MATERIALSINNOVATION @TMS

Full Speed Ahead:
Materials Innovation @ TMS Launches at TMS 2012

Join TMS in celebrating the launch of its new strategic initiative focused on accelerating the discovery, development, and deployment of materials systems and processes: Materials Innovation @ TMS.

What you experience at TMS 2012 is just the beginning of what Materials Innovation @ TMS can offer you. For the latest news on Materials Innovation @ TMS programs, resources, and activities, visit our website at **materialsinnovation.tms.org**.

Materials Innovation @ TMS Learning and Networking Opportunities

TMS 2012 Annual Meeting of the Membership
"Fueling Growth and Fostering Innovation"
Featuring the Official Membership Introduction of Materials Innovation @ TMS
Sunday, March 11: 7-8 p.m.
Walt Disney World Dolphin Resort—Southern II

Materials Innovation Gallery **(See page 9 of this program for details.)**
A showcase of ideas, techniques, and principles that can potentially transform the future of materials and manufacturing innovation.
TMS 2012 Exhibition * Booth 441
Open during regular Exhibition hours, starting at noon on Monday, March 12.

Special Plenary Session **(See page 14 of this program for details.)**
"Reaching New Heights: Materials Innovation in the Aerospace Industry"
Wednesday, March 14, 2-3:45 p.m.
Walt Disney World Dolphin Resort—Northern E2

2012 Federal Funding Workshop and Reception **(See page 14 of this program for details.)**
"Funding Opportunities to Advance the Materials Genome Initiative"
4 p.m.: Panel Discussion
5:15-6 p.m.: Networking Reception with Panelists
Walt Disney World Dolphin Resort—Northern C

Preview TMS's New Open Access Journal **(See page 9 of this program for details.)**
Integrating Materials and Manufacturing Innovation (IMMI).
Opportunities to interact with IMMI editor, Chuck Ward, will be available during the conference.

For more information:
Stop by the Materials Innovation @ TMS Information Center located at the TMS Member Welcome Center .

Welcome to the TMS 2012 Annual Meeting & Exhibition!

Dear Colleagues & Friends!

As president of TMS, I offer a warm welcome to our members, society guests, exhibitors, and all other attendees who have gathered here in sunny Orlando, Florida for our 141st annual conference.

While compelling technical programming takes center stage at TMS2012, this meeting will offer a full menu of special events and new incentives for building our future with the TMS Foundation.

We are also introducing a new TMS2012 mobile application for smart phone users that will keep all conference information at your fingertips. See page 2 for more details about this amazing conference tool!

There are also a number of events planned this week to launch our new strategic initiative, Materials Innovation @ TMS, focused on accelerating the discovery, development, and deployment of materials systems and processes. I encourage you to browse the Materials Innovation Gallery at the Exhibition (Page 9), attend the plenary session, "Reaching New Heights: Materials Innovation in the Aerospace Industry," (Page 20) and participate in the other Materials Innovation @ TMS activities highlighted in this program.

Here is a brief synopsis of the other valuable offerings at TMS2012:

Technical Program & Poster Session – Nearly 70 symposia will present the research of some of the world's most distinguished materials scientists and engineers. Technical areas to be covered include: Advanced Characterization, Modeling and Materials Performance; High Performance Materials; Light Metals: Aluminum, Magnesium, and Titanium; Materials and Society: Energy and Sustainable Production; Materials Processing and Production; and Nanoscale and Amorphous Materials.

Networking – Second only to the technical programming offered at TMS2012 are the invaluable networking opportunities. By attending TMS2012 you reap the countless benefits of connecting with colleagues from around the world in person!

Awards Presentation – Honoring outstanding colleagues will be even more exciting with the TMS-AIME Awards Banquet at the World ShowPlace Pavilion East Hall in EPCOT. The banquet will conclude with an amazing fireworks display, "Disney IllumiNations: Reflections of Earth."

Special Lectures – Compelling research and food for thought is on the agenda when you choose to attend a luncheon lecture, plenary session or presentation. See page 22 for more information.

Student Events – TMS realizes the future of the society and profession lies in its student members. Visit the Student Poster contest or enjoy the spirit of competition at the Materials Bowl, sponsored by Alcoa, all day Sunday. Details on student events are on page 28.

Continuing Education – Feel the power of knowledge. TMS2012 features compelling courses and workshops designed to enhance your conference experience.

Welcome to TMS2012 in warm and wonderful Orlando, Florida! Be prepared for the ultimate conference experience.

Sincerely,

Garry Warren

Garry Warren

MEETING INFORMATION

Table of Contents

MEETING INFORMATION

Full Conference Registration

Your full conference registration includes a collected proceedings CD and your badge ensures admission to each of these events:

- Technical & Poster sessions
- Student Poster Contest
- Women in Science Breakfast Lecture *(pre-registrants only)* T
- Admission to TMS Materials Bowl Championship
- Three-day pass to TMS2012 Exhibition
- President's Welcoming Reception *(located in the Exhibit Hall)*
- Happy Hour Reception *(located in the Exhibit Hall)*

Internet Options
Free wireless service will be available in the Author's Coffee area located in **Atlantic B Hall** in the **Dolphin Hotel** Monday through Thursday.

Username: **TMSWireless**
Password: **tms2012ame**
(case sensitive, use all lower case)

CyberCenter Internet work stations, sponsored by Stellar Materials Inc., will be available in the exhibit hall located in the Pacific Room of the Dolphin Resort during regular show hours.

NEW! TMS2012 Mobile Application

TMS is pleased to offer this new mobile application available for the 2012 Annual Meeting and Exhibition. Attendees will be able to easily download this free conference tool from the **Apple iTunes Store for you iPhone or iPad** and through the **Android Marketplace**

Features:

- Latest programming schedule
- Interactive exhibit map
- Hotel information
- Speaker information
- Evaluations
- Schedule changes via Push Notifications (when not using application)
- Much more!

Through the application you will also be able to organize and track those events you wish to attend by building a "My Schedule" list plus quickly narrow current presentations with the "What's on Now?" feature.

To download the TMS Mobile Application, search "TMS Annual Meeting" in your respective device store.

Policies

Badges
All attendees must wear registration badges at all times during the conference to ensure admission to events included in the paid fee such as technical sessions, exhibition and receptions. "Exhibit Only" badges provide exclusive admittance to the show floor for events in the exhibit hall. "Guest" badges are for spouses or companions of registered attendees and used as identification only. "Guest" and "Exhibit Only" attendees" may not attend technical sessions.

Refunds
The deadline for all refunds was February 15, 2012. No refunds will be issued at the conference. Fees and tickets are nonrefundable.

Photography Notice
By registering for this conference, all attendees acknowledge that they may be photographed by TMS personnel while at events and that those photos may be used for promotional purposes.

Audio/Video Recording Policy
TMS reserves the right to all audio and video reproductions of presentations at TMS sponsored meetings. Recording of sessions (audio, video, still photography, etc.) intended for personal use, distribution, publication, or copyright without the express written consent of TMS and the individual authors is strictly prohibited. Contact TMS Technical Programming at (724) 776-9000, ext. 212 to obtain a copy of the waiver release form.

Americans With Disabilities Act
TMS strongly supports the federal Americans with Disabilities Act (ADA) which prohibits discrimination against, and promotes public accessibility for, those with disabilities. In support of, and in compliance with ADA, we ask those requiring specific equipment or services to contact TMS Meeting Services in advance.

Cell Phone Use
In consideration of attendees and presenters, TMS kindly requests that you minimize disturbances by setting all cell phones or PDAs on "silent" while in meeting rooms.

Recycling
Discard badges and programs in the bins located in the Registration area.

Be materials-minded. *Join* TMS *in reducing, reusing and recycling.*

Schedule of Events

as of February 23, 2012

TMS Meetings & Events are scheduled on the following days, times and locations:

Key: D Dolphin Hotel S Swan Hotel

FUNCTION	TIME	LOCATION	ROOM	ACCESS*
Saturday, March 10, 2012				
Exhibit Move-In	8:00 AM to 5:00 PM	D	Pacific	O
Committee Meetings				
Professional Registration Writers Workshop and Committee Meeting	9:00 AM to 5:00 PM	S	Peacock 1	R
TMS Foundation Board of Trustees Meeting	2:00 PM to 5:00 PM	D	President's Suite #200097	R
Professional Registration Committee Dinner	6:00 PM to 8:00 PM	S	Peacock 2	R

T2 - Ticket Required, can be purchased/picked up at door

Schedule of Events

as of February 23, 2012

Key: D Dolphin Hotel   S Swan Hotel

Special Presentations				
Short Course: Electrowinning and Electrorefining of Copper and Zinc	8:30 AM to 4:00 PM	D	Europe 2	T
Short Course: Integrated Computational Materials Education	8:30 AM to 4:00 PM	D	Europe 3	T
Short Course: Process Energy Modeling: Spreadsheets and Beyond	8:30 AM to 4:00 PM	D	Europe 6	T
Short Course: Estimation of Slag Properties	8:30 AM to 4:30 PM	D	Europe 10	T
Workshop: Lead Free Solders	9:00 AM to 4:30 PM	D	Asia 3	T1
Short Course/Workshop Breaks, Lunch	10:30 AM to 3:00 PM	D	Asia 4 & 5	T
Volunteer Leadership Program Leadership Materials: Tools to Build Your Career	1:00 PM to 4:00 PM	D	Northern A4	R
ABET Refresher Training	3:00 PM to 5:00 PM	S	Sandpiper	R
TMS Meeting of the Membership	7:00 PM to 8:00 PM	D	Southern II	O

* O - Open to all attendees
R - Restrictions Apply

T - Ticketed Event
T1 - Pre-Registration Ticket Required
T2 - Ticket Required, can be purchased/picked up at door

Meet the Candidate Employment Poster Session

Sunday, March 11 • 6:30 to 8 p.m. • Dolphin Hotel, Atlantic Room

Organized by the TMS Young Leaders Committee, this new TMS event is designed to create networking opportunities for young professionals that will allow them to connect with potential employers for post-doctoral, full-time, or faculty positions. Candidates will present a poster to potential employers from various universities, industries, and national labs.

