld method. With fixed B0´ as 4, isothermal bulk modulus at ambient pressure was estimated as 169(2) GPa, according to a second-order Birch-Murnaghan equation of state.

H-1: Effect of Multiple Reflows on Interfacial Reaction and Tensile Property of Sn-xAg-0.5Cu Solder Joints with Cu Substrate: *Long-Tai Chen*[1]; [1]National Cheng Kung University

The interfacial reactions and tensile properties of SAC105 and SAC305 solder joints were investigated during multiple reflows. A continuous needle-type Cu6Sn5 IMC layer was formed at the solder/Cu interface. With the increasing number of reflows, the thickness of IMC on all reaction samples increased gradually and the IMC grain coarsened. The needle-type spalling of the Cu6Sn5 IMC was observed in the liquid-state reaction for the solder alloys. It was found that the bonding strength of the 1Ag and 3Ag solder joints tended to increase slightly with an increase in the number of reflow cycles. The 3Ag solder joints provided the excellent mechanical properties before five cycles of reflow. The fracture of all 1Ag and 3Ag solder joints mainly occurred in the bulk solder. The ductile fracture indicated that the bonding strength of solder joints could significantly influenced by the thickness and morphology of the interfacial IMC.

H-2: Microstructure Change of Au Stud Bumps Joined with Sn-3.5Ag Solder with Flip Chip Bonding Parameters: Young-Kyu Lee[1]; Won-Myoung Ki[1]; Jeong-Han Kim[2]; *Sehoon Yoo*[2]; Chang-Woo Lee[2]; [1]University of Science & Technology; [2]Korea Institute of Industrial Technology

In this study, effect of flip chip bonding parameters on the formation of intermetallic compounds (IMCs) between Au stud bumps and Sn-3.5Ag solder was investigated. Flip chip bonding was performed at 260°C and 300°C with bonding time of 5, 10, and 20 sec. AuSn, $AuSn_2$, and $AuSn_4$ IMCs were found at the interface of the joint, and $(Au, Cu)_6Sn_5$ IMC was observed near Cu pad in the joint. At bonding temperature of 260°C, $AuSn_4$ IMC obviously grew more than other Au-Sn IMCs as bonding time increased. At bonding temperature of 300°C, $AuSn_2$ IMC clusters, which were surrounded by $AuSn_4$ IMC, were observed in the solder joint due to fast diffusivity of Au to molten solder with increased bonding temperature. Bond strength of Au stud bump joined with Sn-3.5Ag solder was approximately 23 gf/bump and fracture mode of the joint was intergranular cleavage between $AuSn_2$ and $AuSn_4$ IMCs.

H-3: Physicochemical Properties of Sb, Sn, Zn and Sb-Sn, SAC and SAC+Bi Alloys: *Tomasz Gancarz*[1]; Janusz Pstrus[1]; Wladyslaw Gasior[1]; Hani Henein[2]; [1]Institute of Metallurgy and Material Science PAS; [2]Department of Chemical and Materials Engineering, University of Alberta, Edmonton, AB, Canada

The aimed of this work is comparing several methods for the measurement of physical properties for molten SAC, SAC+Bi and SbSn alloys. The method used for viscosity in this work is the modified capillary and free flow method[1]. For surface tension and density, using the maximum bubble pressure method and the dilatometer technique compared with free flow method, respectively, for SAC and SAC+Bi alloys at 550K to 1200K temperature. Investigation were undertaken on the new equipment for five SbSn alloys at 550K to 850K temperature. The results show that all the physicochemical properties decrease with temperature and with increasing Sb content in the SbSn alloy. The method was confirmed on pure metals Sb, Sn, Zn and compared with the literature data. Keywords: viscosity, density, surface tension, Sb, Sn, Zn, SAC, SbSn. 1. T. Gancarz, Z. Moser, W. Gasior, J. Pstrus, H. Henein, Int. J. Thermophys. 32, 1210 (2011)

H-4: The Different Failure Mechanism of the Ni UBM in the Lead-Free Solder Joints under Constant Current Stressing at Various Temperatures: *Chung Kuang Lin*[1]; Wei An Tsao[1]; Chih Chen[1]; [1]National Chiao Tung University

The Ni under bump metallization (UBM) is one of the most common reaction layer used for flip-chip solder joints. Under the current-stressing test, observe two different failure mechanisms at various-temperatures. Above the 150 ^oC, the void-formation is the major mechanism under the electromigration-test. In the other hand, the major mechanism changed to the intermetallic compound (IMC) formation below the 150 ^oC. However, according to the results, the thickness of IMC between the Ni and Sn affects significantly the dominant failure mechanism. At higher temperature, the more electromigration flux of Ni atom penetrates the IMC layer to react with Sn and forms thicker IMCs. By contrast, the IMC layer inhibits the electromigration flux of Ni atom at lower temperature. Therefore, the Sn atom in the cathode-side migrates to the anode side during current-stressing test. The void-formation under the IMC layer in the cathode-side becomes the major failure mechanism at lower testing-temperatures.

H-5: The Electromigration Behavior of Ni_3Sn_4 in Sn2.5Ag Solder Joints: *Chun-Yi Wu*[1]; Chih Chen[1]; [1]National Chiao Tung University

Microbumps have been adopted for interconnects in 3D-IC packaging. The bump height decreases to 10-20 µm . Due to the small volume of solder and high current-denisty, intermetallic compounds (IMCs) forms rapidly in the solder joints during electromigration. So the electromigration performance of IMC become a critical issue. In this study, 5 µm Sn2.5Ag solder joint with 50 µm copper column and 3 µm electrical nickel in the chip-side and 5 µm electroless nickel in the substrate-side. After aging for 500 hours at 200^{o}C, all the solder joints transform into the IMCs. Electromigration tests were performed at a current-density of 10^4 A/cm^2 at 200^{o}C. The bump resistance was measured by using Kelvin structure, and defined the bump resistance to increase 20%, 50%, 100%, 500% initial bump resistance as failure stages. There was longer incubation time than SnAg solder bump. Failure mechanisms of the Ni_3Sn_4 will be discussed in the meeting.

H-6: Thermal Cycling Test on Sn2.3Ag Microbump with Different UBM Structure after Heat Treatment.: *Chun-Chieh Mo*[1]; Yon-Chun Liang[2]; Chih Chen[2]; [1]National Chiao Tung University ; [2]National Chiao Tung University

Metallurgy interaction in microbump with different under-bump-metallization (UBM) structures after thermal cycling test (TCT) was examined in this study. The microbump specimens were fabricated by a solder reflow process using a lead-free Sn-2.3Ag solder. The UBM structures are classified as Cu/Sn2.3Ag/Cu, Cu/Sn2.3Ag/Ni, and Ni/Sn2.3Ag/Ni with different bump heights. After different reflow times at 260°C, the microbumps were tested under cycling from -55°C to 125°C each cycle, and the cycle time is 1 hour. The fatigue crack was observed at IMC/solder interface in Cu/Cu UBM structure after reflow at 260°C for 6 minutes. As increased with the reflow time , the Cu6Sn5 IMC bridged and blocked the crack propagation. The crack propagation phenomenon of Cu/Ni and Ni/Ni UBM structure are also discussed.

H-7: Real Time Monitoring of Whisker Growth Failure Using by 3-D Geometry Comb Pattern: *Won Sik Hong*[1]; Chul Min Oh[1]; Do Seop Kim[2]; [1]Korea Electronics Technology Institutue(KETI); [2]Hyundai Motor Company

Most international specifications of whisker growth evaluation have recommended long term test duration and periodical monitoring of whisker length. But it is impossible to know exact failure time as these test method. Thus, to solve the problem, this study proposed the feasibility of in situ monitoring method related to whisker formation and growth with specimen gab. To measure the whisker growth failure occurrence time, we prepared 1μm thickness pure Sn electroplated Cu plate(t=192μm, 30X0.7mm) for real time monitoring of whisker growth. After conformal coating on the Cu plate specimen, two Cu plates which maintain 150μmgab was fixed with insulator and we applied DC voltage for measuring insulation resistance. If whisker growth occurs, we made test cell to detect the insulation resistance drop, continuously. The whisker failure criteria was 10^{6} Ω. Through this experiment, we confirmed the feasibility of in situ monitoring for whisker growth.

H-8: Recrystallization-Induced Void Migration in Electroplated Cu Films: *Sunghwan Kim*[1]; Jin Yu[1]; [1]KAIST

An analysis based on cross-sectional micrographs is presented that addresses the recrystallization-induced void migration in 20 μm thick electroplated Cu films. Specimens were isothermally aged at T (T = 573, 623, 673 K) for varying time. For morphological investigation, scanning electron microscopy, transmission electron microscopy, and focused ion beam microscopy were used. In addition, studies of preferred orientation of Cu films by thin film x-ray diffractometer were performed before and after isothermal aging. It was shown that voids were formed at the interface between non-recrystallized grains and recrystallized grains. Formation of voids in the Cu films was highly affected by aging temperature, and radius of voids was increased and voids migrated to the surface of Cu films with increasing aging time. Results indicate that recrystallization by isothermal aging of Cu films induced migration of voids and formed voids relieved the stress of Cu films during morphological transformation of Cu grains.

H-9: Vibration Test at Elevated Temperature for Pb-Free Solders: *Yong-Ho Ko*[1]; Young-Kyu Lee[2]; Jeong-Han Kim[1]; Sehoon Yoo[1]; Chang-Woo Lee[1]; [1]Micro-Joining Center, Korea Institute of Industrial Technology, Incheon, 406-840, Korea; [2]Dept. of Electronic Packaging Engineering, University of Science & Technology, Daejeon, 305-333, Korea

The vibration reliability at elevated temperature was evaluated for Pb-free solders (Sn3.5Ag, Sn0.7Cu and Sn5.0Sb). The electrical resistance increased and shear strength decreased during the vibration test at elevated temperature. The resistance increment and the shear strength degradation of Sn3.5Ag solder joints were the highest among three solders, while those of Sn0.7Cu were the smallest. For the Sn3.5Ag samples, crack propagation occurred within Cu6Sn5 IMC during the vibration test at the elevated temperature. On the other hand, no crack formation and propagation was observed for the Sn0.7Cu and Sn5.0Sb solder joints. The fracture mode of Sn0.5Cu after the shear test was ductile. On the other hand, the fracture mode of the Sn3.5Ag solder joints showed ductile to brittle transition as the test time increases. Among three solders, Sn0.7Cu was the most stable under the vibration at elevated temperature.

H-10: Wettability and Interfacial Microstructure of Pb-Free Sn3.5Ag Alloy Powders on Cu Substrate: *Jin Zhao*[1]; Weipeng Zhang[1]; Tingting Song[1]; Yulai Gao[1]; Qijie Zhai[1]; [1]Shanghai university

Sn3.5Ag powders in different sizes were prepared by arc technique. Powders in different sizes mixed with Rosin Mildly Activated (RMA) fluxes were soldered on pure Cu substrate. The contact angle is a critical parameter to affect the quality of solder joints. Presently the Pb-free Sn3.5Ag solder has been widely applied in industry. However, its wettability on Cu substrate is not good enough, and the contact angle of commercial Sn3.5Ag solder paste is about 26°. In contrast, the contact angles of the Sn3.5Ag solder paste prepared in the present study are 16.1°, 13.9 °, and 21.4 °respectively, depending on the specific characteristics of the powders. So good wettability was obtained attributing to the novel technique to prepare Sn3.5Ag powders. In addition, the intermetallic compounds (IMCs) were observed by optical microscope and scanning electron microscope, and the results showed that continuous intermetallic compounds layer formed, confirming the validity of the packaging.

Radiation Effects in Ceramic Oxide and Novel LWR Fuels: Poster Session

O-1: Microstructural Investigations of Ion (KR, XE) Irradiated CEO2 and UO2 With and Without Impurities: *Brian Kleinfeldt*[1]; Weiying Chen[1]; Bei Ye[1]; Yinbin Miao[1]; Aaron Oaks[1]; James Stubbins[1]; [1]University of Illinois at Urbana-Champaign

The importance of understanding microstructural damage processes in nuclear fuel as a result of radiation is becoming increasingly important in developing and modeling new fuels. Irradiation damage processes are studied in UO2 and CeO2 through simulated fission product damage using Kr and Xe ion beams at temperatures from 0-800C. Primarily ex situ irradiations are performed on thin films that are then characterized through transmission electron microscopy. 150 keV Xe ions are used for bubble implantation while higher energy (1MeV) Kr atoms are used for defect creation. The role of impurities (La) is investigated by comparing Kr and Xe bubble growth and formation for the different materials as a function of dose. The impurity concentration varies from 0-25% molar. The comparison of these two materials is important as CeO2 is often used as a surrogate material for UO2 due to their common fluorite structure and similar properties.

S-1: Effect of Nanosized Cobalt Amounts on WC-Co Sintered Bulks Fabricated by Spark Plasma Sintering (SPS): Joon-Woo Song[1]; Sol Lee[1]; Rumman Md. Raihanuzzaman[1]; Hyoun-Seon Hong[2]; *Soon-Jik Hong*[1]; [1]Kongju National University; [2]Institute for Advanced Engineering(IAE)

In this research, different compositions of WC-7.5wt%Co, WC-7wt%Co, WC-6wt%Co, WC-5wt%Co have been used, where ball milling and subsequent sintering were applied on the mixed powders. Since cobalt is becoming more expensive these days, one of the primary intention was to reduce the amount of cobalt or replace it with nano-sized cobalt, in order to improve the mechanical properties. Low energy ball milling for 1 hour at a speed of 100 rpm was used, while spark plasma sintering was applied on the ball milled powders at 1300°C with a holding time of 10 minute. FE-SEM and HR-TEM were used for each compositions, after sintering, and micrographs were analysed to observe the difference in microstructure, crack formation, densification behaviour and hardness. In addition, other mechanical properties, including fracture toughness, of the sintered bodies were attempted to analyse as well.

R-1: AMD Treatment Using Rice Husk as Biosorbent: *Flávia Silvas*[1]; Bianca Medeiros[2]; Daniella Buzzi[3]; José Oliveira[2]; Ivo Schneider[4]; Denise Espinosa[3]; Jorge Tenório[3]; [1]Polythecnic School of São Paulo University ; [2]Instituto Federal de Educação, Ciência e Tecnologia do Espírito Santo; [3]Polythecnic School of São Paulo University; [4]Universidade Federal do Rio Grande do Sul

AMD is one of the main problems associated with mining activities and the techniques used in their treatment may be the biosorption. The aim of this work was to study the rice husk as a biosorbent for the AMD treatment keeping constant: pH (2.6), biomass concentration (1g/L), temperature (25°C) and agitation (175rpm). And varying the contact time of 5, 20, 60 and 240 minutes. Rice husk samples will be characterized before and after the biosorptives tests through analysis of SEM and IR. The micrographs indicate the occurrence of micro-precipitation and changes in biomass physical structure. Since the infrared spectra indicate changes in functional groups present in the biomass before and after the biosorptives tests. AMD synthetic solutions will be analyzed by ICP in order to quantify the metals concentration captured by biomass.

R-2: Incorporation of Building Rejects in Portland Cement: *Shirley Cosin*[1]; Francisco Valenzuela Diaz[1]; [1]University of São Paulo

A procedure for incorporating building rejects in Portland cement was studied. Cylindrical test bodies with 2,5cm of diameter and 5,0cm of height were done using 50 parts of water for each 100 part of cement. The test bodies were incorporated with 1, 5, 10 and 20 parts of rejects for each hundred parts of cement. After 28 days of aging in humid chamber they were tested for compression strength, porosity and density. The best performing composition was used in a new batch of test bodies with 5,0cm of diameter and 10,0cm of height. After 28 days of aging, they were tested for compression strength, porosity and density. The incorporation of 10 parts showed the best results and this composition was used in pilot production blocks which were tested for compression strength and lixiviation showing mechanical properties in accordance with the technical standards, making this incorporation procedure suitable for industrial application.

J-1: Effect of Al on the Oxidation Behavior of Alloys from Nb-Cr-Si System: *Amanda Gutierrez*[1]; Nydia Esparza[1]; Brenda Arellano[1]; Shailendra Varma[1]; [1]UTEP

Oxidation behavior of Nb-30Cr-10Si and Nb-30Cr-10Si-(5,10) Al alloys has been investigated in a range of temperatures from 700 to 1400°C. Alloys were subjected to 24 hour exposure to air at the oxidation temperature and then furnace cooled to room temperature. Weight gain per unit area (W) has been used to follow the oxidation behavior as a function of temperature. Characterization was performed using XRD and EDS and x-ray mapping modes in SEM. The Al addition to the alloy has been found to be beneficial for enhancing oxidation resistance. Samples with no Al suffered from 100% pesting at 1000°C even though oxidation at higher temperatures was much better. Al addition, however, demonstrates internal oxidation by the formation of Al2O3 at the interface between the solid solution and silicides. High temperature oxidation, particularly, is superior with Al addition.

Solid-State Interfaces II: Toward an Atomistic-Scale Understanding of Structure, Properties, and Behavior through Theory and Experiment: Poster Session

D-1: Adhesion Strength at Cu(111)/α-Alumina(0001) Interfaces with Metal Dopants in Alumina Dispersion-Strengthened Copper: Kelun Zhao[1]; Xuanhui Qu[2]; *Shaojun Liu*[3]; [1]Materials Science and Engineering Division, Shenzhen Graduate School, Harbin Institute of Technology; [2]State Key Laboratory for Advanced Metals and Materials,University of Science and Technology Beijing; [3]State Key Laboratory for Powder Metallurgy, Central South University

The local bonding and adhesion strength at the heterogeneous metal/oxide interface are strongly influenced by the presence of impurities and dopants. In the present work, the atomistic structure and the energetics of Cu(111)/α-alumina (0001) interfaces with a various of metal dopants are investigated by using the first-principles methods and density functional theory. Based on the analysis of the electronic structure of interfaces and the segregation energies of dopants at Cu(111)/a-alumina(0001) interfaces, it is found the stability of interfaces is dependent on the structure and chemistry of Cu(111)/α-alumina(0001) interfaces. The adhesion strength of Cu(111)/α-alumina(0001) interfaces is significantly enhanced by Ag doping, while it is slightly reduced by Ni doping. In contrast, metal dopants (Ti, Zr, Hf, and Zn) could result in the crack of Cu(111)/α-alumina(0001) interfaces and subsequently the decrease of adhesion strength. These are in a good consistent with the observed experimental results in alumina dispersion-strengthened copper.

D-2: Atomistic Simulation of Doped (La,Y,Mg) a-Alumina Interfaces for Transparent Ceramic Applications: *Abhishek Tewari*[1]; Sandra Galmarini[1]; Paul Bowen[1]; [1]Ecole Polytechnique Federale de Lausanne

To achieve high Real Inline Transmittance (RIT) for transparent applications with alumina, fully dense ultrafine crystalline alumina is desired. Doping of alumina with transition elements (e.g. Y, Mg, La) has been an effective tool for controlling the grain size during the sintering step, moreover codoping being even more effective. This may be attributed to the segregation of dopants at the grain boundaries, producing the grain or solute drag effect. However, the atomistic mechanisms behind these observations, especially codoping effect, are still not clear. The current goal is to understand the atomistic mechanisms behind doping and codoping using atomistic modeling methods. Studies on 9 surfaces and 9 grain boundaries showed segregation of dopants to be energetically favorable in all the cases and a coordinative arrangement was observed in case of codoping. When linked to Monte Carlo simulations and a microstructural model, nominal solubilities and second phase precipitate diagrams can be predicted.

D-3: Atomistic Simulations of Nanoindentation and Nanoscratching of Thin Films: *Xuan Sun*[1]; Tzu-Ray Shan[1]; Simon Phillpot[1]; Susan Sinnott[1]; [1]University of Florida

Molecular dynamics (MD) simulations are used to investigate the atomic scale responses of semiconductor/gate oxide interfaces to nanoindentation and nanoscratching. The simulations utilize the variable charge, empirical charge optimized many-body (COMB) potential to simulate the mechanical response of the interfacial systems to a rigid semispherical indenter. The particular interfaces investigated are between Si and SiO_2 or HfO_2 of different film thicknesses. The nanoscratch tests are conducted at various normal loads. Phenomena such as plastic deformation, pile-ups, and wear are also observed. The predicted hardness, reduced modulus, fracture mechanism, and friction coefficient are determined, as well as the effect of dynamic charge transfer to the overall results.

D-4: Grain Boundary - Dislocation Interaction: Linking Molecular Dynamics and Dislocation Dynamics: *Sebastian Echeverri Restrepo*[1]; Barend Thijsse[1]; Lucia Nicola[1]; Xiaoming Liu[2]; Erik van der Giessen[2]; [1]TUDelft; [2]University of Groningen

Molecular dynamics (MD) is a powerful tool that can be used to describe the behavior of dislocations and interfaces at the nano scale. Nevertheless, due to current computational limitations, as the size of the simulated sample increases, alternative methods have to be considered, like 2D dislocation dynamics (2D-DD). An effort to link MD with 2D-DD is presented. Since 2D-DD works under the assumption of an isotropic medium, a bicrystal with a misorientation that minimizes the effects of anisotropy is generated. Then a dislocation is inserted into one of the crystals and a stress is applied to the sample in such a way that the dislocation is made to interact with the grain boundary. This is done for various stress values. Qualitative and quantitative analyses of the interaction are presented.

D-5: In Situ TEM investigation of Electrical Current Effect on Aluminum Interconnect: *Degang Xie*[1]; Zhiwei Shan[1]; [1]Center for Advancing Materials Performance from the Nanoscale (CAMP Nano)

Electro-migration is the phenomenon that metallic atoms are transported by electron wind due to high electrical current density in the metal line.Factors like interconnect length, crystallographic texture, grain size and its distribution, and grain boundary structures have been extensively documented to have a major impact on electron-migration induced plasticity. Consequently, understanding the exact mechanism and evolution of electrical current effect on interconnect has become critical for designing reliable devices. In situ TEM will become the best tool for studying the microstructure evolution of nanoscale interconnects under the effect of electrical current. In this work, we developed a novel method for preparing samples that can be studied in situ inside a TEM under the effect of electrical current. By employing a Hysitron PI95 ECR type holder, we found that the defects density inside the Al grains can be reduced dramatically by the applied current which we termed as electrical annealing.

D-6: Phase Field Crystal Simulation of Curvature Driven Grain Boundary Migration.: *Vishal Yadav*[1]; Nele Moelans[1]; [1]Katholieke Universiteit Leuven

A systematic study of grain boundary migration on the atomistic scale is carried out using the Phase Field Crystal (PFC) method. Since the PFC model is atomistic in space and diffusive in time, it can depict realistic grain boundary structures during grain boundary movement. In this study, the effect of misorientation between grains, grain geometry, grain size and temperature on the structure, energy and mobility of the grain boundaries is analyzed. At certain temperatures and misorientation angles, faceting is observed which slows down the grain boundary migration. It is also observed that in some cases, triple junctions slow down the grain boundary migration by pinning grain boundaries.

D-7: Quantification of Compositional Effects on Transformation Kinetics in High Strength Low Alloy Steels Using In Situ TEM: *Asher Leff*[1]; Michael Grimes[2]; Nerea Isasti[3]; Christopher Winkler[1]; Pello Uranga[3]; Mitra Taheri[1]; [1]Drexel University; [2]Lehigh University; [3]University of Navarra

High strength low alloy steels (HSLAS) contain a small fraction of various alloying elements to produce increased thermal and mechanical stability. Although the individual effects of these additives are known, the interactions between them are not well understood and are critical to the behavior and kinetics of grain boundaries, dislocations and precipitates. Two HSLAS containing Niobium (Nb) and either Molybdenum (Mo) or Vanadium (V) were compared. HSLAS containing both Nb and Mo are known to retain their strength at higher temperatures than comparable alloys, while the combination of Nb and V yields similar but less drastic effects. In situ TEM tempering experiments have been carried out in order to compare the effects of the alloy components on precipitation, grain growth, and phase transformation kinetics. By achieving a greater understanding of these mechanisms, the composition and processing procedure of HSLAS can be optimized to predictively improve their thermal and mechanical properties.

D-8: Segregation-Induced Phase Transformation on Grain Boundaries in Fe-Mn: *Michael Herbig*[1]; Pyuck-Pa Choi[1]; Dirk Ponge[1]; Dierk Raabe[1]; [1]Max-Planck-Institut für Eisenforschung GmbH

In order to deepen our understanding of the nucleation of new phases on defects, in particular grain boundaries, it would be desirable to know the phase distribution, orientation and elemental composition around the defects on the nanometer scale. Our approach to gather this information is the combination of transmission electron microscopy (TEM) and atom probe tomography (APT). Investigations have been done on the binary Fe-Mn system. After quenching from the austenite regime the material is composed of 100% martensite. During tempering Mn segregates to the grain boundaries where new austenite is formed. APT samples containing the grain boundaries of interest were prepared using focused ion beam milling and then investigated by TEM and APT.

D-9: Study of Shear Behavior of Al, TiN, and Their Interface Using *ab intio* Method: *Satyesh Yadav*[1]; Xiang-Yang (Ben) Liu[1]; Rampi Ramprasad[2]; Amit Misra[1]; [1]Los Alamos National Laboratory; [2]Institute of Materials Science, CMBE

Recently 2 nm Al-TiN multilayer nanocomposites measured high flow strength, high deformability and unusually high work hardening rate. Due to high proportion of interfaces in such system it is important to understand their role in achieving such exceptional mechanical properties. In this *ab intio* work we use density functional theory to study shear behavior of Al, TiN, and coherent Al/TiN interface under uniaxial stresses. We find that the ultimate shear strength of the interface is of the order of ultimate shear strength of Al or TiN depending on the Ti or N termination at the interface, respectively. As a first step, we establish the slip system in Al and TiN by considering both the ultimate shear strength and volume relaxation. We then develop a methodology to calculate the shear strength of interfaces, so that the shear strength does not depend on number of layers in the supercell.

D-10: The Effect of Molybdenum on Nb,Ti(C,N) Precipitate Evolution and Grain Refinement in a High-Temperature Carburizing Steel: *Charles Enloe*[1]; John Speer[1]; Kip Findley[1]; [1]Colorado School of Mines, Advanced Steel Processing and Products Research Center

Coarsening and compositional evolution of mixed Nb,Ti(C,N) carbonitride precipitates have been investigated in molybdenum-bearing microalloyed SAE 4120 steel. The effects of molybdenum on niobium-bearing carbonitride interfacial energy and niobium diffusion during reheat to carburizing temperatures were of special focus. Characterization of precipitate evolution is fundamental to process design for the retardation of abnormal grain growth at increasingly high processing temperatures. The experimental characterization techniques include analytical scanning transmission electron microscopy (STEM) and three dimensional atom probe tomography (APT). A reduction in the ripening rate of carbonitrides was observed in molybdenum-bearing alloys containing 0.05 wt pct and 0.10 wt pct niobium. Molybdenum incorporation was observed in spheroidal carbonitrides less than 30 nm in diameter, but APT and STEM investigations revealed no appreciable molybdenum segregation to the particle/matrix interface.

T.T. Chen Honorary Symposium on Hydrometallurgy, Electrometallurgy and Materials Characterization: Poster Session

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Hydrometallurgy and Electrometallurgy Committee, TMS: Materials Characterization Committee

Program Organizers: Shijie Wang, Rio Tinto Kennecott Utah Copper; J. E. Dutrizac, CANMET; Michael Free, University of Utah; J. Y. Hwang, Michigan Technological University; Daniel Kim, Rio Tinto Kennecott Utah Copper

Monday PM	Room: Atlantic Hall
March 12, 2012	Location: Dolphin Resort

Funding support provided by: Rio Tinto Kennecott Utah Copper, ASARCO, and Freeport McMoRan

P-1: A Kinetics Study on the Hydrometallurgical Recovery of Vanadium from LD Converter Slag in Alkaline Media: Fereshteh Rashchi[1]; [1]University of Tehran

TBA

P-2: Annealing Effects in Martensitic Transformation Temperature of the Ni-Ti Shape Memory Alloy Rapidly Solidified: *Walman Castro*[1]; Carlos de Araújo[1]; George Anselmo[1]; [1]Universidade Federal de Campina Grande

One important challenge of microsystems design is the implementation of miniaturized actuation principles efficient at the micro-scale. Shape memory alloys (SMAs) have early on been considered as a potential solution to this problem as these materials offer attractive properties like a high-power to weight ratio, large deformation and the capability to be processed at the micro-scale. Ti45Ni55 shape memory alloy was prepared by melt spinning technique at different wheel speed. The effect of annealing at different temperatures on a rapidly solidified/melt-spun Ni-Ti alloy has been investigated in depth. The analysis of these treatments was made by means of DSC. Changes on martensitic transformation temperatures in Ti44,8Ni55,2 melt spun ribbons were observed with the increase if the wheel speed and variation of annealing temperature.

P-3: As(III) Oxidation with Bacteria and AP: *Qian Li*[1]; Qiong Deng[1]; Hong-Jing Yuan[1]; Yong-Bin Yang[1]; Tao Jiang[1]; [1]Central South University

Bio-pretreatment is a hot research subject to refractory arsenic-bearing gold ores. However, the product of As(III) is poisonous to the bacteria, so the technical application is limited.Bio-oxidation action of As(III) with or without bacteria or AP is investigated. The results indicated that it is an effective method of using AP as oxidant to enhance As(III) to As(V) without bacteria. In the condition with bacteria, the Fe2+ will be oxidized by the AP and the energy for bacteria will be reduced. Moreover, there is great influence between the different ways to add AP. When the AP is added into the solution after the bacteria being survived, the bacterial activity will be stronger than it is added at the beginning. The AP can reduce arsenic level of the solution to make the bacteria alive, which makes the bio-oxidation more effective.

P-4: Comprehensive Utilization of Waste Printed Circuit Boards: *Yu Xia*[1]; Long-Sheng Yi[1]; Qi-Ming Feng[1]; Qian Li[1]; [1]Central South University

The comprehensive utilization of valuable metals from the waste printed circuit boards is investigated. The waste printed circuit boards are crushed and separated into two parts of 26.20% metal and 73.80% nonmetal materials by crushing machine. The metal materials, which contained copper, zinc, tin, lead, gold, silver et.al, were leached by sulfuric acid and hydrogen peroxide. After two-stage leaching, the leaching rates of Cu, Zn, Sn, Pb was 99.99%, 100.00%, 100.00%, 2.47% .The leaching residue contained 74.31%Pb, 15.39%Ag and 8.29% Au. The study result has guiding significance for the recycle and reuse of waste printed circuit boards.

P-5: Dephosphorization of Yunnan Refractory High- Phosphorus Low-Manganese Ore by Shaking Table and Hydrometallurgical Processing: Guodong Lai[1]; Zebiao Zhang[1]; Jinhui Peng[1]; Lijuan Chu[1]; Shixing Wang[2]; [1]Faculty of Metallurgy and Energy Engineering; [2]Yunnan Institute of Product Quality Supervision and Inspection

The beneficiation of poor manganese ore containing phosphate gangue is very difficult by conventional processes, due to the similarities in physico-chemical properties of constituent minerals in the system. The shaking table gravity concentration process and mixing concentrated strong acid selective intensified leaching process were used for dephosphorisation of Yunnan manganese ore. The leaching process was effective. The effects of intensified leaching time, solid-liquid ratio and particle size were investigated. The relevant leaching factors were optimized as -0.125+0.088 mm particle size ore with 68% nitric acid for 24 h when using a solid-liquid ratio of 1:1 at room temperature and pressure atmosphere. Under these conditions, the P/Mn ratio was reduced from 0.0107 to 0.0056, and the grade of manganese was increased from 12.32% to 42.76%. The dissolution of manganese during leaching was negligible.

P-6: Dissolution Behavior of Impurities in Scheelite Mineral in Oxalic Acid Solutions: Ahmet Kalpakli[1]; Sedat Ilhan[1]; *Cem Kahruman*[1]; Ibrahim Yusufoglu[1]; [1]Istanbul University

Scheelite mineral is the main raw material in tungsten production. In hydrometallurgical processes, extraction of tungstate ions is very important. During the leaching of scheelite mineral in oxalic acid solutions, tungsten completely dissolves as chelate complex. Scheelite mineral includes impurities along with calcium tungstate. Determination of dissolution of these impurities is important for further tungsten production stages. In this study, scheelite mineral was dissolved in oxalic acid solutions and the dissolution of impurities were investigated. The quantities of dissolved impurities were determined by ICP – OES and characterization of undissolved impurities in leach residues were carried out by SEM – EDS analysis.

P-7: Effect of Different Parameters on Synergistic Separation of Nickel and Cadmium from Sulphate Solutions using D2EHPA and Cyanex 302: *Ataollah Babakhani*[1]; Fereshteh Rashchi[1]; Ehsan Vahidi[1]; Alireza Zakeri[2]; [1]University of Tehran; [2]Iran University of Science & Technology

Synergistic effect of Cyanex 302 on the solvent extraction of nickel and cadmium from sulphate solution with D2EHPA diluted in kerosene was investigated with the aim of increasing the separation efficiency. Experiments were carried out in the pH range of 0.1–5.0 using sole D2EHPA and D2EHPA-Cyanex 302 mixtures in different ratios. Increasing Cyanex 302 to D2EHPA ratios in the organic phase caused a left shifting of the extraction isotherm of cadmium and a right shifting of the extraction isotherm of nickel. As a result, optimum separation was found with a Cyanex 302 to D2EHPA ratio of 0.1: 0.5. In the present system, effect of a modifying reagent such as TBP was studied. Influence of various diluents including kerosene and carbon tetrachloride was also investigated.

P-8: Electrochemical Reduction of TiO2-Rich Slag to High-Titanium Ferroalloy in the CaCl2-NaCl Melt: *Qian Xu*[1]; [1]Northeastern University

The high-titanium ferroalloy was electrochemically prepared in the CaCl2-NaCl melt from the titania-rich slag with 70% mass percent TiO2, which was provided by the Titanium Plant of Panzhihua Iron and Steel Group Corporation, Sichuan, China. The product mainly contained TiFe and Ti with impurities of Si, Al and Mg. When the titania-rich slag was upgraded by the joint process of alkali-activation and acid leaching, the effective removal of the impurities was achieved, and metallic Ti with minor amount of TiFe alloy can be produced by electro-deoxidation. An investigation into the reaction pathway of the electrochemical reduction was performed in order to better understand the reaction mechanism of the process for preparation of high-titanium ferroalloy.