Visit the San Antonio, Texas Booth...site of TMS2013

Next to the Visit Orlando Concierge booth in the TMS Member Welcome Center Located in the Dolphin Hotel Atlantic Hall

Schedule of Events

as of February 23, 2012

Key: D Dolphin Hotel S Swan Hotel

Committee Meetings				
TMS Financial Planning Committee	7:00 AM to 9:30 AM	S	Parrot 1	R
Professional Registration Leadership Committee	8:00 AM to 10:00 AM	S	Teal	R
TMS Board of Directors Meeting	9:30 AM to 1:30 PM	S	Lark	R
REWAS Organizing Committee	10:00 AM to 11:30 AM	S	Peacock 1	R
Recycling and Environmental Technologies Committee	12:00 PM to 1:30 PM	S	Toucan 1	O
Accreditation Committee	12:30 PM to 2:30 PM	S	Toucan 2	R
Aluminum Processing Committee	1:30 PM to 2:30 PM	S	Parrot 1	O

TMS ANNUAL MEETING OF THE MEMBERSHIP

Sunday, March 11 • 7 to 8 p.m. • Dolphin Southern II

Don't miss this important membership engagement opportunity—highlighted by the official introduction of **Materials Innovation @ TMS**, the society's newest strategic initiative.

Also planned:

- Preview of new projects and programs for 2012
- TMS's most recent accomplishments — including publication of its latest energy materials report on behalf of the U.S. Department of Energy
- TMS's recent and expected financial performance

Speakers:

- Garry Warren.....................2011 TMS President
- Wolfgang Schneider..........2012 TMS President
- Stanley M. Howard............TMS Financial Planning Officer
- Warren H. Hunt ....TMS Executive Director

Member Welcome Center

Dolphin Hotel, Atlantic Hall • Daily
Sunday: 7 a.m. to 6 p.m. • Monday: 7 a.m. to 6 p.m. • Tuesday: 7 a.m. to 5:30 p.m.
Wednesday: 7 a.m. to 5:00 p.m. • Thursday: 7 a.m. to 3:30 p.m.

Learn and gather information about your membership, volunteering with TMS, the TMS Foundation, and all of our upcoming events and activities! Discover all TMS can offer as, "Your Professional Partner for Career Advancement".

IOMMMS Global Materials Forum: Materials in a Green Economy: An International Perspective,

Monday, March 12 • 2 p.m. • Dolphin Hotel, Northern A4

Ten presentations, including an invited talk by AIME President Brajendra Mishra, “The Role of Materials Recycling in Economic Sustainability”, will be offered.

MATERIALSINNOVATION @TMS

MATERIALS INNOVATION GALLERY

Monday, March 12 through Wednesday, March 14
TMS2012 Exhibition Hall - Dolphin Hotel, Pacific Room

Welcome to TMS’s showcase of ideas on how the techniques and principles that form the foundation for Materials Innovation @ TMS can potentially transform the development and deployment of advanced materials. A special feature of the TMS 2012 Exhibition, the Gallery has been designed to provide a visually compelling glimpse of how these concepts can potentially transform the future of materials and manufacturing innovation. You’ll also have the opportunity to learn about the array of resources that are being offered as part of Materials Innovation @ TMS — highlighted by a preview of *Integrating Materials and Manufacturing Innovation (IMMI)*, TMS’s new, peer-reviewed Open Access publication.

The Materials Innovation Gallery will be open throughout the conference during regular exhibition hours, so stop by often!

Sunday: 7 a.m. to 6 p.m. • Monday: 7 a.m. to 6 p.m. • Tuesday: 7 a.m. to 5:30 p.m.
Wednesday: 7 a.m. to 3:30 p.m. • Thursday: 7 a.m. to 3:30 p.m.

PREMIUM ITEMS DONATION PROGRAM*

Help the TMS Foundation continue to support these society-building initiatives:

- Young Leaders Program
- Materials & Society *(Past projects include: TMS- Engineers Without Borders-USA Mali, Africa Project Partnership)*
- Vittorio DeNora Prize for Environmental Improvements in Metallurgical Industries
- TMS Scholarship Program

Receive these items for donations of the following correlating amounts:

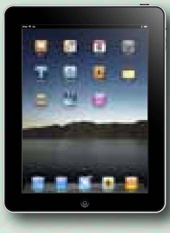
$10 – TMS Pin

$25 – TMS Umbrella

$50 -- Periodic Table Mug

$250 – Apple TV

$500 – Kindle Fire



$1,000 – i-Pad

**The Premium Item Donation Program will run through April 15.*

Disney Drawings

Enter to win Disney Park Hopper passes through a daily drawing held for the duration of the conference. Simply drop your business card off at the Foundation Booth.

MATERIALSINNOVATION @TMS

Special Plenary Session:
Reaching New Heights: Materials Innovation in the Aerospace Industry
Wednesday, March 14 • Dolphin Hotel, Northern E2

New materials development is at a crucial stage of evolution, with Integrated Computational Materials Engineering (ICME) and new data sharing breakthroughs paving the way to remarkable time and cost reductions in product deployment. Through a series of compelling case studies, this program offers insights that can be applied to many aspects of product manufacturing, with significant impact on economic security and the race to heightened competitiveness.

Federal Funding Workshop and Reception
"Funding Opportunities to Advance the Materials Genome Initiative"

Panel Discussion: 4 p.m. • Reception: 5:15 to 6 p.m.
Wednesday, March 14 • Dolphin Hotel, Northern C

Don't miss this highly interactive session on funding opportunities related to the U.S. Materials Genome Initiative (MGI), as presented by program leaders from an array of federal funding agencies. Networking reception sponsored by the Georgia Institute of Technology.

Schedule of Events

as of February 23, 2012

Key: D Dolphin Hotel S Swan Hotel

Committee Meetings				
TMS Board of Directors	8:00 AM to 11:30 AM	S	Lark	O
Graduate Student Advisory Council	9:00 AM to 10:00 AM	S	Toucan	R
Ni-Co 2013 Organizing Committee	12:00 PM to 1:30 PM	S	Sandpiper	R
Met Trans B Editorial Meeting	1:00 PM to 3:00 PM	S	Parrot 2	R
TMS-SME Leadership Meeting	3:30 PM to 4:30 PM	D	President's Suite #200097	R
Women in Materials Science and Engineering Committee	4:00 PM to 5:00 PM	D	Asia 5	R
Materials and Manufacturing Leaders Summit Reception & Dinner	6:00 PM to 9:00 PM	D	Northern D	R

* O - Open to all attendees
R - Restrictions Apply

T - Ticketed Event
T1 - Pre-Registration Ticket Required
T2 - Ticket Required, can be purchased/picked up at door

Schedule of Events

as of February 23, 2012

Key: D Dolphin Hotel S Swan Hotel

FUNCTION	TIME	LOCATION	ROOM	ACCESS*
Thursday, March 15, 2012				
All Conference Events				
Author's Coffee	7:00 AM to 8:00 AM	D	Atlantic	R
Registration	7:00 AM to 3:30 PM	D	Atlantic	O
TMS Member Welcome Center	7:00 AM to 3:30 PM	D	Atlantic	O
TMS Foundation Center	7:00 AM to 3:30 PM	D	Atlantic	O
TMS Programming Support Center	7:00 AM to 3:30 PM	D	Atlantic	O

MATERIALSINNOVATION @TMS

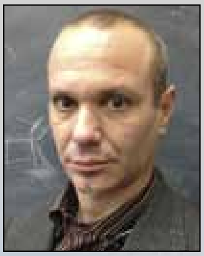
Special Plenary • Reaching New Heights:
Materials Innovation in the Aerospace Industry

Wednesday, March 14 • 2 p.m. to 3:45 p.m.
Dolphin Hotel, Northern E2

The aerospace industry is a demonstrated leader in materials innovation and acceleration. Through a series of compelling case studies, this program offers insights that can be applied to many aspects of product manufacturing, with significant impact on economic security and the race to heightened competitiveness. (Presented in cooperation with *Integrating Materials and Manufacturing Innovation* (*IMMI*) TMS's new Open Access journal.)

Moderator: Charles Ward, Chief, Metals, Ceramics, & Nondestructive Evaluation Division, U.S. Air Force Research Laboratory; Editor, *Integrating Materials and Manufacturing Innovation*

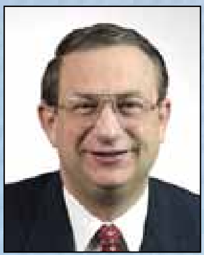
TOPICS AND SPEAKERS:



James Warren
Leader, Thermodynamics and Kinetics Group, Metallurgy Division National Institute of Standards and Technology; Technology Advisor to the Director on the Materials Genome

Topic: Materials Genome Initiative

The Materials Genome Initiative (MGI) is a new, multi-stakeholder effort to develop an infrastructure for accelerating advanced materials discovery and deployment in the United States. This talk will provide a brief introduction to the MGI, and set the stage for the case studies discussed in this session.



Robert E. Schafrik
General Manager, Materials and Process Engineering Department
GE Aviation

Topic: ICME: Promise and Future Directions

GE Aviation has been engaged in various aspects of integrated computational materials engineering (ICME) for 10 years, driven primarily by the desire to implement new materials development within half the standard time. To accomplish this, a close relationship with design engineering and supply chain has been established.

Charles Kuehmann
President and CEO
QuesTek Innovations LLC

Topic: Lessons Learned from the Trenches and Implications on ICME and the MGI

The Materials Genome Initiative challenges innovation in materials modeling and engineering methods, enabling new materials to reach commercial application in half the time of current capabilities. In this new paradigm, a specific engineering problem must dictate the priorities for developing MGI-and ICME-related modeling, tools and data, not the other way around.

Michael Dudzik,
Vice President Science & Technology, Washington Operations, Lockheed Martin Corporation

Rick Barto, Program Manager, Advanced Technology Laboratory, Lockheed Martin Corporation

Topic: Enabling the Era of Hybrid Materials – A Tipping Point of Change

The ongoing state-of-the-art transition in the field of materials science, from metal alloys to composites to hybrid materials, offers the aerospace market unique design solutions to meet ever demanding requirements in product manufacturing cost reduction, system performance enhancement, and total lifecycle sustainability. A review of recent successes achieved through better utilization of computational physics, material data management, certification, and the manufacturing supply chain will be presented.

Materials Innovation @ TMS is TMS's new strategic initiative.
The following programs have been developed as part of this effort.

Federal Funding Workshop & Reception

Funding Opportunities to Advance the Materials Genome Initiative

(Organized by the TMS Public and Governmental Affairs Committee)

Wednesday, March 14
Panel Discussion: 4 p.m. • Reception: 5:15 p.m.
Dolphin Hotel, Northern C

This highly interactive session will examine funding opportunities related to the Materials Genome Initiative (MGI), as presented by program leaders from an array of federal funding agencies. Panelists will provide an overview of current MGI activities in their agencies and present a look to the future, with significant time for questions from the audience. Continue the dialogue during the networking reception, sponsored by the Georgia Institute of Technology, designed to promote one-on-one conversation with the panelists.

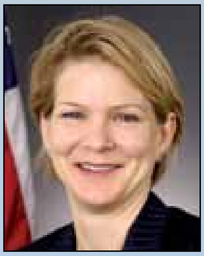
TOPICS AND SPEAKERS

Diana Farkas,
Program Director, Condensed Matter and Materials Theory, Division of Materials Research National Science Foundation

Topic: Looking for Transformative Approaches for the Materials Genome Initiative

Diana Bauer
Director of the Office of Economic Analysis U.S. Department of Energy

Topic: New Efforts on Computational Materials



Julie Christodoulou
Director, Naval Materials Division
Office of Naval Research

Topic: Basic Research Challenge in Materials

Michael Caton
Senior Materials Research Engineer
Materials & Manufacturing Directorate
Air Force Research Laboratory

Topic: Advancing Superalloys

Don't Miss These Other Materials Innovation @ TMS Opportunities

Materials Innovation Gallery: Browse a visually compelling showcase of ideas—developed as a special feature of the TMS 2012 Exhibition—on implementing materials innovation principles, techniques, and concepts. (See page 9 for details.)

Preview of *Integrating Materials and Manufacturing Innovation* (*IMMI*): Learn more about TMS's new Open Access journal that combines peer review rigor with enhanced digital content to rapidly share knowledge and learning on innovations, from materials discovery through manufacturing. Opportunities to interact with the *IMMI* editor, Chuck Ward, will be presented throughout the conference.

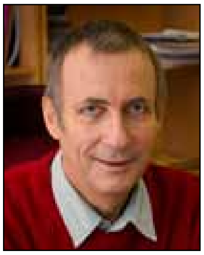
Annual Meeting of the Membership: Start your conference by attending this important membership engagement opportunity—highlighted by the official introduction of **Materials Innovation @ TMS**, (See page 6 for details.)

For additional information, stop by the Materials Innovation @ TMS Information Center at the TMS Member Welcome Center or visit our website at **materialsinnovation.tms.org**.

Lectures & Luncheons

Extraction & Processing Division Distinguished Lecturer-Plenary Session International Smelting Technology Symposium (Incorporating the 6th Advances in Sulfide Smelting Symposium)

Monday, March 12 • 8:40 a.m.
Dolphin Hotel, Northern A3



Speaker: **Theo Lehner,** Boliden Mineral AB, Sweden

Topic: Conservation & Development: Industrial Learning in Non-Ferrous Smelting

About the Topic: This lecture will present thoughts and experience on the following issues in Non-Ferrous Smelting: conservation and its corollary waste; development; industrial learning curves. Waste occurs in many shapes, be it losses of material, loss of health, loss of ability or knowledge. Development in non-ferrous smelting over the last decades has changed many a flow sheet, but also ended many projects. Operations have adapted to new processes and new conditions.

Young Leaders Tutorial Luncheon Lecture

Tuesday, March 13 • Noon
Swan Hotel, Northern C

Speaker: **Michael Demkowicz**, Massachusetts Institute of Technology, USA

Topic: Becoming a Better Scientist by Learning the History of Science

About the Topic: A scientist educated in the current curricula finds it difficult to defend scientific perspectives to skeptical non-scientists. He will propose that this educational gap be filled by making the history of science part of the typical science curriculum. In this talk, Demkowicz will present several topics from the history of science that could serve as case studies to be incorporated into such a class.

Light Metals Division Luncheon Lecture

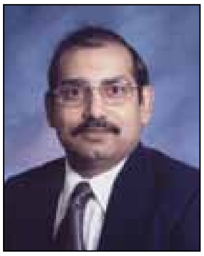
Wednesday, March 14 • Noon
Swan Hotel, Osprey

Speaker: **Diana Bauer**, Director of the Office of Economic Analysis, U.S. Department of Energy's Office of Policy and International Affairs.

Topic: The Department of Energy's 2011 Critical Materials Strategy

About the Topic: Bauer will present an overview of the DOE's Critical Materials Strategy.

Invited Talks



Speaker: **Brajendra Mishra,** AIME President, a professor at the Colorado School of Mines and 2006 TMS President

Brajendra Mishra will present two talks:

IOMMMS Global Materials Forum: Materials in a Green Economy: An International Perspective Symposium

Monday, March 12 • 2:10 to 2:30 p.m.
Dolphin Hotel North A4

Presentation Title: The Role of Materials Recycling in Economic Sustainability.

Integrative Materials Design: Performance and Sustainability Symposium

Tuesday, March 13 • 11:05 a.m.
Dolphin Hotel Europe 2

Award-Winning Speakers

Extraction & Processing Division/Materials Processing & Manufacturing Joint Division Luncheon and Institute of Metals/ Robert Franklin Mehl Award Lecture

Tuesday, March 13 • Noon
Swan Hotel, Northern C

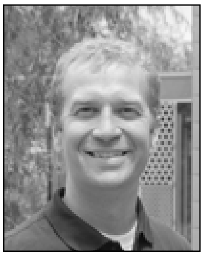
Speaker: **Subra Suresh**, Director of the U.S. National Science Foundation (NSF)

Topic: Nanomechanics of Engineered and Biological Materials

Vittorio de Nora Prize Lecture

Tuesday, March 13 • 11:25 a.m.
Dolphin Hotel, Europe 5

Speakers: **Antoine Allanore**, Massachusetts Institute of Technology, USA; and



James Yurko, Electrolytic Research Corporation, USA

Topic: Development of Electrometallurgical Processes for 21st Century Metal Extraction

About the Topic: This presentation will first briefly present some existing extraction methods, in particular electrometallurgical ones, pointing-out the advantages and issues related to the current state-of-the art. The second part of the talk will present how breakthrough electrochemical processes have recently been developed to adapt to environmental and energy constraints, taking the example of low- and high-temperature electrochemical extraction processes scaled-up for transition and light metals.

2012 Shri Ram Arora Award

Wednesday, March 14 • 3 p.m.
Swan Hotel, Pelican 2

Speaker: **Anjali Sharma**, University of Delhi

Topic: Novel Sensor Structure of SnO2 Thin Film Integrated with Catalytic Micro-Discs for the Detection of Trace Level NO2 Gas

About the Topic: An improvement in the sensing response, response time and recovery time could be attributed to the spill-over of sensing gas molecules over the uncovered surface of SnO2 thin films by WO3 micro-discs catalyst.

JIM International Scholar Award Winner

Tuesday, March 13 • 8:30 a.m.
Dolphin Hotel, Southern II

Speaker: **Noritaka Saito**, Kyushu University

Topic: Effect of Shear Stress on Crystallization Behavior of Mold Flux for Continuous Casting

About the Topic: This presentation will focus on how modern steelmaking involves handling slags and fluxes mostly in the temperature region between liquidus and solidus, to fully exploit their functional capabilities and the various methods researchers have developed to study the crystallization behavior of them.

Networking & Social Events

Student Mixer

Sunday, March 11 • 8:30 10:30 p.m.
Dolphin Hotel, Southern III

Meet and mingle with the next generation of materials scientists and engineers as peer mentors in an informal social setting.

President's Welcoming Reception

Monday, March 12 • 5 to 6:30 p.m.
Dolphin Resort, Pacific Room

Gather with 2011 TMS President Garry Warren and colleagues for an informal social event in the exhibition hall.

Honorary & Memorial Dinners

All honorary dinners will be held Monday, March 12. Tickets are needed for admission to these events and may be purchased at the Registration Desk in Dolphin Resort, Atlantic Room.