P-9: Evaluation of Banana Fibers Density with Different Diameters: *Nathalia Rosa*[1]; Lucas Martins[1]; Sergio Monteiro[1]; [1]UENF

Polymer composites reinforced with natural fibers are gaining interest of several engineering sectors due to specifics advantages such as lower cost and lower density as well as environmental benefits associated with the fact that natural fibers are renewable, biodegradable, recyclable and neutral with respect to CO2 emissions. Among these natural fibers, the banana fiber has been studied as possible reinforcement in polymer composites. In spite of works conducted on the diameter dependence of the tensile strength, no investigation has been conducted so far to evaluate the relation between the density and different diameters. Then, the objective of this work is to evaluate the banana fibers density to the different diameters. It was found an inverse correlation between the diameter and the fiber density. This correlation could be explained in terms of defects and microstructural characteristics by means of SEM observation.

P-10: Interdiffusion Studies between Ti-5Ta-2Nb Alloy and 304L Austenitic Stainless Steel Joined by Explosive Cladding Process: *Sudha Cheruvathur*[1]; Prasanthi T.N[1]; Saroja S[1]; Vijayalakshmi M[1]; [1]Indira Gandhi Centre for Atomic Research

In this study, evolution of the interface microstructure in explosively clad joints of Ti-5Ta-2Nb and 304L austenitic stainless steel due to heat treatment is elaborated. Heat treatment in the temperature range of 823 to 1273K resulted in considerable microstructural and microchemical changes at clad interface. Diffusion path followed at each temperature was identified based on electron microprobe analysis. From elemental concentration profiles, diffusion coefficient of the alloying elements was calculated using Den Broeders and Hall's method. Diffusion of Fe in \945 Ti (10^{-16m2}/sec) was found to be faster (10^{-15m2}/sec) than diffusion of Ti in \947-Fe (10^{-18m2}/sec). Diffusion of Fe in bcc \946-Ti phase was found to be faster than the self diffusion of Ti (10^{-17m2}/sec). Apparent activation energy for the formation of zones containing \946-Ti and intermetallic phases was obtained as 183 and 32kJ/mol respectively. Concentration dependence of interdiffusion coefficients was calculated which will be discussed in the paper.

P-11: Leaching S from Pressure Acid Leaching Residue of Zinc Concentrate: Paraments Optimization Using Response Surface Methodology: *Lijuan Chu*[1]; Zebiao Zhang[1]; Peng Peng[2]; Guodong Lai[1]; Guo Cheng[1]; [1]Kunming University of Science and Technology; [2]University of Minnesota

The pressure acid leaching residue of zinc concentrate contains large quantity of sulfur. The present study attempts to leach sulfur using a mixture of ammonium sulfide and water solution at 25□. Effects of three leaching variables: ammonium sulfide concentration, leaching time, liquid to solid ratio on the sulfur leaching rate were investigated. The process conditions were optimized using response surface methodology based on the central composite design. From the analysis of variance (ANOVA), the significant factors on response were identified. The optimum conditions for leaching elemental sulfur from pressure acid leaching residue of zinc concentrate were obtained by using ammonium sulfide concentration of 2.5mol/L, leaching liquid-solid ratio of 6.5:1 and leaching time of 7 min. Under the optimum experimental conditions, a maximum of 98.50% of sulfur was extracted. The experimental results obtained agreed satisfactorily with the model predictions, with a correlation coefficient (R2) of 0.99.

P-12: Measurement of Contact Angle for Iron Ore Particles: *Xiaobo Huang*[1]; Xuewei Lv[1]; Chenguang Bai[1]; Rende zhang[1]; Maojun Zhou[2]; [1]College of Materials Science and Engineering,Chongqing University; [2]Ironmaking plant, Baoshan Iron & Steel Co., Ltd.

Wettability of the iron ore plays a great role during iron ore granulation process. As a characterization of wettability, the contact angle of iron ore particles was measured via Washburn Osmotic pressure method, which is a deformation of capillary penetration method. Correctness and accuracy of the experiment are always affected by some factors, which are the main topics of this study. It was found that the compaction status in the packed beds, the size distribution of the particles, temperature and humidity all affect the testing process. The optimal measurement conditions are suggested as follow:(a) sample with size distribution of 240-400 mesh (61μm -38μm);(b) Consistency and stability of temperature and humidity. The advancing contact angles of five ores varied from 20 to 85°, and have a notable correlation with chemical and physical properties.

P-13: Mixture Design Applied to the Electrochemical Reduction Of $CaWO_4$ to W: *Metehan Erdogan*[1]; Ishak Karakaya[1]; Orhan Gökçe Göksu[2]; [1]Department of Metallurgical and Materials Engineering, Middle East Technical University; [2]Other

An experiment (mixture) design was created to study the process parameters of the electrochemical reduction of $CaWO_4$ to W in molten $CaCl_2$-NaCl eutectic mixture. Temperature, applied voltage and Kanthal wire winding of the $CaWO_4$ pellets were selected as the process parameters and allowed to vary between the predetermined minimum and maximum values. The rates of the electrochemical reductions were interpreted from the variations of current and total charge vs. time graphs under different conditions. The analysis pointed out 640°C and 2.81 V from the created mixture design for the fastest reduction and it was seen that the effect of Kanthal wire winding on the output current was less pronounced when compared to the other two parameters.

P-14: Preparation and Characterization of PBT/Clay Nanocomposite: Mariana Sartori[1]; Rene Oliveira[1]; Francisco Díaz[2]; Vijaya Rangari[3]; Angel Ortiz[1]; *Esperidiana Moura*[4]; [1]Instituto de Pesquisas Energéticas e Nucleares - IPEN-CNEN/SP; [2]Universidade de São Paulo - USP; [3]Tuskegee University; [4]Instituto de Pesquisas Energéticas e Nucleares - IPEN-CNEN/SP

This work presents the preparation and characterization of a nanocomposite based on PBT and Brazilian smectitic clay (bentonite chocolate clay). Before being incorporated as clay nanoparticles in PBT resin, the clay was organically modified by the addition of a quaternary salt and sodium carbonate. PBT/Clay nanocomposite (96.3:3.70 wt %) was obtained by using a twin-screw extruder machine. After extrusion process, the nanocomposite was characterized by tensile, flexural and impact tests, SEM, Vicat, HDT, DSC, TGA and XRD tests. The results showed that the properties of the nanocomposite obtained were superior to those of neat PBT. Concerning the temperature of thermal distortion (HDT) an expressive gain of around 45 % was presented to PBT/Clay nanocomposite compared to PBT evidencing the interaction of nanofiller with the polymeric matrix.

P-15: Removal of Pb(II) by Modified Watermelon Peel Adsorbent: *Kai Huang*[1]; Lianyun Liu[1]; Bo Jiang[1]; Hongmin Zhu[1]; [1]University of Science and Technology Beijing

Watermelon peel is selected as a novel adsorbent to remove Pb(II) from aqueous solution. A simple saponification process is proposed to modify the peel and the adsorbent is characterized by SEM and FTIR. The effects of pH, contact time, initial concentration of Pb(II), biosorbent dosage and temperature on adsorption of Pb(II) are investigated. Different models are used to fit experimental data and indicating that the adsorption process follows Langmuir model and pseudo-second-order model. The maximum adsorption capacity obtained from Langmuir model is 1.05mol kg-1 for the prepared sorbent. Equilibrium time is attained at 5-10min for the studied concentrations. Thermodynamic parameters indicate that the adsorption process is endothermic and spontaneous. So the watermelon peel can be used as an effective and low-cost biosorbent for removal of Pb(II) from aqueous solution.

P-16: Sulphuric Acid Leaching Germanium from Germanium Dust and Fume: Process Optimization Using Response Surface Methodology: *Wankun Wang*[1]; Jinhui Peng[1]; Zebiao Zhang[1]; Shixing Wang[1]; [1]Kunming University of Science and Technology

Germanium leaching from germanium dust and fume was carried out using sulphuric acid. Response surface methodology, based on a five level, four variable central composite designs, was employed to obtain the best possible combination of liquid/solid ratio, leaching time, sulphuric acid concentration and leaching temperature for germanium leaching. The experimental data obtained were fitted to a one-order polynomial equation using multiple regression analysis and also were analyzed by analysis of variance. The 3-D response surface plot and the contour plot derived from the mathematical models were applied to determine the optimal conditions. The conditions were: liquid/solid ratio of 10, leaching time of 1 h, sulphuric acid concentration of 15.75 mol/L, and leaching temperature of 87.8 □. Under these conditions, the germanium leaching rate was 65.14%, which is well in close agreement with the value predicted by the model. The samples were characterized before and after leaching using X-ray diffraction.

P-17: Surfaces Improvement by Mecano-Chemicals Processes: *Isaias Hilerio*[1]; Miguel A. Barrón[1]; Roberto T. Hernández[1]; Alejandro Altamirano[1]; [1]UAM Azcapotzalco

The principal objective of finishing surfaces is protect and/or decorate them. This can obtain by adding or removing material of the work surface.. In this work we'll be interested in develop the improvement of surfaces by remotion of material. The Barreling or Polishing by Friction Method is utilized. The process is based in the rubbing or friction by abrasives. The pieces are arranged in the barrel with a natural or synthetic abrasive and an additive. The machine produces a rotating movement on the pieces. The rubbing action is developed when the superior layer of the charge is sledded to the inferior extreme when the barrel rotates, which can be hexagonal or octagonal to facilitate the skidding of the charge. To rotate the barrels is used an impulsion with wheel spindle or rolling pins, that the can be ride horizontally or tilted to produce an additional movement of the charge.

P-18: The Effect of Temperature on Complex Permittivity and Microwave Absorption Properties of an Ilmenite Concentrate at 2450MHz: Chenhui Liu[1]; *Libo Zhang*[1]; Jinhui Peng[1]; Bingguo Liu[1]; Hongying Xia[1]; Wei Li[1]; [1]Key Laboratory of Unconventional Metallurgy, Kunming University of Science and Technology

Dielectric property is an important limiting factor in the development of microwave processing minerals and ores. In this study, we used an open-ended coaxial sensor method to measure the complex permittivity of an ilmenite concentrate (41%TiO2) and microwave absorption properties from room temperature to 100 °C. The results show that both the dielectric constant and loss factor increase with temperature rising at 2.45GHz, the loss tangent have a linear relationship with temperature at 2.45GHz. Microwave absorption properties of this ore are highly dependent on temperature and frequency. The research will be helpful in explaining the thermal running of microwave dielectric heating the ilmenite concentrate.

P-19: Thermal Characterization of Jute Fibers by TGA/DTG and DSC: *Isabela Silva*[1]; Victor Silva[1]; Alice Bevitori[1]; Sergio Monteiro[1]; [1]UENF

Several natural fibers are increasingly being considered as viable alternatives to substitute glass fiber in polymer composites reinforcement. In practice, lignocellulosic fibers extracted from plants have shown a real potential for this substitution. Their comparative advantages are lower density an cost as well as renewability, biodegradability, recyclability and neutrality with respect to CO2 emission, which is responsible for global warming. By contrast, the thermal resistance of the lignocellulosic fibers is restricted and may affect their application in engineering composites.

Jute fibers is worldwide used in many single items and is now considered for composite reinforcement. The mechanical proprieties of the jute fiber has been extensively investigated but only limited works have been devoted to its thermal characterization. The present work investigated these characterization in terms of thermo-gravimetric analysis TGA/DTG and differential colorimetry, DSC. It was found that the jute fiber starts deteriorating around 150ºC and undergoes total degradation at 500ºC.

P-20: Thermal Decomposition Kinetics of the Thermal Decomposition Products of Ammonium Heptamolybdate Tetrahydrate in Air and Inert Gas Atmospheres: *Hande Çavusoglu*[1]; Cem Kahruman[1]; Ibrahim Yusufoglu[1]; [1]Istanbul University

In this study, decomposition intermediate solid products of ammonium heptamolybdate tetrahydrate were obtained and thermal decomposition reaction kinetics were investigated under air and inert gas atmosphere, using nonisothermal thermogravimetric analysis, differential thermal analysis and mass spectrometry and isothermal thermogravimetric analytical techniques and activation energies, frequency factors were calculated and appropriate kinetic models were proposed. The characterization of the intermediate solid products obtained in each decomposition step was carried out by X-ray Powder Diffraction and Fourier Transform - Infrared analytical techniques.

Ultrafine Grained Materials VII: Poster Session

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Nanomechanical Materials Behavior Committee, TMS: Shaping and Forming Committee

Program Organizers: Suveen Mathaudhu, U.S. Army Research Office; Xiaoxu Huang, Risø National Laboratory for Sustainable Energy, Technical University of Denmark; Hyoung Seop Kim, POSTECH; Terence Langdon, University of Southern California; Terry Lowe, Manhattan Scientifics, Inc. ; Ruslan Valiev, Ufa State Aviation Technical University; Xiaolei Wu, Institute of Mechanics, Chinese Academy of Sciences; Michael Zehetbauer, University of Vienna

Monday PM	Room: Atlantic Hall
March 12, 2012	Location: Dolphin Resort

T-1: Application of High-Pressure Torsion for Thick Samples: *Hideaki Iwaoka*[1]; Zenji Horita[1]; [1]Kyushu University

High-Pressure Torsion (HPT) is a powerful method to make ultrafine grains in materials. Although HPT is applicable to hard and less ductile materials, there is a practical limitation that it can be used only with samples typically less than 1 mm thick. Thus far, we have processed by HPT a high-purity Al with 4 mm thickness. It was shown that the strain was introduced more intensely in the center of thickness on the cross section. This area expands with increasing number of revolutions and expansion saturates before covering entirely. However, it is probable that this can be due to characteristic behavior of high-purity Al because its hardness decreases by intense strain. In this study, thick Cu or Al alloys samples are used, whose hardness does not decease by intense strain for HPT processes. Microstructural observation across the thickness is carried out using transmission electron microscopy to correlate with hardness variation.

T-2: Bulk Ultra-fine Grained Materials from Reprocessed Machined Chips: *S Giribaskar*[1]; Gouthama[1]; [1]Indian Institute of Technology Kanpur

Focus of the present investigation is on the development of bulk ultra-fine grained materials by rotary swaging of plane–strain machined Al-Li alloy chips having ultra-fine grains. The premise is that machined chips are severely deformed during plane–strain machining process to have ultra-fine grains and it should be possible to obtained bulk ultra-fine grained material by bottom-up approach. Hence efforts are made to develop bulk ultra-fine grained material by cold swaging process and optimal thermomechanical treatments. SEM is used to study the flow characteristics of material due to the shearing action during the plain-strain machining process. TEM used to investigate the microstructural characteristics of as-machined chips and as-swaged chip compacts. It has been shown that the chips formed are having grains in the size range from sub-micron meter to nanometer range. Microstructural evolution in as-machined chips and swaged compacts before and after optimal annealing treatments are also presented and discussed. Present study suggests that machining might be an attractive processing route for producing bulk materials with ultra-fine structures.

T-3: Carbide Free Bainitic Steel: *Xiaoxu Zhang*[1]; [1]McMaster University

Carbide-free bainitic steels exhibit excellent combination of strength and ductility. The microstructure and mechanical properties are investigated in a steel containing 0.4%C-2.8%Mn-1.8%Si. The microstructure was characterized using optical and transmission electron microscopy. It consisted of bainitic ferrite, martensite and retained austenite, which are all in nano-scale. These microstructures exhibited a long elasto-plastic transition with very high initial work hardening rates and delay the onset of necking. Strain path reversals to measure the Bauschinger effect showed that this high hardening rate results from kinematic hardening due to the mechanical contrast of the microstructural constituents. The fracture properties were also investigated to reveal the importance of the prior austenite grain boundaries on the fracture process. The former austenite grain boundaries are believed to initiate fracture in the present materials. The fracture strength is improved by refining the prior austenite grain.

T-4: Characterization of Al- Al Laminates Processed by ECAP: *Sapthagireesh Subbarayan*[1]; Hans Jorgen Roven[1]; [1]NTNU

ECAP has been widely used to process Al alloys to produce ultra fine grained structures; however, the application of ECAP for the processing of laminates and bimetals at room temperature has not been reported so far. The present work demonstrates the ability of ECAP for processing laminates using ECAP at room temperature. Al - Al laminates processed by ECAP at room temperature found to have bonded very well. Samples evolved with no interface and complete bonding was possible even after one pass. EBSD studies have been carried out to characterize the microstructure evolution to determine the grain size, grain shape structure and misorientation relationship. The effect of stacking, effect of strain, effect of back pressure and oxidation on the microstructure evolution has been studied. Microhardness was also investigated and correlated to the microstructure evolution.

T-5: Concurrent Structural Evolution of the FCC and BCC Phases in Duplex Stainless Steel Induced by High-Pressure Torsion: *Yang Cao*[1]; Yanbo Wang[1]; Xiaozhou Liao[1]; Roberto Figueiredo[2]; Simon Ringer[1]; Terence Langdon[3]; Yuntian Zhu[4]; [1]The University of Sydney; [2]Federal University of Minas Gerais; [3]University of Southern California; [4]North Carolina State University

High-pressure torsion (HPT) has been the most effective severe plastic deformation technique for grain refinement to produce bulk nanostructured materials. Previous investigations of HPT processing concentrated mostly on single-phase materials or multi-phase alloys with only a small amount of secondary phases. However, many practical materials are of two phases with comparable volume fractions of each phase. Understanding how HPT processing will affect the structure and the mechanical properties of dual-phase materials is therefore very important. Here we apply transmission electron microscopy and scanning electron microscopy to investigate the microstructural evolution of a duplex stainless steel processed by HPT. The material comprises roughly the same volume fractions of the face-centered cubic austenite (the gamma phase) and the body-centered cubic ferrite (the alpha phase). The relative deformation of the two phases at different deformation stages will be presented in detail.

T-6: Dynamic Torsion Deformation of Ultrafine Grained Ferrite-Martensite Steel Fabricated by ECAP: *Hyunmin Kim*[1]; Young Gun Ko[2]; Dong Hyuk Shin[3]; Sunghak Lee[1]; [1]POSTECH; [2]Yeungnam University; [3]Hanyang University

The paper dealt with the dynamic deformation behavior of ultrafine grained (UFG) ferrite-martensite steel fabricated by equal channel angular pressing (ECAP) together with subsequent heat treatment. A martensite structure used as a perform microstructure was deformed by 4-pass ECAP and, then, heat-treated in an intercritical regime for 10 minutes, which would lead to the resultant microstructure consisting of ferrite and martensite grains of ~ 0.8 μm with their homogeneous mixtures. Dynamic torsion assessment utilizing Kolsky bar exhibited that the total strain of the UFG ferrite-martensite sample was approximately twice as large as that of the deformed martensite sample whilst the shear stress became lower with the introduction of multi-phase. In addition, observation of the localized area beneath the fractured surface revealed that adiabatic shear bands of ~ 20 μm appeared in the deformed martensite sample, which minimized the total strain, whereas they were barely formed in the UFG ferrite-martensite sample.

T-7: Effect of Preheating on Microstructure and Mechanical Properties of Ultrafine Grained AA1050 Deformed by Accumulative Roll Bonding (ARB) Method: *Kuiyu Cheng*[1]; Cheng Lu[1]; Lihong Su[1]; Kiet Tieu[1]; [1]University of Wollongong

Ultrafine-grained AA1050 sheets have been produced by accumulative roll bonding (ARB). Two ARB processes with and without preheating have been compared in this study. The preheated ARB process heated the specimens at 250oC for 3 mins prior to rolling. The microstructures of the ARB specimens at different positions along the thickness have been investigated by transmission-electron-microscope (TEM). It has been found that all ARBed specimens present strong rolling texture with elongated grains in the middle part of the sheet and roughly equiaxed grains near the surface regardless of the preheating. However, less grain refinement and more in-grain dislocations have been found in the preheated specimens. The bond strength test, tensile test and superplasticity test have been conducted in an Instron-type machine. The results showed that the preheating improved significantly bonding strength and slightly increased ductility at room temperature. However, the superplasticity behaviour seemed to be independent of the preheating.

T-8: Effects of Ageing after Cryogenic and Warm Rolling on Mechanical Properties of Al 6061 Alloy: *Nageswararao Palukuri*[1]; Jayaganthan R[1]; [1]IIT Roorkee

Cryogenic rolling conjunction with static ageing was used to develop high strength ultrafine grained precipitation hardenable Al 6061 alloy in the present work. Cryogenic (93K) and warm rolling (418 K) followed by the static ageing treatment (393 K for 60 hrs) were used for the simultaneous improvement of strength as well as ductility of Al 6061 alloy. It was found that micro hardness and tensile strength (119 HV, 365 MPa) of combined cryogenic and warm rolled specimens are more than cryorolled specimens (101HV, 295 MPa) alone. Based on XRD, DSC and TEM observations, it may be concluded that the improved mechanical properties are attributed to faster dynamic ageing than dynamic recovery during warm rolling, which leads to slight decrease in dislocation density. Post deformation ageing treatment was given for precipitation of the retained second phase in solid solution in order to increase the strength and ductility by static recovery.

T-9: Effects of Ball Milling and High-Pressure Torsion for Improving Mechanical Properties of Al-Al2O3 Nanocomposites: *Maki Ashida*[1]; Zenji Horita[1]; [1]Kyushu University

Powder consolidation is feasible using HPT and thus makes it possible to produce a bulk form of metal-ceramic nanocomposites at lower temperature. In the present study, effects of Ball Milling and HPT process on the mechanical properties and microstructure of Al-Al2O3 nanocomposites were investigated. Powder mixture of Al-30vol%Al2O3 was processed by BM for 100-200 min at a rotation speed of 200-400 rpm. The mixture was then consolidated by HPT at room temperature under a pressure of 3.0 GPa for 10 revolutions. For comparison, the Al-Al2O3 composites were prepared by HPT without BM. Microstructures were characterized by optical microscopy and transmission electron microscopy including X-ray diffraction analysis. Density, Vickers microhardness were also measured. By applying BM at 300 rpm, the HPT-processed ring sample showed a uniform dispersion of nano-sized Al2O3 particles in the Al matrix. Hardness was enhanced by BM and HPT in comparison to that processed by HPT without BM.

T-10: Effects of High-Pressure Torsion Parameters on the Microstructure and Mechanical Properties of Bulk Metallic Glasses: *Bal Bashyal*[1]; Yanbo Wang[1]; Dongdong Qu[2]; Megumi Kawasaki[3]; Xiaozhou Liao[1]; Simon Ringer[1]; Terence Langdon[3]; Jun Shen[2]; [1]The University of Sydney; [2]Harbin Institute of Technology; [3]University of Southern California

Although bulk metallic glasses (BMGs) have superior mechanical properties including high strength, high hardness and large elastic limit, their practical structural applications have been severely limited by their poor ductility due to shear localization and strain softening leading to catastrophic failure. Substantial efforts have been made to explore methods which improve the ductility of BMGs. In this presentation, we apply the quasi-constrained high-pressure torsion (HPT) technique with varying values of processing parameters (pressure and strain) to manipulate the structure of Zr-based BMGs and to explore the effect of structural change on the mechanical behaviour of the materials. X-ray diffraction, differential scanning calorimetry, scanning electron microscopy, focussed ion beam lithography, microindentation, and in-situ deformation transmission electron microscopy are used in this investigation.

T-11: Engineering Surface Microstructures Using Severe Plastic Deformation in Machining: M. Ravi Shankar[1]; *Saurabh Basu*[1]; Sepideh Abolghasem[1]; [1]University of Pittsburgh

Machining processes are widely utilized in the manufacture of engineering components. Surface generation by material removal during chip formation in this process involves severe plastic deformation over a broad range of strains (1-10), strain-rates (10-10^5) and thermomechanically-coupled temperature rises (ambient to ~melting temperature). Here, we present opportunities for endowing bulk metals with ultra-fine grained microstructures through combinatorial choices of strains, strain-rates and temperatures across this spectrum of thermomechanical conditions using machining. These include controlling grain and subgrain scale, distribution, grain-boundary structure, dislocation-densities etc. Opportunities for engineering novel multifunctional property combinations inherited from grain-refined surfaces, directly using machining are also discussed.

T-12: Enhanced Mechanical Properties of Ultrafine Grained Titanium Deposits Fabricated via High-Velocity Impacts of Micron-Sized Particles: *Gyuyeol Bae*[1]; Jae-Il Jang[1]; Changhee Lee[1]; [1]Hanyang University

Kinetic spraying (or cold spraying) has emerged as a new and innovative particle deposition technique because the process operates at low temperature and high pressure compared with conventional thermal spraying processes. Micron-sized particles impacted subsequently at high velocities (i.e., subjected to severe plastic deformation) undergo strain-induced adiabatic heating, accompanied by shear instability. These thermomechanical characteristics of metallic particles upon impact at high strain rates enable both metallurgical bonds formation and microstructural refinement of the deformed particles. Especially, due to the low processing temperature and high deposition rate, this process is suitable for rapid production of oxidation sensitive materials, such as titanium. Here, we report randomly orientated equiaxed ultrafine- and nanocrystalline grains formed homogeneously over wide areas inside the kinetic-sprayed pure titanium deposits. Also, these features are analyzed through finite element simulations considering conductive heat transfer, and directly correlated to improved mechanical properties that were evaluated by microindentation and nanoindentation experiments.

T-13: Estimation of Friction under High Pressure – Application to High Pressure Tube Twisting (HPTT): *Arnaud Pougis*[1]; Jean-Jacques Fundenberger[1]; Laurent Faure[1]; Sylvain Philippon[1]; Roxane Arruffat[1]; Laszlo Toth[1]; [1]University Paul Verlaine

Severe Plastic Deformation (SPD) processes are used to obtain ultra-fine grain materials by achieving very high strain under hydrostatic pressure. The friction has to be very low in some process (ECAP) but very large for other (HPT, HPTT). Most of numerical analyses do not take in account the friction into the simulations. The contact is assumed to be sticked for HPTT processes. An experimental setup is presented to evaluate the coefficient of friction under high pressure. Numerical simulations are carried out to simulate the SPD process High Pressure Tube Twisting, the effect of the friction during the deformation and load requirement.

T-14: Evaluation of Hardness Homogeneity and Mechanical Properties in an Aluminum Alloy Processed by High-Pressure Torsion: *Shima Sabbaghianrad*[1]; Megumi Kawasaki[1]; Terence Langdon[1]; [1]University of Southern California

Processing by high-pressure torsion (HPT) was performed on Al-7075 alloy samples at room temperature. The alloy was annealed at 480°C and processed by HPT under a pressure of 6.0 GPa up to 10 turns. Vicker's hardness values obtained from the samples show that the hardness value is lower at the center of all the samples and higher as it moves farther from the center, moreover an increase in the hardness is observed by increasing the number of turns in HPT. Mechanical testing and microstructural analysis support the results obtained from the hardness testing.

T-15: Fatigue Behavior of Friction Stir Processed Ultrafine Grained 8242 Al Alloy: *Mageshwari Komarasamy*[1]; Nilesh Kumar[1]; Rajiv S. Mishra[1]; [1]Missouri University of Science and Technology

The ultrafine grained (UFG) microstructure in 8242 Al alloy was produced by friction stir processing. The cyclic properties of UFG materials were evaluated using fully reversible bending fatigue and compared with the coarse grained microstructure. The microstructure of UFG material before and after cyclic deformation was characterized using orientation imaging microscopy. Particular emphasis was given to the role of microstructure on evolution of deformation structure. Transmission electron microscope was used to determine the dislocation structure in the tested samples. The influence of grain size on transition of fatigue mechanism from persistent slip band to persistent shear band is discussed. The fractured samples were inspected under scanning electron microscope to understand the failure mechanism in UFG material.

T-16: High Strength Al 6061 Alloy by the Application of Cryogenic and Warm Rolling: *Ui Gu Kang*[1]; HoJin Lee[1]; WonJong Nam[1]; [1]Kookmin Univ.

The ultrafine-grained Al 6061 alloy which was fabricated by the combination of cryogenic rolling with warm rolling, exhibited high strength, ultimate tensile strength, 420MPa. The strengthening effect was compared with the results by other severe plastic deformation methods. This notable increase of tensile strength was achieved by the formation of fine precipitates during warm rolling. The presence fine precipitates of diameter below 100nm, in ultrafine-grained matrix, were confirmed with TEM and STEM. Estimated precipitation-strengthening by the fine precipitates was approximately 150 MPa. Based on the results, it was found that the cryogenic rolling combined with warm rolling would be effective in increasing strength and expending application area in industries.

T-17: Influence of Deformation Route on Microstructure Evolution of Ferrite Steels via Shear Rolling with Differential Speeds: *Jae Sik Lee*[1]; Jordan Suharto[1]; Young Gun Ko[1]; [1]Yeungnam University

The effect of deformation routes on microstructure evolution of ferrite steels fabricated by differential speed rolling (DSR) was investigated in this study. Under the DSR condition giving an effective strain of ~0.4 per each passage through the rolls whose speed ratio was 1:4 for lower and upper rolls, respectively, samples were rotated using three different routes such as no rotation, vertical 180° rotation, and vertical-horizontal 180° rotation, which were designated as routes A, B, and C. Microstructural observation using electron back-scattered diffraction and transmission electron microscope showed that the role of shear deformation on microstructure change in ferrite steel was pronounced. In addition, mechanical assessment was analyzed in terms of micro-hardness and tension tests at room temperature and discussed in relation to shear characteristics determined by DSR routes.

T-18: Influence of Texture on the Strength and Fracture Behavior of Severe Plastically Deformed Nickel: *Georg Rathmayr*[1]; Reinhard Pippan[1]; [1]Erich Schmid Institute of Materials Science

Severe plastic deformed (SPD) materials are of particular interest due to their interesting mechanical and physical properties. For example, SPD materials exhibit high yield stresses by simultaneously keeping a high elongation to failure which is clearly contrary to conventional cold worked materials. During SPD deformation, a shear texture develops in the final microstructure. In the current work we focused on the texture influence on the strength and fracture behavior of high purity SPD deformed nickel which was investigated by using different oriented macro tensile samples. We used nickel because it is a "model material" in the SPD community. Beside the results of the orientation dependency of the mechanical properties, the limiting factor of inclusion on the ductility is outlined. Furthermore, a detailed discussion about the influence of deformation temperature and the beneficial influence of carbon on the mechanical properties will be presented.

T-19: Influence of Ultrafine Grained Microstructure on the Superplastic Deformation Mechanism of 7075 Al Alloy: *Arun Mohan*[1]; Partha De[1]; Rajiv Mishra[1]; [1]Missouri University of Science and Technology

Commercially available rolled 7075 Al plates were friction stir processed (FSP) to obtain ultrafine grained (UFG) material with average grain size of ~0.6 µm. Thermal stability of UFG microstructure was investigated to decide on the optimum temperature range for superplasticity. Tensile tests were done in the temperature range of 300-450°C in the strain rate range of 10-3s-1 to 10-1s-1. The UFG test results were compared with fine grained FSP 7075 Al alloy with grain sizes ranging from 3 to 8 µm. In UFG 7075 Al, superplastic strain rate was higher and superplastic temperatures were significantly reduced compared to fine grained 7075 Al. Normalized stress versus normalized strain rate plot was used to compare the kinetics of superplastic flow in UFG and fine grained 7075 Al. Analysis of grain size dependence, stress exponent and activation energy revealed the role of grain boundary sliding in the superplastic deformation of UFG 7075 Al.

T-20: Microstructure and Mechanical Properties of 5005/6061 Laminated Composite Processed by Accumulative Roll Bonding: *Lihong Su*[1]; Cheng Lu[1]; Guanyu Deng[1]; Kuiyu Cheng[1]; Kiet Tieu[1]; Xudong Sun[1]; [1]University of Wollongong

The 5005/6061 laminated composite has been fabricated by the accumulative roll bonding (ARB) using commercial 5005 and 6061 aluminium alloy. In the ARB process. The materials were heated at 250 °C for 5 min before each rolling process and were deformed up to four cycles to an equivalent strain of 3.2 and form a 5005/6061 laminated composite. Mechanical properties and microstructure of the laminated composites were tested. The hardness and tensile strength increases and the grain size decreases with ARB cycles. Ultrafine grains elongated along the rolling direction are developed during the ARB process. The thickness of the grains of both the 5005 and 6061 layer are less than 200 nm after the fourth cycle. The uniform elongation decreases after the first and second cycle and increases slightly after the third and fourth cycle ARB. The hardness of the 5005 layer is slightly lower than that of the 6061 layer.

T-21: Microstructure Evolution in an UFG Al-7Mg Alloy Processed by ECAP during Subsequent Annealing: *Min Zha*[1]; Yanjun Li[2]; Ragnvald Mathiesen[3]; Hans Roven[1]; [1]Department of Materials Science& Engineering Norwegian University of Science& Technology (NTNU); [2]Sintef, Materials and chemistry; [3]Department of Physics, Norwegian University of Science& Technology (NTNU)

A binary Al-7Mg alloy has been processed by equal channel angular pressing (ECAP) via route Bc. After 5 passes ECAP, an ultrafine grained (UFG) material with an average grain size of ~0.2 \956m and a Vickers hardness value of ~205 is obtained. In order to study the thermal stability of the UFG alloy, a series of annealing treatments have been carried out. The microstructure evolution of the alloy during annealing has been characterized by transmission electron microscopy (TEM) and electron backscattered diffraction (EBSD). The recovery and recrystallization behavior of the alloy is discussed and also compared with the coarse grained Al-7Mg alloy processed by 3 passes ECAP.

T-22: Novel C-Extrusion towards Ultra-Fine Grained Aluminum: *Terje Hals*[1]; Hans Roven[1]; [1]Norwegian University of Science and Technology

The present highly novel approach explores the potentials for producing UFG commercial purity aluminium extrusions. The primary goal is to demonstrate grain refinement towards the sub-micrometer range. Variations in granular feedstock characteristics, deformation temperature, extrusion speed and accumulated strain are investigated. The produced materials are subjected to characterization methods such as FEG-SEM, high resolution EBSD, nano-indentations and mechanical testing. The obtained results are compared to similar material produced by conventional extrusion and standard ECAP performed at room temperature. It should be noted that the applied deformation processing method has the potential to be combined with ECAP, producing UFG materials in a continuous manner.

T-23: Plasmanitriding of HSLA Steels with Ultrafine Grained (UFG) Surface Layers: *Jennifer Schuster*[1]; Enrico Bruder[1]; Clemens Mueller[1]; [1]TU Darmstadt

Linear flow splitting (LFS) is an innovative process to produce bifurcated profiles in integral style. Due to severe plastic deformation, an UFG-microstructure evolves. Because of their geometry, LFS-profiles are qualified for wear loaded applications as linear guides, which makes plasmanitriding of the profiles reasonable to increase their hardness and wear resistance. Up to now it is uncertain, to which extend the hardness of UFG-microstructures can be enhanced by nitriding and if the UFG-microstructure with its outstanding mechanical properties can be preserved during the nitriding process.The experimental results on different linear flow split HSLA steels clearly reveal that nitriding leads to a considerable increase in hardness, which is significantly more pronounced in UFG-microstructures than in classically cold formed microstructures. Furthermore it will be shown on the base of EBSD and HREM measurements that nitriding leads to a stabilization of the UFG-microstructure, so that nitriding becomes feasible even at 500 °C.