T.T. Chen Honorary Dinner
6:30 to 8 p.m. • Dolphin Resort, Northern B Room

Emeritus Professor George D.W. Smith Honorary Dinner
6:30 to 8 p.m. • Swan Resort, Lark Room

Robert Ritchie Honorary Dinner
6:30 to 8 p.m. • Swan Resort, Osprey 1

Randall M. German Honorary Dinner
6:30 to 8 p.m. • Swan, Toucan Room

Dinner in Memory of Patrick Veyssière
6:30 to 8 p.m. • Swan, Osprey 2

Tuesday, March 13,
World ShowPlace Pavilion, EPCOT

TMS will honor the best among the materials science & engineering community. Incoming 2012 TMS President Wolfgang Schneider will also be recognized and will present his vision for the new year. This year, the banquet will be held in the **World ShowPlace Pavilion in EPCOT** and will include a **Disney fireworks display, "IllumiNations: Reflections of Earth,"** to close the event. **Shuttles will board at 5:30 p.m. outside of the Europe Ballrooms Foyer on the Lobby/3rd Level of the Dolphin Hotel and depart for EPCOT at 5:45 p.m.**

Attendees are reminded to wear their name badges and bring their banquet tickets in order to board the busses and gain admittance to the **EPCOT World Showplace**. For guests needing assistance, a shuttle will be available for transport to the private area.

Following the banquet, TMS staff and Walt Disney World Guides will direct guests to the **Italy Pavilion Dock** for the fireworks show and accompanying dessert. Shuttles will meet guests behind the Italy Pavilion for transport back to the Swan and Dolphin, the Coronado Springs, and the Caribbean Beach Resorts at the conclusion of **IllumiNations**.

ADVANCE TICKETS ARE REQUIRED FOR THIS LIMITED SEATING EVENT. T

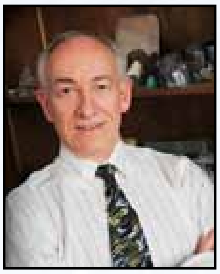
Wolfgang Schneider,
2012 TMS President

About the 2012 TMS President

Wolfgang Schneider is the head of the research and development center of Hydro Aluminum Rolled Products Business in Bonn, Germany and is also a professor of metallurgy at the Technical University of Berlin. A TMS member since 1996, Schneider's vision for his presidency is growing the mission of TMS, with more emphasis on professional development.

"During my presidency, my focus will be on innovation that can expand the product and service portfolio of TMS. One specific area I feel requires more attention is our professional education strategy. I would also like to see more emphasis on the technical agenda and volunteer structure with the focus on technical divisions and committees, which are responsible for the major programming activities of TMS." Schneider received his Dipl.-Ing. degree in foundry technology, as well as his doctorate in metallurgy, from the Technical University of Berlin. He has published more than 140 technical papers and is named as an inventor in nine patents.

As a member of the Society, Schneider served as chair of the TMS Light Metals Division from 2007-2010 and on the TMS Board of Directors from 2003 to 2006 in the membership development area. He has also volunteered in various other capacities for TMS since 1997. His service included: Cast Shop Technology Symposium subject chair, Aluminum Committee chair, Strategic Advisory Committee member, and Nominating Committee member. Schneider has also received several Society awards, including the TMS Light Metals Award in both 1990 and 1995. He has been active in a number of other societies, such as the German Society of Material Science DGM and the German Foundrymen Society VDG.



Society Awards presented by 2011 TMS President Garry Warren

Garry W. Warren is professor in the Department of Metallurgical and Materials Engineering, and Director of the Materials Science Program at the University of Alabama, Tuscaloosa. He is active in the TMS Extraction & Processing Division (EPD) and has served in numerous capacities. Warren has also served at the society level on the TMS Programming Committee, the TMS Financial Planning Committee, the TMS Publications Coordinating Committee, and the TMS Board of Directors.

SOCIETY AWARDS

TMS Fellows Class of 2012

Ian Baker
Sherman Fairchild Professor of Engineering,
Dartmouth University

David Dunand
James and Margie Krebs Professor, Northwestern University

Sung-Kwon Kang
Research staff, IBM Corporation

Pradeep Rohatgi
Professor, University of Wisconsin

Alexander Scott Distinguished Service Award
Ramana Reddy
University of Alabama

Application to Practice Award
Mark Taylor
University of Auckland

Brimacombe Medalist(s)
Robert Hyers
University of Massachusetts
Paul Krajewski
General Motors Company
Zi-Kui Liu
Pennsylvania State University

Bruce Chalmers Award
A. Lindsay Greer
University of Cambridge

Cyril Stanley Smith Award
Mats Hillert
Royal Institute of Technology

Early Career Faculty Fellow Award
Michael Demkowicz
Massachusetts Institute of Technology

Educator Award
Marc DeGraef
Carnegie Mellon University

Institute of Metals/Robert Franklin Mehl Award
Subra Suresh
National Science Foundation

Morris Cohen Award
Michael Ashby
University of Cambridge

Shri Ram Arora Award
Anjali Sharma
University of Delhi

Vittorio de Nora Prize for Environmental Improvements in Metallurgical Industries
Antoine Allanore
Massachusetts Institute of Technology
James Yurko
Electrolytic Research Corp.

Student Activities

Sunday

TMS2012 Materials Bowl
Noon to 8:30 p.m. • Dolphin Hotel, Southern IV
Elimination Rounds – **Noon to 3 p.m.**
Final Championship Round – **8:00 p.m.**

Student teams compete for cash prizes and earn the right to take home the traveling trophy after conquering three rounds of intense, materials science-based questions.

Student Mixer
8:30 to 10:30 p.m. • Dolphin Hotel, Southern III

Put on your dancing shoes to meet and mingle with peers in an informal social setting.

Monday

Poster Contest Judging
5 to 6:30 p.m. • Dolphin Hotel, Atlantic

Tuesday

Best of Show Judging – Ribbon Presentation
10:30 to 11:30 a.m. • Dolphin Hotel, Atlantic

Career Forum
3 to 5 p.m. • Swan Hotel, Osprey 2

Organized by the TMS Young Leader Committee, this session will feature speakers from a variety of materials science backgrounds and career stages who discuss how to navigate a career path to ultimate goals.

Career Panel

Julia Greer,
Cal Tech

Eric Brown,
Los Alamos National Laboratory

Frank DelRio,

SPECIAL INFORMATIONAL SESSION: Congressional Science and Engineering Fellowship Program

Monday, March 12 • 1 to 2 p.m.
Swan Hotel, Parrot 2 Room

Speakers:

Jennifer Nekuda Malik
2011-2012 TMS/MRS Congressional Science and Engineering Fellow

Topic: Engineering Public Policy: Science in Government

Edward Herderick
2009-2010 TMS/MRS/ACerS Congressional Science and Engineering Fellow

Topic: The Transition from PhD candidate to Congressional Staffer to Engineer in the Materials Industry

Have you ever considered learning about the field of science policy in the U.S. Senate and House of Representatives?

The TMS/MRS Congressional Fellowship Program offers an amazing opportunity for scientists at all stages of their careers to spend a year as a special legislative assistant in the United States Congress in Washington, DC.

TMS2012 offers a snapshot of this experience via this informational session featuring testimonials from Jennifer Nekuda Malik, current Fellow, who is a staff member on the Senate Energy and Natural Resources Committee, and Edward Herderick, who served on the staff of Ohio Senator Sherrod Brown during his Fellowship. The pair will discuss their day-to-day agenda, education, and benefits to their personal career advancement. An opportunity for questions and discussion will follow.

Mark Your Calendar

Upcoming Meetings

TMS provides numerous opportunities for advancing research and collaboration on the latest technology through a series of diverse conferences and workshops. For the ultimate in professional development and networking, make the face-to-face connections at these events designed to engage the materials science and engineering community.

TMS2012

141st Annual Meeting & Exhibition

26th EXHIBITION

March 11-15, 2012 • Swan & Dolphin Resort
Orlando, Florida

Exhibit Hours

Monday, March 12..12 p.m. - 6:30 p.m.
Tuesday, March 13 ....10:30 a.m. - 6:00 p.m.
Wednesday, March 14...10:30 a.m. - 3:00 p.m.

Company Descriptions

ABB Inc. **Booth #300**

ABB Analytical Measurements designs, manufactures and markets high-performance analytical system solutions and spectroradiometers for petroleum, chemical, life sciences, academic, semiconductor, metallurgy and remote sensing/aerospace markets. Building on more than 39 years of experience in analytical instrumentation, ABB has established itself as a worldwide leader in inclusion and hydrogen measurements in liquid aluminum. The company offers a complete range of analytical solutions to the aluminum industry: AlSCAN™ hydrogen analyzer, LiMCA inclusion analyzer, Prefil®-Footprinter melt cleanliness analyzer, PoDFA inclusion identification and quantification analysis. ABB also offers metallographic analysis service for its customers.

Across International **Booth #113**

Founded and based in New Jersey, United States, Across International supplies crystal substrates, laboratory equipment, in the area of heat treatment and material processing for universities, research facilities and labs. We have more than 15 years of industrial manufacturing experience in drying ovens, ball mills, lab furnaces, pellet presses and pressing dies.
Our goal is to build up business partnerships with friends around the world. We provide quantity discounts and will reply to your requests within the same business day; 100% customer satisfaction is always our first priority.

Advanced Dynamics Corp., Ltd. **Booth #101**

For over four decades, Advanced Dynamics (ADCL) has supplied our global customer base with state-of-the-art material handling systems for carbon plants and cast houses.

Our handling technology includes fully automated or semi-automated equipment for anode handling and cleaning, aluminum ingot and T-Bar handling, sawing and packaging systems. We also have experience in specialty systems for the magnesium, copper, zinc, steel and lead industries.

ADCL is a one-stop shop for your material handling needs including mechanical and controls engineering, fabrication, assembly, test and commissioning. Whether you need a new system or upgrades to existing systems or simply individual pieces of equipment, we can help improve your company's productivity. Remember, "Our ingenuity delivers productivity" when you think of ADCL for your next project.

Advanced Scientific Technology & Management Research Institute **Booth #226**

Almeq Norway AS **Booth #506**

ALMEQ Norway AS is an engineering and marketing company for a wide range of equipment and services to aluminium smelters worldwide.

The long term objective for the company is to be a leading supplier of own equipment as well as an export marketing partner for other well accepted manufacturers of machines and equipment for the primary aluminium smelters worldwide.

Aluminium International Today **Booth #105**

Aluminium International Today is the aluminium industry's leading international publication reporting on aluminium production and processing. Founded in 1989, it provides a wealth of technical features aimed at equipping producers and processors with information on latest developments. Added to this is a digest of industry news, contracts, events, new technology and conference reports. Supported by the Aluminium Federation in the UK, Aluminium International Today publishes six times a year in English plus two Chinese issues and two Russian issues. E-mail aluminium@quartzltd.com and visit www.aluminiumtoday.com.

AluminiumNetwork.com **Booth #417**

A Global Network for the Primary Aluminium Industry, AluminiumNetwork.com is your internet-based portal to supply and support you with a wide range of services; your meeting place with like-minded partners who can assist in improving your business and accelerate your project.

The main focus of aluminiumnetwork.com is the primary aluminum industry and it is aimed particularly at:
- Primary producers
- Suppliers of raw materials or intermediates
- Equipment suppliers
- Providers of services, including consulting services and project support.

The AluminiumNetwork.com Consultants / Freelancers database is the perfect source for independent expertise in all of the engineering disciplines, from alumina through to primary aluminum production, including all the support functions of the process. By providing a global platform, AluminiumNetwork.com is THE place to meet with Consultants and Freelancers within the primary aluminum industry. The clients of AluminiumNetwork.com will have access to the Consultants and Freelancers database and will be able to select their required need by qualification and skills.

Please visit www.AluminiumNetwork.com for detailed information.

Company Descriptions

Astrium North America **Booth #333**

Astrium North America is a U.S. based company specializing in program and project management, software engineering, external carrier development and integration services, experiment and payload processing, life and physical sciences hardware and flight simulation and training for the international space community.

ATR **Booth #316**

The ATR National Scientific User Facility offers materials science engineers and scientists the opportunity to test materials in an irradiation environment and perform analyses on the irradiated specimens. Capabilities available include three test reactors and a host of post irradiation examination facilities across the United States. Non-proprietary research is cost-free to U.S. university led teams.

Access to facilities is through a solicitation and review process: The kinds of research solicited include, but are not limited to, advanced materials for high performance reactor systems, understanding light water reactor core materials including austenitic steels and nickel alloys, determining properties of material joints after exposure to a neutron irradiation environment and the applicability of nanostructured materials to radiation resistant applications.

To learn more about ATR NSUF, please visit our website at: http://atrnsuf.inl.gov.

AUMUND Foerdertechnik **Booth #501**

With their proven track record in materials handling and storage from mineral processing to hot materials handling the AUMUND Group offers engineered and cost effective solutions for the primary aluminium production process.

Controlled cooling and clean handling of bath material in the primary aluminium smelting process with the AUMUND Cooling conveyor for hot bath material:

- Economical and efficient handling
- Defined cooling from 850°C down to below 100°C
- Drastic reduction of HF emission through controlled suction
- Improved environmental and health conditions
- Reduced investment and operating cost

AUMUND's head office is located in Rheinberg, Germany. E-mail at metallurgy@aumund.de. Contact Person/Designation: Matthias Moritz / General Manager

Beijing Antaike Information Development Co., Ltd **Booth #332**

Beijing Antaike Information Development Co., Ltd, relying on the industrial status and background of China Non ferrous Metals Industry Information Center, focuses on researching and analyzing the production, consumption, market, management, and industrial policies of non ferrous metals industry and uses the information within the industry to push forward the overall development of the industry. We provide information and consultancy services for global metals markets, and the construction of enterprise information technology as well as their brand promotion.
engineering and production of special mobile and stationary equipment for the aluminium and non ferrous metals industry. The full range of purpose designed machines covers different types of equipment performing a large number of operations in pot-rooms, rodding shops and cast-houses.
The Company's aim is to provide the most innovative, rational, cost effective and user friendly technical solutions.
Among the most significant families of mobile equipment are the Tapping Vehicles, Anode Transporters, Crucible Transporters and Tilters, Alumina/ AlF3 Feeding Vehicles, Furnace Charging Vehicles and Furnace Tending Vehicles, Multipurpose Anode Changers and Crust Breakers. Beside its line of purposed designed vehicles, Techmo provides a number of stationary equipment such as Crucible Cleaning Machines, the Crucible Tilting stations and the Anode Butts Cleaning Stations.

Big C: Dino-Lite Scopes **Booth #340**

Big C offers the Dino-Lite Portable Digital Microscope, which provides high-quality microscopy video interfacing to PC and MAC with clear and steady imaging and 10X–200X magnification. The included software "DinoCapture" makes it easy and convenient to take snapshots, record videos, manipulate images, and save and e-mail discoveries. It is a single lens device with diverse applications.

Company Descriptions

Boreal Laser Booth #319

Boreal Laser makes GasFinder laser based toxic and hazardous gas detectors that are used in a variety of open path (ambient, environmental and safety), stack, vent and process monitoring applications. Portable GasFinders are light, battery operated and easy to set up and use. Multiple path/point GasFinder MC systems can monitor up to eight paths or points with a single analyzer. Both portable and fixed GasFinders are self-calibrating, robust, reliable and maintenance free. GasFinders benefits also include fast one second response, lack of interference from other gases and low cost of ownership. GasFinders are currently available for hydrogen fluoride (HF), hydrogen chloride (HCl), hydrogen sulfide (H2S), ammonia (NH3), methane (CH4), carbon dioxide (CO2), hydrogen cyanide (HCN), ethylene (C2H4) and acetylene (C2H2). Typical applications include Aluminum smelting, Refineries (esp. HF Alkylation), Petrochemical and Chemical Plants, Gas Production and Processing, Green House Gas applications, plus Bricks and Ceramics.

Brochot Booth #200

Brochot SA is the descendent of a very old industrial company going back to the early 19th Century. The Brochot family remained the owners until 1986, when it was bought by its present management.

During the years 1986 to 1992 the new owners were to develop the firm both internally and by external acquisitions along two lines:

- Increasing its sub-contracting work, a thriving activity at the time
- Developing the range of equipment for the production of primary aluminium BROCHOT concentrated on developing and rounding out its know-how In the design and building of special equipment for industry, in the automated "meddle mechanical" area.

Despite having skills and references in other sectors, such as the motor and railway and printing industries, for several years BROCHOT has, for several years seen the bulk of its turnover come from companies producing primary aluminium and magnesium.

Buss AG Booth #116

Buss AG is an established Swiss manufacturer of value-added mixing and kneading systems for various applications.

The genuine Buss Kneader technology, developed by Buss AG in 1945, has meanwhile made its mark in the aluminium and other industries. Today, more than 2500 BUSS Kneaders are in operation worldwide, 250 thereof in the continuous production of carbon pastes.

For nearly 60 years, the Buss Kneader has been the benchmark for reliable and cost-effective mixing of anode pastes. Now Buss AG is proud to present
a new Kneader generation, the four-flighted KX series, designed for even more intensive mixing and micro-dispersion at considerably higher output rates and lower investment cost.

The genuine Buss Kneader technology is the best choice for a reliable low production cost and customer approved production of high quality anodes.

Buss ChemTech and Laeis Booth #431

Buss ChemTech AG (BCT):
as the world leader in equipment supply and technologies for the aluminium industry based on 60 years experience, offers high developed and fully dedicated applications for Anode manufacturing and Aluminium Fluoride production, covering:

- Modular and fully continuous running Green Anode Plants, e.g. the KAS Carbon Plant in Pavlodar
- Pitch Melting Plants based on unique, highly efficient function incl. appropriate storage
- BCT Paste Kneader with latest major improvements, the most efficient paste preparation application
- Coke Preheater, Paste Cooler and Hydraulic Anode Press integrated to the process

BCT is providing original parts and worldwide on-site support for all maintenance, operating and process aspects to ensure you an efficient and reliable production.
Since September 2011, Buss ChemTech is joining KRESTA Industries, a private owned industrial group with 700 employees, own fabrication facilities and full EPC services. A further step to successfully serve our customers with guaranteed solutions.
www.buss-ct.com

LAEIS GmbH:
offers hydraulic presses MEGA 2500/1600 AV for production of prebaked anodes. These presses are modifications of the renowned HPF presses, supplied more than 600 times to different industries, optimally adapted to anode production requirements. With die areas up to 1800 x 850 mm^2 and filling depth up to 1400 mm practically all anode formats can be produced. A vacuum system provides for optimal densification and even density distribution over the whole anode volume. The special weighing and mould filling system together with the sophisticated press control guarantees extremely high accuracy and reproducibility of anode weight and height. Depending on anode formats, production capacity is up to 50-60 t/h in a single line. The remarkably lower forming temperature results in higher green strength, avoids a separate water cooling and reduces the emission of PAH and other pitch volatiles.
www.laeis.eu

Company Descriptions

CA Picard International **Booth #415**

C.A. PICARD is specialized in manufacturing of high quality wear parts for continuous kneaders for the manufacture of green anodes for the primary aluminum industry.