T-24: Production of High-Strength Ultra-Fine Grained Joints in AA2014 by Multiple Pass Friction Stir Welding: *Geo Harrison*[1]; Preetam Anbukarasu[1]; Ganapathy Subramanian[1]; [1]College of Engineering Guindy, Anna University

AA2014 is one of the high strength and low density aluminum alloys having various industrial applications. Conventional welding processes yield unsatisfactory results in AA2014. Friction stir welding is an advanced joining process which can produce welds with appreciable mechanical properties. This process not only produces sound welds but also helps in reduction of grain size along the weld zone. When AA2014 T6 plates were subjected to multiple pass friction stir welding, joints with very high grain refinement and low grain size were obtained. The specimens also exhibited good tensile properties and micro-hardness values. Multiple-pass friction stir welding is a possible method for producing ultra-fine grained joints in AA2014 alloy.

T-25: Recrystallization Microstructure and Microtexture in an Ultrafine-Grained AlMgSi Alloy: *Aicha Loucif*[1]; Thierry Baudin[2]; François Brisset[2]; Roberto Figueiredo[3]; Rafik Chemam[1]; Terence Langdon[4]; [1]University Annaba; [2]University Paris-Sud France; [3]Federal University of Minas Gerais; [4]Departments of Aerospace & Mechanical Engineering

Microstructure and microtexture evolution were experimentally studied using EBSD measurements during an isothermal annealing treatment at 250°C of an AlMgSi alloy. The alloy had an initial grain size of 150 µm and was subjected to high-pressure torsion (HPT) up to 5 turns under an applied pressure of 6.0 GPa. The processing by HPT refined the microstructure to a mean grain size of approximately 500 nm. The annealing treatment gave grain growth so that the grain size reached about 2.5 µm after 15 minutes. The results show the strength directly correlates to the grain size and decreases when the grain size increases. An orientation distribution function (ODF) calculation revealed an isotropic texture for the initial state. After deformation, the ideal torsion texture components, in particular the C {001}<110> component, tended to develop. The texture sharpness increased during the annealing temperature.

T-26: Repetitive Corrugation and Straightening Rolling as a State of the Art Bulk Deformation Procedure: Arya Mirsepasi[1]; *Mahmoud Nili-Ahmadabadi*[1]; Mohammad Habibi-Parsa[1]; Hadi Ghasemi-Nanesa[1]; [1]University of Tehran

Much attention has been directed recently to ultra-grain refining of metallic materials, where the grain size is reduced to less than 1µm. It has been reported that ultrafine grains can be obtained by different methods of severe plastic deformation (SPD) such as equal channel angular pressing (ECAP), high pressure torsion (HPT), and accumulative roll bonding (ARB) as the most renowned ones. A recently developed SPD procedure called repetitive corrugation and straightening rolling (RCSR), has shown promising results in fabrication of UFG metallic materials to induce high strains after repetitive cycles. RCSR consists of corrugated rolls accompanying the capability of changing the position of the samples during different routes. Samples of Fe-Ni-Mn martensitic steel sheets were intensively deformed to a large accumulated strain by RCSR procedure. Microstructural and mechanical properties of the samples were studied by the aid of optical and scanning electron microscopy as well as mechanical testing.

T-27: Scaling up Equal-Channel Angular Pressing and its Effect on Billet Homogeneity: *Stephanie Hunger*[1]; Martin F.-X. Wagner[1]; Matthias Hockauf[1]; [1]Chemnitz University of Technology

Equal-channel angular pressing (ECAP) is a well known method for the processing of ultrafine-grained materials. Recently, several attempts have been made to upscale this process from laboratory scale to industrially relevant dimensions. In the present study, we investigate the influence of upscaling ECAP on billet homogeneity for oxygen-free high conductivity copper. The material was processed up to 8 passes at room temperature in two similar tools with cross sections of 15 x 15 mm² and 50 x 50 mm², respectively. Post-ECAP hardness area plots from the longitudinal planes of the billets indicate the presence of similar gradients (in terms of the degree of plastic deformation) after both small and large scale ECAP. These findings are also supported by microstructural characterization using electron backscatter diffraction. Our study reveals an excellent reproducibility of microstructural features and mechanical properties after ECAP processing in laboratory and industrial scale.

T-28: Severe Plastic Deformation on Surfaces by Exploiting Transitions in MaterialRemoval by Machining: *Yang Guo*[1]; Narayan Sundaram[1]; Srinivasan Chandrasekar[1]; [1]Purdue University

It is shown using direct image correlation measurements that large strains can be imposed over regions extending hundreds of micrometers in depth by “machining” with highly negative rake angle tools. The key to this method of severe plastic deformation (SPD) on surfaces is suppression of chip formation and transitions to various forms of flow, wherein material displaced by the tool forms various types of stationary "waves" ahead of the tool, as distinct from dead metal zones and chips. The conditions for establishing these waves, and the deformation imposed as the material traverses them are characterized by measurement and simulation. By compounding the deformations using appropriate tool designs, very large strains are imposed on the surface and into the depth. Ultrafine grained (UFG) microstructures consistent with the large deformation are observed.

T-29: Synthesis and Mechanical Properties of Cnt Reinforced Copper Based Nanocomposites: *Koteswararao Rajulapati*[1]; K Sreelatha[1]; V V S S Srikanth[1]; K Bhanu Sankara Rao[1]; [1]University of Hyderabad

Copper and copper based alloys have widely been used for electrical and thermal applications due to their high electrical and thermal conductivity. However when copper was strengthened by grain refinement, electrical conductivity has come down due to grain boundary scattering. Therefore, in order to have materials with high electrical conductivity as well as high strength, efforts are made to reinforce nanostructured copper matrix with carbon nano tubes (CNTs). Owing to their high electrical and thermal conductivity, CNTs reinforcement into the copper matrix could improve the performance of composites. In the present work, CNT reinforced copper based nanocomposites are synthesized by ball milling and structural details are investigated by XRD, TEM and Raman analysis. This nanostructured Cu-CNT composite is sintered using uniaxial compression and/or Spark Plasma Sintering to achieve full density and mechanical properties are evaluated micro/nanoindentation. The salient features pertaining to the microstructure, electrical and mechanical properties will be presented.

T-30: Synthesis ,Microstructure and Mechanical Behavior of Bulk Nanostructured Cu-30%Zn Alloy by Spark Plasma Sintering of Cryomilled Powders: *Haiming Wen*[1]; Troy Topping[1]; Enrique Lavernia[1]; [1]University of California, Davis

Powder metallurgy is widely used to synthesize bulk nanostructured metals. Cryomilling is one of the commonly used approaches to producing nanostructured metal powders. Spark plasma sintering (SPS) is an efficient consolidation technique. In this study we report on the synthesis of bulk nanostructured Cu-30%Zn alloy by cryomilling and subsequent consolidation of cryomilled powders by SPS, and microstructure and mechanical behavior of the consolidated bulk material. The results showed that cryomilling resulted in an average grain size of ~ 30 nm, and high density of deformation twins. Nearly full density was achieved after SPS. The sintered sample had a bimodal structure, with majority of grain sizes in the range of ~ 100 nm. A relatively high density of twins was retained after SPS. Mechanical tests showed that the sintered bulk sample had high strength and good ductility. The associated mechanisms were ascertained and discussed.

T-31: The Effect of Alloying with Hafnium on theThermal Stability of Chromium Bronze after Severe Plastic Deformation: *Daria Shangina*[1]; Natalia Bochvar[1]; Sergey Dobatkin[1]; [1]A.A.Baikov Institute of Metallurgy and Materials Science, Russian Academy of Sciences

The structure, microhardness, and electrical resistivity of the Cu-0.75%Cr and Cu-0.66% Cr-0.89%Hf alloys after high pressure torsion (HPT) have been studied. The alloys were deformed in two initial states: in the as-quenched state (T=900°C) and after annealing (T=600°C). The initial heat treatment of the Cu-Cr alloy affects the properties of the material after following heating: quenching compared to the annealing significantly increases the thermal stability of the alloy (up to 250°C and 150°C, respectively). It is shown that alloying with hafnium improves the properties of low-alloy chromium bronze, and the strengthening of the Cu-Cr-Hf alloy upon HPT is substantially higher than that of the Cu-Cr alloy, both for the "quenching + HPT" and "annealing + HPT" regimes. In the alloy with hafnium, the softening begins at substantially higher temperature (450°C), which is the same for both treatments. The work was supported by RFBR (project no. 10-08-00594).

T-32: The Effects of Deformation Strain and Temperature on Microstructures and Tensile Properties in a Commercial Purity Aluminium: *ShinWoong Jeong*[1]; Ho Jin Lee[1]; Won Jong Nam[1]; [1]Kookmin University

The microstructures of a commercial purity aluminium (Al 1050) deformed at cryogenic temperature was investigated, compared with that deformed at room temperature. The microstructural evolution with increasing the deformation strain was investigated using transmission electron microscope for sample deformed at both temperatures. The results showed that the deformation at cryogenic temperature produced a higher work hardening rate than the deformation at room temperature at low strain. The difference of hardness might be attributed to the difference of the rate in accumulating dislocations during deformation. However, at high strain the difference of hardness between two deformation temperatures becomes negligible. This would come from the occurrence of dynamic recovery. In addition, the kinetic of softening behavior during post-deformation annealing was discussed with the data from differential scanning calorimeter.

T-33: Transmission Electron Microscopy and Synchrotron X-ray Texture Analysis of BCC Metals Processed by High Pressure Torsion: *Jonathan Ligda*[1]; Brian Schuster[2]; Yang Ren[3]; Qiuming Wei[1]; [1]UNC Charlotte; [2]Army Research Laboratory; [3]Argonne National Laboratory

Grain refinement by severe plastic deformation, specifically high pressure torsion (HPT), is capable of introducing large amounts of strain into disks with only millimeter dimensions, resulting in nanometer level grain sizes. However, this is an inhomogeneous process, creating a strain gradient between the center and edge of the disk. Differing amounts of total strain could lead to a change in the deformation texture and microstructure with position. Texture analysis of six body center cubic metals processed by HPT is done by collecting transmission Debye-Scherrer patterns at multiple locations across the sample disk. Studies are performed at the Advanced Photon Source in Argonne National Lab, using beamline 11-ID-C. Using a focused ion beam microscope, transmission electron microscope lamellas are also created at multiple locations to record any microstructure changes. The combination of methods allows for an accurate record of any microstructure changes, which could influence the mechanical properties of the material.

T-34: UFG-Surface Layer on DD11 Mild Steel Profiles Produced by Linear Bend Splitting (LBS): *Vanessa Kaune*[1]; Clemens Müller[1]; [1]Technische Universität Darmstadt

An approach to improve global properties of a component is the generation of an ultrafine grained (UFG) surface layer induced by surface severe plastic deformation (SSPD). Linear Bend Splitting (LBS) is a new continuous process, which generates bifurcated profiles in integral style from plain metal sheet. Due to the high deformation in the splitting zone, an UFG microstructure develops on the surface of the produced flanges up to a depth of several hundred microns. In the present paper, the linear bend splitting process will be presented with special regard to the SSPD aspects, leading to UFG micro structural gradients in the flanges. On the low alloyed mild steel DD11, the microstructure and the mechanical properties of the linear bend split profiles are investigated, using EBSD measurements, hardness indentations and tensile tests. From the results, some interesting technical applications of LBS will be derived.

T-35: Ultrafine Grain Refinement of Biomedical Co-Cr-Mo Alloy from Cryogenic Burnishing for Enhanced Wear Resistance: *S. Yang*[1]; Z. Pu[1]; O.W. Dillon[1]; D.A. Puleo[1]; J.C. Outerio[2]; I.S. Jawahir[1]; [1]University of Kentucky; [2]Catholic University of Portugal

Co-Cr-Mo alloy was subjected to a novel mechanical processing method-cryogenic burnishing; the surface of Co-Cr-Mo pins was burnished with a custom tool under a liquid nitrogen spraying condition. The processing led to a more than 100 µm thick surface layer with remarkably refined microstructures formed on the surface. From an initial grain size of 80 µm, an ultrafine-grained microstructure with a grain size of approximately 500 nm was obtained within this surface layer due to severe plastic deformation (SPD) induced dynamic recrystallization (DRX) and effective cooling by liquid nitrogen. The grain refinement due to DRX was identified by means of scanning electron microscopy (SEM) observations. Large compressive residual stresses and deep compressive residual stress field (more than 200 μm) were identified on the surface and within subsurface layers by X-ray diffraction measurements. The wear performance of the cryogenically burnished pins was evaluated by pin-on-disc wear tests.

T-36: Unusual Martensite Decomposition in a UFG Cu-Al Alloy: *Guofan Zhang*[1]; Xavier Sauvage[2]; Jing Tao Wang[1]; Nong Gao[3]; Terence. G. Langdon[4]; [1]NUST; [2]University of Rouen; [3]University of Southampton; [4]University of Southern California

The phase decompositions of both coarse-grained and as-processed ultrafine martensite were investigated in Cu-11.8wt.%Al alloys. High Pressure Torsion (HPT) was used to process the alloy. The microstructures were characterized by optical microscopy (OM), X-ray diffraction (XRD), scanning electron microscopy (SEM) and transmission electron microscopy (TEM) and the microhardness of all states was measured. The results show that, before the $\beta' \rightarrow (\gamma_1 + \alpha)$ decomposition reaction, some transition phases appear firstly in the coarse martensite, while the ultrafine martensite skips the transition phase and the $\beta' \rightarrow (\gamma_1 + \alpha)$ decomposition reaction occurs directly in the early stage of annealing. It was also found that the decomposition of the ultrafine martensite is much faster than in the coarse-grained state although there are similar phases after annealing.

T-37: Wear Resistance of Nanocrystallined Cu-Diamond Composites Processed by HIgh PressureTorsion: *Eun Yoo Yoon*[1]; Dong Jun Lee[1]; Taek-Soo Kim[2]; Ha-Guk Jeong[2]; Chong Soo Lee[1]; Hyoung Seop Kim[1]; [1]POSTECH; [2]Korea Institute of Industrial Technology (KITECH)

In this work, superior mechanical properties of nanocrystalline metal matrices embedded with diamonds were obtained by HPT. Neither heating nor sintering was required with the HPT process so that an in situ consolidation was successfully achieved at ambient temperature. Significant nanocrystalline structures by increasing diamond volume fractions were observed by EBSD. Hardness and wear resistance of the Cu-diamond nanocomposites are enhanced, compared to those of Cu matrix. The enhancement of the hardness is due to good bonding in Cu-diamond interfaces and high relative density of the nanocomposites. The diamonds Cu-matrix nanocomposite gives significantly enhanced wear resistance by retarding the peeling of Cu grains during sliding wear process. This study was supported by a grant from the Fundamental R&D Program for Core Technology of Materials (10037206) funded by the Ministry of Knowledge Economy, Korea.

General Poster Session: Session I

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Extraction and Processing Division, TMS Light Metals Division, TMS Materials Processing and Manufacturing Division, TMS Structural Materials Division

Monday PM	Room: Atlantic Hall
March 12, 2012	Location: Dolphin Resort

Session Chair: To Be Announced

W-1: A Novel Simultaneous Thermal Analysis (STA) Furnace with Tungsten Heating Element for Measurements under High-Purity Inert Gas Atmospheres and High Vacuum: *Ekkehard Post*[1]; Bob Fidler[2]; [1]NETZSCH Geraetebau GmbH; [2]NETZSCH Instruments North America, LLC

Many high-melting metals form metal carbides or also eutectic systems with carbon. By trying to determine the melting point of such metals by means of the differential thermal analysis (DTA) technique in a furnace with carbon heating elements, this value is often false or too low. This is generally due to the carbon-containing atmosphere in these furnaces which can be explained by the considerable vapor pressure of the carbon at such high temperatures. This can also cause problems during melting of high-melting oxides. Here, premature decomposition can occur.A tungsten furnace, however, allows for an oxygen- and carbon-free atmosphere during DTA measurements and therefore yields the true values for the melting point and melting enthalpy. This poster illustrates the design of the furnace and STA instrument, respectively. With the example of measurement results on metals/ceramics, the differences in the results obtained with a graphite furnace and a tungsten furnace are presented.

W-2: A Study on Fatigue Strength of Railroad Truck: *Sung Cheol Yoon*[1]; Jeongguk Kim[1]; Sung Hyuk Park[1]; Dong Hoe Koo[1]; Kang Youn Choe[1]; [1]Korea Railroad Research Institute

This paper describes the results of structural analysis and loading test of a truck frame. The purpose of the analysis and test is to evaluate the safety and functionality of the truck frame under maximum load. The truck system consists of the truck frame, suspensions, wheel-sets, a brake system and a transmission system. Among these components, the truck frame is the major component subjected to the vehicle and passenger loads. The truck frame, which is a running system for railway rolling stock, is a key structural part that supports the car body's load. And it significantly influences the safety of the passengers and the railway vehicle, running performance, and riding comfort. The performance test was conducted by installing the strain gauge where high stress is expected under each load condition, based on the result of the structural analysis.

W-3: A Study on Production of Fe-Cr-Ni-Ti Alloys by Metallothermic Processes: *Cem Colakoglu*[1]; Murat Alkan[1]; Onuralp Yücel[1]; [1]Istanbul Technical University

This study covers information about Fe-Cr-Ni-Ti alloys production by metallothermic reduction of Fe_2O_3-Cr_2O_3-NiO-TiO_2 powder mixtures. Metallothermic reactions were realized by using a stainless steel SHS reactor. Different ratios of Cr/Ni/Ti were carried out in the metallothermic experiments, and addition of excess stoichiometric amount of Al_2O_3 powders were added to the initial mixture. The raw materials, alloys and slags were characterized by using XRD (X-Ray Diffractometry), and Scanning Electron Microscobe (SEM).

W-4: Ab Initio Optical Properties of Orthorhombic CdGeO3: *Eudenilson Albuquerque*[1]; Umberto Fulco[1]; [1]Universidade Federal do Rio Grande do Norte

The structural and optoelectronic properties of orthorhombic perovskite cadmium germanate CdGeO3 was studied using quantum first principles calculations based on the density-functional theory (DFT) formalism, considering both the local density and generalized gradient approximations, LDA and GGA, respectively. Our results suggest that it has some features of a wide band gap semiconductor and that it is potentially useful for optoelectronic applications. The electronic part of the GGA dielectric constant for CdGeO3 as a polycrystalline sample is 6.29, and the optical absorption presents its first pronounced peak due to electronic transitions from valence bands to conduction bands originated mostly from Ge 4s orbitals. A comparison with the corresponding results for CaGeO3 orthorhombic is also performed, showing how the replacement of Ca (Pauling ionic radius 0.99 Å) with Cd (Pauling ionic radius 0.97 Å) modifies the electronic band structures and partial densities of states, as well as their optical properties.

W-5: An Investigation of the Electrochemical Properties of TiAlCrN PVD Coated in STS316: *Min-Seok Moon*[1]; Kee-Do Woo[2]; Min-Goo Lee[2]; Je-Ha Oh[3]; Shin-Jae Kang[4]; Dae-Up KIM[5]; [1]Chonbuk National University, Jeonju Institute of Machinery Carbon Composites; [2]Chonbuk National University; [3]Jeonju Institute of Machinery and Carbon Composites; [4]Chonbuk National University, Jeonju Institute of Machinery and Carbon Composites; [5]Korea Institute of Industrial Technology

Bipolar plate is a key component of PEMFC and other Fuel Cell system, and it has a big portion of the weight and total cost of a fuel cell stack. Nowadays, many investigators consider replacement bipolar plate materials from non-porous graphite to the metallic bipolar plate. In this study, try to TiAlCrN nitride coating process on an austenitic stainless steel (STS316) by PVD technology (plasma enhanced reactive evaporation) to increase the corrosion resistance of the STS316. STS316 has good corrosion resistance in the atmosphere. This study is the focus on this coated material could potentially be used in PEMFCs as a bipolar plate material provided. It is also satisfying the physical and mechanical property such as the interfacial contact resistance, light weight, high mechanical strength and manufacturing ability.

W-6: Atomistic Simulations of Oxygen Diffusion in Alumina: Ulrich Aschauer[1]; *Abhishek Tewari*[2]; Paul Bowen[2]; [1]Eidgenössische Technische Hachschule Zurich; [2]Ecole Polytechnique Federale de Lausanne

Understanding diffusion is a cornerstone in materials science. Nevertheless, solid state diffusion mechanisms are poorly understood even for well-studied systems, such as alumina. Previous simulation studies have failed to capture experimental observations, calculated activation energies being smaller than experiment. We developed a new approach based on the combination of Metadynamics and kinetic Monte Carlo simulations, to simulate oxygen vacancy diffusion in alumina. A set of highly correlated low energy transitions forms closed triangular loops, which do not contribute to macroscopic diffusion. Vacancy diffusion is governed by jumps with relatively higher activation energy, but still lower than that reported experimentally. The method was further developed for a fully periodic environment enabling the study of the atomic diffusion of oxygen in alumina, which allows us to compare simulation results with experimental Oxygen atomic diffusion plots. Effect of dopant/defect association is the focus of current study to explain the high experimental activation energies.

W-7: Bonding between Al and Cu by both Vacuum Hot Pressing and Solid-Liquid Hybrid Sheet Fabrication Process: *Kwang Seok Lee*[1]; Yong-Nam Kwon[1]; [1]Korea Institute of Materials Science

Cladding between dissimilar metals has attracted great attention indebted to their unique advantage for the viewpoint of multi-functionality. For example, Al/Cu bimetallic joint materials have advantages due to their excellent properties combining aluminum's lightweight, low density, corrosion resistance, with copper's high conductivity. However, aluminum surface is easily oxidized which hinders Al-Cu joint in metallurgical bonding. From bad to worse, various intermetallic compound (IMC) layers are usually generated on the Al-Cu interface at elevated temperatures, which causes detrimental effect on both mechanical properties and electrical conductivity of the entire hybrid composite. In order to overcome aforementioned drawback, we systematically investigated the possibility to bond between the dissimilar metals like Cu and Al using both the solid-based vacuum hot pressing and hybrid sheet fabrication technique by utilizing solid Cu-liquid Al. The influence of process conditions upon the interface microstructure and subsequent physical/mechanical properties for the entire composites was then discussed.

W-8: Characterization and Performance of Novel Amorphous Oxide Anodes for Chlorine Evolution in Industrial Electrolysis Using Chloride-Based Solutions: *Akari Miwa*[1]; Masatsugu Morimitsu[1]; [1]Doshisha University

This paper presents a novel amorphous oxide anode for chlorine evolution from chloride-based solutions used in industrial electrolysis such as chloro-alkali electrolysis, electrowinning, and electroplating. The amorphous oxide was produced by thermal decomposition of a precursor solution. The characterization of the oxide was carried out with XRD, SEM, and XPS. The performance of the anode was also investigated using aqueous solutions containing chloride ions, in which chlorine evolution is the main reaction on the anode. The results indicated that the developed anode showed a low chlorine overpotential comparable to commercially available dimensionally stable anodes with ruthenium and titanium composite oxides.

W-9: Characterization of an Aged Ti49Ni26Au25 Shape Memory Alloy: *Todd Butler*[1]; Mohamed Abdalla[2]; B. Hornbuckle[1]; Ronald Noebe[3]; Glen Bigelow[3]; Gregory Thompson[1]; Mark Weaver[1]; [1]Univ of Alabama; [2]Tuskegee University; [3]NASA Glenn Research Center

Ternary NiTi-X based alloys, where X = Pt, Pd, Hf, Au or Zr, show promise as high temperature shape memory alloys (HTSMAs). In comparison to binary NiTi alloys, some hypostoichiometric versions of these ternary compositions exhibit higher transformation temperatures and better mechanical stability due to the formation of nano-scale precipitates. In this study, Ti49Ni26Au25 (at.%) was solution annealed at 1050 °C for 3 hours and aged at 400 °C. Peak hardness was achieved after aging for 48 hours, which was slow in comparison to similar alloys with Pt and Pd additions. The structure and chemistry of the phases formed in this alloy were characterized by x-ray diffraction, transmission electron microscopy, scanning electron microscopy, energy-dispersive x ray spectroscopy, and three-dimensional atom probe tomography. The results will be discussed relative to other potential precipitate-reinforced HTSMAs.

W-10: Characterization of Oxide Bifilm Inclusion Defects in Vacuum Cast Ni-Base Superalloy: *Max Kaplan*[1]; Gerhard Fuchs[1]; [1]University of Florida

Oxide bifilms are reported to form during turbulent pouring of castings via furling of a thin skin of oxide that forms on the surface of the melt by reacting with residual environmental oxygen. This oxide is said to entrain into the bulk of the material, reside in the interdendritic region of the alloy, and unfurl and inflate by ingress of dissolved gasses to create casting porosity. It has also been reported that EDS is a viable technique for characterizing bifilms found in vacuum cast Ni-base superalloys. B1900 was used to investigate casting porosity and dendritic structures within casting porosity appearing to be coated by bifilms. Examination by SEM imaging and characterization by EDS were utilized. The results of this work did not indicate the presence of bifilms, and instead led to explanation of casting porosity with more conventional concepts.

W-11: Combined Cavitation and Particle Erosion of Brass: Amarendra H.J.[1]; *Gajanan Chaudhari*[1]; S.K. Nath[1]; [1]IIT Roorkee

The material removal in hydraulic components may occur either by particle erosion or cavitation erosion or by the combined action of both. A novel method is employed that combines the effect of particle erosion and cavitation erosion, in order to test brass under laboratory conditions. Triangular prismatic bluff bodies are used as cavitation inducers in the conventional slurry pot tester. In the slurry pot the brass test specimens are exposed to water/slurry, with and without cavitation inducers. Analysis of the wear results reveals significant variations in material loss confirming synergistic erosion damage. Effects of the apex angles and positioning of the cavitation inducer with respect to the test specimen are systematically investigated.

POSTERS

W-12: Determination of Interfacial Heat Transfer and Air-gap Formation during ingot Casting into Permanent Metal Moulds: *Jason Swan*[1]; [1]University of Birmingham

The formation of an air gap at the casting-mould interface during solidification significantly affects local cooling rates and the magnitude of heat transfer mechanisms. The thickness of the air-gap was investigated experimentally by optically measuring displacements of the mould and the casting surface during solidification of Aluminium and Nickel-based alloys cast into cylindrical grey cast iron moulds. Temperature measurements of the mould and casting allowed Interfacial Heat Transfer Coefficients (IHTC) to be calculated. The measured IHTC values were used to validate a numerical model of heat transfer and shrinkage during casting. It is predicted for the Nickel-based alloy when the air-gap is below 0.3mm heat conduction is the dominant heat transfer process; above 0.3mm radiation is the dominating factor. Due to the lower temperatures in Aluminium the transition from conduction being dominant to radiation is predicted to occur at 2.3mm; above the expected air-gap magnitude in these experiments.

W-13: Development of 3D Porous Nickel Electrodes for Hydrogen Production: *Valentín Pérez-Herranz*[1]; Isaac Herráiz-Cardona[1]; Emma Ortega[1]; José García-Antón[1]; [1]Universidad Politécnnica de Valencia

The production of hydrogen is of particular interest because hydrogen is considered as a clean fuel. Hydrogen production via electrolysis of water from alkaline aqueous electrolytes is a well-established conventional technology. However, the high energy consumption retrains its large-scale application at present. This work focusses on the development of nickel electrodes with excessive surface areas. The construction of 3D porous structures was achieved by means of a hydrogen bubble dynamic template, prepared from electrochemical deposition processes. Cu was electrodeposited and grew within the interstitial spaces between the hydrogen bubbles to form a macroporous film of Cu nanoparticles on the substrate. Subsequently, a Ni layer was electrodeposited on the Cu template. The hydrogen evolution reaction was evaluated in alkaline media by means of steady-state polarization curves and electrochemical impedance spectroscopy. The developed electrodes exhibited a significantly reduced overpotential for the HER when comparing to the commercial smooth Ni electrode

W-14: Development of Fretting Fatigue Parameter: *Hyukjae Lee*[1]; [1]Andong National University

New multi-axial, critical plane based, fretting fatigue crack initiation parameter is developed by the addition of a new term into the Modified Shear Stress Range (MSSR) parameter. The newly developed parameter (MSSR') is then used to evaluate fretting fatigue life of titanium alloy, Ti-6Al-4V with various contact conditions. Finite element analysis is also used in order to obtain stress distribution on the contact surface during fretting fatigue test, which is then used for the calculation of fretting fatigue parameter. The MSSR' parameter shows better performance in predicting fretting fatigue lives from the conventional fatigue data, and less scattering within fretting fatigue data with different contact geometries.

W-15: Development of $Ru_xTi_{1-x}O_2$/Ti Anodes by Low Temperature Thermal Decomposition for Nickel Electrowinning: *Masaru Matsuda*[1]; Masatsugu Morimitsu[1]; [1]Doshisha University

Smart anodes, MSA™, consisting of a composite oxide, $Ru_xTi_{1-x}O_2$, formed on a titanium substrate for nickel electrowinning were developed by thermal decomposition of a precursor solution containing ruthenium and titanium compounds. Low temperature thermal decomposition produced less crystalline or amorphous composite oxides on the substrate, and such oxides showed a high catalytic activity for chlorine evolution and reduced the cell voltage of nickel electrowinning from chloride-based solutions. The effects of the thermal decomposition temperature on the crystallographic structure, the surface morphology, and the performance of the anode will be shown.

W-16: Effect of Al2Ca Addition and Mg Content on Microstructure and Tensile Properties of Diecast Al-9Si-2Cu-Mg Alloys: *Jung Ho Seo*[1]; Nam-Seok Kim[1]; Young-Ok Yoon[1]; Shae K. Kim[1]; [1]Korea Institute of Industrial Technology

Al-Si-Cu-Mg casting alloys are widely used in the automotive components because of high fluidity and high corrosion resistance. Although it is well known that the strength of Al alloys increases with increasing Mg content, the Mg content is kept under 0.3 wt% in most current Al-Si-Cu-Mg casting alloys. That is because Mg-based oxides and hard inclusions which decrease melt fluidity and mechanical properties are formed more largely during alloying and casting due to the high oxygen affinity of Mg especially in mass production on-site. In this study, the effect of Al2Ca addition and Mg content on microstructure and tensile properties of diecast Al-9Si-2Cu-Mg alloys were investigated. The ingots for high pressure diecasting were prepared from Al-9Si-2Cu with Mg master alloys containing Al2Ca for the addition of Al2Ca and high Mg in Al-9Si-2Cu. Microstructure and tensile properties of these diecast alloys were examined in comparison with those of conventional Al-9Si-2Cu-Mg alloys.

W-17: Effect of Be and CaO on the Ignition Resistance of Mg Melts: *Lee Jin-Kyu*[1]; Yang Won-Seok[1]; Kim Shae K.[1]; [1]Korea Institute of Industrial Technology

Molten Mg and Mg alloys are easily oxidized and ignited without melt protective gases during melting and casting processes due to their high reactivity. There have been 3 approaches to overcome this problem. The molten Mg should be protected from oxidation by blanketing the surface with flux or protective gases. Beryllium is added into almost Mg alloys. It has been revealed to be very useful in terms of suppressed ignition of Mg melts, related melt cleanliness and ensuring safety during manufacturing and application. However, beryllium addition should be carefully handled due to its toxicity. CaO added Mg alloys (Eco-Mg alloys) can improve ignition resistance of Mg melts and melt quality. This paper will discuss the effect of beryllium addition on ignition resistance of Mg melts under protective gas atmosphere. The ignition resistance results were evaluated in comparison with those of CaO added Mg alloys.

W-18: Effect of Ca Addition on Creep and Mechanical Properties in Mg-4Zn Alloys: *Gun Young Oh*[1]; Hyun Kyu Lim[1]; Shae K Kim[1]; [1]KITECH

Mg alloys exhibit a promising combination of properties including low density, high specific strength, stiffness, good process-ability, and adequate ductility. Because of these attractive properties, Mg alloys are considered to have a strong potential for weight saving in automotive and aerospace components. The researches on Mg alloys so far mainly concentrated on the improvement of strength and ductility of the conventional alloy systems such as AZ91 alloys. But Mg-Al alloy system is unstable for use at temperatures above 120□ because of its poor creep resistance and strength at elevated temperature. In the present study, the effect of Ca addition on creep and mechanical properties in Mg-4Zn alloys has been investigated. Creep properties of Mg-4Zn based alloys measured at 150□ under applied stresses of 80 MPa were improved with increasing Ca content. This result comes from the existence of thermally stable phases such as Mg2Ca and Ca2Mg6Zn3 phases.

W-19: Effect of Carbon on Structural Changes in Ni_3Al Phase: Andrzej Janas[1]; Ewa Olejnik[1]; Beata Grabowska[1]; *Jacek Nawrocki*[2]; [1]AGH University of Science and Technology; [2]WSK Rzeszow S.A.

The paper presents the X-ray diffraction and metallographic studies of carbon influence on structural changes in Ni_3Al phase. The base alloys were prepared maintaining the nominal atomic ratio of Ni/Al = 3:1. Next, carbon was instilled into the liquid alloy at a rate of 0.2, 0.25, 0.5, 0.75, 1 and 1.25 wt.% by weight for individual alloys, respectively. Final castings were cut into pieces and specimens were prepared for X-ray diffraction and microscopic studies. Their phase composition was analyzed together with structural changes occurring within the Ni_3Al phase. Some changes in the lattice constants of Ni_3Al phase were noticed, and they amounted to

0.3580 nm and 0.3589 nm for 0.2 wt.% C and 1.25 wt.% C, respectively. In the alloy containing 1.25 wt.% C, a graphite (001) atomic plane was noticed. This result was also confirmed by researches with SEM imaging, in which numerous graphite precipitates of lamellar and nodular shape were observed.

W-20: Effect of Carbon on Wear Resistance in Self-Lubricating Fe-Cr-C-Mn-Cu Alloys: Ki Nam Kim[1]; *Myung Chul Park*[1]; Gyeong Su Shin[1]; Min Ho Shin[1]; Seon Jin Kim[1]; [1]Hanyang Univ.