PICARD manufactures kneading teeth, wearing plates / liners and screw flights out of high wear resistant qualities.

Chongqing Runji Alloy Co., LTD. / Okaya (U.S.A.), Inc **Booth #323**

We specialize in producing all kinds of alloying tablets. We are continuing to improve, modernize and expand our company's production capacity in order to increase productivity and efficiency. Our acquisition of the largest Mn ore mines in Jingxi County, Guangxi province of China, has increased our capacity to more than 3 million tons and our new production line of Mn flakes has also been completed with an annual capacity of 30,000 tons. With the development of these programs along with our state-of-the-art production management, technologies and facilities, we can guarantee enough raw material supply at very competitive price levels while maintaining our high level of quality.

Information about our partners: Okaya (U.S.A.), Inc. is an international trading house that provides representation in North America for Chongqing Runji Alloy Company, LTD. This partnership is an example of Okaya's expansion of our business domain from its core area of iron and steel to various related fields of business. We can also perform marketing, logistics and processing functions to fulfill our role as the "Best Global Sourcing Partner". As an independent trading company with a high level of flexibility, Okaya will continue to propose insightful and creative business opportunities by looking at various areas with a broad perspective. Also visit us online at www.okaya.co.jp/en

Company Descriptions

CIMM **Booth #426**

As the company certified by ISO9001:2008 and international projects contractor accredited by P.R.China, CIMM GROUP is a healthy and fast growing integrated multinational corporation professionally engaged in providing technology, engineering, manufacturing, trade and EPC service in fields of aluminium and steel, minerals, metals and metallurgy, cement and construction, refinery and petrochemical, ports and shipyards, oil and gas, power generation and transmission, green resource, and energy, etc.

CIMM GROUP is also the leading raw material and equipments supplier for aluminium smelters. Some of the products are aluminium fluoride and cryolite, anode, cathode, silicon metals, refractory, insulation bricks, silicon nitride bonded silicon carbide blocks, CPC, aluminium tablets, etc. and some of equipments are Pot Tending Machine, Stacking Crane, Furnace Tending Assembly, Aluminium Ladle cleaning Machine, Vibration Machine, Anode Clamp, Crush Breaker and assorted Spare Parts, etc., which have been supplied to overseas markets to establish good and steady relationships with Australia, Brazil, India, Russia, Middle East, Kazakhstan, Europe, USA, etc. The supplied products have a great reputation among our customers. CIMM GROUP is always committed to be a trustworthy business partner.

Claudius Peters **Booth #318**

In the field of materials handling and processing, from stockyard, pneumatic conveying, silo, clinker cooler, grinding mill and packing & dispatch systems, Claudius Peters are experts in the Cement, Coal, Alumina, Gypsum and Bulk Handling industries.

Claudius Peters Projects GmbH, Germany and Claudius Peters Technologies SAS France are part of the Technologies Division of Claudius Peters Group GmbH, headquartered in Buxtehude, near Hamburg, with regional offices in the Americas, Europe, China and the Far East, offering turnkey and semi-turnkey systems.

The group's other principal division, Aerospace, is engaged in the manufacture of aircraft parts for the European Airbus programme. Claudius Peters Group GmbH is a wholly owned subsidiary of Langley Holdings plc, a privately controlled UK engineering group.

CMI Novacast Inc **Booth #131**

CMI Novacast Inc. is a privately held company founded in 1972 as Cast Metals International by Paul R. Gouwens. At that time, it was a consulting firm endeavoring to introduce new technologies to the United States from foreign countries. One of the companies introduced was GAAA of Lyon, France. GAAA was in the business of producing electromagnetic pumps for metering of molten metal. GAAA opened an office in Elk Grove Village, Illinois, in 1973 to service the North American market. GAAA was purchased by Novatome in 1978, and in 1981 the French government nationalized Novatome with the requirement that all work in aluminum cease. At that time, Cast Metals International changed its name to CMI Novacast Inc. and took over the production and sale of the pumps as designed by Novatome.

CMI Novacast's commitment to all customers is to deliver the most reliable, predictable, and high-performance low pressure or gravity casting system in the industry.

Colt International **Booth #104**

Colt is a global supplier and manufacturer of natural and mechanical ventilation systems.
The principal activity of Colt is the supply of specialist products and systems in the field of building services with particular emphasis on gravity ventilation and the environmental control of industrial and commercial buildings. Especially for the aluminum industries, Colt is supplier of

- Static Roof Ventilators for reduction area and anode bake building
- Controllable Air intake louvers for air intake in the basement of reduction, anode bake buildings and cast houses
- Claustra Wall , manufactured from reinforced fiber plastic
- Pot hoods/covers for pots.

MISSION STATEMENT: Our vision is to make the world a better place in which to live and work by helping to make the environment associated with buildings healthy, safe, productive and comfortable.

CompuTherm LLC **Booth #518**

CompuTherm, LLC, expertise in thermodynamics and kinetics, develops computational tools for industrial applications in the broad field of materials science and engineering. The products of CompuTherm include the Pandat software and thermodynamic databases for numerous alloy systems, such as Al-, Ni-, Ti-, Mg-, Fe- based alloys. These products are currently used by hundreds of users worldwide. Pandat is a powerful software package for the calculation of multi-component, multi-phase equilibrium and related properties. In addition to the phase diagram calculation and optimization modules,
a precipitation module and a diffusion module are currently being developed in the framework of the Pandat software. In the past 15 years, CompuTherm has collaborated with academic and industrial partners and has worked on many government-sponsored projects. CompuTherm also develops tailor-made software and databases for specific applications, provides consulting services to materials industries and collaborates with other institutions working on challenging programs with potential commercial payoffs.

Company Descriptions

CSM Instruments **Booth #231**

CSM Instruments has been leader in the development of instruments for advanced materials testing for over thirty years.

CSM Instruments offers a wide range of instruments and testing services for surface mechanical properties characterization, including: Hardness Testers, Scratch Testers and Tribometers. 3D-imaging options are available with the ConScan or AFM objective. CSM Instruments manufactures standalone instruments as well as testing modules that can be combined together on an automated platform.

Additionally, we have a thorough sample testing service and demonstration laboratory in Boston, MA where you can send us your samples for evaluation or take a firsthand look at our instruments.

Cytec Industries, Inc. **Booth #512**

Cytec collaborates with mining companies to optimize their operations through the delivery of innovative chemical technologies. We utilize our superior application expertise to develop solutions based on our customer's specific needs. We offer technologies that:

- Decrease the cost of operations
- Provide better recovery and selectivity
- Process difficult ores
- Prevent or limit employee's exposure to hazards
- Optimize the use of natural resources
- Minimize waste and re-tooling
- Do not require on-staff scientists or engineers

Cytec is committed to partnering with our customers to meet their needs. Our network of technical staff provides on-site technical assistance worldwide. We are dedicated to on-time delivery, even to the worlds harder to reach areas. Our unique approach to servicing our customers has made Cytec the leading provider of reagents to the mining industry.

Company Descriptions

Daifuku Webb Co/Webb Aluminum Booth #312

Daifuku Webb Company is a recognized leader in the field of engineered material handling systems and equipment. Our full line of integrated material handling products are computer controlled to efficiently automate rod/anode assembly, and green or baked anode operations.
Our product line includes:

- Automatic Guided Vehicles
- Power and free conveyors
- Roller conveyors
- Heavy-duty chain conveyors
- Automated Storage and Retrieval Systems
- Custom designed automation equipment

From raw materials handling and transport to anode, molten metal, and cast ingot handling to automated storage of work-in-process and finished product, Daifuku Webb Company has nearly 50 years of material handling and control experience in the Aluminum Industry.

Danieli Corus Technical Services Booth #115

Using proven technology, Danieli Corus helps clients in the primary metals industry achieve maximum performance. We bring reliability, economic benefits and minimized emissions to aluminium producers world–wide.
Based on specialized know–how and vast experience, Danieli Corus offers engineering and contracting services as well as consultancy at all levels of development. Danieli Corus is a client–focused, solutions–driven company. It offers an integrated approach to all aspects essential to success in an increasingly competitive global industry.

Danieli Corus provides efficient, cost–effective and versatile scrubbing technologies for the aluminium smelting industry. We are best known for our proprietary dry scrubbing technology, incorporating the patented vertical radial injection (VRI) system, for the control of emissions from potlines, carbon anode baking furnaces and green carbon plants. Danieli Corus also commissioned the two largest wet scrubbers ever built at an aluminum smelter for the reduction of sulfur emissions from the potlines.

Today, based on our proprietary dry scrubbing technology and our versatile wet scrubbing technology, numerous fume and gas treatment plants have been built for primary aluminum smelters around the world.

Dubai Aluminium Co., Inc. Booth #517

Dubai Aluminium ("DUBAL") owns and operates one of the world's largest single-site primary aluminium smelters. The DUBAL complex, built on an 480-hectare site in Jebel Ali, Dubai, comprises a one million mtpa smelter, a 2,350 MW power station (at 30˚C), a large carbon plant, extensive casting operations (1.267 million mtpa), a water desalination plant and other facilities.