Recently, because of safety and environmental concerns, there has been a tendency to use solid self-lubricating composites for bearing materials. In this study, we developed a Fe-Cr-C-Mn-Cu cast composite alloy as a self-lubricating composite and investigated the effect of carbon on the formation of protective tribofilms during sliding. The wear resistance of these materials is mainly affected by carbon concentrations because wear transitions from delamination to tribo-oxidation, reducing wear rate. The improved wear resistance likely results from protective tribofilms that form on the surface during sliding.

W-21: Effect of Dispersed SiC and Y2O3 Particles on the High-Temperature Oxidation of AZ91D Magnesium Alloys: *Min Jung Kim*[1]; Chenguang Zhao[1]; Seulki Kim[1]; Dong Bok Lee[1]; [1]Sungkyunkwan University

AZ91D magnesium composites containing SiC and Y2O3 dispersoids were cast, and their high-temperature oxidation was investigated in air. In case of Y2O3-containing composites, oxidation rates increased linearly, with an increase in the temperature and time. SiC particles did not oxidize during oxidation, and increased the oxidation resistance through diminishing the exposed surface area. With the increase in the amount of SiC particles from 5 to 10, and to 20 wt.%, the oxidation resistance increased. In case of SiC-containing composites, Al and Mg diffused into Y2O3 particles to form (Al,Y)O and to supersaturate within Y2O3. Although Y2O3 increased the oxidation resistance, the composite experienced rapid oxidation and burning, because non-protective MgO was the main oxide. Acknowledgement. This work is the outcome of “Environment-friendly and Energy-efficient Manufacturing Technology of Eco-Mg” program (No. 10035292-2010-01) funded by the Korea government Ministry of Knowledge Economy (MKE).

W-22: Effect of Hydrothermal Process on the Relative Surface Area of Porous Ni-Based BMG Foam: *Ji Su Kim*[1]; Do-Hyang Kim[2]; Min-Ha Lee[1]; [1]Kitech; [2]Yonsei University

Metallic foams are under consideration as highly functional material, such as energy absorbers or ultra-lightweight, due to their porous structure combined with desirable strengths at relatively low densities. In current study, Ni-based metallic glass foams were fabricated by extruding powder mixtures comprised of metallic glasses blended with various kinds of fugitive phases followed by dissolution of the fugitive phases in an aqueous chemical solution to yield the final porous structure. The effect of surface treatment by hydrothermal process on the specific surface area in porous Ni59Zr20Ti16Si2Sn3 metallic glass was investigated. As a result of hydrothermal reaction, intermetallic phases was growth on the surface of warm extruded porous Ni59Zr20Ti16Si2Sn3 metallic glass under high pressure and temperature autoclave conditions during 12 hr, 24 hr and 48 hr, respectively. The characterization of hydrothermal processed Ni-based metallic glass foam was evaluated by SEM, XRD, DSC and BET method.

W-23: Effect of Porosity on Room Temperature Thermal Conductivity and Mechanical Properties of Porous Ti2AlC: *Liangfa Hu*[1]; Sandip Basu[2]; Rogelio Benitez[2]; Ibrahim Karaman[1]; Miladin Radovic[1]; [1]Materials Science and Engineering Program, Texas A&M University; [2]Department of Mechanical Engineering, Texas A&M University

The ternary compound Ti2AlC - one of the best studied materials from the MAX phase family - is a potential material for high temperature structures due to its high oxidation resistance and damage tolerance. Whereas, the properties of fully dense Ti2AlC have been well characterized, little is known about processing and properties of porous Ti2AlC. In this work, we demonstrate a simple and inexpensive way to process porous Ti2AlC with controlled porosity and pore-sizes, using NaCl as the pore former. Porous Ti2AlC with porosity levels ranging from 5 to 75 vol.% and different pore-sizes, i.e 45-90 um, 180-250 um and 355-500 um, were successfully fabricated and characterized. The effects of porosity on the room temperature thermal conductivity, elastic moduli and compressive strength of porous Ti2AlC are determined. It follows that porosity becomes a useful microstructural parameter that can be used to tune thermal and mechanical properties of Ti2AlC.

W-24: Effect of Powder Morphology, Powder Preheating,

Nozzle Geometry on the Properties and Deposition Behavior of Titanium Coating in Cold Spray: *Kee-Ahn Lee*[1]; Jae-Nam Hwang[1]; Ji-Sang Yu[1]; Hyung-Jun Kim[2]; [1]Andong National University; [2]RIST

Cold spray deposition using Ti powder was carried out to investigate the effects of powder morphology (spherical and irregular), powder preheating (30°C and 500°C) and nozzle geometry (round and plate) on the coating properties such as deposition efficiency, porosity, hardness, and microstructure. The in-flight particle velocity of powder in cold spray process was directly measured using PIV equipment. The correlations of in-flight particle velocity with the coating properties were tried. Coating layer by using irregular morphology powder represents lower porosity, and higher deposition efficiency & hardness. Porosity also decreases and deposition efficiency and hardness increase with increasing pre-heating temperature. The particles using round nozzle shows higher in-flight particle velocity, thus results in better coating properties. The deposition mechanism of particles in cold spraying process was also discussed. [supported by “the program for the Industrial Strategic Technology Development” and “the program for the Training of Graduate Students in Regional Innovation”, Korea]

W-25: Effect of Processing Parameters on Morphology of Electrodeposited CZTS Thin Films: *Marilene Serna*[1]; Eguiberto Galego[1]; Lalgudi Ramanathan[1]; [1]CNEN-IPEN/SP

CZTS (Cu_2ZnSnS_4) thin films are viable materials for low-cost thin film type solar cells. The effect of electrolyte pH and temperature as well as deposition sequence on the morphology of electrodeposited CZTS films was studied. Control of CZT film morphology is essential to avoid loss of tin and to allow diffusion of sulfur during annealing. The three elements were electrodeposited on Mo foil, in stages from corresponding unstirred baths. In each bath, the pH was controlled by addition of sodium hydroxide and choline cloride. In-between baths with distinct pH, the substrate was dipped in dilute sulfidric acid. Comparison of micrographs suggests that sodium hydroxide and choline chloride helped smooth the surface of each layer in the stack.

W-26: Effect of Reactive Extrusion on the Mechanical Properties of PLA Blends: *Gustavo Brito*[1]; Shirley Cavalcanti[1]; Pankaj Agrawal[1]; Edcleide Araujo[1]; Tomás Mélo[1]; [1]Federal University of Campina Grande - UFCG

Biodegradable polymers has attracted great attention in the latest years. Due to its characteritics, the poly(lactic acid) presents potencial to replace some petroleum-based polymers. Unfortunately, the inherent brittleness of PLA prevent it from practical applications. Blending PLA with other polymers presents a measure to obtain toughened polymers. However, most of the systems are immiscible, so they need to be compatibilized. An in situ reaction between the components during melt-blending, forming copolymers at the interface, is one manner to obtain a good compatibilization. In this study, attention was focused on the improvement of the mechanical properties of PLA, especially, impact strength. The PLA was blended with two flexible polymers, one with reactive groups and the other one without reactive groups. Mechanical tests and morphological analysis were carried out. The flexible polymers with reactive groups presented a better interaction between the components of the blend and greater impact strength.

W-27: Effect of the Seed Layer on the Growth of ZnO Nanorod Arrays: *Kyung-Bong Park*[1]; Jun-Ho Shin[1]; Hyukjae Lee[1]; [1]Andong National University

ZnO nanorod arrays on the ZnO seed layer are synthesized for Dye Sensitive Solar Cell (DSSC). ZnO thin film as a seed layer is prepared by spin-coating, and the grain size and preferred orientation of the seed layer are strongly depend on the post annealing condition. These gran size and preferred orientation of the seed layer also affect the growth characteristics of the ZnO nanorod arrays, which grow on the seed layer using chemical bath deposition. Finally, the current –voltage characteristics of the DSSC using ZnO nanorods are measured with a solar cell test system.

W-28: Effect of Thiodiglycolamide Addition to Di-n-hexyl Sulfide on the Pd(II) Extraction Rate: *Hirokazu Narita*[1]; Mikiya Tanaka[1]; Shinji Ueno[2]; [1]National Institute of Advanced Industrial Science and Technology; [2]N. E. CHEMCAT

For the palladium extraction, di-n-hexyl sulfide (DHS) has been widely introduced for practical use. Although they can selectively extract Pd(II) from acidic chloride solution, the Pd(II) extraction is very slow. Therefore, in this study, we investigated the effect of thiodiglycolamide (TDGA) addition to DHS on the extraction rate of Pd(II) from hydrochloric acid solutions. In the 0.1 M DHS (diluent: 80 vol% n-dodecane and 20 vol % 2-ethylhexanol)-5 g/L of Pd(II) in 1 M HCl system, it takes more than 240 min to attain the extraction equilibrium. In contrast, the Pd(II) extraction is accelerated by adding a small amount of N,N'-dimethyl-N,N'-di-n-octyl-thiodiglycolamide (MOTDGA): the extraction percentage of Pd(II) with 0.01 M MOTDGA-0.09 M DHS reaches almost 100% in the very short extraction time (= 5 min).

W-29: Effect of TiO2 Composite Photoelectrode on the Photovoltaic Efficiency of Dye-Sensitized Solar Cells: *Kyung-Bong Park*[1]; Jin-Il Park[1]; Hyukjae Lee[1]; [1]Andong National University

One-dimensional nanomaterials in dye-sensitized solar cells are expected to improve the electron transfer and light scattering, which can enhance the light-to-electricity conversion efficiency of dye-sensitized solar cell (DSSC). However, the reduced surface area of one-dimensional nanomaterials as compared to the nanoparticulates can be detrimental. Thus, TiO2 nanoparticles/nanowire composite electrode was prepared by hydrothermal method in this study in order to improve the electron transfer without costing the high surface area. The experimental results showed that the DSSC made of TiO2 nanoparticles/nanowire composite photoelectrode had better photovoltaic performance than those with TiO2 nanoparticulate or nanowire photoelectrodes.

W-30: Effects of Different Gas Additions in Hydrogen for Hydrogen Storage Capacity on Li-Based Hydrides after Pressure Cycling: *Wen-Ming Chien*[1]; Joshua Lamb[1]; Dhanesh Chandra[1]; [1]University of Nevada, Reno

Lithium imide/amide hydriding/de-hydriding pressure equilibrium isotherms were obtained at 255°C after cycling with different gas additions in hydrogen between Li2NH and LiNH2. The results showed that the nitrogen addition both improved the hydrogen capacity as well as improved the stability of the hydrides after cycling. Other results by using different gas additions in hydrogen showed the loss of the hydrogen storage capacity after cycling. After 560 pressure cycles, 100 ppm O2 in hydrogen were most detrimental (0.4 wt%H2 capacity remaining out of ~5.6 wt.%) as compared to 100 ppm H2O in hydrogen gas (2 wt%H2). It was found that 1.65 wt.% hydrogen remained after 500 cycles by using industrial hydrogen. The 100 ppmN2 addition in H2 improved the hydrogen storage capacity to 7.0 wt.% after 853 cycles, and for 20%N2 in H2, the capacity was improved to 9.0 wt.% after 516 cycles.

W-31: Effects of Heat Treatment on the Anisotropic Fatigue Behavior of Rolled Aluminum 2024: *Jaclyn Avallone*[1]; [1]ASU

Fatigue crack nucleation and initial propagation in Al 2024-T351 exhibits anisotropic behavior, due to preferential alignment of inclusions and crystallographic orientations parallel to the rolling direction. However, studying these effects individually is complicated experimentally. In this work, 2024-T351 samples were heat treated to the O condition to eliminate the effects of the initial temper, while keeping the alignment of the inclusions unchanged. Materials were first characterized using EDS and EBSD, followed by tensile and cyclic plasticity experiments performed in smooth samples to evaluate the plastic behavior of the two tempers. Finally, tests were performed in notched samples to study crack nucleation and short crack growth and their correlation to size and chemistry of broken inclusions, and crystal orientation of the grains containing the nucleation sites. The results are compared and discussed, with emphasis on the individual roles of inclusions and matrix plasticity on anisotropic fatigue behavior of rolled Al 2024.

W-32: Effects of Modified Sintering on Mechanical Properties of Nd-Fe-B Sintered Magnets: *Jin Woo Kim*[1]; Se Hoon Kim[1]; Sun Yong Song[1]; Young Do Kim[1]; [1]Hanyang University

Sintered Nd-Fe-B magnets have attracted considerable attention in recent decades for application in the motors of hybrid or electric vehicles due to their excellent magnetic properties. However, Nd-Fe-B permanent magnets have very low bending strength and fracture toughness, strictly limiting their use in such application areas. Many researchers have shown that the Nd-rich phase was essentially important for high mechanical properties. This study applied a modified sintering process to improve mechanical properties by controlling the Nd-rich microstructure in the production of Nd-Fe-B sintered magnets. Further, it examined the effect of change in the microstructure in accordance with sintering behaviors and process conditions on mechanical properties, thereby attempting to present optimal conditions of the sintering process.

W-33: Effects of Mo, W, Si on the Solid Particle Erosion Resistance of Austenitic Fe-12Cr-0.4C-5Mn-xMo/W/Si Alloys: *Ki Nam Kim*[1]; Hye Won Kim[1]; Jae Yong Yun[1]; Jun Ki Kim[2]; Seon Jin Kim[1]; [1]Hanyang Univ.; [2]Korea Institute of Industrial Technology

Solid particle erosion (SPE), which implies the removal of material from component surfaces due to successive impacts of hard particles, has been recognized as a serious in various engineering applications such as hydrotransport lines, power plants and gas turbine blades. Recently, present authors confirmed that a strain-induced martensitic transformation (SIMT) improved abrasive, adhesive wear and cavitation erosion resistance in Fe-based alloys. . While the mechanism of SPE is different from that of abrasive, adhesive wear and cavitation erosion, it was considered that the SIMT may have a significant effect on improving the solid particle erosion resistance by absorbing the impact energy of particles. The present study is a part of a project in which SPE resistance improves by applying a SIMT; the effect of Mo, W, Si on the SPE resistance of austenitic Fe-12Cr-0.4C-5Mn-xMo/W/Si alloys was investigated in terms of the SIMT.

W-34: Effects of Pulsed Magnetic Annealing on the Grain Boundary of Primary Recrystallized Microstructure in the Grain-Oriented Silicon Steel: *Junjun Huang*[1]; Lihua Liu[1]; Xin Xia[1]; Xiang Jiang[1]; Lijuan Li[1]; Qijie Zhai[1]; [1]Shanghai University

In this work, the effects of pulsed magnetic field applied during the annealing of grain-oriented silicon steel on the grain boundaries in the primary recrystallizated microstructure were investigated. Samples of cold rolled grain-oriented silicon steel were annealed under pulsed magnetic field with the maximum strength 1T from three different directions-rolling direction, transverse direction and normal direction at the temperature of 700°C for 16 minutes. Electron Backscattering Scanning Diffraction (EBSD) technology was used to measure grains for texture determination, and software called Channel 5 was used to calculate the messages of boundaries. Results show that pulsed magnetic field can influence the development of grain boundaries. It is found that the frequency of the low angle boundaries increases when pulsed magnetic field is applied, especially from the rolling direction. Compared to the ordinarily annealed sample, the frequencies of CSL boundaries vary in samples annealed with pulsed magnetic field in different directions.

W-35: Elastic Properties of Ti-Nb-Ta-Zr-O Alloys: *Masakazu Tane*[1]; Takayoshi Nakano[2]; Shigeru Kuramoto[3]; Masashi Hara[3]; Mitsuo Niinomi[4]; Naohisa Takesue[5]; Takeshi Yano[5]; Hideo Nakajima[1]; [1]The Institute of Scientific and Industrial Research, Osaka University; [2]Graduate School of Engineering, Osaka University; [3]Toyota Central Research and Development Laboratories Incorporated; [4]Institute for Materials Research, Tohoku University; [5]Graduate School of Science, Fukuoka University

Elastic properties of cold-worked Ti-Nb-Ta-Zr-O alloys, referred to as Gum metal, were investigated with a focus on the effects of the oxygen concentration, electron–atom (e/a) ratio, and cold working process. The temperature dependence of the microstructures and elastic properties of single crystals and cold-worked polycrystals with different oxygen concentrations was analyzed, which revealed that Young's modulus increases upon 90% cold working due to formation of the \945'' (orthorhombic) martensite or ω (hexagonal) phase with high elastic modulus in the β(bcc) phase matrix. However, the Young's modulus after the cold working decreases with increasing oxygen concentration, because oxygen addition decreases the amount of the formed α'' and ω phases while retaining the low-stability phase. Therefore, cold working and oxygen addition achieve a low Young's modulus and high strength at the same time.

W-36: Electrochemical Capacitance of Polyaniline, Evaluated in Acid and Neutral Systems: *Omar Martinez Alvarez*[1]; Ma. Concepcion Arenas Arrocena[2]; Héctor Hugo Rodriguez Santoyo[1]; José Ulises Cruz Perez[1]; [1]Universidad Poltécnica de Guanajuato; [2]Universidad Nacional Autónoma de México

Electrochemical capacitors (EC) are novel energy storage devices that posses high power density, exhibit excellent pulse charge/discharge property and very long life. The Polyaniline (PANI) is considered the most promising material in the supercapacitors due to its high capacitive characteristics, low cost and ease of synthesis. In this work we present a comparative study of charge storage in acid and neutral electrolytic systems 1M H2SO4 and 1M NaNO3. The electrodes were prepared by electropolymerization of polyaniline (PANI) on the vitreous carbon. The surface morphology of electrodes was characterized by scanning electron microscopy (SEM) and atomic force morphology (AFM). The electrochemical properties of electrodes and the capacitive behavior of the electrodes were systematically studied using cyclic voltammetry (CV) and constant current charge/discharge tests. Is important to mention that the specific capacitance of PANI electrodes is strongly influenced by the electrolytic system used and is manifested in the responses obtained.

W-37: Electrochemical Recovery of Zinc Present in the Spent Pickling Baths Coming from Hot Dip Galvanizing Processes: *Valentín Pérez-Herranz*[1]; Jordi Carrillo-Abad[1]; Montserrat García-Gabaldón[1]; Emma Ortega[1]; [1]Universidad Politécnnica de Valencia

Hot dip galvanizing processes offer a simple and effective method for corrosion protection of steel. In this process, during the pickling step, HCl reacts with iron and iron oxides. Spent pickling baths contain hydrochloric acid, $ZnCl_2$ and $FeCl_2$ as principal compounds. Due to the inadequate existing techniques to treat the spent pickling solutions, the decrease of natural reserves of non-ferrous metals and the requirement of environmental protection, in the present work, the cathodic electrodeposition of zinc present in the spent pickling baths coming from hot dip galvanizing industries is studied. As the electrode potential was shifted towards more negative values, the fractional conversion increased. Simultaneously, the specific energy consumption decreased initially due to the increase in the zinc conversion rate but decreased for the most cathodic potential value due to hydrogen evolution reaction. Even though iron deposition does not take place for any experimental condition under study.

W-38: Electronic Transport in Quasiperiodic Graphene p–n–p Junctions: *Manoel Vasconcelos*[1]; Luciano da Silva[1]; [1]Universidade Federal do Rio Grande do Norte

Graphene is a promising candidate material for future microelectronic devices. It is a sheet of crystal carbon that behaves as a ballistic conductor with a long mean free path, that can be locally gated, whose interaction of carriers with electrostatic barriers is influenced by Klein tunneling. This effect has been studied for periodic potentials and the effect of disorder on the charge transport through multiple barriers has been considered. Here we investigate the interaction of charge carriers in graphene with a series of p–n–p junctions arranged according to a deterministic quasiperiodic Fibonacci sequence. Spectra of quasi-confined states are calculated for several generations of the sequence. Our results show that, as the Fibonacci generation is increased, the dispersion relation form energy bands distributed as a Cantor-like set. Besides, the electronic tunneling probability as a function of energy shows a large transmission peak for small incidence angles.

W-39: Estimating Stress Exponent of Advanced Materials through Spherical Indentation Creep Test: *In-Chul Choi*[1]; Byung-Gil Yoo[1]; Yong-Jae Kim[1]; Moo-Young Seok[1]; Jae-il Jang[1]; [1]Hanyang University

Among various nanoindentation creep tests, the constant-load method using a sharp tip may be the most popular one. However, here it was found that there can be some difficulties in applying the method to estimate creep exponent, and thus we proposed a modified way to use a spherical tip. Both sharp and spherical indentation creep experiments were performed on nanocrystalline materials and metallic glasses that are known to show creep-like behavior at room temperature. The results suggest that spherical indentation creep may produce more reliable data than sharp indentation creep.

W-40: Evaluation of Mechanical Properties of Polymer Matrix with Bionanocomposites Poly (Lactid Acid) - PLA: *Shirley Cavalcanti*[1]; Gustavo Brito[1]; Pankaj Agrawal[1]; Edcleide Araújo[1]; Tomás Mélo[1]; [1]UFCG

In the last 50 years from oil polymers have been widely used due to its versatility and relatively low cost. But oil is an exhaustible raw materials and polluting nature. In this context, Biodegradable polymers have attracted considerable attention. Poly (lactic acid) - PLA is a biodegradable polymer that has high fragility preventing its use inpractical applications. For this reason, we used copolymers, methyl acrylate and glycidylmethacrylate in an attempt to improve some mechanical properties. Thereforemechanical tests and morphological analysis were performed. In general, we observed the formation of different morphologies directly interfered in the performance of mechanical properties.

W-41: Evaluation of Structural Strength in Tank Car: *Sung Cheol Yoon*[1]; Jeongguk Kim[1]; [1]Korea Railroad Research Institute

To check the structural strength of the body in the Tank car, load was added to the underframe of the Tank car. The objective of this study is to evaluate whether or not the underframe of a Tank car under the maximal strength is safe. The carbody of rolling stock is a principal structure that supports major equipment of the underframe and the tank freight. Therefore, the strength evaluation of this structure is important. Both structural analysis and loading test were performed under the loading condition. Prior to the evaluation of structural strength, finite element method was used for structural analyses on stress distribution in a carbody of a Tank car. The strain gauges were attached on the car based on FEM results. The test results showed that the carbody is safe under the condition of the designed load.

W-42: Evolution of Internal Strain and Microstructure in Depleted Uranium in the Presence of Hydrides: *Elena Garlea*[1]; T. A. Sisneros[2]; D. W. Brown[2]; S. C. Vogel[2]; J. S. Morrell[1]; [1]Y-12 National Security Complex; [2]Los Alamos National Laboratory

The aging effects on mechanical behavior of depleted uranium in the presence of hydrides have been investigated by in-situ neutron diffraction. Cylindrical compression specimens of rolled depleted uranium were

POSTERS

charged with three different amounts of hydrogen, specifically 0 wppm, 0.3 wppm, and 1.8 wppm hydrogen, and tested at room temperature. The as-rolled condition was kept as reference. The strain measurements were carried out by in-situ uniaxial compressive loading, to 10% macroscopic strain, to monitor the evolution of lattice strain. Neutron diffraction strain results were coupled with bulk texture studies to understand the effects of hydrides on deformation modes responsible for the observed behavior. The investigation of microstructures developed during the hydrogen charging and loading process showed grain growth and enhanced twinning activity.

W-43: Existence of Niobium in Ductile Iron and Its Effect on the Morphology of Graphite Ball: *Sun Xiaoliang*[1]; [1]ShangHai University

Niobium is a powerful carbide forming element, and its partial solid solution in austenite which improves the stability and quench-hardening ability of supercooled austenite. Niobium can refine grain and improve the mechanical properties in the role of the grey cast iron. However, published work on the effect of niobium on ductile is very few. This paper mainly studies the existence of niobium in ductile iron and its effect on graphite ball which was quantitatively analysised by the image analysis software. The results showed that, with the increasing amount of niobium,micro hardness of matrix increased obviously and the size and number of Nb-rich phase increased and enrichment of Nb-rich phase appeared.When addition of niobium was below 0.55 wt%, number and spheroidization rate of graphite ball was similar, but too much addition of niobium will decreased the number and spheroidization rate.

W-44: Experimental Indicators of Materials Processing Progress in Mechanical Alloying: *Priya Radhi Santhanam*[1]; Edward Dreizin[1]; [1]New Jersey Institute of Technology

Mechanical milling is widely explored to prepare advanced alloyed and composite materials. However, transfer of production from lab-scale to large scale manufacture is often ambiguous. Recently, a simplified approach was proposed, in which the rates of energy transfer to the material from milling tools were calculated for three different mills using discrete element modeling (DEM). These rates, taken as a function of the milling time, were correlated with the averaged rates of increase in the yield strength of an oxide reinforced composite. The results were encouraging and required additional validation. In the present study, correlations between the power consumption, torque, and rpm of an attritor mill and the powder refinement are examined. Such real-time indicators of milling progress do not require recovery of the powder samples and offer a convenient option for materials, for which measurements of yield strength are impractical.

W-45: Experimental Study on the Behavior of Slag Entrapment and Inclusion Removal in 44 t Ladle with Argon Blowing: *Shu-Guo Zheng*[1]; [1]Northeastern University

The powder entrapment and inclusion behavior in 44 ton ladle with argon blowing was studied in a water model. The effect of gas flowrate on powder entrapment in the ladle was investigated by choosing the mixture of kerosene and vacuum pump oil simulated as slag, and the effects of time and gas flowrate on inclusion removal were investigated by choosing emulsion drops simulated as inclusions. The results show that the critical gas flowrate for powder entrapment was 0.66 Nl/min, and the powder entrapment occurred continuously with those gas flowrates larger than 3.31 Nl/min. Most of the inclusions can be removed in eight minutes, and all the inclusions which can be removed almost disappeared from the system in twenty-eight minutes. The inclusion removal rate decreased first and then increased with the increase of gas flowrate. Furthermore, it had been found that the inclusion removal was in exponential relationship with gas blowing time.

W-46: Fabrication and Property Evaluation of Titanium Sputtering Target by Spark Plasma Sintering: *Hyun-Kuk Park*[1]; Ik-Hyun Oh[1]; Hee-Jun Youn[1]; Jung-Han Ryu[1]; [1]KITECH / Automotive Components Center

Spark Plasma Sintering is utilized to consolidate Titanium for sputtering target. Densification to near theoretical density in a relatively short time can be accomplished using this process. Sintered-body of Ti (Diameter 150, Thichkness 6mm) with a relative density of up to 99.5% and average grain sizes of about 30 micro-meter without purity could be obtained by sintering temperature at 1000 for 5 min under a pressure of 50 MPa pressure. The sintered-body had specific resistance of 8.63 X 10^{-6} Ω•cm.

W-47: Fabrication of Lotus-Type Porous Copper by Centrifugal Casting Technique: *Yun-Soo Lee*[1]; Hyeong-Tae Kim[1]; Myoung-Gyun Kim[2]; Soong-Keun Hyun[1]; [1]Inha University; [2]Research Institute of Industrial Science & Technology (RIST)

A centrifugal casting technique was developed to fabricate, under low hydrogen pressure similar to atmospheric pressure level, lotus-type porous copper with long cylindrical pores aligned parallel to the solidification direction. The molten copper under a hydrogen gas pressure of 0.1MPa was poured into the mold using a rotational velocity of 200-1000RPM. The effects of rotational velocity on the porosity and the pore morphology were investigated. The porosity of each specimen fabricated by rotational velocity of 200-1000RPM was 55.4%-43.4% and the average pore diameter of each specimen was 338.3μm-150.2μm respectively. These results show smaller pore diameter than those of conventional fabricating process under 0.1MPa[1]. It is concluded that the centrifugal casting technique is a promising method for the manufacturing cost reduction and safety production of lotus-type porous metals.Reference [1] H. Nakajima, Prog. Mater. Sci. 52 (2007) 1091-1173.

W-48: Fabrication of Porous Cu by Freezing CuO/Camphor-Naphthalene Slurry: *Myung-Jin Suk*[1]; Sung-Tag Oh[2]; Si-Young Chang[3]; [1]Kangwon National University; [2]Seoul National University of Science and Technology; [3]Korea Aerospace University

Porous Cu with macroscopically aligned channels was synthesized using a freeze-drying process. CuO powder and camphor-naphthalene alloy are used as the source material of Cu and sublimable vehicles, respectively. The slurry of camphor-40wt% naphthalene alloy mixed with CuO powders was prepared by milling at 60°C with a small amount of dispersant. Freezing of a slurry was performed in Teflon cylinder attached to a copper bottom plate cooled at -40°C while unidirectionally controlling the growth direction of the camphor-naphthalene vehicle. Pores were generated subsequently by sublimation of the camphor-naphthalene vehicle during drying. The green body was hydrogen-reduced at 200°C for 30 min, and sintered at 500°C for various time under a hydrogen atmosphere. Microstructural characteristics were analyzed by XRD and SEM. All of the samples showed porous structure after sintering, and composed of only Cu phase. Microstructural evolution depending on processing was discussed.

W-49: Fabrication of Sintered-Body Ti from Hydride Dehydride Ti Powder for Machine Tool and It's Mechanical Properties: *Ik-Hyun Oh*[1]; Hyun-Kuk Park[1]; [1]KITECH / Automotive Components Center

Spark Plasma Sintering method is utilized to consolidate Titanium from Hydride dehydride Ti powder. Densification to near theoretical density in a relatively short time can be accomplished using this process. Sintered-body of Ti (Diameter 100, Thickness 2mm) with a relative density of up to 99.8% and average grain sizes of about 60 micro-meter could be obtained by sintering temperature at 1000 for 5 min under a pressure of 60 MPa pressure. The average micro vickers hardness and tensile strenge were about 350 kg/mm2 and 350 MPa, respectively.

W-50: Finite Element Simulation of the Roll Forming Process of HSLA Steel Profiles: *Guadalupe Maribel Hernández Muñoz*[1]; Patricia del C. Zambrano Robledo[1]; Martha Patricia Guerrero Mata[1]; Luis Leduc Lezama[1]; [1]Universidad Autonoma de Nuevo Leon

A key part of the global economy is the automotive industry, which involves designing of automotive parts, optimizing processes and materials, among other things. The most important automotive parts are cold formed, manufactured mainly through the process of roll forming which is also considered highly productive for the manufacturing of profiles. The characteristics and properties for High Strength Low Alloy Steel makes it a widely used in the manufacture of various automobile parts, such as rails, beams, braces, suspension arms and other parts. This paper presents the results of a numerical simulation using the element finite method with ABAQUS™, modeling of a symmetrical rectangular profile section from HSLA 50 steel, carried out by a cold forming process through rollers, also known as roll forming process. The parameters selected for this study are the roll forming line velocity and the inter-distance between roll stations. Results will allow optimization of the process.

W-51: First-Principles Coupled Calphad Modeling of BaO-TiO2 and La2O3-TiO2 Pseudo-Binary Systems: *Lei Zhang*[1]; Chad Althouse[1]; James Saal[2]; Dongwon Shin[3]; Shunli Shang[1]; Yi Wang[1]; Zi-Kui Liu[1]; [1]Pennsylvania State University; [2]Northwestern University; [3]Oak Ridge National Laboratory

Compounds from BaO-TiO2 and La2O3-TiO2 have excellent dielectric, piezoelectric and electro-optic properties, making them competitive candidate materials for relevant applications. However, their thermodynamic properties have not been generated and made into database, though they are crucial for manufacturing those materials. In this research project, I searched all the experimental data and then modified the two pseudo-binary systems with assisting from First-principles calculation. Every compound from these systems has been defined with a reasonable thermodynamic description and phase diagrams are obtained. For BaTiO3, a new sub-lattice model is used based on the latest defect reactions. The results can be readily used by industry as a reference for future manufacturing and other simulations such as phase field method.

W-52: Friction and Wear of AZ31B Magnesium Alloy during Sliding against Tool Steel: *Yong-Suk Kim*[1]; Hyuk Woo Kwon[1]; [1]Kookmin University

Galling is the most frequently observed surface damage during hot forming of magnesium alloys. This study was undertaken to examine tribological phenomena during sliding of tool steel against AZ31B Mg alloy and to find out formation mechanism of the galling. Reciprocating sliding of tool steel (AISI D2 and H13) against the Mg-alloy plate was carried out at various temperatures and normal loads. Surface roughness of the tool steel was also varied to see the effect of the roughness on the galling. Friction coefficient was measured during the sliding to monitor the interaction between the surfaces. To investigate the galling, surface of the tested Mg-alloy plate was examined by SEM and the friction-coefficient variation was analyzed. It was found that magnesium particles were transferred from the plate to the tool steel by asperity rupture and aggregation; they were oxidized to become hard oxide particles, which resulted in the galling.

W-53: Friction Stir Welding of High Melting Temperature Material Plate: *Sang-Hyuk Kim*[1]; Kwang-Jin Lee[1]; Ik-Hyun Oh[1]; Kee-Do Woo[2]; [1]Korea Institute of Industrial Technology; [2]Chonbuk National University

The friction stir welding (FSW) is a potential candidate for the joining of dissimilar and high melting temperature. However, to apply FSW in high melting temperature materials such as steel or Ti alloys etc., the tool with super heat-resisting and abrasion resistance are needed. And suitable parameters such as rotation speed of tool, travel speed are must considered. The tool material was manufactured by Spark plasma sintering method using WC-X%Co. Because WC have High melting point(2900°C), high hardness(1780Hv) and high elastic modulus(72,000kg/mm2). Diameter of shoulder and probe of the tool is 15ø and 4.5ø, respectively. The process parameters were : rotation speed, 500~700rpm ; travel speed, 60~180mm/min. the rotating probe travelled along the butt line between the two base materials. Optical microscope, Scanning electron microscope were applied to investigate the microstructure of weld region. Vickers-hardness, tensile test were carried out to analyze the mechanical properties of the joint.

W-54: Grain Refining Effect of Al2Ca in A383.0 Al Alloy: *Nam-Seok Kim*[1]; Jung-Ho Seo[1]; Young-Ok Yoon[1]; Shae K. Kim[1]; [1]Korea Institute of Industrial Technology

Die casting, one of casting processes, has many advantages such as high productivity, excellent casting surface and possibility of making thin parts. Therefore, this process has widely been used from transportation equipment to electrical components. Especially, many Al alloy parts are manufactured by this method because they have good castability. In the A383.0 Al alloy, the strength increases with increasing Mg content. On the other hand, the Mg addition is limited under 0.1wt% since it accelerates the formation of Mg-based oxides and hard inclusions during alloying and casting due to its high oxygen affinity, causing the drop in the mechanical properties of alloys and melt fluidity. In this study, the results of Al2Ca added A383.0 Al alloy about grain refining effect and mechanical properties were compared with those of conventional A383.0 Al alloy. Microstructure observation was carried out using OM and SEM. Mechanical properties were evaluated by tensile and hardness tests.