High quality aluminium products are made in three main forms: foundry alloy for the automotive industry; extrusion billet for construction, transport and industrial applications plus billets for forging processes in automotive industries; and high purity aluminium for the electronics and aerospace industries. More than 300 customers are served in at least 45 countries worldwide, predominantly in the Far East, Europe, the ASEAN region, the MENA region and North America. A quality-focused, customer-centered and innovation-drive organization, DUBAL holds ISO 9001, ISO/TS 16949, ISO 14001, ISO/IEC 27001, ISO/IEC 20000-1, and OHSAS 18001 certification.

DUBAL also owns 50% of Emirates Aluminium ("EMAL") in Al Taweelah, Abu Dhabi, where Phase I with a smelter capacity of 750,000 mtpa was fully commissioned by the end of 2010. EMAL Phase II is currently under construction. With a view to securing its alumina requirements, DUBAL has invested actively in greenfield bauxite/alumina projects in Republic of Guinea, Brazil, Cameroon and India. These projects are in various stages of development.

DUBAL's in-house developed, proprietary reduction cell technologies, DX Technology and DX+ Technology (operating at 380 kA and 420 kA respectively), currently rank among the best reduction technologies available. DX Technology has already been installed at industrial scale at DUBAL (40 cells) and EMAL Phase I (756 cells); while DX+ Technology has been specified for EMAL Phase II (444 cells).

EBSD Analytical Booth #233

EBSD Analytical provides advanced microstructural materials characterization services using EBSD/EDS/SEM techniques. We specialize in providing texture, grain size, ODF, grain boundary analysis, and phase ID including elemental composition. With over 16 years experience in EBSD, you can trust that the results we provide will be of the highest quality.

Company Descriptions

EDAX Inc. **Booth #218**

EDAX is a leading provider of innovative materials characterization systems encompassing Energy Dispersive Spectrometry (EDS), Wavelength Dispersive Spectrometry (WDS), Electron Backscatter Diffraction (EBSD) and Micro X-ray Fluorescence (XRF).

EDAX's two TEAM™ analysis systems, TEAM ™EDS and TEAM™ Pegasus are both easy to use and offer Smart Features, which provide analytical intelligence to enable users to easily obtain exceptional results. TEAM™ EDS is the industry's most advanced EDS Analysis System. The newly released TEAM™ Pegasus is a world class materials characterization solution, providing users with both crystal structure and elemental composition results in one easy-to-use EBSD/EDS package. In addition the Orbis micro-XRF elemental analyzer provides small and micro-spot analysis and mapping.

EDAX also offers camera and detector solutions to meet all your analysis needs.

EDAX develops the best solutions for micro- and nano-characterization, where elemental and/or structural information is required, making analysis easier and more accurate. www.edax.com

EGYPTANODE **Booth #424**

EgyptAnode is a merchant coke calcining and baked carbon anode production facility, aiming to produce high quality carbon materials to be used in the aluminium industry worldwide. EgyptAnode is set to build its own calciners as a 1st phase of its project, with a 300,000 MT capacity of high quality calcined coke (Anode & Fuel grade) with start-up scheduled in 3rd Quarter 2013,while the anode production is scheduled to be in 2015.

The facility is located in Suez, Egypt, on the Southern entrance of the Suez Canal, on the Red Sea, and a short distance from Egypt's Mediterranean ports, giving it an ideal location to the Middle East market, Europe, and the Americas.

Eirich Machines, Inc. **Booth #522**

Eirich Machines designs, manufactures and supplies batch and continuous machinery and systems for the processing of raw materials, compounds, waste and residues in a wide range of industries. Our complete line of products for mixing, agglomerating, pelletizing, grinding, granulating and plasticizing range from laboratory size units to 250 ft^3 capacity machines. Eirich High Intensity Mixers can also be equipped with vacuum. The results of this process technology are synonymous worldwide for some outstanding achievements in the solution of problems in diverse applications.

Energoprom Group **Booth #202**

Energoprom Group is one of the most efficient companies of non-raw material sector of the Russian economy, runs business globally and supplies more than 50% of its production to the world market.

The Group is the fifth largest world producers of carbon and graphite products.

The main activity - production of high technological electrode, cathode and other carbon and graphite products for steel, aluminum, ferroalloy, silicon, chemical, nuclear and engineering industries.

The Group includes five companies: Novocherkassk, Novosibirsk, Chelyabinsk Electrode Plants, Doncarb Graphite and Aviauglerod, which are located in close proximity to consumers.

Farra Engineering, Ltd. **Booth #526**

Farra Engineering is a New Zealand based company that in conjunction with aluminium smelters in New Zealand and Australia has developed two machines to increase efficiency and safety in the carbon bake plants.

The Pit Maintenance Unit (PMU) provides easy and safe access to the bake pits for routine maintenance, utilizing one or two traversing cages that lower down into the pits. The unit can service up to 8 pits before simply relocating via the overhead crane and the beautifully balanced single point lifting attachment on the unit. To complement this we have developed a Flue Wall Building Station (FWBS) that allow tradesmen to safely and efficiently build the brick flue walls from an elevated platform, utilizing four interconnected rack and pinion drives to keep the flue wall rock steady and perfectly level. The wall drops down after every completed row of bricks and once fully completed it is easily removed for subsequent installation in the bake pits.

Our PMU's are installed in most recent new builds including Qatalum and Emirates Aluminium in the Middle East and the FWBS in the Hydro smelter at Kurri Kurri in Australia.

Company Descriptions

Fives Solios — Booth #407

FIVES SOLIOS is one of the companies of Fives, a major International Group, with considerable experience in industrial engineering and management of large projects all over the world. Fives Solios is specifically dedicated to the Aluminium Industry and develops innovative solutions in order to comply with more and more stringent environmental standards while increasing safety and reliability. Fives Solios most particularly works on reducing energy consumption in its process technologies.

- Reduction: Gas Treatment Centers on electrolysis pots and Bath Processing Units.
- Carbon: High Capacity Green Anode Plants, Pitch storage and processing, Liquid Pitch Marine Terminal, Firing & Control Systems for anode baking furnaces, and Fume Treatment Centers on anode baking furnaces.
- Casthouse Area: Melting and Holding furnaces including water cooling systems as well as integration of downstream casting machines, Heat Treatment furnaces for rolling mills and associated control systems.

www.fivesgroup.com

FLSmidth — Booth #225

FLSmidth is your major equipment supplier from Bauxite Mining and Refining through Calcination and Smelting. Every day, worldwide, our equipment crushes, conveys, grinds, digests, clarifies, precipitates, stores, and calcinates bauxite to produce alumina. Combining the respected brand names of MÖLLER, KOCH-MVT, FULLER-TRAYLOR, WEMCO, EIMCO, DORR-OLIVER, PNEUMAPRESS, KREBS, ABON, RAHCO, CEntry, Conveyor Engineering and Raptor, FLSmidth offers a broad range of equipment and processes while increasing recoveries, lowering energy consumption, and providing proven reliability. We also offer metallurgical testing utilizing the expertise of FLSmidth Dawson's metallurgical laboratories. FLSmidth is your One Source, One Partner providing integrated solutions that will save you valuable time on your project schedule!

Company Descriptions

Gannon University **Booth #139**

Founded in 1925 in Erie, Pennsylvania, Gannon University is a comprehensive Catholic institution that encourages the professional and personal growth of its students through a holistic education. Gannon University offers an Online Master's in Engineering Management (MS-EM) degree designed to help professional engineers put their careers on track for increased responsibility as an engineering manager or project director. The online engineering management program curriculum blends the best in advanced engineering studies and advanced coursework in business. Engineering professionals who complete Gannon University's MS-EM are poised to assume additional leadership responsibilities to advance their career.

Gautschi Engineering GmbH **Booth #212**

Gautschi Engineering GmbH is a leading supplier of equipment for primary aluminum casthouses and recycling plants.
The product range of Gautschi™ includes:

- Melting – and holding furnaces
- Pusher-type furnaces for rolling slab
- Homogenizing furnaces for extrusion billet and rolling slab
- Multiple chamber furnaces for coil and foil annealing
- Single coil annealing furnaces
- Horizontal D.C. casting plants
- Open mould ingot casting and stacking plants
- Vertical D.C. Casters for extrusion billet and rolling slab
- AIR GLIDE® and AIRSOL VEIL® mould technology

GE Aviation **Booth # 207**

GE Aviation is the world's leading producer of large and small jet engines for commercial and military aircraft. We also supply aircraft-derived engines for marine applications and provide aviation services. GE Aviation's technological excellence, supported by continuing substantial investments in research and development, has been the foundation of growth, and helps to ensure quality products for customers.

GES **Booth #219**

GES, supplying quality graphite to various industries for over 25 years, represents some of the leading graphite producers worldwide. The fine grain extruded, molded and iso-molded grades cover three distinct grain sizes. Offerings include cathode blocks, rods for molten metal pump shafts and support posts, large block for pump bases, and rounds for rotor heads. GES provides competitive pricing, technical support, and convenient warehousing to meet your needs. Our Technical Sales personnel will be available in our booth to discuss your application and which grades will meet your requirements.

Gillespie + Powers, Inc. **Booth #324**

A Corporation engaged in the design, supply, installation, and maintenance of industrial aluminum melting and process furnaces, refractory systems, acid-proof construction, and specialty refractories, as in waste incineration.