W-55: Heat and Moisture Transfer and Shrinkage during Drying of Ceramic Materials: *José Nascimento*[1]; Ariosvaldo Sobrinho[1]; Antonio Lima[1]; Luiz Pontes[2]; Mirtes Carvalho[3]; Karla Campos[4]; [1]UFCG; [2]LMPC/UFPB; [3]UAEC/UFCG; [4]UFCG/LMI

This work reports a transient three-dimensional mathematical model to describe the simultaneous heat and mass transport and shrinkage. The model assumes to be constant thermo-physical properties and convective boundary condition at the surface of the solid. The governing equations were solved using finite-volume method and implicit fully formulation. The mathematical formulation was used to describe the drying of ceramic bricks, in the following air drying conditions: temperatures T=60, 80 and 110ºC and relative humidity's RH=10.07, 4.66, 4.96, 2.30 and 1%, respectively. The experimental tests were made using two clay materials for production of red ceramic and white ceramic (ball-clay). Several results of the mean moisture content and temperature along the process are shown and analyzed. Numerical results were compared with experimental data and the transport coefficients were determined.

W-56: Hidrotalcite with Gentamicine, of the Type Mg0.68Al0.32(OH)2 (NO3)0.32•0.1H2O, Formed by Chemical Coprecipitation in Controlled Atmosphere: *Hector Hugo Rodriguez-Santoyo*[1]; Omar Martínez-Alvarez[1]; [1]Universidad Politecnica de Guanajuato

This work consisted in the development for coprecipitation and characterization for X-ray diffraction of a hidrotalcite of the type Mg0.68 Al0.32(OH)2(NO3)0.32•0.1H2O, capable of liberate in vitro gentamicin. The objective of this project was to generate a new material capable of remedy infections for the bacteria Staphylococcus Aureus, when this bacterium is introduced fortuitously in the body of a patient through of implants o prosthesis. A new method at the vacuum for condensation of vapor was developed of the hidrotalcite synthesis. Gentamicin was introduced in ionic clay, for a process of ionic interchange. The sensibility to the new product was tested in Staphylococcus aureus antibiograms. The results suggest a high sensibility of this kind of bacteria to the new product.

W-57: High Temperature Compressive Deformation Behavior of Ni-Fe-Cr-Al Based Porous Metal: Sung-Whan Choi[1]; Jung-Yeol Yun[2]; Young-Min Kong[3]; Byung-Kee Kim[3]; *Kee-Ahn Lee*[1]; [1]Andong National University; [2]Korea Institute of Materials Science; [3]University of Ulsan

This study investigated the high temperature compressive deformation (25°C~800°C) behavior of Ni-Fe-Cr-Al porous metal manufactured via powder process. Two different porous metals – 30 PPI (Pores Per Inch) and 40 PPI – were used. The densities were 0.49 g/cm^3 for the 30PPI and 0.68 g/cm^3 for the 40PPI material. Those materials were to consist of γ phase and Ni_3Al. The compression results, regardless of temperature, revealed typical three stages of deformation behavior (elastic, plateau, and densification region). At all temperatures, 40 PPI (a higher density) showed higher strengths than those of 30 PPI. However, the difference of strength continuously decreased with increasing temperature. Fractography

POSTERS

revealed that the fine cracks easily propagated along interphase boundary in the strut regardless of deformation temperature and porosity condition. Based on these results, the mechanism of high temperature deformation of porous metal was also discussed. [Supported by the Fundamental R&D program for Core technology, Korea]

W-58: High Temperature Mechanical Behavior Fe-12Cr ODS Containing Nb: *SungSoo Kim*[1]; Dae Whan KIM[1]; Jin Sung Jang[1]; [1]Korea Atomic Energy Research Institute

In order to increase operating temperature in next generation nuclear reactors, the oxide dispersion strengthened (ODS) alloy is promising for this purpose. The ferritic martensitic steel based on Fe-Cr ODS alloy is a candidate material due to the excellent resistance to neuron damage during service. Two kinds of Fe-12Cr-0.3%Y2O3 ODS with and without niobium were prepared by same process. The elemental powders were mechanical alloyed, and the ODS alloys were prepared by spark plasma sintering (SPS), HIP, and hot rolling. The high temperature tensile behaviors were investigated up to 800°C and compared. The effect of niobium addition on the mechanical behavior is pronounced at above 600°C. The 2% Nb addition improves the yield strength at 700°C by 50%. This seems to be due to the formation of fine intermetallic compound of Cr2Nb and Fe2Nb during high temperature deformation.

W-59: Hydrogen Absorption in CexGd1-x Alloys: *Joseph Bloch*[1]; [1]NRCN

The effect of alloying on the thermodynamics of hydrogen absorption was studied for CexGd1-x alloys (0=x=0.5) at temperatures between 600°C and 800°C and for a pressure range 10-2 - 102 Pa. The terminal solubility of hydrogen in Gd is approximately four times higher than in Ce in the temperature range between 800 and 1000 K. At a given temperature, the hydrogen solubility and the terminal solubility were found to decrease with increasing x. This behavior is different than for substitutional solutions of the vanadium and the titanium groups for which the hydrogen terminal solubility increases with increasing solute concentrations. The heat of formation of the dihydride exhibits a pronounced maximum around x=0.3. This observation correlates with the presence of intermediate Sm-type (delta) phase around this composition. It is concluded that the hydride associated with the delta phase is considerably more stable than both cerium and gadolinium dihydrides.

W-60: Impact of the Sequence of Strain Hardening and Precipitation Hardening on Mechanical Properties of Grade 6201 AlMgSi Alloy Wire: *Beata Smyrak*[1]; [1]AGH - University of Science and Technology

Precipitation-hardenable AlMgSi alloys grade 6101 of 0.5% Mg and 0.5% Si contents, are used for the construction of homogenous wires in overhead power lines. The suitability of these alloys lies in the characteristics of their electrical and mechanical properties within a wide range of heat treatment. Development of AlMgSi wires technology resulted in producers' competitive attempts to obtain more and more sublimated mechanical and electrical properties. The dominating group of alloys with increased electrical conductivity is the AlMgSi alloy group, these are HC, EHC and EEHC type materials with tensile strength at approximately 300 MPa and electrical conductivity lower than conventional wires (30nOm-31.2nOm). This paper is a comprehensive analysis of the technologies for the manufacturing of wires from AlMgSi alloys. It shows the possibility of shaping the mechanical and electrical properties of rods and wires.

W-61: Improved Room-Temperature Hydrogen Sensing Characteristics of Nanocrystalline Tin Oxide Through Fabrication of Nanowire Arrays: *Rameech McCormack*[1]; Nozomi Shirato[2]; Amit Kumar[1]; Umesh Singh[1]; Hyoung Cho[1]; Ramki Kalyanaraman[2]; Sudipta Seal[1]; [1]Univeristy of Central Florida - MMAE; [2]University of Tennessee Knoxville - MMAE

Tin Oxide (SnO_2) nanowire arrays were prepared on oxidized Si substrates by nanosecond pulse laser irradiation. Characterization of device using Atomic Force Microscopy showed the SnO_2 nanowires were of 20 nm in diameter and tens of microns in length. The SnO_2 nanowire and precursor thin film were tested for sensing hydrogen gas from 6000-300 ppm. It was observed that the electrical response of nanowire was drastically improved compared to that of the thin films. The intrinsic properties due the SnO_2 nanowire structure correlates to simultaneous increases in the unbounded surface atoms and surface to volume ratios. Consequently, manipulation of the depletion layer and chemical reactions involved in sensing hydrogen gas are more pronounced. Thus, improved detecting capabilities towards hydrogen were observed. The fabricated SnO_2 nanowire arrays reveal potential for producing devices that have ultra-low detection limits for hydrogen gas also fast response and recovery time for real-life hydrogen sensing applications.

W-62: Industrial Use of a New Ultrasound Spray for Cooling and Wet Gas Treatment in the Pyrometallurgical Processes: *Milorad Cirkovic*[1]; Vlastimir TRUJIC[1]; Željko KAMBEROVIC[1]; [1]Mining and Metallurgy Institute Bor

This paper presents the results of a new industrial use the ultrasonic spray for gas cooling from sulphide copper concentrate roasting in the fluo solid reactor and the results of wet gas treatment (washing) in the scrubber plant during treatment the secondary copper bearing raw materials in RTB Bor (Serbia). The use of a new ultrasonic nozzle for gas cooling from the fluo solid reactor resulted as a necessity because the efficiency of existing installed spray of foreign manufacture was very bad. The possibility of its dismantling (disassembly) has allowed a complete cleaning and reliable operation and the nozzles, currently used, are in a continuous operation over a decade. The new design of ultrasonic spray and its successful use for cooling and cleaning the metallurgical gases will be applied in modernization the Copper Smelter in RTB Bor.

W-63: Influence of Heat Treatment on the Corrosion of Steels in CCS Environment: Anja Pfennig[1]; Sabrina Schulz[1]; *Axel Kranzmann*[2]; Thomas Werlitz[1]; Stephan Wetzlich[1]; Enrico Bülow[1]; Jan Tietböhl[1]; Christian Frieslich[1]; [1]HTW Berlin; [2]BAM

With CO2 being one reason for climate change carbon capture and storage (CCS) is discussed to mitigate climate change. When emission gases are compressed into deep geological layers CO2-corrosion can easily cause failure of injection pipes. Differently heat treated steels used as injection pipe (X46Cr13, X20Cr13 and X5CrNiCuNb16-4) were tested in in-situ laboratory corrosion experiments where synthetic aquifer water was saturated with technical CO2 at a flow rate of 3 l/h. After 1000 h of exposure time pits are found on all 3 with maximum pit heights around 20 µm. Corrosion rates obtained via mass loss vary in a wide range (0,005 to 2.5 mm/year). The least amount of pits is found on hardened steels with martensitic microstructure where X5CrNiCuNb16-4 shows less pits than X46Cr13 followed by X20Cr13. The complicated multiphase corrosion scale reveals FeCO3, alpha-FeOOH, gamma-FeOOH, FeS and Fe8O8(OH)8Cl1.34 as well as spinelphases of various compositions.

W-64: Influence of Hf on Inhibiting Precipitation in Ni-rich NiTiPdHf Shape Memory Alloys: *Anne Coppa*[1]; Ron Noebe[2]; Glen Bigelow[2]; Mark Weaver[1]; Greg Thompson[1]; [1]The University of Alabama; [2]NASA Glenn Research Center

The transformation characteristics of Ni-rich NiTiPd and NiTiHf alloys can be significantly improved through the formation of nanoscale precipitates. In the Ni-rich NiTiPd alloys, cuboidal precipitates denoted as the P-phase, have been observed. This phase has a monoclinic unit cell with laminate variant stacking. The precipitates observed in Ni-rich NiTiHf alloys are plate-like in morphology but specifics of the crystal structure have yet to be defined, though effort is continuing. In the present work, a Ni-47Ti-23Pd-2Hf was studied. In this quaternary alloy, precipitation of either phase or any other precipitate phase typically observed in Ni-rich NiTi alloys (i.e., Ni4Ti3, Ni3Ti2 or Ni3Ti) was inhibited. Even after 300 hours of aging at 400°C, the matrix crystal structure remained B2. Although the alloy does not exhibit precipitation, an increase in hardness was observed with aging time. The results will be discussed in terms of atom probe tomography and transmission electron microscopy.

W-65: Influence of Process and Thermo-physical Parameters on the Heat Transfer at Electron Beam Melting of Cu and Ta: *Katia Vutova*[1]; Veliko Donchev[1]; Vania Vassileva[1]; Georgi Mladenov[1]; [1]Institute of electronics, Bulgarian Academy of Sciences

Electron beam melting and refining (EBMR) in vacuum is an ecological friendly method for metal purification, scrap regeneration and reuse of expensive metals and special alloys needed for all areas of human activity. The thermal transfer processes are important for production of metal blocks with good quality and the mathematical modeling is a tool for studying and control of these processes.The temperature variations of the thermal conductivity and the heat capacity for Ta and Cu are estimated and are taken into account in the presented heat model. Some results on the influence of the casting velocity, beam power and ingot dimensions on the heat streams through different boundaries and on the crystallization front shape for EBMR of Cu and Ta are presented and discussed.Calculated and experimentally obtained crystallization front forms are compared and a good correspondence is observed.Electron beam casting conditions for obtaining of good quality cupper ingot are optimized.

W-66: Infrared Thermographic Characterization of Tensile Fracture in Railway Steels: *Jeongguk Kim*[1]; [1]Korea Railroad Research Institute

The tensile fracture behavior of railway steels, which are used for railway vehicle components such as wheel, axle, bolster, etc., was characterized using the infrared (IR) thermographic method with a high-speed infrared camera. The tensile specimens were prepared from the actual railway vehicle parts, which were used for over 20 years. An infrared camera was used to monitor damage evolution during tensile testing in terms of surface temperature measurements. A qualitative image analysis was conducted to explain failure mode and mechanisms in different railway steel samples based on infrared thermographic images obtained during tensile testing. Moreover, the microstructural characterization using scanning electron microscope (SEM) was performed to correlate the mechanical failure mode with thermographic results. In this investigation, an IR camera and SEM characterization method were used to facilitate a better understanding of fracture behavior of different types of railway steels during tensile testing.

W-67: Investigating Strain-Induced Martensitic Transformation in Steel through In-Situ TEM Test: Yong-Jae Kim[1]; *In-Chul Choi*[1]; Byung-Gil Yoo[1]; Takahito Ohmura[2]; Jae-Il Jang[1]; [1]Hanyang University; [2]National Institute for Materials Science

Strain-induced phase transformation from metastable austenite to martensite in steels has attracted lots of scientific and engineering interests due to a resultant mechanical improvement, i.e. the combination of high strength and good ductility. Although it is well known that the size of materials can affect their mechanical properties (such as strength and elastic modulus), there have been little efforts to investigate the strain-induced transformation behavior of steels in nano-scale. In this regard, we investigated the strain-induced martensitic transformation of steel in nano-scale with ex-situ and in-situ nanoindentation experiments. Examined material was a metastable austenite phase steel with a composition of Fe-0.04C-5Mn-12Cr (wt.%). The austenite-to-martensite transition was systematically analyzed with the indentation load-displacement data and the TEM images. Additionally, we compared the result of nanoindentation tests with that of macro uni-axial test and investigated the size effect of phase transformation behavior.

W-68: Investigation of the Polymer Composite Materials Reinforced by Hybrid Carbon and Basalt Fibers: *Nikoloz Chikhradze*[1]; Guram Abashidze[1]; Levan Japaridze[1]; [1]Mining Institute/Georgian Technical University

Carbon fiber reinforced plastics are considered as high-costly materials. This circumstance highly decreases an economic efficiency of large-dimensional, materials consuming items and structural elements, including the blades of wind turbines, produced from these materials. To solve this problem in the paper the possibilities of the partial replace of the carbon fibers in the plastics by basalt fibers of local (Country Georgia) production is considered. The basalt reinforcing elements was prepared from raw material with chemical composition: SiO2 – 15,3%, CaO - 10,8%, Fe2O3 - 12,1%, CaO - 10,8%, Na2O – 4,2%, MnO – 0,7%, TiO2 – 0,7%. The strength on tension and compression, elasticity modulus and Poisson ratio of the composites prepared by the use of proposed hybrid reinforcing means and by various technologies were determined. In the work the results of the composites testing on bending, shift and fatigue are presented.

W-69: Laboratory Testing Results of Kinetics And Processing Technology of the Polymetallic Sulphide Concentrate Blagojev Kamen - Serbia: *Milorad Cirkovic*[1]; Željko Kamberovic[1]; Vlastimir Trujic[1]; [1]Mining and Metallurgy Institute Bor

This work presents the laboratory testing results of kinetics the oxidation process and sample processing of the sulphide polymetalic concentrate Blagojev Kamen. Characterization of this raw material is based on the chemical analyses, XRD results, DTA analysis, etc. For these investigations, the sulphide concentrate with the following content was used, in %: Cu – 2.3; Fe – 19.8; S – 27.19; Zn – 9.13; As – 0.167; Pb – 15.63; SiO2 – 17.93; CaO – 0.97; Al2O3 – 1.43; Ag – 480 g/t; Au – 659 g/t. Kinetic investigations of oxidation processes were carried out under isothermal conditions within the range of temperature from 400 to 625°C. Pyrometallurgical treatment of this type of polymetallic concentrate, in the laboratory conditions, was carried out using the oxidative roasting and then the reduction smelting was done in the Taman's furnace.

W-70: Manufacturing and Macroscopic Properties of Cold Sprayed Cu-Ga Coating Material for Sputtering Target: *Kee-Ahn Lee*[1]; Young-Min Jin[1]; Byeong-Cheol Choi[1]; Dong-Yong Park[2]; Hyung-Jun Kim[3]; [1]Andong National University; [2]Tae-Kwang Tech.; [3]RIST

This study attempted to manufacture a Cu-Ga coating via the cold spray process and to investigate the applicability of the layer as a sputtering target material. Changes made to the microstructure and properties of the layer due to annealing heat treatment were also evaluated. The results showed that Cu-20%Ga coating layers could be manufactured via cold spray process. With the coating layer, the \149; -Cu and Cu3Ga were found to exist inside the layer regardless of annealing heat treatment. With thermal treatment ongoing, the porosity and hardness tended to drop dramatically. A sputtering test was actually conducted using the sputtering target Cu-Ga coating layer (~ 2 mm thickness). It was confirmed that the cold sprayed Cu-Ga coating layer may be applied as a sputtering target material. [supported by "the program for the Industrial Strategic Technology Development" and "The Program for the Training of Graduate Students in Regional Innovation", Korea]

W-71: Material Characterization of TRISO Particles Using Nanoindentation: *Jenny Martos*[1]; [1]UC Berkeley

The mechanical properties of Tristructural Isotropic (TRISO) coated fuel particles, which are used in High Temperature Gas Cooled Reactors (HTGR), are being explored with the use of nanoindentation. The silicon carbide layer of the TRISO particle is considered to be the most important since it acts as a pressure vessel in order to contain gaseous and solid fission products and therefore must withstand high stresses during irradiation. Nanoindentation techniques are being explored to measure Young's modulus and hardness of the different layers in the TRISO particles. In addition, fracture toughness of the silicon carbide layer is measured using nanoindentation techniques. TRISO particles subjected to various processing parameters and sample treatments are being explored in order to investigate the effect on the mechanical properties.

W-72: Mechanical Properties of Nanocomposites Based on PA6 Blends: *Pankaj Agrawal*[1]; Gustavo Brito[1]; Bartira Cunha[1]; Shirley Nobrega[1]; Edcleide Araújo[1]; Tomás Mélo[1]; [1]Federal University of Campina Grande - UFCG

Nanocomposites based on Polyamide 6 (PA6) blends were developed using an organically modified clay (organoclay) and a compatibilizer. The nanocomposites were prepared in two steps. First, PA6 was pre-mixed

POSTERS

with the organoclay in an internal mixer forming a concentrate. In the second step,this concentrate was diluted in either PA6, PA6/EG or PA6/HDPE blends in a twin screw extruder . The degree of dispersion of the clay in the polymer was evaluated through X-Ray Diffraction (XRD) and Scanning Electron Microscopy (SEM). XRD Results indicated that for PA6/EG/CL20A and PA6/EG/HDPE/CL20A nanocomposites, a partially exfoliated structure was obtained. SEM analysis results showed that the organoclay is well dispersed in the polymers. The presence of the compatibilizer improved the impact strength of the blends and the nanocomposites.

W-73: Mechnical Behavior of Porous NiAl Fabricated by Unidirectional Solidification: *Ji-Woon Lee*[1]; Soong-Keun Hyun[1]; Mok-Soon Kim[1]; Takuya Ide[2]; Hideo Nakajima[2]; [1]Inha University; [2]Osaka University

Porous NiAl with porosity of 32.3% was fabricated by unidirectional solidification. The mechanical behavior of porous NiAl was investigated under compression tests at temperatures of 298K, 673K and 873K. Nonporous NiAl exhibited brittle behavior at temperature up to 673K. Porous NiAl, however, exhibited ductile behavior even at 673K. All specimens showed ductile behavior at temperature of 873K. Different behavior between porous and nonporous NiAl with regard to temperature can be attributed to crack tip blunting and dislocation escape through pores. Anisotropic mechanical properties between parallel and perpendicular solidification directions to the compressive direction were also shown in both porous and nonporous NiAl. This behavior is due to inherent anisotropy of NiAl and orientation of cylindrical pores especially in the case of porous NiAl. Crystallographic orientation of each solidification direction to the compressive direction was confirmed by electron backscattered diffraction.

W-74: Microstructural Characterization of Aged MAR-M247(Nb) Nickel-Based Superalloy: *Renato Baldan*[1]; Carlos Nunes[1]; Gilberto Coelho[1]; Paulo Ricardo Azevedo Silva[1]; [1]USP - University of São Paulo

MAR-M247 superalloy has excellent mechanical properties and oxidation resistance. The aim of this work is to evaluate microstructural changes in the MAR-M247(Nb) superalloy (10.2 wt % Co; 10.2 W; 8.5 Cr; 5.6 Al; 1.6 Nb; 1.4 Hf; 1.1 Ti; 0.7 Mo; 0.15C; 0.06 Zr; 0.02 B; Ni balance) due to different aging heat treatments. The samples were submitted to solution heat treatment at 1260oC for 8 hours and aging in single and double steps at 780, 880 and 980°C for 5, 20 and 80 hours. The materials in the as-cast condition as well as those from the heat treatments were characterizated with SEM-FEG with EDS and DTA experiments. The results have shown that solution heat treatment at 1260ºC for 8h dissolves the gamma/gamma prime eutectics and precipitates small gamma prime particles during the cooling from the heat treatment to room temperature whilst aging heat treatment grows the gamma prime phase.

W-75: Microstructure and Property Modifications in Mould Steels Treated by Pulsed Electron Beam: *Kemin Zhang*[1]; [1]Shanghai University of Engineering Science

Surface modifications on AISI H13 and D2 mould steels generated by the low energy high current pulsed electron beam (LEHCPEB) treatments have been investigated. From the observations of SEM, XRD and electron back scattering diffraction (EBSD) determinations, the microstructure modifications were studied in details. It is found that the formation of the metastable micorstructures in the surface layer are related to the very rapid heating, melting, solidification and cooling induced by the LEHCPEB irradiation. After the LEHCPEB treatment, the wear resistance of the mould steels can be effectively improved. This can be mainly attributed to the higher hardness of the ultra fine structures formed on the top surface and the hardened subsurface layers after treatment.

W-76: Modeling Cyclic Creep Relaxation in Fiber-Reinforced Gasketing Materials: *James Williams*[1]; Ali Gordon[1]; [1]University of Central Florida

Gasket materials, which are applied as seals in bolted connections, are generally subject to step loading as a part of normal operation. The time-dependent response of fiber-reinforced gasket materials is strongly dependent on factors such as flange detail, lubricity, mechanical load history, etc. Characterizing the time- and history-dependence of these materials has been identified as a technique by which materials selection and mechanical load history can be designed. Using a multi-scale experimental setup, the mechanical response of a white glass reinforced Teflon is characterized. A constitutive model for the load history of the material is developed. The research is applicable to support the design and selection of materials used in flanges such at the Ground Umbilical Carrier Plate as a part of the Shuttle Transportation System.

W-77: Modeling of Al/W Granular Porous Composites during Dynamic Deformation: *Karl Olney*[1]; Vitali Nesterenko[1]; David Benson[1]; [1]UCSD

Aluminum/Tungsten granular composites are materials which combine high density and strength with the ability to undergo bulk distributed fracture of Al matrix into small particles under impact or shock loading. They are processed using cold and hot isostatic pressing of W particles/rods in the matrix of Al powder. The presentation will describe modeling of these materials under dynamic conditions simulating low velocity high energy impact in drop weight test (10 m/s) and behavior during explosive shock loading. It will be demonstrated that morphology of W component and bonding between Al particles dramatically affects their strength, shear localization and mode of fracture of Al matrix. The support for this project provided by the Office of Naval Research Multidisciplinary University Research Initiative Award N00014-07-1-0740.

W-78: Morphology of Nanocrystalline ZnO Prepared from Aqueous Solutions: *Eguiberto Galego*[1]; Marilene Serna[1]; Lalgudi Ramanathan[1]; [1]CNEN-IPEN/SP

Zinc oxide (ZnO) has been used in a variety of applications, because of its electrical, optical, and acoustic characteristics. This material has been also used as electrodes in thin film type or dye sensitized solar cells. The morphology of nanocrystalline ZnO is vital to obtain an ideal surface for use in these applications. In this study, nanostructured ZnO was prepared by sequentially dipping the substrate in several chemical baths. Experiments were conducted with a special rig in which the time, temperature, and extent of agitation of the baths were controlled by a microcomputer. Use of this rig along with control of solution pH and concentration enabled fabrication of ZnO nanorods and nanograins. Comparison of micrographs of the deposits indicated that pH and temperature have a marked influence on morphology.

W-79: Nanocomposite of Platinum Particle by Liquid Chemical Phase Reduction: *Jin Ho Lee*[1]; Jin Woo Kim[1]; Se Hoon Kim[1]; Young Do Kim[1]; [1]Hanyang University

Platinum (Pt) has been widely used such as catalyst of fuel cell and exhausted gas clean system due to high catalytic activity. In this study, we synthesized Pt nano particle by using polyol process which is one of liquid chemical phase reduction method. It is known that liquid chemical phase reduction is one of the high yield processes and could control size and shape during synthesis. $H_2PtCl_6 \cdot 6H_2O$, used as a precursor, was dissolved in diethylene glycol and $AgNO_3$ is added as metal salt in order to form particular shape of platinum nano particle. Also, we added polyvinylpyrrolidone (PVP) as capping agent for reducing the size and dispersed the particles. We made comparison of synthesized platinum particles depending on temperature and time during synthesis using particle size analyzer (PSA). And Transmission Electron Microscopy (TEM) is used to analyze morphologies and patterns.

W-80: Organic Coatings to Prevent Molten Aluminum Water Explosions in Aluminum Plants: *Alex Lowery*[1]; Joe Roberts[2]; [1]Wise Chem LLC; [2]Pyrotek Inc.

It was over 60 years ago; the first reported molten metal explosion from a bleed-out during direct chill casting in an aluminium mill was reported. Soon thereafter testing was performed to determine the root cause of the explosion. Upon determination of the root cause, an investigation to determine if any preventive measures could be instituted to prevent the explosions was conducted. Results found that a specific organic coating (e.g., Tarset Standard) prevented molten metal explosions, whereas some specific organic coatings initiated the explosions. Fifteen years ago the U.S. Department of Energy in conjuncture with the Aluminum Association reinvestigated the root cause of the molten metal explosions. Testing revealed that an initiation or trigger had to be present for a molten metal explosion to occur. Testing identified three additional coatings that could afford protection.

W-81: Oxidation Resistances of Al2Ca Added Al-5Mg Alloy: *Shae K. Kim*[1]; Gun-Young Oh[1]; Young-Ok Yoon[1]; [1]KITECH

Al–Mg alloys have attracted considerable attention for a wide range of applications due to excellent corrosion resistance, formability and weldability in automotive industry. However, the heat treatment of the A1-Mg alloys is limited under an ambient atmosphere at high temperatures because of their poor oxidation resistance. The continuous oxidation during heat treatment leads to alloy damage by the formation of thick oxide layer on the surface. The oxide layer may have undesirable effects on the production and performance of the alloys. A study has been performed to improve the oxidation resistance of Al-Mg mainly by Be addition. However, it is difficult to be handled and should be limited due to its toxicity. The aim of this study is to investigate the effect of Al2Ca and Al2Ca added Mg contents on the behavior of the oxidation resistances of Al-5Mg alloy. The oxidation test was carried out with thermogravimetric analysis (TGA).

W-82: Phase Decomposition in Isothermally-Aged Fe-Cr Alloys: *Victor Lopez-Hirata*[1]; Erika Avila-Davila[2]; Hector Dorantes-Rosales[1]; Maribel Saucedo-Muñoz[1]; [1]Instituto Politecnico Nacional (ESIQIE); [2]Instuto Tecnologico de Pachuca

Phase decomposition was studied during aging of Fe-32 and 40 at.%Cr alloys by means of TEM, hardness and the numerical solution of the nonlinear Cahn-Hilliard differential partial equation using the explicit finite difference method. Results of the numerical simulation permitted to describe appropriately the mechanism, morphology and kinetics of phase decomposition during the isothermal aging of these alloys. The growth kinetics of phase decomposition was observed to be very slow during the early stages of aging and it increased considerably as the aging progressed. The morphology of decomposed phases consisted of an interconnected irregular shape with no preferential alignment for short aging times and a further aging caused the change to a plate shape of the decomposed Cr-rich phase aligned in the <110> directions of the Fe-rich matrix. The increase in hardness seems to be associated with the coherency and nanometer size of the spinodally-decomposed phases in the aged alloys.

W-83: Physical Modeling on the Effect of Nozzle Clogging on Mold Flow: *Suzhou Wu*[1]; [1]Wuhan University of Science and Technology

SEN clogging often occurs during continuous casting of low carbon Al-killed steel. Clogging materials remain in the nozzle are likely to cause bias flow of molten steel in mold, which will lead to slag entrapment. At the same time, in order to remove clogging materials, method of the rapid opening and closing stopper to flush the nozzle outlet was used. This situation will result in serious fluctuation of mold level and then could lead to breakout. In current study, effect of two states of nozzle clogging on mold flow was modeled through physical water modeling. 'Recovery time' is used to describe the mold flow status from the 'non-state' to the 'steady-state' process due to nozzle clogging being washed away from nozzle. Effect of nozzle outlet angle and casting speed on the recovery time will be discussed.

W-84: Plasticity and Fracture of Vintage Steel under Varying Stress-States, Strain Rates and Temperatures: *Ruth Hidalgo-Hernandez*[1]; Paul Allison[1]; Mark Horstemeyer[2]; Kennan Crane[1]; Vince Charito[1]; [1]US ARMY Corps of Engineers -ERDC; [2]Mississippi State University

The use of vintage materials in the nation's infrastructure presents a problem determining the state of structures built from these aging systems and how to properly protect the systems from loading conditions such as seismic activity. Researchers are investigating the microstructure and mechanical response of vintage steels under varying stress-states, strain-rates, and temperature effects. The material response under tension, compression, and torsion examines stress-state effects. While quasi-static and dynamic experiments provide strain rate response data, and the elevated temperature experiments elaborates on how the material behaves under different temperature conditions. The investigation allows an understanding of the mechanical behavior of vintage steel alloys and compares them to modern steels. The microstructure and mechanical property data is being used to calibrate an internal state variable (ISV) plasticity-damage model developed for cast materials, and adapted to wrought, powder metals, and extruded materials, for the prediction of material behavior under varying loading conditions.

W-85: Polaritons in Photonic Crystal at THz Frequency Range: *Umberto Fulco*[1]; Eudenilson Albuquerque[1]; [1]Universidade Federal do Rio Grande do Norte

We study polaritons modes arising from the propagation of a phonon-polariton excitation at the THz frequency range, in periodic and quasiperiodic (Fibonacci type) photonic structure comprised of alternating layers of both positive and negative refractive index materials. The choice of the THz frequency range is justified because current THz modulators based on semiconducting structures have the desirable property of being broadband, relevant to THz interconnects. Therefore, further improvement of the performance characteristics are welcome for practical applications, and in fact a possible application of the present model is an efficient active device that can be engineered to operate at THz frequencies. We make use of a theoretical model based on a transfer matrix treatment to simplify the algebra. We present also a quantitative analysis of the results, pointing out the distribution of the allowed photonic bandwidths for high generations, which gives a good insight into their localization and power laws.

W-86: Porosity Characterization of Surrogates for Oxide Nuclear Fuels: A Statistical Analysis of Correlationsamong Grain Boundary Misorientation, Pore Distribution and Processing Conditions.: *Robert McDonald*[1]; Karin Rudman[1]; [1]Arizona State University

Porosity plays an important role in oxide fuel performance because of its influence on microstructure reconstruction, i.e., recrystallization is known to initiate at large lenticular pores interacting with grain boundaries. Porosity also affects the rate of fission gases release, i.e., they act as vacancy sources for nucleating gas bubbles. A relationship between local microstructure (crystallography, geometry and topology) and porosity (size, distribution, shape, location) is needed as input for microstructurally explicit mesoscale simulations to model these phenomena. Therefore, samples of d-UO2 manufactured under different conditions and oxygen stoichiometries were studied using Scanning Electron Microscopy to collect statistical data on porosity for several samples. These data were compared to electron backscattering diffraction maps to find correlations between grain boundary misorientation, pore character and pore location for different processing conditions. Results are discussed in terms of grain boundary and pore interactions and their potential effects on grain boundary mobility during microstructural evolution.

W-87: Potential Fiberboard Material from Cow Manure and Disposable Water Bottle: *Boon-Chai Ng*[1]; Marlene Murray[1]; Craig Bradfield[1]; Roy Pritish[1]; [1]Andrews University

In this pilot project readily available solid cow manure from the nearby Andrews University dairy farm was rinsed to remove any feces, dried, and then tested for any life bacteria. This fiber material is then blended with shredded disposable plastic water bottle to form a "green' composite material. This composite material was placed in a cylindrical mold and heated to various temperatures to allow bonding of the thermoplastics to the fiber. The heated composite material was subsequently compacted with a 10,000 lbs. load using the universal tensile tester. Results showed that the composite material heated to a temperature of 250 C for an hour before compacting with a 10,000 lbs. load produced a well bonded fiberboard

W-88: Preparation of Pb Free Solder (Cu–Ag-Sn) Particles by Ultrasonic Spray Pyrolysis and Hydrogen Reduction (USP-HR) Method: Çigdem Toparli[1]; *Burcak Ebin*[1]; Sebahattin Gürmen[1]; [1]Istanbul Technical University

Electronic industry has been striving to find suitable material replaced Sn-Pb solder paste due to environmental concerns of using lead. Cu-Ag-Sn solder alloy is the most promising candidate as lead free solders due to low cost, low melting point, good mechanical properties and superior solderability. Nanocrystalline Pb free solder Cu–Ag-Sn alloy particles were synthesized by ultrasonic spray pyrolysis and hydrogen reduction method. Stoichiometric amount of copper, silver and tin salts were used to prepare precursor solution in desired concentration. Particles obtained by hydrogen reduction of the aerosol droplets of the precursor solution under constant H2 flow rate at 1000°C. Shape morphology, size, chemical composition and crystal structure of the particles were investigated by scanning electron microscope (SEM), energy dispersive spectroscopy (EDS) and X-ray diffraction (XRD). The results show that nanocrystalline Cu-Ag-Sn ternary alloy particles were prepared in submicron size range with spherical morphology.

W-89: Processing and Characterization of NiTi-MAX Phase Composites Prepared by Spark Plasma Sintering: *Ankush Kothalkar*[1]; Liangfa Hu[1]; Francesco Schaff[1]; Sandip Basu[1]; Miladin Radovic[1]; Ibrahim Karaman[1]; [1]Texas A&M University

Herein we report the fabrication of shape memory alloy (SMA) – MAX phase composites by spark plasma sintering (SPS) of equiatomic NiTi and Ti_3SiC_2 or Ti_2AlC powders at temperatures in the range of 960-1000^oC under 100 MPa uniaxial load. The microstructure and phase composition along the interfaces of these two-phase composites were studied using Scanning Electron Microscopy (SEM) and Energy-Dispersive Spectroscopy (EDS). The phase evolution near the interfaces in SPSed composites depends significantly on sintering temperature, because of the formation of Ni-Ti liquid phase at temperatures higher than 980^oC. Differential Scanning Calorimetry (DSC) has been carried out to confirm the martensitic phase transformation, and estimate the volume fraction of transforming NiTi phase in the SPSed composites. Thermo-mechanical properties of the composites are also discussed, along with practical implications of the results on inducing compressive stresses in ceramic MAX phases through phase transformations in SMA.

W-90: Processing of c-BN Film from B4C Target Using R.F. Magnetron Sputtering: Seungkeun Oh[1]; *Youngman Kim*[1]; [1]Chonnam National University

The cubic boron nitride (c-BN) film has unique physical and chemical properties such as extreme hardness next to diamond, excellent chemical inertness, high thermal conductivity, and thermal stability. In this study, c-BN thin films were processed on WC substrates using B4C targets in R.F. magnetron sputtering system as a function of substrate bias voltage. The morphology and thicknesses of the deposited films were observed. Fourier transform infrared microscopy (FT-IR) were used to analyze the bonding characteristics of c-BN. Intensity of absorption band of FT-IR corresponding to B-C and C-N bond were increased with increasing the substrate bias voltages. Possible mechanisms for the formation of c-BN films were also discussed.

W-91: Reciprocal Space Configurational Kinetics of Amorphous SystemsW: *Volodymyr Bugaev*[1]; Mariya Rasshchupkyna[1]; Alexander Udyansky[2]; Miguel Castro-Colin[1]; Peter Wochner[1]; [1]Max Planck Institute for Intelligent Systems; [2]Max Planck Institute for Iron Research GmbH

We propose a reciprocal-space kinetic approach for inhomogeneous systems, based on the correlation correction algorithm (CCA) [1] and atomic density functional theory [2]. This concept deals with cooperative reciprocal-space atomic density modes and takes into account coupling in effective atomic interaction modes. The set of dominant modes, corresponds to the minimal negative value of the Fourier component of the renormalized effective pairwise interaction potential Veff(q). It is visualized that interference of the dominant modes leads to long-living structural states, e.g. clusters with discernible symmetries, recently revealed by the X-ray cross-correlation analysis [3] from coherently scattered X-rays.[1] V.N.Bugaev, A.Udyansky, O.Shchyglo, H.Reichert, H.Dosch, Phys. Rev. B. 74, 024202-1 (2006).[2]Y.M.Jin, A.G.Khachaturyan, J. App. Phys. 100, 013519-1 (2006).[3]P.Wochner, C. Gutt, T.Autenrieth, T.Demmer, V.N.Bugaev, A.D.Ortiz, A.Duri, F.Zontone, G.Gruebel, H.Dosch, P. Natl. Acad. Sci. USA. 106, 11511 (2010).

W-92: Refinement of Ligaments of Nanoporous Ag Ribbons by Controlling the Surface Diffusion of Ag: *Tingting Song*[1]; Yulai Gao[1]; Zhonghua Zhang[2]; Qijie Zhai[1]; [1]Shanghai University; [2]Shandong University

Nanoporous silver (NPS) with different nanoporosity was manufactured by chemical dealloying of rapid solidified Al-Ag ribbons consisting of two distinct phases of a-Al(Ag) and Ag2Al. The as-dealloyed samples were characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM), and energy dispersive X-ray (EDX) analysis. It has been found that the width of the average ligaments can be dramatically decreased and be more homogeneous when surfactants were added to the H2SO4 solution, which would definitely increase the specific area of NPS and is pretty desirable for certain applications, such as catalyst, absorption, etc. The finer ligaments were attributing to the hindered surface diffusion of Ag atoms by surfactants, and the surface diffusion coefficient (Ds) of Ag was decreased from the order of 10-14 to 10-16 m2/s as a result of surfactants. This simple method to reduce the ligament width of NPS is also anticipated to prepare the other related nanoporous metals.

W-93: Relationship between Heat Input and Microstructure and Mechanical Properties of Laser Beam Welded Superalloy Inconel 718: *Akin Odabasi*[1]; Necip Ünlü[2]; Gültekin Göller[2]; M. Niyazi Eruslu[2]; E. Sabri Kayali[2]; [1]Firat University; [2]Istanbul Technical University

Autogenous butt, laser beam welds were carried out using Inconel 718 alloy sheets (2.1 mm thick). The relationship between heat input laser beam welding (LBW) and the microstructural and mechanical properties of superalloy Inconel 718 were investigated. Nine different heat inputs in the range of 61.29–90.09 Jmm^{-1} were applied to evaluate the geometry of weld seams. Full penetration was achieved in all weld experiments. Optical and field emission scanning electron microscopy and microhardness tests were performed. Test results indicate that increasing the amount of heat input from 61.29 Jmm^{-1} to 90.09 Jmm^{-1} presented solidification rates between $1.27x10^5$ and $1.46x10^6$ $^oCs^{-1}$. The hardness property of the weld samples decreased with the increasing the heat input.

W-94: Role of Work Hardening during Sliding Wear of Heat Treated 2024 Al Alloy: *Yong-Suk Kim*[1]; Hyuk Woo Kwon[1]; Gonam Kim[1]; [1]Kookmin University

In the present study, the role and effect of strain hardening during dry sliding wear of 2024 Al alloy was investigated. Dry sliding wear tests were performed on the naturally aged (T4), artificially aged (T6) and solution treated 2024 Al alloy using a pin-on-disk wear tester at various loads and for differing sliding distances. Alumina balls were employed as a counterpart. Wear rates of the alloy with various microstructures due to different heat treatments were compared; and related with work hardening during the wear, which varied greatly with the microstructure. The work hardening was evaluated by measuring cross-section hardness as a function of distance from the worn surface. Work-hardening at the wearing surface affected the wear of the Al alloy significantly by forming a surface-deformation layer, which was closely connected with wear-particle generation. The hardened layer also acted as a protecting layer that resists further progress of wear.

W-95: Silver Uptake from Dilute Cyanide Solution Using Activated Charcoal: *Bihter Zeytuncu*[1]; Onuralp Yucel[1]; [1]Istanbul Technical University

The adsorption of silver cyanide on activated charcoal from dilute cyanide solution of 200 ppm has been investigated. The effects of different adsorption parameters on the silver adsorption percentage are reported in detail. The percent of silver adsorption increased with a raising amount of adsorbent, as well as with increasing retention time and temperature. Additionally, the experimental rate data is explained by use of a kinetic equation. The characterization of activated charcoal was analyzed by X-Ray Diffraction (XRD).

W-96: Structural and Electrical Characteristics of Ba2DyNbO6: *Suharto Chjatterjee*[1]; Koushik Biswas[2]; Mukul Pastor[2]; Mukul Pastor[2]; [1]Ace Calderys Ltd; [2]Indian Institute of Technology,Karagpur, India

The electro ceramic material Ba2DyNbO6 has been prepared by a standard solid-state reaction technique. Structural analysis was performed with XRD in which dominant (98%) cubic perovskite phase was found. The tolerance factor of the sample was found to be 0.891 suggesting that the sample is stable. The FTIR analysis showed good bond strength in the sample. The experimental results of impedance spectrum indicate that the material exhibits (i) electrical resistance due to bulk material up to 575oC (ii) negative temperature coefficient of resistance (NTCR)-type behaviour and (iii) temperature-dependent relaxation phenomena up to 500oC. The behaviour of the modulus spectrum is suggestive of temperature-dependent ion hopping mechanism for electrical conduction (charge transport) in the system. The AC conductivity spectrum was found to obey Jonscher's universal power law. Conductivity phenomenon has been explained with respect to thermal activation resulting in mobile charges.

W-97: Study of Stacking Fault Formation Probability under Loading in High Manganese Steels: *Mihyun Kang*[1]; Wanchuck Woo[1]; Vyacheslav Em[1]; Yong Kook Lee[2]; Eunjoo Shin[1]; Back-Seok Seoung[1]; [1]KAERI(Korea Atomic Energy Reserch Institute); [2]Yonsei University

Since the reason of the excellent mechanical properties of the high manganese steels has been known to the twinning induced plasticity (TWIP) phenomenon, stacking faults and twinning formation have been extensively studied under deformation. We measured diffraction of (111) and (222) during tensile loading up to ~800MPa stopped at 7 different loading steps using neutron diffraction. Difference of the peak shifts between the two reflections increases as the loading increases even though the peak shifts should be same when considering the elastic strain with crystallographic point of view. The difference was correlated to the stacking fault probability (SFP) based on the Warren's analysis of twin faulting and peak shifts. The analyzed results can suggest quantitative variations of SFP as a function of loads in TWIP steels.

W-98: Synergistic Extraction and Solvent Extraction of Uranium from Sulfate Solutions – A Comparative Study: *Rajesh Kumar Jyothi*[1]; Chul-Joo Kim[1]; Jin-Young Lee[1]; Joon-Soo Kim[1]; Ho-Sung Yoon[1]; [1]Korea Institute of geoscience and Mineral Resourses (KIGAM)

Energy consumptions growing vigorously throughout the world in new millennium, this fact drive the researchers towards energy related research and development areas. The present scientific study focused on uranium extraction from sulfate solutions by using amine based extractants as promising reagents. The present efforts made on two different extraction methodologies such as solvent extraction process and synergistic solvent extraction process for uranium. For the extraction phenomena the following conditions are fixed: the temperature (25oC), time (30 min), aqueous: organic phase ratios (A:O = 1:1) for all experiments. Synergistic extraction process tested the ability of the extractants to recover the title metal with amines as extractants as well as synergists and organophosphorus reagents used as synergists with amines. For the uranium analysis in aqueous solutions ICP-OES used as analytical instrument.

W-99: Synthesis and Characterization of Metallic Oxides: *Eduardo Brocchi*[1]; Rodrigo Souza[1]; Marina Doneda[2]; Jose Campos[3]; Ana Cristina Wimmer[1]; Rogério Navarro[1]; [1]PUC-Rio; [2]VALE; [3]CBPF

Due to recent great interest on nanostructured materials this work is related to an alternative synthesis method as compared to the already established aqueous phase precipitations and gaseous species reactions. It deals with the pyrolisis of Fe, Cu, Ni, Zn and Al nitrates, including a theoretical thermodynamics decomposition approach and the corresponding experimental characterizations of the products, by XRD and SEM. The thermodynamics have shown that these decompositions can start in the temperature range between 150°C and 550°C and the XRD patterns have confirmed the formation of Fe2O3, CuO, NiO, ZnO and Al2O3. SEM indicates the occurrence of a typical particles agglomerated structure for Fe, Cu and Ni oxides while the two others are formed either as faceted crystal (ZnO) or in the pancake shape (Al2O3). Further analysis by the Rietveld method proved that this methodology can be used to produce oxides with nanosized particles content.

W-100: Synthesis and Characterization of Nacre-Inspired Nanocomposites: *Omar Rodriguez-Negron*[1]; Carlos Morales-Del Valle[1]; Ruth Hidalgo-Hernandez[2]; Robert Moser[2]; Paul Allison[2]; Mei Chandler[2]; Charles Weiss[2]; Philip Malone[2]; [1]UPRM/ ARMY ERDC; [2]US ARMY ERDC

The U.S. Army Engineer Research and Development Center (ERDC) is currently synthesizing and characterizing bioinspired nanocomposites utilizing the multi-layered hierarchical design principles found in nacre. Electrophoreticelectro transport deposition and hydrothermal hot pressing are methods currently being investigated in order to synthesize nacre's hierarchical structure. Both methods are intended to provide the ability to control the crystallographic form, crystal size and crystal location within a polymer matrix. Calcium acetate and ammonium carbonate are the chemical compounds employed with the purpose of replicating calcium carbonate biomineralization. The influence over precipitate mineralogy of different reactants concentrations as well as the presence of magnesium acetate or strontium acetate was also investigated. X-ray diffraction is employed in characterizing the crystal structures being synthesized while scanning electron microscopy is used in determining the size and shape of the crystal structures forming. Initial results suggest the approach may produce useful new composites.

W-101: Synthesis and Electrochemical Performance of LiMnBO3 as a Novel Li-Ion Battery Materials: *Hyukjae Lee*[1]; Yong-Suk Lee[1]; [1]Andong National University

As a new cathode material for Li-ion batteries, LiMnBO3 is prepared by solid state reaction using Li2CO3, H3BO3, and MnCO3. At lower calcination temperatures, less than 600°C, monoclinic phase is obtained, while hexagonal phase is obtained at higher calcination temperature, above 800°C. To improve the electronic conductivity, LiMnBO3/C composites are also prepared using a carbon black or organic carbon precursor. The electrochemical measurements show that the monoclinic LiMnBO3 has the higher capacity than hexagonal counterpart and the enhanced electrochemical performance from the LiMnBO3/C.

W-102: Synthesis of SiC Nanoparticles for Ink-Jet Printing: *Jong-Woong Kim*[1]; Young-Sung Kim[2]; Sung-Jei Hong[1]; Hyun-Min Cho[1]; [1]Korea Electronics Technology Institute; [2]Seoul National University of Science & Technology

SiC has been known for high hardness, wear resistance and good resistance to oxidation, thermal shock, and corrosion. More importantly, it has good thermal conductivity, which makes it possible for applications in fabrication of micro hotplates. Here we intended to fabricate various SiC patterns for use as micro hotplates by ink-jet printing. For application

POSTERS

of the ink-jet printing to fabricate SiC micro patterns, ink composed of SiC nanoparticles, solvent and additives are needed. In order to achieve uniform thin film from the ink, fine sized SiC nanoparticles less than 100 nm has to be uniformly dispersed. In this study, we employed a mechanical milling method that is called as the ultra apex mill (UAM). The SiC nanoparticles were synthesized by the UAM and SiC ink was formulated with ethylene glycol based solution. The patterns were made by ink-jetting, then a high temperature annealing was followed to fabricate the micro hotplates.

W-103: Synthesis, Characterization and Application of Core-Shell Oxide Nanoparticles: *Yuanbing Mao*[1]; Suresh Alaparthi[1]; [1]University of Texas-Pan American

Miniaturization in various industries has led to the requirement for multifunctionality. Here we have developed some core-shell nanostructures with strong interfacial couplings. These nanostructures have at least three advantages: (i) to realize multifunctionality, (ii) to provide novel functions not available in single-component materials or structures, and (iii) to achieve enhanced properties and breaking the natural constraints of single-phase materials. These nanoparticles are thoroughly characterized by x-ray diffraction, scanning electron microscopy, (high resolution) transmission electron microscopy, selected area electron diffraction, and energy-dispersive x-ray spectroscopy, as well as ultraviolet-visible, Fourier transform infrared and Raman spectroscopes to delineate their structure and composition. Their luminescent and magnetic properties have been systematically studied. The aimed applications of these core-shell nanoparticles mainly include: (1) national security, such as core-shell nanoparticles for gamma-ray radiation detection; and (2) information storage, such as multiferroics and exchange-biased magnetic materials.

W-104: TEM Study of Crystal Defects in Laves Phase Alloys: *Ke Wang*[1]; Kwo Young[2]; Leonid Bendersky[1]; [1]NIST; [2]Energy Conversion Devices

Transmission Electron Microscopy (TEM) was employed to investigate the crystal defects in AB2 type Nickel Metal Hydride (NiMH) battery alloys. A high density of stacking faults and micro twins were found within the cubic C15 Laves phase. In contrast, high density dislocations appeared in the hexagonal C14 Laves phase. A typical grain boundary structure was observed between C14 and C15 phases. The orientation relationship between two Laves structures was determined to be {111}<110>C15// {0001}<11-20>C14. These results reveal that the stacking fault energies (SFE) of C14 and C15 Laves phases are very different. These crystal defects in the material are believed to play an important role in the hydrogen absorption/desorption behavior during electrochemical process for hydride electrode alloys.

W-105: The Effect of Die-Shape and Die Parameters in ECAP on the Microstructure and Flow Properties of Some 2-Phase Alloys: *Nithyanand Prabhu*[1]; B Kashyap[1]; P Hodgson[2]; Rahul Kulkarni[1]; Pabitra Palai[3]; V Srinivas[4]; [1]Indian Institute of Technology Bombay; [2]Deakin University; [3]Tata Steel; [4]Vizag Steel Plant

Equi-channel angular pressing (ECAP) of a Pb–Sn eutectic alloy up to six passes in a T-shaped die, rather than a conventional L-shaped die, was studied for grain refinement. Microstructure predominately changed in the early part of the ECAP process and became equiaxed and uniformly distributed in both the longitudinal and the transverse sections after four passes. There occurred substantial softening over the first two passes & ductility increased drastically. Various tensile properties and concurrent microstructural evolution were used to develop a mutual relationship among them. The effects of die channel angle (ø) in hot (~623 K) ECAP on microstructure, and tensile and compressive flow properties of AZ80 Mg alloy were investigated at room temperature. Flow stresses in tension and compression are found to increase with decreasing value of die angle. There appears flow asymmetry between tension and compression with the latter exhibiting greater flow stress and strain to failure.

W-106: The Effect of High Superheat on the Solidification Structure and Carbon Segregation of Ferrite-Based Alloy: Honggang Zhong[1]; *Yi Tan*[1]; Huigai Li[1]; Xinping Mao[2]; Qijie Zhai[1]; [1]Shanghai University; [2]Guangzhou Zhujiang Iron and Steel Co., Ltd.

The Ferrite-based alloy was melted and poured in-situ to investigate the effect of high superheat on the solidification structure and macrosegregation of permanent mold casting. The alloy solidified horizontally from the chill wall in a furnace, which be shut down after the alloy liquid be poured. The coarse equiaxed dendritic grains, which diameters are more than 5mm, are observed with high superheat (80-120 K), and the secondary dendritic arm spacing increases with superheat increasing. However, the degree of carbon macrosegregation K(C), which is defined as the ratio of concentration of solute (Ci) to average concentration of solute (Cave), are less than 1.2, which indicate the fluctuations of carbon concentration are small.

W-107: The Effect of Oxygen Vacancies on the Stability and Reactivity on Rutile TiO2 (110) and Its Reconstructions: *Jackelyn Martinez*[1]; Tzu-Ray Shan[1]; Susan Sinnott[1]; Simon Phillpot[1]; [1]University of Florida

Rutile TiO2 (110) is often used as the base surface for heterogeneous catalysts for many important metal nano-clusters. To better understand reactivity of the surface, a computational study of this surface was carried out using an empirical, variable charge potential for Ti and TiO2 based on the charge-optimized many body (COMB) framework. The surface energies of the pristine (110) surface along with reconstructed and stepped surfaces were determined, and compared to literature results. The effect of oxygen vacancies on the surface energy of the differing (110) rutile surfaces was also explored. In addition, the defect energies of surface and subsurface oxygen defects were calculated. The defect formation energy depends on the distance below the surface which suggests that sub-surface vacancies should have little or no effect on the reactivity of this surface. This work is supported by NSF (DMR-1005779).

W-108: The Formation and Characterization of Al Metal Matrix Composite Reinforced by Ni60Nb20Zr20 Amorphous Powders: *Pee-Yew Lee*[1]; [1]National Taiwan Ocean University

The Ni60Nb20Zr20/Al metal matrix composite powders with 10~50 wt% Ni60Nb20Zr20 amorphous powders were prepared by high energy ball milling of the corresponding amorphous and pure Al powders. The Ni60Nb20Zr20/Al metal matrix composite powders were then consolidated into bulk discs by vacuum hot pressing methods. The DSC result shows that the melting temperature of Al matrix was shift to lower temperature with increasing of milling time. The Vicker's microardness of bulk samples can be promoted by increasing the amount of Ni60Nb20Zr20, milling time and hot pressing time. The corrosion behavior of 40 wt % Ni60Nb20Zr20/Al metal matrix composite discs in four different corrosive media was studied using the potentiodynamic method. The resultant polarization curves indicated the Ni60Nb20Zr20/Al-based metal matrix composite has poor corrosion resistance either in strong acid or strong alkaline solutions. However, it is noted the alloy exhibits the best corrosion resistance in 3.5wt. % NaCl.

W-109: The Formation of an Eutectic Mixture for Predicting the Ideal Solubility of Thermally Stable and Unstable Compounds: *Rodolfo Pinal*[1]; Ryan McCain[1]; [1]Purdue University

The melting properties of organic compounds are critical to the solubility behavior of APIs (active pharmaceutical ingredients). Solubility of poorly water soluble APIs is one of the largest challenges in formulation development. Estimating solubility by means of the melting temperature and heat of fusion is a widely established practice. However, a common problem in drug development is that some APIs are thermolabile and undergo chemical decomposition before melting. This situation makes the essential melting parameters experimentally inaccessible. Eutectic microcrystalline mixtures offer the potential advantage of increased dissolution rates at lower temperatures without changing the selected crystalline form of the API. Eutectic mixtures also offer a means to overcome the hurdles imposed by thermal limitation. The purpose of this work was to develop and test a thermodynamic model for estimating the enthalpy of fusion of thermolabile compounds, based on the entropy of fusion, thus enabling further prediction of their ideal solubility.

W-110: The Importance Role of Sulfur in Autogenous Copper Smelting Technology: *Ljubisa Misic*[1]; Vlastimir Trujic[1]; Tatjana Trujic[1]; [1]Mining and Metallurgy Institute

There are many reasons why sulfur represents one of the most important question in the copper pyrometallurgical processes. The most of the copper sulfide concentrates contains approximately 1 to 1.5 ton of sulfur (2 \8722 3 t SO_2) per each ton of the produced copper. Sulfur has chemical, technological, energy and ecological importance in the copper smelting processes. In the last decades, energetical and ecological aspects of sulfur is the most considerable and the best solution of its are incorporated in the autogenous copper smelting processes.

W-111: The Solid-State Sn/Ni Interfacial Reaction Under Three-Point Bending: *Chih-Ming Chen*[1]; Wen-Kai Liao[1]; [1]National Chung Hsing University

Effect of strain on the Sn/Ni interfacial reaction annealed at 200 oC is investigated. A bi-layer of Sn/Ni deposited on a Si substrate is subjected to tensile or compressive strain by virtue of a three-point bending apparatus. Enhanced growth of the Ni3Sn4 phase formed at the Sn/Ni interface is observed under both tensile and compressive strains. The Ni layer subjected to strains exhibits significant microstructure evolution, which is suggested to play a crucial role for the enhanced growth of the Ni3Sn4 phase.

W-112: The Study of Thermal Properties and Devitrification Behaviors of Al-RE-TM Amorphous System: *Song-Yi Kim*[1]; Gwang-Yeob Lee[1]; Min-Ha Lee[1]; [1]Kitech

Al-based amorphous with minor additions of rare earth elements and transition metals were technical interest, because of their extraordinary high strength. Recently, amorphous with high glass forming ability with wide supercooled liquid region which defined by temperature range between glass transition temperature (Tg) and crystallization temperature (Tx) have been reported in many alloy systems. Various kinds of techniques have been tried to promise potential process obtaining a fast densification without crystallization during the consolidation of amorphous. In this study the effect of RE addition on the Al-based amorphous was evaluated and the structure and property of Al-RE-TM (transition-metal) were investigated by various techniques. Thermal and physical properties of the Al-based amorphous were characterized using DSC and XRD. Crystallization kinetics of Al-based amorphous was analyzed by applying modified Johnson-Mehl-Avrami equation from the isothermal annealing results of Al-based amorphous at various temperatures.

W-113: The Variability of Small Crack Growth in Notched Bars of IN100: *D'Anthony Ward*[1]; Andrew Rosenberger[2]; Dennis Buchanan[3]; [1]University of Dayton ; [2]Air Force Research Laboratory; [3]University of Dayton Research Institute

Small crack growth appears to be the critical link to predict the minimum fatigue life using fracture mechanics. The present study builds upon our current understanding of small crack initiation and growth in smooth bars and assesses the growth of small cracks in fracture critical locations associated with areas of high stress concentrations, e.g. bolt holes, fillets, balance flange scallops, etc. Results indicate that the same initiation mechanisms are operable in smooth and notched bars. Generally the same small crack growth mechanisms exist in the two conditions, however, the concentrated stress in the notched geometry promotes the formation of additional cracks ahead of the main crack such that the effects of crack merging must be considered. Furthermore, replicate notch fatigue tests indicate that the minimum fatigue life can be discovered even when interrogating only the small volume of material at the notch.

W-114: Thermal Analysis of the Composition of Poly(Acrylic Acid)/ Carboxymethylstarch Used as a Polymeric Binder: Beata Grabowska[1]; Mariusz Holtzer[1]; Sonja Eichholz[2]; Krzysztof Hodor[2]; Ewa Olejnik[1]; [1]AGH University of Science and Technology; [2]Applications Laboratory Thermal Analysis, NETZSCH-Gerätebau GmbH

Samples of poly(acrylic acid)/carboxymethylstarch used as a binding agent in molding sands were investigated. Methods of thermal analysis were applied to assess the thermal stability of the investigated polymer sample by estimation of temperature and thermal effects of transformations occurring during its heating. In the temperature range -100-1000°C none polymorphic transformations were found. It was established that the degradation process starts at a temperature app. of 130°C. On the bases of the analysis of volatile products of the polymer decomposition performed by means of the IR spectral method and the thermo gravimetric method coupled 'on-line' with the mass spectrometry the signals for low molecular masses were found in the temperature range: 300-400°C. This indicates that the degradation process occurs, polymer chains are undergoing fragmentation and low molecular compounds are formed. At the higher temperature range compounds and alkyl radicals of higher mass numbers are formed.

W-115: Thermal Radiation Spectra in Photonic Crystals: *Luciano da Silva*[1]; Manoel Vasconcelos[1]; [1]Universidade Federal do Rio Grande do Norte

In this work we investigate the behavior of a light beam normally and obliquely incident on a one-dimensional multilayer photonic structure, composed of a positive refractive index material (SiO2) and a polaritonic metamaterial (LiTaO3), arranged in a periodic and quasiperiodic (Fibonacci) fashions. Their emission spectra are determined by means of a theoretical model based on Kirchoff's second law, together with a transfer matrix formalism. We discuss the radiation spectra for both the ideal case, where the negative refractive index material can be approximated as a constant in the frequency range considered, as well as the more realistic case, taking into account the frequency dependent magnetic permeability and the electric permittivity characterized by a polaritonic dielectric function. Our main result shows that the quasiperiodic structure presents a more rich thermal radiation spectrum than observed in the periodic case, pointing it as a good candidate for designing efficient negative index refraction filter.

W-116: Thermographic Defects Evaluation of Railway Bogies: *Jeongguk Kim*[1]; [1]Korea Railroad Research Institute

The lock-in thermography was employed to evaluate the defects in railway bogies. Prior to the actual application on railway bogies, in order to assess the detectability of known flaws, the calibration reference panel was prepared with various dimensions of artificial flaws. The panel was composed of structural steel, which was the same material with actual bogies. Based on the defects information, the actual defect assessments on railway bogie were conducted with different types of railway bogies, which were used for the current operation. In summary, the defect assessment results with thermography method showed a good agreement as compared with the conventional inspection techniques. Moreover, it was found that the novel infrared thermography technique could be an effective way for the inspection and the detection of surface defects on bogies since the infrared thermography method provided rapid and non-contact investigation of railway bogies.

W-117: Thermographic Monitoring of Braking in Railway Brake Shoe: *Jeongguk Kim*[1]; Sung-Cheol Yoon[1]; [1]Korea Railroad Research Institute

The damage evolution due to generation of hot spots and/or thermal bands on railway brake shoe has been considered the main degradation mechanism in brake shoe. Therefore, the understanding of the formation of hot spots and/or thermal bands is important for a better understanding of material design as well as enhancement of materials properties in railway brake shoe. In this investigation, during braking up to maximum speed of 300 km/h, the thermographic temperature analysis of railway brake shoe was quantitatively performed to investigate the degradation mechanism of brake shoe. The analysis of surface temperature changes on railway brake shoe was conducted using a high-speed infrared camera. Through the analysis of thermographic monitoring images, the temperature evolution with different braking speeds was qualitatively evaluated. In this investigation, the qualitative investigation results on the temperature evolution of railway brake shoe was summarized and presented.

W-118: Titania Based One-Dimensional Nanomaterials for Lithium Ion Batteries: *Hyukjae Lee*[1]; Young-Jun Kim[2]; Jong-Hwan Park[1]; [1]Andong National University; [2]Korea Electronics Technology Institute

Recently, TiO2 based materials are drawing much attention as anode materials for lithium ion batteries due to its safety, abundance in nature, chemical stability, and non-toxicity. However, their low lithium ion diffusivity and electronic conductivity deteriorate reversible capacity and high rate performance. To overcome this, nanostructuring of TiO2 has been exploited to reduce transporting path for lithium ions and electrons. Of particular interest is 1D- nanostructures since their interesting size, shape related properties. In this study, various titania and lithium titanate 1D-nanostrutures are prepared and their lithium electrochemical performances are compared. Further, the effects of the surface treatment and doping are investigated.

W-119: Toxic Metals in Ash Residue from Electronic Waste Dismantling and Incineration Practices: *Kathleen Hibbert*[1]; Oladele Ogunseitan[1]; [1]University of California, Irvine

This research investigates the toxic metals and chemicals in residual ash after burning of electronic waste (e-waste). These toxins can leach into soil and water systems, and can be dispersed widely in the environment; thus creating a public health risk to populations. Currently, e-waste is the fastest growing form of solid waste, yielding over 2 million tons of material generated annually in just the United States. Approximately 90% of e-waste is discarded, with incineration recognized as a common procedure for recycling and disposal globally. We investigated the chemical residues in ash generated from incinerated cell phone components divided into four categories: screens, plastics, circuit-boards and batteries. Results from ash residue analysis that have raised initial concern have revealed seventeen metals including beryllium, cadmium, copper, lead, nickel and zinc. Results have also identified PCBs, PBDEs and furans.

W-120: Wettability and Interfacial Microstructure of Pb-Free Sn3.5Ag Alloy Powders on Cu Substrate: *Jin Zhao*[1]; Weipeng Zhang[2]; Tingting Song[2]; Yulai Gao[2]; Qijie Zhai[2]; [1]Shanghai university; [2]Shanghai University

Sn3.5Ag powders in different sizes were prepared by arc technique. Powders in different sizes mixed with Rosin Mildly Activated (RMA) fluxes were soldered on pure Cu substrate. The contact angle is a critical parameter to affect the quality of solder joints. Presently the Pb-free Sn3.5Ag solder has been widely applied in industry. However, its wettability on Cu substrate is not good enough, and the contact angle of commercial Sn3.5Ag solder paste is about 26°. In contrast, the contact angles of the Sn3.5Ag solder paste prepared in the present study are 16.1°, 13.9 °, and 21.4 °respectively, depending on the specific characteristics of the powders. So good wettability was obtained attributing to the novel technique to prepare Sn3.5Ag powders. In addition, the intermetallic compounds (IMCs) were observed by optical microscope and scanning electron microscope, and the results showed that continuous intermetallic compounds layer formed, confirming the validity of the packaging.

Biological Materials Science Student Poster Contest: Poster Session

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS: Biomaterials Committee
Program Organizers: Nima Rahbar, University of Massachusetts Dartmouth; Candan Tamerler, Istanbul Technical University; Po-Yu Chen, National Tsing Hua University; Molly Gentleman, Texas A&M University

Monday PM	Room: Atlantic Hall
March 12, 2012	Location: Dolphin Resort

Session Chairs: Nima Rahbar, University of Massachusetts Dartmouth; Po-Yu Chen, National Tsing Hua University; Candan Tamerler, University of Maryland Baltimore County

I-1: Addition of Apatite Microparticle to Cell Cultures- Effects on Differentiation: *Amanda Farley*[1]; Laura Datko[1]; Marian Kennedy[2]; Delphine Dean[1]; [1]Clemson Bioengineering; [2]Clemson Materials Science and Engineering

Recent studies show that hard particles added to suspensions of cell growth media can stimulate bone marrow stem cells (BMSCs). This study looks at the response of dental pulp stem cells (DPSCs) and Osteoblasts to 40µm diameter Hydroxyapatite (HA) and Fluorapatite (FA) particles for cranial reconstruction applications. BMSCs were also studied to compare to the previous results of other research groups. Cells were given 24hrs to adhere in individual wells and then a 10mg/mL suspension of either HA or FA microparticles were added to 2/3 of the wells, with remaining wells left as a control. ALP and BCA assays were run on days 1,3,5 and 14. Antibody stains and confocal imaging were done for collagenI and osteocalcin. In general, the control cells produced more protein, osteocalcin, and collagenI, and had higher levels of ALP specific activity than cells cultured with microparticles. The authors would like to acknowledge funding from NIH (Award number:092228).

I-2: Adhesion and Interfacial Fracture Toughness between Hard and Soft Materials: *Nima Rahbar*[1]; Sina Youssefian[1]; [1]Umass Dartmouth

To quantify adhesion between the drug-eluting layer and a Parylene C primer, Brazil nut sandwich specimens were prepared mimicking the layers of drug-eluting stent coating. These samples were stressed to fracture, and the resulting initial cracks at the Parylene C/drug and Steel interface were used to measure the dependence of interfacial fracture energy of mode mixity. The mating fracture surfaces were then analyzed using scanning electron microscopy (SEM) and energy dispersive x-ray spectroscopy (EDX). The interfacial energy release rates were obtained over a wide variety of mode mixities. Adhesion and fracture mechanics models were used to estimate the mode mixity dependency of interfacial fracture toughness. Fracture toughness was found to be larger under higher mode mixity than that under lower mixity and the analytical model showed close agreement with experimental results. The experimental adhesion results between the Parylence C and Stainless Steel are later verified using a Molecular Dynamics simulation.

I-3: Cellulose-based Nanocomposiite as a Potential Scaffold in Cardiovascular Tissue Engineering: *Parisa Pooyan*[1]; Rina Tannenbaum[1]; Hamid Garmestani[1]; [1]Georgia Institute of Technology

Cellulose nanowhiskers (CNWs) with its renewable and environmentally benign nature, and its abundance and excellent biocompatibility could potentially open a new avenue in cardiovascular tissue engineering for small caliber grafts. Inspired by this bioapplication, we have designed a fully bio-based nanocomposite of aligned CNWs embedded in a matrix of cellulose acetate possessing a controlled biodegradability, 3D porosity, and non-acidic byproducts as opposed to degradable PLA/PGA. To ensure uniform distribution, CNW were delicately extracted from a multi-stage process and dispersed in a solvent of choice prior to mixing with the matrix to inhibit whiskers flocculation. Comparable to Carbon Nanotubes

POSTERS

or Kevlar, CNWs imparts significant strength and directional rigidity to the composite even at 0.2 wt% yet doubles that within a controlled magnetic field of only 0.3T. We believe our fibrous porous aligned nanocomposite could have ground-breaking features withstanding the physiological pressure and mimicking the topographical texture of the native extracellular graft.

I-4: Comparison of Composites with Biological or Synthetic Hydroxyapatite Scaffolds: *Steve Lee*[1]; Ekaterina Novitskaya[1]; Antoni Tomsia[2]; Po-Yu Chen[3]; Joanna McKittrick[1]; [1]University of California, San Diego; [2]Lawrence Berkeley National Laboratory; [3]National Tsing Hua University

Most bone substitute materials are primarily based on hydroxyapatite. Their shortcomings include low strength due to the porosity required for osteointegration and difficulty of fabrication. We have developed new polymer/hydroxyapatite composite that is porous, strong as natural bone and is easy to fabricate. The designs use scaffolds from either biological or synthetic hydroxyapatite. The biological hydroxyapatite scaffold was formed by deproteinizing samples of cancellous bovine femur bone and the synthetic hydroxyapatite scaffold was formed by freeze casting. Both scaffolds have 25-40 vol.% mineral, inside the range of natural bone. The scaffolds were filled with biocompatible polymers such as PMMA and various epoxies. The composites have an order of magnitude higher compressive strength than that of bovine femur bone. Composite materials based on these fabrication methods could potentially find use in prostheses where low weight and good strength are required. This work is supported by NSF, Ceramics Program Grant DMR1006931.

I-5: Effects of Heat Treatment and Moisture on Mechanical Properties of Bamboo: *Peter Kotowski*[1]; Nima Rahbar[1]; [1]Umass Dartmouth

This talk presents experimental and numerical studies on the deformation mechanisms of bamboo in torsion, bending, and fatigue. The microstructure of bamboo can be considered as a material composed of non-uniformly distributed longitudinal fibers that are segmented by nodes. Using specially designed fixtures, samples of kiln dried bamboo were cut and tested in torsion with varying moisture to determine the effects on the torsional strength of bamboo. Finite element simulation was also used to study the torsional strength and bending of bamboo. The toughness of bamboo was studied for each case. Also, simple four point bending tests with strain gauges on 5-inch strips of bamboo determined the variation of the elastic modulus in culm segments. This data was integrated into conducting fatigue testing and obtaining an S-N curve. The results are presented to reflect how heat treatment and moisture along with bending and fatigue affect the mechanical behavior of bamboo.

I-6: In Vitro Restoration of Tooth Root via Protein-Derived Mineralization Peptides: *Mustafa Gungormus*[1]; Ersin Oren[1]; Hanson Fong[1]; Jeremy Horst[1]; Malcolm Snead[2]; Ram Samudrala[1]; Martha Somerman[1]; Candan Tamerler[1]; Mehmet Sarikaya[1]; [1]University of Washington; [2]University of Southern California

In the quest for developing biomimetic restoration protocols, we describe here remineralization of hydroxyapatite (HAp) microlayer on the root of mammalian tooth using peptides designed by similarity analysis of natural mineral-binding proteins and biocombinatorially selected peptides. The bioinformatics approach provides, e.g., amelogenin-derived peptides (ADPs) with various functions (surface affinity, mineralization or rate control) We demonstrate case studies where ADPs are used to remineralize artificial tooth root lesions. When treated with ADPs, exposed dentin remineralizes in a relatively short time, and the mineral is mechanically well-integrated with dentin and withstands clinically relevant stresses. Furthermore, in vitro cytocompatibility assays demonstrate that the newly formed mineral creates an environment to promote adhesion and proliferation of periodontal ligament cells. The designed mineralization peptides offer great potential for clinical applications leading to development of effective biomimetic therapies for root carries. The research was supported by GEMSEC, an NSF-MRSEC (DMR# 0520567) at the UW.

I-7: Kinetics of Phosphate Ion Cerium Oxide Nanoparticle Interaction and Effect on Redox Activity of Bare and Functionalized Cerium Oxide Nanoparticles: *David Letter*[1]; Amit Kumar[1]; Vanessa Moosavifazel[1]; Soumen Das[1]; William Self[1]; Sudipta Seal[1]; [1]AMPAC

Cerium oxide nanoparticles (CNPs) have drawn interest in biomedical science due to their superoxide dismutase and catalase mimetic activity. However recent studies have indicated that these activities can be altered by the presence of phosphate ions. It is necessary to understand the kinetics of the CNP phosphate ion interaction. The purpose of this study is to elucidate the CNP and phosphate ion interaction at different pH(6-8). Bare and functionalized CNPs with poly-ethylene glycol and dextran were used to do time-based assay using UV-Vis and photoluminescence spectroscopy. To evaluate whether the surface change is temporary or permanent in the buffer, the bare and functionalized CNPs were washed and characterized. Moreover, superoxide dismutase and catalase mimetic activity will be estimated to find bare and functionalized CNPs redox activity after exposure to phosphate ions. These experiments should give insight to how phosphate can affect CNPs catalytic function in biological systems.

I-8: Nanotechnology For Drug Formulation: Improving Solubility of Insoluble Drugs: *Aeriel Murphy*[1]; Dennis Leung[2]; [1]University of Alabama; [2]Merck Sharp & Dohme Corporation Inc.

Many of the marketed drugs we use today are practically insoluble. Nanomaterials science is being studied to improve the solubility of these drugs. Nanosize particles are ideal because they cover more surface area which improves exposure and bioavailability and they have faster dissolution rates in the body. Nanoparticle stability is a major issue because Van der Waals forces cause the particles to aggregate and clump together and Ostwald Ripening causes the particles to increase in size over time. Because of the stability issues polymer/surfactant stabilizers are being studied to help prevent aggregation and recrystalization. In this experiment, drug nanosuspenion formulations were created using three model compounds and five different stabilizers. Each drug/stabilizer combination was tested for particle size, zeta potential, solubility, and chemical stability. The purpose of this experiment is to understand why certain drug/stabilizer combinations are more efficient than others by analyzing what properties make each combination unique.

I-9: Molecular Modeling of Adhesion Between Hydrogels and Polyurethane Fibers: *Hossein Salahshoor*[1]; Nima Rahbar1; 1University of Massachusetts Dartmouth

Nano-scale modeling of hydorgels will lead to better understanding of their mechanical properties. Agrawal et. al. have previously reinforced hydrogels with polymer fibers to enhance their mechanical properties. In this study, both fibers and hydrogel are modeled using molecular dynamics (MD) framework using Condensed-Phased Optimized Molecular Potential (COMPASS) as the force field for the simulations. The hydrogel is modeled as a cross-linked polymer with Polyethylene Glycol Diglycidyl Ether (PEGDGE) as epoxy and Jeffamines as the curing agents. Hydrogel is constructed by mixing both chemicals in the presence of water followed by curing at 60-70° C. Mechanical properties of both hydrogel and fibers are studied and verified separately. Finally, the interface between hydrogel and polymer is studied. Interfacial energy is estimated by summation of the kinetic, non-bonded and potential energies. The interfacial energy per unit area of contact is computed and compared as a measurement of the interface strength.

I-10: Cortical Bone Fractures Initiate at Fatigue Microcracks Located Near Elevated Intracortical Porosity but not Elevated Mineralization: *Travis Turnbull*[1]; Ryan Roeder1; 1University of Notre Dame

The hypothesis that intracortical porosity provides stress concentrations for fracture initiation at pre-existing fatigue microcracks has been overlooked due to an inability to nondestructively measure intracortical porosity and large attention given to microcracks that predominately form within more

POSTERS

highly mineralized tissue. Post-mortem investigations of these microcracks are inherently limited to cracks that did not lead to fracture and may be misleading with respect to understanding fracture risk. Therefore, the spatial correlation between intracortical porosity, mineralization levels, and fatigue microdamage within specimens subjected to cyclic uniaxial compression followed by a tensile overload was measured for the first time using registered images in micro-computed tomography. Fatigue microcracks that subsequently acted as fracture initiation sites were spatially correlated with elevated levels of intracortical porosity, but not mineralization. This suggests that clinical fracture risk assessment could be improved by measuring intracortical porosity which is now clinically feasible due to recent advances in computed tomography.

EMPMD 2012 Technical Division Student Poster Contest

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division

Monday PM	Room: Atlantic Hall
March 12, 2012	Location: Dolphin Resort

SP-1: Vertically Aligned Carbon Nanotubes as Active Electrodes for Metal Substrate Supercapacitors: *Radu Reit*[1]; Justin Nguyen[1]; William Ready[1]; [1]Georgia Tech Research Institute

The aim of this project is to create dense growths of vertically aligned carbon nanotubes on various conductive substrates. Vertically aligned carbon nanotubes present a larger pore size as compared to activated carbon or nonaligned carbon nanotubes, increasing the motility of the ions contained in the electrolyte separating the two electrodes. By utilizing various combinations of a diffusion barrier layer and catalyst support layers, vertically aligned nanotube growth can be controlled to alter height and density. Current testing has produced samples on Inconel substrates with specific capacitance values of 51.1 ± 14.7 F/g and samples on aluminum substrates with specific capacitance values of 321.1 ± 86.1 F/g. With further optimization of the spatial distribution of vertically aligned carbon nanotubes, as well as the addition of pseudocapacitative elements to the current configuration, more powerful supercapacitors can be designed with potential applications in hybrid energy vehicles.

SP-2: Controlling Phase Evolution in Thin Film PZT by Switching pO2 during Crystallization: *Patrick Wanninkhof*[1]; Sung Wook Min[1]; Jacob Jones[1]; [1]University of Florida

As devices have decreased their power consumption, piezoelectric ambient vibration energy harvesting has become an attractive alternative to batteries. Thin film Lead Zirconate Titinate (PZT) can be easily integrated into MEMS devices and micro sensors using established semiconductor fabrication technology. This study explores phase evolution during the crystallization of these thin films. We used time-resolved in-situ XRD and SEM to investigate the effects of switching pO2 during annealing. Previous studies observed that an intermetallic compound PtxPb forms at the interface of PZT thin film and platinum electrode between 300 and 450 C; in this experiment the atmosphere was switched from oxidizing to reducing at intermediate temperatures during annealing, 350, 400, and 450 C. The pO2 during the dwell at 600 C influences the texturing of the perovskite structure, which affects the piezoelectric coefficient and energy conversion efficiency of the thin films.

SP-3: Correlation between Multi-scale Microstructure and Creep Properties of Micron Scale Coarse Grained Solder Interconnects: *Subhasis Mukherjee*[1]; [1]University of Maryland, College Park

The mechanical properties of SnAgCu solder are controlled by their multiscale coarse grained microstructure. A secondary creep model has been proposed which captures two homogeneous lower length scales of the solder joints – nano scale Ag3Sn IMCs dispersed in Sn-Ag eutectic region and micron scale Sn dendrites embedded in Sn-Ag silver eutectic phase reinforced with micron scale Cu6Sn5 IMCs. Several morphological characteristics such as radius and volume fraction of dispersoids and reinforcements, size of Sn dendrites, distribution of IMCs in the matrix have been investigated and incorporated into a multiscale mechanistic creep model of dislocation climb and detachment to capture the dominant strengthening mechanisms. Theoretical insights into the influence of anisotropy of Sn on the viscoplastic properties of coarse grained solder interconnect are provided. The model is capable of effectively capturing the effect of alloy composition on SAC solders thereby helping in optimization of the viscoplastic behavior of SAC alloys.

SP-4: Effect of Doped Atom Magnetism On electronic Transport through C59X and C69X(X = B and N) Molecular Junctions: *Hamidreza Vanaie*[1]; Mojtaba Yaghobi[2]; Zahra Sedaghat[3]; [1]Islamic Azad University ; [2]Islamic Azad University; [3]Tehran University of Medical Sciences

In this paper, a theoretical study of spin-polarized quantum transport through a CnX molecular junction is presented applying the Keldysh non-equilibrium Green's function formalism. The effects of contacts, doped atom and cage type and the gate and bias voltages on spin-polarized quantum transport through the CnX molecular junction are considered in calculations. The calculations indicate that the spin-dependent local density of states of the CnX molecules is the cause of magnetic moment on every carbon atom in the vicinity of the doped atom. Also, the spin polarization can reach as high as about 100% with proper selection of bias and gate voltages.

SP-5: Fabrication and Design of a Thin Film Triode Type Carbon Nanotube Field Emitter as an Electron Source: *Graham Sanborn*[1]; Jud Ready[1]; Stephan Turano[1]; [1]GT

Electron sources are commonly used in many technological fields for applications ranging from space propulsion, display technologies, X-ray sources and vacuum electronics. Considering the advancements in electronics in recent times, the electron source has not significantly changed. Carbon nanotubes have shown favorable properties for field emission and performance as electron sources. The objective of this work is to optimize and understand CNT electron emission in a compact and lightweight design. This work presents the fabrication of a carbon nanotube field emission device using a Spindt type cathode design, which incorporates arrays of etch pits into a thin film substrate. Several process improvements were made to maintain electrical isolation of the gate, a single point failure. These improvements resulted in a unique cathode design that incorporates substrate etching to form pits containing bundles of carbon nanotubes. In addition, the carbon nanotube synthesis methods are presented.

SP-6: Improving Charge Transfer Characteristic of Graphene for Triiodide Reduction in Dye-Sensitized Solar Cells: *Santanu Das*[1]; P Sudhagar[2]; Ved Verma[1]; Dong Hoon Song[2]; Eisuke Ito[3]; S. Y. LEE[3]; Yong Soo Kang[2]; Wonbong Choi[1]; [1]Florida International University; [2]Hanyang University; [3]RIKEN-ASI

Graduate Student. We report the fabrication and functionalization of large scale graphene and its electrocatalytic properties towards iodine reduction in the dye sensitized solar cell (DSSC). The as grown graphene film, contained few layers of monolayer graphene sheet as confirmed by Raman spectroscopy and HRTEM. Further, the graphene film was reacted with CF4 reactive ion plasma and fluorine ions were successfully doped in graphene as confirmed by XPS and UV-photoemission spectroscopy. From AFM and Raman spectroscopy, we confirm that the fluorinated graphene shows no structural deformations compared to the pristine graphene except an increase in surface roughness. Electrochemical measurements reveal that the enhancement of catalytic activity of graphene for iodine reduction with increasing plasma treatment time, which was attributed to an increase of graphene's catalytically active sites for charge transfer. Furthermore, the fluorine doped graphene was characterized as a DSSC counter electrode showing ~2.56% photon to electron conversion efficiency with ~11mAcm-2 current-density.

SP-7: Mechanical Behavior of DGEBA-DAPSONE Epoxy Networks from Molecular Dynamics Simulations: *Abhishek Kumar*[1]; Veera Sundararaghavan[1]; [1]Aerospace Department

Simulations were performed to study high strain and high strain rate mechanical behavior of epoxy-amine (Di-Glycidyl Ether of Bisphenol A cured with diamino diphenyl sulfone) cross-linked polymer networks through the entire stress - strain profile before fracture (elastic regime, plastic regime, yield point) under both glassy and rubbery conditions relevant for energy-dissipating light-weight composite materials. Approaches were developed to compute the phonon dispersion curves from MD simulations using velocity–velocity autocorrelation function in reciprocal space and non–local averaging kernels in Fourier space from the phonon dispersion curves.We did research on epoxy failure using atomistic techniques and non–local theory. The approaches developed here allow one to predict the strain at which failure will occur in an ideal structure even before synthesis of the epoxy polymer, using only the knowledge of the chemical structure.

SP-8: Nanotechnology and Its Applications: *Abhijeet Gaikwad*[1]; [1]JBIMS

Nanotechnology is the projected ability to make things from the bottom up, using techniques and tools that are being developed today to place every atom and molecule in a desired place. If this form of molecular engineering is achieved, which seems probable, it will result in a manufacturing revolution. Presently our handling of the molecular manufacturing process is very crude, we move atoms around in great heaps and pile them together, but we lack the ability to snap them together in a meaningful way. With nanotechnology, we'll be able to snap together the fundamental building blocks of nature easily, inexpensively and in almost any arrangement that we desire. In this paper the author presents the basic concept of Nanotechnology with a focus on Nanocomputing. Further this paper takes a review of applications of nanotechnology in the fields of transportation, data storage, space exploration, national security, energy and information systems.

SP-9: New Numerical Method to Calculate the True Optical Absorption of Hydrogenated Nanocrystalline Silicon Thin Films and Solar Cells: *Fatiha Besahraoui*[1]; [1]Oran University

The enhanced optical absorption measured by Constant Photocurrent Method (CPM) of hydrogenated nanocrystalline silicon thin films is due mainly to bulk and/or surface light scattering effects. A new numerical method is presented to calculate both true optical absorption and scattering coefficient from CPM absorption spectra of nanotextured nanocrystalline silicon films. Bulk and surface light scattering contributions can be unified through the correlation obtained between the scattering coefficient and surface roughness obtained using our method.

SP-10: Surface Morphology and Phase Distribution of Zn and Zn-Co Alloy Coatings, Obtained by Direct Current: *Meysam Heydari Gharahcheshmeh*[1]; Ahmed Touhami[2]; [1]University of Texas at Brownsville ; [2]University of Texas at Brownsville

Zn and Zn-Co alloy coatings were electrodeposited on AISI 1018 steel specimens from weakly alkaline Glycine solutions by using direct current. The surface morphology, chemical composition and phase distribution of coatings were investigated using SEM, EDS and XRD. The results showed that increasing current density during deposition, increases cobalt content of the alloy coatings. It was also shown that increasing current density, up to 15 mA cm^{-2}, decreases the grain size and further increase in current density increases the grain size of the deposit. XRD results showed that Zn–Co alloy coatings with 1.95 and 3.34 wt.% Co are consisted of two phases (η and γ), but Zn–Co alloy coatings with lower cobalt content have single phase structure (η-phase).

SP-11: The Temperature and Excitation Intensity Effects on the Photoluminescence Spectra of InAs/InP Quantum Dots: *Fatiha Besahraoui*[1]; [1]Oran University

The optoelectronics properties of InAs /InP quantum dots (QDs) are investigated by means of photoluminescence (PL) measurements. The mechanisms of electron-heavy/light hole recombination which is responsible of the PL peaks appearance are explored in this study. The electron-hole recombinations are influenced by the temperature and the laser excitation intensity. The PL signal and its yield are reduced with the increase of temperature. Especially, in high energies range.The PLE measurements are very sensitive to the excitation intensity. From an appropriate value of Laser excitation, the energies levels will be saturated, which favors the light emission.The bands filling is translated by a widening in the PL spectrum towards the high energies range.

SP-12: Towards Ultra-thick Battery Electrodes: Aligned Carbon Nanotube – Enabled Architecture: *Kara Evanoff*[1]; Javed Khan[2]; Alexander Balandin[2]; Alexandre Magasinski[1]; W. Jud Ready[1]; Thomas Fuller[1]; Gleb Yushin[1]; [1]Georgia Institute of Technology; [2]University of California

Increasing the specific capacity of Li-ion battery electrodes and minimizing the relative weight and volume of inactive components by increasing the electrode thickness are important for further improvements of Li-ion technology. Conventional electrodes contain active particles mixed with conductive additives and a polymer binder in a mixture typically limited by thickness and homogeneity, porosity control, tortuous diffusion paths, and high electrical and thermal resistances. We report the fabrication of ultra-thick (1 mm) electrodes composed of vertically aligned carbon nanotubes uniformly coated with Li-alloying materials (here, silicon) through vapor deposition techniques. The electrodes demonstrate a specific capacity much larger than standard graphitic anodes, high Coulombic efficiency, and stable performance for 250 cycles. With thermal conductivity >400 W•m-1K-1, the electrode provides a significantly lower thermal resistance than a densely packed nanoparticle-based electrode of similar thickness. Since most degradation processes in Li-ion batteries are temperature-dependent, the achieved results are of great practical significance.

SP-13: Applying Taguchi Method for Optimization of Pulsed TIG Welding Process Parameters of AZ31 Magnesium Alloy Weldments: *Alireza Amirkhani*[1]; Alireza Ebrahimi[2]; Rasool Azari Khosroshahi[2]; [1]Tekin Joosh Asia Company; [2]Sahand University of Technology

In this research, Taguchi method with an orthogonal array of L9 (34), was used for optimizing the parameters of pulsed TIG welding to obtain optimum mechanical properties (UTS) of AZ31 Magnesium alloy weldments. On this basis, the main parameters of pulsed TIG welding, including peak current (80-120 A), base current (20-40 A), pulse frequency (1.6-5 Hz), and welding speed (200-300 mm/min), each in three levels, were investigated. Then, the effect of each parameter on ultimate tensile strength (UTS) was evaluated. In addition, to choose a proper set of parameters, results were analyzed by variance analysis (ANOVA).

EPD 2012 Technical Division Student Poster Contest

Monday PM — Room: Atlantic Hall
March 12, 2012 — Location: Dolphin Resort

SP-14: Aluminun-zinc Dealloying: A Comparative Analysis of Processing Methods for Porous Metals: *Rafael Soler-Crespo*[1]; Elvin Estremera[1]; Ulises Barajas-Valdes[1]; Amarilis Declet[1]; Oscar Suarez[1]; Arturo Hernandez-Maldonado[1]; [1]University of Puerto Rico - Mayaguez

Dealloying is the removal of a metallic element in a binary alloy by means of controlled corrosion processes. Due to its chemical nature, we selected aluminum-zinc binary alloys system as suitable candidates for dealloying using free or electrochemical corrosion. The application of an electrochemical potential with a galvanic cell aids in breaking the natural passivation on the surface of the alloy. Therefore, we prepared highly porous substrates from these distinct routes controlling various parameters. Aluminum-zinc alloys were specially cast and dealloyed using both pathways; varying composition, processing time and solidification rate upon alloy processing. Optical microscopy, scanning electron microscopy and image analysis permitted the microstructure characterization of the resulting porous material. Hardness measurements were performed to understand the behavior of the substrate, according to the processing technique used. The results show that alloy composition and cooling rate have a prominent effect in the properties of the obtained porous substrate.

SP-15: Delaminating and Recycling of Printed Circuit Boards using Supercritical Carbon Dioxide: *Mariela Robledo*[1]; [1]Arizona State University

Currently, traditional metallurgical processes are being used for the recycling of printed circuit boards which require high energy input, provide limited economic returns, and are environmentally harmful. The objective is to test a new, exciting technology using carbon dioxide, which is abundant and environmentally benign, in supercritical conditions to delaminate and recycle PCB. Recent experimental results show successful delamination of the printed circuit board using the supercritical carbon dioxide process, in addition to being non-hazardous for the environment. Future work includes integrating other processes to this approach to understand the polymer degradation mechanism and identify previous components of contamination threats.

SP-16: A Novel Synthesis Method for Titanium Dioxide Pigment – Eliminating Direct CO2 Emissions: *Scott Middlemas*[1]; Z. Zak Fang[1]; Peng Fan[1]; [1]University of Utah

Titanium dioxide (TiO2) has been widely used as pigment in paints, paper and cosmetic products, as well as high-tech applications such as PV Cells, semiconductors, biomedical devices and air purification. TiO2 pigment is primarily produced by the high temperature chloride process, resulting in considerable CO2 emissions. A novel hydrometallurgical process for making TiO2 pigment without CO2 emission is investigated. The new method promises to eliminate direct CO2 emissions, consume significantly less energy, and produce minimal environmental waste. The novel process involves molten salt roasting of titania slag, with subsequent leaching, solvent extraction, hydrolysis, and calcination stages, resulting in high-purity anatase or rutile pigments while realizing significantly reduced environmental impacts. Pigment whiteness is critically sensitive to trace amounts of discoloring impurities such as iron and chromium. Several methods for reducing the levels of these impurities are investigated. Energy consumption and emission models are also developed.

SP-17: Dielectric and Magnetic Losses of Iron Oxides in Microwave Ironmaking: *Zhiwei Peng*[1]; [1]Michigan Technological University

Dielectric and magnetic losses of iron oxides in the microwave ironmaking process were evaluated based on the characterizations of microwave absorption properties of hematite, magnetite and wüstite. The equations for determining the losses were first derived from Maxwell's equations. It was subsequently followed by the microwave permittivity and permeability measurements of the oxides using the cavity perturbation technique. The calculation of the losses shows that microwave ironmaking strongly depends on the dielectric losses of hematite and wüstite as well as the magnetic loss of magnetite.

SP-18: Dimethyl Sulfoxide: An Alternative to NMP for Electrochemical Performance of Cathode Active Materials in Lithium Ion Battery: *Oluwatosin Bankole*[1]; Lixu Lei[1]; [1]Southeast University,

The effect of extracting and doping cathode active material of lithium ion battery, LiMn1/3Ni1/3Co1/3O2 with dimethyl sulfoxide (DMSO) instead of the commonly used N-methylpyrrolidone (NMP) on the electrochemical performance of the battery has been investigated. Observation shows that doping the cathode materials with DMSO will increase the conductivity of the battery especially for the LiMn1/3Ni1/3Co1/3O2 calcined with the discharge capacity of 210 mAhg-1 and 152 mAhg-1 at 0.1C rate in the third and twenty-one cycles with approximately 70% and 61% discharge-charge efficiencies respectively. The X-ray diffraction patterns obtained revealed that LiMn1/3Ni1/3Co1/3O2 has been successfully recycled by DMSO used. The results of the electrochemical performance show that NMP could be replaced with relatively cheap DMSO on the basis of its effective battery conductivity and also being environmentally safe according to the Data Safety Sheet.

SP-19: Electrochemistry of Enargite: Reactivity in Alkaline Solutions: *Robert Gow*[1]; Courtney Young[1]; Hsin Huang[1]; Greg Hope[2]; Yasushi Takasaki[3]; [1]Montana Tech; [2]Griffith University; [3]Akita University

The presence of enargite (Cu_3AsS_4) is problematic in gold processing as it is refractory, increasing cyanide and oxygen consumption, and environmentally hazardous. Selective leaching and treatment of the arsenic would prove advantageous to conventional gold leaching methods. The reactivity of enargite samples from Montana, US and Quiruvilca, Peru were studied under alkaline conditions, pH range of 8-13, using a cyclic voltammetry corrosion cell setup. Raman spectra of the surface were taken during and after cycling to compare surface species against theoretical predominance diagrams. Under slightly oxidizing conditions, covellite (CuS) peaks were found on the surface in a short matter of time, above ~0V vs SHE for pH 9-13, suggesting arsenic leaching, but for longer conditioning times, elemental sulfur peaks were also found, which created a passivating surface layer. By operating above pH 12, under reducing conditions, ~-0.500V vs SHE, arsenic can be leached as a thioarsenate ($AsS_{(4-x)}O_x^{3-}$), without sulfur formation.

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division

Monday PM	Room: Atlantic Hall
March 12, 2012	Location: Dolphin Resort

SP-20: Feasibility Study of the Fabrication of a Niobium Diboride/Aluminum Composite: *Jose Moreno Quiles*[1]; Neshma Lopez[1]; [1]University of Puerto Rico - Mayaguez

Despite the low density of ceramics, an appealing characteristic for aerospace applications, diboride compounds cannot be used in critical applications due to their brittle nature. The purpose of this research was to study physical properties of niobium diboride specimens containing different levels of aluminum. In the fabrication of the new composite, different homogenization techniques were used, including jar milling and high energy ball milling. Powder samples are shaped into green bodies using a cylindrical chamber pressed to 7500 psi. The samples were sintered at 600°C for two hours in a vacuum capsule to avoid oxidation. It was found that boride particles size reduction by fragmentation is the key to highly homogeneous samples and that ball milling is an effective method to homogenize the dispersed phase distribution in the composite. Also, percentages of aluminum ranging from 25 to 40 wt % were found to be more effective in the sintering process.

SP-21: Mechanical Behavior of Cast Mg AZ31-B Alloy Produced by Magnetic Suspension Melting Process: Paige Boehmcke[1]; Nagy El-Kaddah[1]; Aeriel Murphy[1]; [1]Univ of Alabama

This poster describes the mechanical behavior Mg AZ31-B alloy produced via the Magnetic Suspension Melting (MSM) technique at a low superheats. In comparison to the dendritic structures observed in conventionally cast alloys, it was found that casting via MSM at low superheat produced a fine globular grain structure. In the MSM cast alloy, the Mg17Al12 phase formed mainly at the grain boundaries, in contrast to conventional castings which exhibited dendritic entrapment within the grains. Charpy impact energies for the MSM castings were equivalent to published values for Mg-Al-Zn alloys. Conventional castings exhibited large regions of quasi-cleavage decohesion and microshrinkage voids whereas in the MSM castings the cleavage facets were smaller and less numerous, and the percentage of microvoids was higher, suggesting a higher potential for plastic deformation.

SP-22: Effect of Precipitates on Shear Banding during Deformation of Mg Alloys: *Frank Sapienza*[1]; Zachary Bryan[1]; Michele Manuel[1]; [1]UF

Magnesium alloys that contain reinforcing particles exhibit increased strength, but have decreased ductility due to extensive shear banding and void nucleation. Research in steels and aluminum alloys has shown that altering the particle volume fraction affects the homogeneity of plastic flow and can increase the propensity for shear band formation. To improve the ductility of magnesium alloys, the connection between particles and shear band formation must be elucidated. The effect of varying precipitate volume fraction on the deformation behavior of Mg-Al alloys under shear loads at strain rates of 10^{-4} to 10^{-2} mmsec^{-1} and temperatures of 25°C and 300°C has been characterized. The formation and propagation of shear bands under these deformation conditions was examined in relation to the initial microstructure. These experiments highlight the role of precipitates on the shear deformation and shear banding behavior of magnesium alloys. This research is supported by the National Science Foundation (Award#: DMR-0845868).

SP-23: The Effect of Scandium Additions on the Degradation Behavior of Magnesium in Simulated Body Fluid: *Nancy Nguyen*[1]; Harpreet Brar[1]; Michele Manuel[1]; [1]University of Florida

With advances in health care and technology, the human life expectancy has increased and the need for bioabsorable orthopedic and cardiac implants is following suit. So far research has shown that magnesium is a good candidate for biodegradable implant applications. It has high specific strength, high fracture toughness, and an elastic modulus that is comparable to that of human bone. Additionally, Mg and it corrosion products are non-toxic. However, the application of pure magnesium in implant applications is limited by its low ultimate strength and high corrosion rate. Addition of alloying elements has shown to alleviate this problem by improving both strength and corrosion resistance. This paper analyzes the effect of scandium additions on the degradation behavior of magnesium in Hank's solution. Hydrogen evolution measurements were used to determine the rate of degradation while the microstructure and corrosion products were analyzed using optical and electron microscopy.

SP-24: Evaluation of the Mechanical Response of a Bcc Mg-Li-Al/C Composite: *Ryan Hooper*[1]; Zachary Bryan[1]; Michele Manuel[1]; [1]University of Florida

Mg alloys with more than 11 weight percent Li exhibit a bcc crystal structure that has been documented to give greatly improved ductility; however, these alloys possess limited strength. The addition of secondary phases via precipitation or ex-situ addition has shown great promise in the strengthening of these alloys. In this study C was added to a Mg-Al-Li alloy due to its potential to react with Al to form Al_4C_3, which would strengthen the bcc matrix. Microscopy and x-ray diffraction were used to determine the extent of the Al-C reaction. The composite was then tested in tension and the results were compared to the monolithic matrix, specifically looking for increases in strength while retaining the desirable ductility of the alloy. This study provides insight into a method of in situ synthesis of a potential strengthening phase in Mg alloys. This work was funded by National Science Foundation Grant#: DMR-0845868.

SP-25: Experiments and Modeling of Low-Cycle Fatigue of Extruded 6061 Aluminum Alloy: *Andrew Brammer*[1]; J Jordon[1]; [1]The University of Alabama

In this study, we reveal the micromechanics of fatigue damage with respect to microstructure in an extruded 6061 aluminum alloy. Low-cycle fatigue tests were conducted in strain control at room temperature and relative humidity. Scanning electron microscopy observations were made on the fracture surfaces to distinguish the three stages of fatigue damage. Fatigue cracks were found to initiate primarily from intermetallic particles at or near the surface. In the microstructrurally/ physically small crack growth regime, the fracture surface displayed a rough and brittle like fracture along the propagation direction. Striation spacings were measured and were found to vary across grain boundaries. In the long crack regime the striation spacings became more uniform, indicating that crack growth was less influenced by microstructure. Finally, a multistage fatigue model based on the relative microstructural sensitive features quantified in this study was employed to capture the fatigue damage experimentally observed in this alloy.

SP-26: Application of Computational Thermodynamics and Precipitation Kinetics to Light Weight Al Alloy Design: *Danielle Belsito*[1]; Richard Sisson[1]; [1]Worcester Polytechnic Institute

The U.S. Military needs structural materials for air and land transportation vehicles that provide superior mobility as well as protection from the impact of improvised explosive devices (IEDs) and projectile artillery to increase soldier survivability. To meet that need, new high strength, high toughness, light weight alloys are being developed. This project focuses on an effort to develop an alloy to be applied for a cold spray application. Initial efforts involve the development of multi-component phase diagrams, isotherms, and isopleths using thermodynamic and kinetic software, Thermo-Calc, Pandit and TC-PRISMA®, to predict the microstructure and performance of this alloy and therefore performance. Precipitation and dispersion hardening will be investigated, including the effect of potential cohesive precipitate-forming elements. Additional factors affecting process results will also be examined, including the process control agents and cryomilling process parameters. Finally, characterization of the powders and coatings will be performed using TEM, SEM, XRD, and SIMS.

SP-27: A Study of Biodegradable Mg-Ca-Sr Alloys: *Ida Berglund*[1]; Harpreet Brar[1]; Malisa Sarntinoranont[1]; Benjamin Keselowsky[1]; Michele Manuel[1]; [1]University of Florida

Magnesium (Mg) has properties like high specific strength and an elastic modulus comparable to that of bone, and it is non-toxic and also susceptible to dissolution. It is therefore an ideal candidate for biodegradable orthopedic implant applications. The low corrosion resistance and yield strength of pure Mg is, however, a major limitation that needs to be addressed in the fabrication of these materials. One approach to increase the mechanical properties and corrosion resistance of Mg is by adding alloying elements. For this study, calcium and strontium were chosen as alloying elements for their biocompatibility, strengthening potential and grain refining properties. Different compositions of the Mg-Ca-Sr system were fabricated and their degradation rate in Hanks' solution was established. The microstructures of the alloys were also characterized before and after immersion. It was shown that Mg-1.0Ca-0.5Sr has good potential for orthopedic implant applications.

SP-28: New Numerical Method to Calculate the True Optical Absorption of Hydrogenated Nanocrystalline Silicon Thin Films and Solar Cells: *Fatiha Besahraoui*[1]; [1]Oran University

The enhanced optical absorption measured by Constant Photocurrent Method (CPM) of hydrogenated nanocrystalline silicon thin films is due mainly to bulk and/or surface light scattering effects. A new numerical method is presented to calculate both true optical absorption and scattering coefficient from CPM absorption spectra of nanotextured nanocrystalline silicon films. Bulk and surface light scattering contributions can be unified through the correlation obtained between the scattering coefficient and surface roughness obtained using our method.

SP-29: Oxidation Behavior of Zr56Al16Co28 Metallic Glasses: *Wenhuan Cao*[1]; jiliang Zhang[1]; Chan Hung Shek[1]; [1]City University of Hong Kong

The oxidation behavior of Zr56A16Co28 bulk metallic glass was studied in synthetic air over the temperature range of 673–923 K. The oxidation kinetics of the metallic glass follows a two-stage or single parabolic rate law from 673K to 923K. Cobalt oxides precipitated on the topmost oxide layer of the metallic glass during oxidation. The observations on their morphologies show that the size and amount of these precipitations both increased with elevated temperature. A high resistance against oxidation in Zr56Al16Co28 bulk metallic glasses was observed below crystallization temperature: Only about 2μm-thickness scale formed after oxidation for ten hours at 773K. The oxidation is accelerated dramatically at 823K. However, the oxidation resistance was enhanced at a further increased temperature, 923K, which was likely attributed to the formation of large amounts of Al2O3 and m-ZrO2.

SP-30: Sensitivity Analysis of Crack Initiation Life of a 2-grain Model of Ti-6Al-4V: *Daniel Sparkman*[1]; Harry Millwater[1]; Somnath Ghosh[2]; [1]University of Texas at San Antonio; [2]John Hopkins University

Crack initiation in Ti-6Al-4V has been observed to occur in a grain with a hard orientation for basal slip neighboring a grain with a soft orientation. A crystal plasticity model of 2 grains was exercised considering the Schmid Factor of the soft grain, the misorientation angle between the two grains, and the soft grain size as random variables. A probabilistic sensitivity analysis of the time-to-crack-initiation was employed to ascertain the relative importance of the random variables. It was found that the Schmid Factor had the largest effect on the variance of the crack initiation life and that grain size and misorientation angle had little effect. A local sensitivity analysis found larger Schmid Factors result in smaller mean life and larger variance.

SP-31: Effects of Pulsed Magnetic Annealing on the Grain Boundary of Primary Recrystallized Microstructure in the Grain-Oriented Silicon Steel: *Junjun Huang*[1]; Lihua Liu[1]; Xin Xia[1]; Xiang Jiang[1]; Lijuan Li[1]; Qijie Zhai[1]; [1]Shanghai University

In this work, the effects of pulsed magnetic field applied during the annealing of grain-oriented silicon steel on the grain boundaries in the primary recrystallizated microstructure were investigated. Samples of cold rolled grain-oriented silicon steel were annealed under pulsed magnetic field with the maximum strength 1T from three different directions-rolling direction, transverse direction and normal direction at the temperature of 700 for 16 minutes. Electron Backscattering Scanning Diffraction (EBSD) technology was used to measure grains for texture determination, and software called Channel 5 was used to calculate the messages of boundaries. Results show that pulsed magnetic field can influence the development of grain boundaries. It is found that the frequency of the low angle boundaries increases when pulsed magnetic field is applied, especially from the rolling direction. Compared to the ordinarily annealed sample, the frequencies of CSL boundaries vary in samples annealed with pulsed magnetic field in different directions.

SP-32: The Role of Solute Nature on the Deformation Behavior and Texture Evolution in Magnesium Alloys: *Zachary Bryan*[1]; Ryan Hooper[1]; Michele Manuel[1]; [1]University of Florida

Rare earth solutes alter the basal-dominated texture exhibited by conventional magnesium alloys during recrystallization and lead to increased ductility. The unique texture component that arises has been attributed to shear band nucleation and solute drag effects. The rare earth solute characteristics that are needed for texture modification, however, remain unclear. This work systematically varied solute size and stacking fault energy through alloy selection to determine their individual and combined effects on the mechanical properties and annealed texture. Mechanical tests were performed at temperatures from 100 to 350°C and strain rates from 10^{-3} to 10^{-1} s^{-1} to elucidate the effect of dynamic strain aging on texture evolution. This research ultimately evaluates the role of solute size and stacking fault energy on the rare earth texture evolution. This work is supported by the National Science Foundation (Award#: DMR-0845868) and the Department of Energy Office of Science Graduate Fellowship (Contract#: DE-AC05-06OR23100).

SP-33: The Temperature and Excitation Intensity Effects on the Photoluminescence Spectra of InAs/InP Quantum Dots: *Fatiha Besahraoui*[1]; [1]Oran University

The optoelectronics properties of InAs /InP quantum dots (QDs) are investigated by means of photoluminescence (PL) measurements. The mechanisms of electron-heavy/light hole recombination which is responsible of the PL peaks appearance are explored in this study. The electron-hole recombinations are influenced by the temperature and the laser excitation intensity. The PL signal and its yield are reduced with the increase of temperature. Especially, in high energies range.The PLE measurements are very sensitive to the excitation intensity. From an appropriate value of Laser excitation, the energies levels will be saturated, which favors the light emission.The bands filling is translated by a widening in the PL spectrum towards the high energies range.

SP-34: X-Ray Radiography of Magnesium MMCs Processed by Electromagnetic Acoustic Transduction: *Hunter Henderson*[1]; Zachary Bryan[1]; Orlando Rios[2]; Alexander Melin[2]; Gail Ludtka[2]; George Lopp[1]; Yu-Min Su[1]; Michele Manuel[1]; [1]University of Florida; [2]Oak Ridge National Laboratory

Magnesium (Mg)-based alloys reinforced with ceramic nanoparticles have attained interest for their improvement in strength and ductility, compared to traditional Mg alloys. A specialized technique known as Electromagnetic Acoustic Transduction (EMAT), magnetically induced sonication, is evaluated with regard to the dispersion of several particle types in Mg. This technique potentially offers several advantages over traditional melt sonication, including non-contact, higher intensity, and smoother energy distribution. The present study investigates a pure Mg and Mg-Li alloys with and without ceramic nanoparticle reinforcement. Radiography investigating the macroscale distribution of particles and the associated causes is presented. The authors would like to acknowledge the support of the National Science Foundation (DMR 0845868), National High Magnetic Field Laboratory User Program, and Department of Energy's Energy Efficiency and Renewable Energy Industrial Technologies Program.

MPMD 2012 Technical Division Student Poster Contest

SP-35: Novel Three-Dimensional Printing Technology for Advanced Modeling and Casting of A356 Impeller: *Blake Whitley*[1]; [1]The University of Alabama

Metal casting is one of the earliest known materials manufacturing methods, and has been employed for millennia for the creation of metal formation into desired forms. In this study, an analytical approach was taken in order to optimize the casting process through conditions of material selection, vent placement, riser placement and dimensions, mold filling orientation, superheat, and pouring rate. Through careful analysis of each of these conditions, we have taken steps to model and simulate the casting of an A356 impeller with optimal physical, microstructural, and mechanical properties. Advanced casting modeling software and mold printing technologies were employed for the creation of the ideal mold for the casting of the desired impeller. Through this systematic casting study, properties of near-net shape castings have been optimized for intricate and complex forms in three dimensions.

SP-36: Processing of Aluminum Wires and Its Effect on Their Electrical Properties: *Grace Rodriguez*[1]; [1]University of Puerto Rico

The present study focuses on the fabrication of aluminum wires by adding NbB2 particles into an aluminum matrix. These particles were obtained by fragmentation in a high energy ball mill, mixing aluminum powder with NbB2. The product obtained was then compacted in a hydraulic press at 119.7 KPa and sintered at 600oC for two hours. Then the sintered pellets were incorporated into molten aluminum. After solidification the ingot was cold rolled to obtain 1mm diameter wires. The treated specimens were mechanically tested and their electrical resistivity was measured and compared with pure aluminum wires. The highest electrical resistivity measured in aluminum wires containing 1 wt.% of NbB2 was 3.509•10-08 O•m compared to 3.061•10-08 O•m of pure aluminum wires cold-drawn under similar conditions. Our results evinced the feasibility of improving the mechanical properties of the material without significantly affecting its electrical resistivity.

SP-37: Frequency and Temperature Dependent Dynamic Mechanical Properties of Metal Matrix – Barium Titanate Composites: *Jack Tilka*[1]; Zachary Bryan[1]; Jacob Jones[1]; Michele Manuel[1]; [1]University of Florida

Ferroelastic reinforced metal matrices have exhibited anomalous dynamic mechanical properties that are believed to be caused by mechanical coupling between the metal matrix and the frequency-dependent ferroelestic reinforcement. To examine this unique behavior, powder metallurgy was used to fabricate a composite consisting of a copper matrix and ferroelastic barium titanate particles. Dynamic mechanical analysis of the storage and loss moduli as a function of frequency and temperature was completed on the composite, as well as the individual copper and barium titanate constituents. These studies are used to determine if there are mechanic properties that extend beyond those predicted by traditional mixing rules or superposition. Ultimately, this reveals details about the unique interaction of constrained ferroelastic particles in a damping matrix. This research was funded by NSF Grant #CMMI-0824352.

SP-38: Novel Manufacturing Processes for Ultra-fine Grained Microstructure in 9310 Steel: *Thomas Kozmel*[1]; [1]Illinois Institute of Technology

Novel manufacturing processes that induce the formation of an ultra-fine grained microstructure may improve the wear resistance and performance of 9310 steel parts currently in use for gears, rotors and shafts. By inducing large amounts of strain during the hot deformation and carefully controlling the deformation temperature, dynamic recrystallization can assist in achieving a very fine grain size throughout the material.Results from preliminary studies investigating the dynamic recrystallization response of 9310 in double cone specimens are presented and discussed.

SP-39: Automatic Combination of Multi-tile EBSD Datasets: *Adam Shiveley*[1]; Adam Pilchak[2]; Paul Shade[2]; Jay Tiley[2]; Donna Ballard[2]; [1]Southwestern Ohio Council for Higher Education; [2]United States Air Force

Electron backscatter diffraction (EBSD) has found extensive use in the field of materials science. Faster acquisition speeds has led to the creation of large datasets using combinations of beam scans and automated stage movements. Stage positioning inaccuracies often lead to missing or duplicated data at tile boundaries. Thus, functions have been implemented to identify grain and phase boundaries in each scan and correlation functions to determine the appropriate offset between adjacent tiles. The advantages and limitations of the method are discussed.

SP-40: Electro-Chemical Mechanical Polishing (ECMP) For Electron Microscopy: *Kevin Shiveley II*[1]; Jay Tiley[2]; Adam Shiveley[3]; Gopel Viswanathan[4]; Christopher Crouse[4]; [1]Universal Technology Corporation; [2]United States Air Force; [3]Southwestern Ohio Council for Higher Education; [4]Universal Energy Systems

Surface preparation is a vital component when characterizing materials. Surface or subsurface damage of the material can adversely impact data quality captured by backscatter electron imaging and electron backscatter diffraction (EBSD) techniques. To address these issues, a low-stress automated polishing device was developed. The system uses pulsed electrochemical reactions within an alkaline electrolyte to generate a thin passivation layer on the surface of the sample, which is removed by the mechanical vibration of the system. Results indicate that applied cyclic electrical potentials remove material faster than typical removal techniques. In addition, electron back scatter diffraction data showed a decrease in subsurface damage using the developed electrochemical–mechanical process compared to standard mechanical polishing techniques. The system design and the application of electrical potentials will be discussed.

SP-41: Synthesis and Characterization of Nacre-inspired Nanocomposites: *Omar Rodriguez-Negron*[1]; Carlos Morales-del Valle[2]; Ruth Hidalgo-Hernandez; Paul Allison[3]; Robert Moser[3]; Mei Chandler[3]; Charles Weiss[3]; Phillip Malone[3]; [1]UPRM/ ARMY ERDC; [2]UPRM; [3]ARMY ERDC

The U.S. Army Engineer Research and Development Center is currently synthesizing and characterizing bioinspired nanocomposites utilizing the multi-layered hierarchical design principles found in nacre. Electro transport deposition and hydrothermal hot pressing are methods currently being investigated in order to synthesize nacre's hierarchical structure. Both methods are intended to provide the ability to control the crystallographic form, crystal size and crystal location within a polymer matrix. Calcium acetate and ammonium carbonate are the chemical compounds employed with the purpose of replicating calcium carbonate biomineralization. The influence over precipitate mineralogy of different reactants concentrations as well as the presence of magnesium acetate or strontium acetate was also investigated. X-ray diffraction is employed in characterizing the crystal structures being synthesized while scanning electron microscopy is used in determining the size and shape of the crystal structures forming. Initial results suggest the approach may produce useful new composites.

SP-42: Synthesis and Properties of Bulk Graphene NanoPlatelets Consolidated by Spark Plasma Sintering: *Andy Nieto*[1]; [1]Florida International University

Graphene nanoplatelets (GNP) are consolidated as a bulk structure by spark plasma sintering (SPS) to study the feasibility of the structure retention at extreme processing conditions. Structural characterization of the sintered GNP pellet is performed using Raman Spectroscopy, X-ray diffraction and scanning electron microscopy. Mechanical and tribological properties are evaluated through nanoindentation and ball on disk wear testing. It is shown that bulk GNP structures can be successfully synthesized through SPS processing at an extreme temperature of 1850 C and a pressure of 80 MPa. GNPs survived the processing with minimal damage to the structure. Energy dissipation mechanisms are observed in the form of bending and sliding of the platelets. The results indicate the potential for GNP to be successfully used as a reinforcing phase in ceramic and metal matrix composites synthesized by SPS.

SP-43: Characterization and Quantification of X65, X80, and X100 Pipeline Steels for Statistical Microstructual Analysis: *Elisa Duesing*[1]; Elizabeth Rust[2]; Brian Welk[1]; Dan Huber[1]; John Sosa[1]; Hamish Fraser[1]; [1]Center for the Accelerated Maturation of Materials; [2]The Ohio State University

Currently, there are no quantitative databases available relating mechanical properties to microstructural features for pipeline steels. The work to be presented focused on determining the feasibility of collecting data for such a database using stereology to objectively quantify scanning electron micrographs. Specifically, three different pipeline steel samples, X65, X80, and X100, were examined. Based upon the microstructural features present in the various steels, quantitative analysis was performed on bainite, martensite, pearlite, and ferrite. Images were analyzed to obtain quantitative values for ferrite grain size, as well as the volume fraction of each phase. Finally, the data collected was used to display the statistical variance of the microstructure within a given sample, as well as between the various pipeline steels. Materials Image Processing and Automated Reconstruction (MIPAR) software developed within the Center of Accelerated Maturation of Materials (CAMM) at The Ohio State University was used for sample analysis.

SP-44: Analysis of Hafnium Addition Effects to Microstructural and Mechanical Properties in the Nickel-Titanium-Hafnium System for Shape-Memory Optimization: *Blake Whitley*[1]; [1]The University of Alabama

Shape-memory alloys have emerged as a smart material of interest to materials scientists in recent years due to their unique physical properties which stem from characteristic microstructural features. Such alloys have become of particular interest for applications in the automotive, aerospace, telecommunications, and robotics industries where their unique material characteristics have seen the greatest potential. In this study, the Nickel-Titanium-Hafnium ternary alloy system has been selected for detailed analysis. The primary concern has revolved around the addition of hafnium to the system, and its effects on both microstructure and physical properties. After heat treatment in an evacuated system, alloys of varying hafnium content were analyzed on the basis of microhardness using Vickers hardness measurements. Changes in microhardness were subsequently correlated with microstructural changes through the employment of optical microscopy in order to monitor phase and precipitate formations.

SP-45: Design of pH and Thermal Sensitive Hydrogels for Catheter Based Minimally Invasive Heart Surgery: *Min Zhang*[1]; James Bush[1]; Travis Busbee[1]; Zhenqing Li[1]; Jianjun Guan[1]; [1]Ohio State Univ

A family of injectable and pH-sensitive hydrogels was developed to deliver cardiosphere-derived progenitor cells (CPCs) to infarcted heart by a minimally invasive approach. The hydrogels were based on N-isopropylacrylamide (NIPAM), propylacrylic acid (PAA) and hydroxyethyl methacrylate-poly(trimethylene carbonate) (HEMA-PTMC). The hydrogels were injectable at physiological pH (7.4), but quickly gelled at pH similar to that in the infarct heart (6.5~6.8). This makes it possible to inject the hydrogels through catheters used for heart injection, and ensure sufficient cell retention after delivery. The hydrogels are also biocompatible. No significant cell death was observed. Furthermore, gel mechan-ical properties can be tuned to mimic the biomechanics of native heart muscle by alternat-ing molar ratio of NIPAM, PAA and HEMA-PTMC. These results demonstrate that the developed hydrogels can potentially be used to deliver cells using minimally invasive approach.

SP-46: Serial Sectioning and 3D Reconstruction of Grains to Obtain Metric and Topological Properties: *Amy Adams*[1]; David Rule[1]; Veena Tikare[1]; Burton Patterson[1]; Robert DeHoff[1]; [1]University of Florida

Grain size and the grain growth process have a significant impact on mechanical and other properties of materials. Just how the grain volume distribution and related topological properties evolve throughout grain growth is still not understood. These distributional characteristics of the grain structure cannot be obtained from normal 2D images and require 3D analysis to obtain. This poster presents serial sectioning at different stages within the grain growth process and the development of 3D reconstruction methods. The initial grain structures were synthesized via powder processing to have wide and narrow initial grain size distributions to compare their evolution throughout grain growth. Metric properties include distribution of grain volumes, surface areas, faces, and integral mean curvatures per face class. Topological properties include the distributions of the grain volume and numbers of faces. It is intended to later compare these experimental results with 3D Monte Carlo grain growth simulations.

SP-47: Atomistic Prediction of Precipitate Strengthening in Nanoscale Metallic Multilayers: *Niaz Abdolrahim*[1]; Ioannis Mastorakos[1]; Hussein Zbib[1]; [1]washington state university

Nanoscale metallic multilayer's (NMM) can play a leading role in the future micromechanical devices due to their high structural stability, mechanical strength, high ductility, toughness and resistance to fracture and fatigue. The design of better NMMs can be achieved by properly tailoring the nanostructure using appropriate materials-by-design algorithms. However, before those materials are put into service in any significant applications, many important fundamental issues remain to be understood. Among them, the role of the second phase particles on the strengthening properties of the nanocomposite materials. The purpose of this work is to address the question if the second phase particles can strengthen the nanoscale materials in the same manner as in bulk crystalline solids. In this view, Cu/Nb thinfilms with spherical Nb particles inside the Cu layer were examined using molecular dynamics simulations and show to exhibit a significant improvement on their mechanical behavior, compared to similar structures without particles.

SP-48: A Review of First-Principles Investigations of Iron Based Alloys Using DFT: *Krista Kalac*[1]; Julia Medvedeva[1]; [1]Missouri S&T

First principles investigations of the behavior of metallic solids have become more widely used as computational power increases. Density Functional Theory (DFT), a commonly used quantum based modeling technique, is used to investigate electronic structures of multi-component systems. DFT provides high accuracy calculations using the plane wave basis for solid state systems. Iron based alloy design has been a continual subject of interest due to the large market and wealth of experimental data. Immediate results of the calculations provide optimum atom positions for various structures, cell parameters, and atom size, as well as the magnetic moment for a given structure. Calculated total energy values and forces on atoms can be used in a wide array of applications, leading to advanced understanding of structural properties, such as the stability of an inclusion or intermetallic phase and their impact on fracture toughness.

SP-49: Characterization of Transformation Toughening in Shape Memory Alloy Reinforced Composites: *Fatmata Barrie*[1]; Michele Manuel[1]; [1]University of Florida

Materials capable of undergoing martensitic phase transformations have been shown to inherently increase the fracture toughness of monolithic and composite materials in a process known as transformation toughening. The toughness behavior has been extensively researched for certain classes of transforming materials such as stabilized zirconia, however not for shape memory alloys (SMAs). Therefore, a fundamental understanding of the martensitic phase transformation on SMA embedded composites is needed to further the development of SMA embedded

POSTERS

composites. A comparative J-integral fracture toughness study was performed using nickel-titanium (NiTi) SMAs and non-transforming aluminum reinforcements embedded within an epoxy matrix. The NiTi was used in the as-received and heat-treated conditions to change the stress that the martensitic transformation was induced. The fracture toughness results will be used to explain the effects of the SMA martensitic transformation on SMA embedded composites. The authors gratefully acknowledge support from the National Science Foundation under grant number CMMI-0824352.

SP-50: Creep Deformation Mechanisms in Grade 91 Steel: *Triratna Shrestha*[1]; Indrajit Charit[1]; Mehdi Basirat[1]; Gabriel Potirniche[1]; Karl Rink[1]; [1]University of Idaho

Grade 91 (modified 9Cr-1Mo) steel is a candidate material for thepressure vessel of the Very High Temperature Reactor (VHTR). The creep behavior of this steel was studied in the temperature range of 873 K to 1023 K and at a stress range of 35 to 350 MPa. Threshold stress correction of the creep data in the higher stress regime yielded a true stress exponent of 5, indicating the operation of high temperature climb-controlled creep. The estimated threshold stresses displayed strong temperature dependence. The origin of the threshold stress was explained in terms of particle-dislocation attractive interaction. Creep tests in the lower stress regime resulted in a stress exponent of 1, indicating the operation of a Newtonian viscous creep mechanism. Furthermore, the rate-controlling creep mechanisms in both the stress regimes were elucidated with the help of transmission electron microscopy (TEM).

SP-51: Crystal Structure and Disorder of Refractory High-Entropy Alloys: *Soumyadipta Maiti*[1]; Walter Steurer[2]; [1]ETH Zurich ; [2]ETH Zurich

The refractory HEA contains metals like W, Mo, Ta, Nb, V, Zr, Hf etc in high proportion and could have potential high temperature applications. Equiatomic WMoNbTa alloy was prepared from powder through arc melting in argon atmosphere. The alloy was annealed and heat-treated at different temperature inside tantalum ampules starting from 1800°C. X-Ray diffraction of both powder and single crystals were performed. SEM-EDX was done to investigate grain sizes and compositional variance of annealed sample. Analysis shows grain size of 80-150 micron and the compositional variance within 2% from expected value. The materials were annealed for long time at intermediate temperature (900-1000\176C, 1-3 weeks) but no significant ordering from BCC structure could be found. The peak broadening analysis from diffraction indicates crystallite domain size of 50nm, which appears unexpected from 100micron grains. This could be explained by grains forming nano-domains and atoms having high atomic displacement parameter.

SP-52: Design of Aluminum-Based Metal Matrix Composite with Self-Healing Capabilities: *Charles Fisher*[1]; Michele Manuel[1]; [1]University of Florida

In order to advance to the next generation of smart structural materials, metal-matrix composites with the ability to self-heal are currently under development. Self-healing has the potential to greatly increase the life-cycle of specific components, especially for processes involving multiple cycles as within the aerospace industry. However, designing new alloy systems which possess the appropriate processing-structure-property relationships for self-healing, however, can be a difficult undertaking. The multifaceted interaction across multiple length scales yields a very complex issue for composite development. To combat this issue, a systems design approach governed by thermodynamics and empirical models was utilized to aid in the selection of materials with potential for self-healing. This study will present the alloy selection process for an Al-based alloy utilizing shape-memory alloy wire reinforcements to aid in self-healing in addition to initial characterization of the composite. Support for this project comes from the National Science Foundation under grant number CMMI-0824352.

SP-53: Analysis of Serrated Flow in Ni-10Pd during High Temperature Instrumented Microindentation: *Bin Gan*[1]; Sammy Tin[1]; [1]Illinois Institute of Technology

Instrumented microindentation tests were carried out on a Ni-10Pd(wt.%) alloy from room temperature to 450°C with loading rates spanning from 62.5 to 1000mN/s. When this single phase, substitutional solid solution was tested at temperatures above 337.5°C, the loading segment of the load-depth curve that was initially smooth became serrated after reaching a critical load. For the same loading rate, increasing the testing temperature from 350 to 450°C resulted in an earlier appearance of the serrated flow with a lower load threshold. At a constant temperature (450°C), increases in the loading rate resulted in an earlier occurrence of the serrated flow with a higher load threshold. A modified cavity expansion model that accounts for the reconfiguration of dislocation substructure as well as the interactions between solute atoms and forest dislocations was developed and used to elucidate the mechanisms responsible for the serrated flow behavior.

SP-54: High Temperature Deformation of Ti-Al-Nb-Cr-Mo Alloys: *Glenn Bean*[1]; Fereshteh Ebrahimi[1]; Hans Seifert[2]; Michele Manuel[1]; [1]University of Florida; [2]Karlsruhe Institute of Technology

Titanium aluminides with $\gamma+\alpha_2$ microstructure have been shown to exhibit good mechanical properties below 700°C, but it is desirable to increase high temperature properties. Limited research has been conducted towards the development of alloys with γ(TiAl)+σ(Nb_2Al) microstructure, and alloys with over 0.5 V_f σ-phase have exhibited excellent high temperature properties up to 1000°C. However, these alloys are brittle at room temperature, prompting the study of alloys with less than 0.5 V_f σ-phase which has led to improvements in room temperature properties. To determine the high temperature performance of these alloys with below 0.5 V_f σ-phase, a series of alloys in the TiAlNb(CrMo) system have been developed, characterized, and tested at elevated temperatures (=700°C). The performance of these alloys has been evaluated at strain rates ranging from 10^{-2} to 10^{-5} s^{-1} and relationships between chemistry, microstructure, and the resulting mechanical properties were investigated. This work has been supported by NSF/AFOSR (DMR-0856622).

SP-55: Influence of Austenite Stability on Steel Low Cycle Fatigue Response: *Greg Lehnhoff*[1]; Kip Findley[1]; [1]Colorado School of Mines

Materials containing metastable austenite, such as multiphase transformation induced plasticity (TRIP) steels, demonstrate exceptional combinations of strength and ductility that allow utilization of thinner automobile structural components for weight reduction purposes. Both the monotonic and fatigue properties of these steels have been shown to depend strongly on the stability of austenite with respect to deformation induced martensite formation. To properly design steel compositions and processing schedules for components subjected to complex loading histories, a fundamental understanding of the factors governing austenite stability is critical. The current work focuses on the effects of austenite composition, namely aluminum and silicon alloying, on resulting austenite properties such as stacking fault energy in fully austenitic steels. These properties will then be correlated to austenite stability and mechanical response during strain-controlled fatigue testing using a modeling approach based on the underlying physical mechanisms of deformation induced martensite nucleation.

SP-56: Mechanical Characterization of Hierarchical Biological Structures: *Rogie Rodriguez*[1]; Wayne Hodo[2]; Paul Allison[2]; Mei Chandler[2]; Jen Seiter[2]; Aimee Poda[2]; Mark Chappell[2]; Brandon Lafferty[2]; [1]UPRM/US Army ERDC; [2]US ARMY ERDC

Research on biological systems such as abalone shell, turtle shell, and human bone revealed carefully arranged multilayered systems. Each layer comprises unique subscale structures resulting in properties far superior to any man-made materials and systems. Understanding such structures will enable pathways to improved bioinspired materials for many applications such as human body amour and high-energy absorbent materials. Therefore, this investigation was focused on studying the mechanical and chemical properties of multilayer biological structures, specifically the alligator gar (*Atractosteus spatula*) fish scales. Scanning electron microscopy on the fish scale cross-section revealed a three-layer arrangement with distinct differences in their morphologies. X-ray fluorescence (μ-XRF) was performed to determine the elemental distribution within the fish scale existing layers. Atomic force microscopy (AFM) was performed on the cross-section for micro and nanostructural characterization. Mechanical testing based on nanoindnetation revealed a functional gradient on the elastic modulus, increasing from the inner to the outer layer.

SP-57: New Numerical Method to Calculate the True Optical Absorption of Hydrogenated Nanocrystalline Silicon Thin Films and Solar Cells: *Fatiha Besahraoui*[1]; [1]Oran University

The enhanced optical absorption measured by Constant Photocurrent Method (CPM) of hydrogenated nanocrystalline silicon thin films is due mainly to bulk and/or surface light scattering effects. A new numerical method is presented to calculate both true optical absorption and scattering coefficient from CPM absorption spectra of nanotextured nanocrystalline silicon films. Bulk and surface light scattering contributions can be unified through the correlation obtained between the scattering coefficient and surface roughness obtained using our method.

SP-58: Recycling of the Alloy AZ91D Departing from Scrap in the Shape of Shavings Contaminated with Mineral Oil: Roberto Lucci[1]; Roger López Padilla[1]; [1]Universidad Tecnológica Nacional Facultad Regional Córdoba

In this paper we present the results of experiments carried out for recycling melting AZ91D alloy, departing from scrap in the shape of small shavings contaminated with mineral oil, which come from machining centers of automotive industry. Due to the large surface exposed and contamination of the shavings, these were upgraded prior to their fusion. Later, the recycling was realized using a device designed for the fusion of the shavings under protective atmosphere of gas argon with mixtures salts. The results showed an average yield of 80% metal recovery. Jointly presented some results of metallographic, mechanical and chemical alloys obtained.

SP-59: Rheological Performance and Compressive Strength of Superplasticized Mortar Cements with SiO2 Nanoparticles Additions: *Luis Zapata*[1]; Genock Portela[1]; O. Marcelo Suárez[1]; Orlando Carrasquillo[2]; [1]University of Puerto Rico, Mayagüez; [2]US Army Corps of Engineers

This paper aims to study the effects nanoparticles of SiO2 (nS) employed in type I Portland cement (PC) mortars at w/b=0.35 and 0.40 (cement:sand ratio=1:3) under various dosages of superplasticizer (SP). Stage I presents Marsh cone tests (MCT) to estimate the rheological parameters of the SP grouts at w/b=0.35 and 0.40. Stage II presents factorial experiments at w/b=0.35 to evaluate the flow area (A ~), fresh density (UW) and air content (AC) in the fresh mortar state. The variables analyzed were statistically significant with respect to nS and SP following nonlinear relationships. Stage III studies the 90 days compressive strengths (Sc) of mortar cubes at w/b=0.35, where the nS content seems to be the noteworthy parameter. The maximum strength was obtained at 1.0 wt%. In all cases, the oversaturation for A ~, UW, and AC was defined positive. SEM examinations show that Sc was controlled by densification of the ITZ.

SP-60: Atom Probe Tomography of Simulated Fission Product Segregation in CeO_2: *Billy Valderrama*[1]; Hunter Henderson[1]; In-Wook Park[2]; Jianling Lin[2]; John Moore[2]; Clarissa Yablinsky[3]; Todd Allen[3]; Michele Manuel[1]; [1]University of Florida; [2]Colorado School of Mines; [3]Univeristy of Wisconsin-Madison

To improve the performance of nuclear fuel, one must understand the irradiation induced defects that lead to the decrease in fuel performance at an atomic scale. Irradiation induced defects, specifically fission gas bubble formation and nucleation, fission product segregation to grain boundaries and clustering, are of interest in this investigation. Characterization techniques, like atom probe tomography (APT) provides the capability to spatially resolve these features at an atomic scale. This study investigates the segregation behavior of fission products (Xenon and Lanthanum) in surrogate nuclear fuel material (CeO_2) using APT. The Xe doped CeO_2 samples analyzed were ion implanted with 400 keV Xe^+ ions and annealed to induce clustering. The La doped CeO_2 sample analyzed was irradiated with 1.8 MeV Kr^+ ions to simulate irradiation induced diffusion of fission products. Commentary will also be provided on the advantages and challenges in using APT to study nuclear fuel. DOE Contract No. DE-AC07-05ID14517.

SP-61: The Development of Nanostructured In2O3 Oxide by Electron Stimulated Oxidation on InP and InSb Surfaces: *Fatiha Besahraoui*[1]; [1]Oran University

We have used the Auger Electron Spectroscopy (AES) and Electron Energy Loss Spectroscopy (EELS) as an appropriated methods of surface characterization to study the effect of the electrons beam on the morphology of InP and InSb surfaces. The electronic bombardment of InP and InSb surfaces leads to the creation of In2O3 nanostructures.The explored AES and EELS spectra of InP and InSb compounds demonstrate the development of In2O3 oxide of small size on the irradiated InP and InSb areas. We have developed these experimental results by using a simulation methods based on the electron-matter interaction process. The CASINO simulation method used in this study shows that the distribution mode of In2O3 nanostructures on InSb surface is most clear than on InP one. This behavior is due to the good stability and the high compactness of InSb compounds compared to the InP one.

SP-62: The Temperature and Excitation Intensity Effects on the Photoluminescence Spectra of InAs/InP Quantum Dots: *Fatiha Besahraoui*[1]; [1]Oran University

The optoelectronics properties of InAs/InP quantum dots (QDs) are investigated by means of photoluminescence (PL) measurements. The mechanisms of electron-heavy/light hole recombination which is responsible of the PL peaks appearance are explored in this study. The electron-hole recombinations are influenced by the temperature and the laser excitation intensity. The PL signal and its yield are reduced with the increase of temperature. Especially, in high energies range.The PLE measurements are very sensitive to the excitation intensity. From an appropriate value of Laser excitation, the energies levels will be saturated, which favors the light emission.The bands filling is translated by a widening in the PL spectrum towards the high energies range.