GLAMA Maschinenbau GmbH **Booth #201**

GLAMA has designed and built heavy-duty Equipment for Aluminium pot rooms, cast houses and anode rodding shops throughout the world for more than 50 years. The following type of equipment is available:

- Anode Changing Vehicles
- Hammer Crustbreakers
- Tapping Trucks
- Anode Pallet Transporters
- Furnace Charging Machines
- Furnace Tending Machines
- Ladle Charging Trucks
- Butt Cleaning Manipulators
- Coil Lift Trucks
- Molten Metal Carriers

GLAMA's experience of many years of producing machines with a unique combination of advanced control and rugged, reliable construction is evident in the several hundred machines now in service. GLAMA equipment withstands the heat, dust, vibration and battering of heavy industry while delivering precise handling performance.
More details: www.glama.de

GNA alutech, Inc. **Booth #103**

A comprehensive range of equipment and unsurpassed reliability and efficiency are at the heart of GNA alutech's success. Leading aluminum works all over the world rely on GNA alutech products and technologies, proof of the company's capacity to respond to the multiple needs and stringent requirements of its clients.

Company Descriptions

Goodfellow Corporation **Booth #341**

Goodfellow supplies small quantities of metals, alloys, ceramics and polymers to meet the research, development and specialist product requirements of science industry worldwide.
The company offers two distinct services:

The first meets the needs of those customers who require small quantities of our standard catalog products for immediate shipment.

The second is for those who require larger quantities or further processing of the company's standard products, or who need products which fall within our general supply capabilities.

Our web catalog lists a comprehensive range of materials in many forms including rods, wires, tubes and foils. There is no minimum order quantity and items are in stock ready for immediate shipment worldwide with no extra shipping charge. Custom made items are available to special order.

Visit Goodfellow Corporation at website: www.goodfellowusa.com or e-mail info@goodfellowusa.com

Gouda Refractories **Booth #414**

Gouda Refractories is an innovative refractory producer (refractory bricks, castables, mortar, self-flowing castables, complex pre-cast shapes) with global experience and a long track record of supplying superior quality refractories all over the world, combined with innovative installation technology for more than 100 years.

Gouda Refractories develops, manufactures, sells and installs top quality refractory linings. Gouda's solutions play an important role in, non-ferrous metal (mainly aluminium), petrochemical, environmental and energy industries. Based on an industry-oriented structure and highly competent employees, Gouda Refractories guarantees an optimal support which results in efficiency and reduction of refractory cost. Gouda Refractories supplies total solutions to customers which are cost effective, state of the art, and reliable. Gouda's R&D department is conducted in close co-operation with its customers and renowned research institutes. Gouda's quality assurance is based on the international ISO 9001 standard.

Guangxi Bama Zhengyu Titanium Industry Co., Ltd **Booth #209**

Guangxi Bama Zhengyu Titanium Industry Co., Ltd is a professional manufacturer of Aluminum master alloys and Aluminum alloying additives in China. We always take innovation as the power of development. We are highly professional, well educated, diligent and full of vigor. In principle of good honesty, equality and mutual benefits, we always keep the modest and prudential attitude, develop more new products, make more friends globally, and provide our customers with qualified products and good service.

Harper International **Booth #236**

Harper International is a global leader in complete thermal processing solutions, as well as technical services essential for the production of advanced materials. Harper serves advanced, cutting-edge material markets with custom-engineered thermal processing systems. Our support to these emerging industries begins in early stages of research and development, whether at corporate R&D centers, universities, government institutions, or start-ups. Harper is a partner through the entire development process assisting in the scale up and commercialization of advanced materials that will change our everyday lives. One thing you won't see at Harper is a cookie cutter line of products that we work to fit into your requirements. We specialize in first-of-a-kind solutions using our exceptional depth and breadth of knowledge. Harper's culture is one of real ingenuity and creativity – we are constantly challenging ourselves to craft the best-engineered technology solutions for our customers' needs.

Company Descriptions

Hencon BV **Booth #102**

Hencon provides a complete range of heavy duty vehicles and vacuum technology solutions for aluminium smelters, aluminium foundries, light metal producers, industrial plants and mining applications. Originally a Dutch company, we developed a broad experience in the supply of solutions for customers in the light metal industry. With our solutions we want to make the difference for our customers and commit ourselves to measurable cost savings. Therefore we design machines that are safe to use and easy to operate and maintain. While at the same time our company is committed to offering you the support you require to make your business a success.

We think global and act local. This resulted in the unique concept of business units of Hencon on your doorstep: such as our service and production plants in the Netherlands, Russia, South Africa, Mozambique and India up to today.

Our goal is to offer our customers solutions to enable them to strive for continuous operating excellence in the lower cost curve of the industry.

With Hencon, you select a partner who has over 55 years of experience in the industry. We translate this knowledge into a durable partnership that shows commitment, creativity and entrepreneurship, in order to make our customers excel.

Whenever you would have questions about vacuum technology solutions, transport equipment and plant logistics; feel free to contact us for:

- Feasibility studies
- Know-how and analyses
- Training
- Support
- New equipment
- Maintenance solutions

Hencon offers tailor-made solutions with a clear eye for your specific needs and production processes. Combined with our know-how, we make the difference with solutions that offer you value for money.

Our clients can be find worldwide in the following countries: Argentina, Australia, Bahrain, Belgium, Brazil, Canada, China, Czech Republic, Denmark, Egypt, France, Germany, Greece, Hungary, Iceland, India, Indonesia, Cameroon, Mexico, Montenegro, Mozambique, Netherlands, New Zealand, Norway, Oman, Poland, Qatar, Romania, Russian Federation, Saudi Arabia, Slovakia, Slovenia, South Africa, Spain, Sweden, Switzerland, Turkey, United Arab Emirates, United Kingdom, United States of America and Venezuela.

Hysitron **Booth #416**

As world leader in nanomechanical test instruments, Hysitron is dedicated to providing next-generation testing solutions for nanoscale mechanical characterization. Hysitron's nanomechanical test instruments provide in-situ SPM imaging in addition to the quantitative measurement of multiple mechanical properties, including hardness, modulus, fracture toughness, interfacial adhesion, and wear resistance. Our instruments feature a full suite of advanced complementary techniques, including nanoDMA® III to continuously obtain elastic-plastic and viscoelastic properties of materials as a function of indentation depth, frequency, and time. Additional Hysitron hybrid techniques include nanoECR® for simultaneous electrical and mechanical property measurements, Modulus Mapping for high resolution property mapping, and elevated temperature testing to determine material properties at operating or processing temperatures. Stop by our booth to see how the industry-leading TI 950 TriboIndenter redefines the world of nanomechanical testing. Hysitron will also be showcasing the PI 95 and PI 85 PicoIndenter®, truly quantitative depth-sensing indenters capable of in-situ observation during testing inside a TEM and SEM.

ICE Publishing **Booth #500**

ICE Science is the new flagship journal collection from ICE Publishing inspiring fresh thinking on how breakthrough research can be practically applied to make energy, materials and medicines ever more efficient and effective. Launching with a series of full-color, bi-monthly journals in 2012, the collection aims to deliver a truly holistic overview of each scientific discipline, bringing together communities that traditionally work in silos to ensure important discoveries and applications are accessible to all those in the field. The first two editions of 'Bioinspired, Biomimetic and Nanobiomaterials', 'Emerging Materials Research' and 'Nanomaterials and Energy' are available free on our booth.

ICE Publishing is the publishing division of the Institution of Civil Engineers (ICE). We produce a wide range of publications sharing expert advice, leading research and best practice. With a history of making research in engineering and allied sciences practically useful since 1836, we offer a unique breadth of experience.

Company Descriptions

InfoSol Inc. Booth #224

InfoSol is a leading provider of Business Intelligence solutions. With an in-house product development team and partnerships with other leading Business Intelligence solutions providers around the world, InfoSol offers the "best in class" and most innovative add-on solutions. These solutions include InfoBurst for Automated Report and Dashboard Bursting/Publishing, along with Intelligent Cache Query for optimal Xcelsius dashboard performance and scalability.

Having more than fifteen years experience in providing end-to-end Business Intelligence applications, InfoSol sees beyond the data to deliver visionary solutions that inspire.

Innovatherm GmbH + Co., KG Booth #213

Innovatherm is the competent partner and the world market leader in anode baking technology. As a subsidiary of the LINGL Company, innovatherm operates in the aluminium industry, providing full service in combustion technology for reconstruction, fine tuning and optimization of existing anode baking furnaces as well as new furnaces including dry adsorption fume treatment plants.

For this purpose, Innovatherm has developed excellent process technologies and concepts with mathematical models, special components for the combustion like burners and gas valves, and future oriented control philosophies for optimal process management as well. For best results these concepts are custom-tailored to maximize plant safety, efficiency and economics.

Latest products established in the market are:

- ProBake Advanced Firing Systems for anode baking furnaces
- ProClean Fume Treatment Plants for the aluminium industry
- ProCast Supervisory Control Systems for primary and secondary Casthouses incl. charging management, target alloy calculation and melting optimization

International Aluminium Journal Booth #235

International ALUMINIUM Journal deals with all facets of aluminium's value chain from the production of the metal via its processing through to recycling. The editorial focus is on smelting and semis production including the suppliers of plant, equipment and technology. Consideration is given to economic, technical and environmental/ecological topics as well as other aspects that affect the metal and its product applications in the different target markets. Aluminium relevant research articles from companies and institutes are also published. The publication is thus of particular interest to smelters and remelters, semis producers, foundries, fabricators and converters, metal traders, semis stock holders and research facilities. International ALUMINIUM Journal is circulated in over 40 countries worldwide – made in Germany, distributed to the world. Published by Giesel Verlag GmbH; visit www.alu-web.de and www.giesel.de.

Jordan Valley Semiconductor Booth #107

Jordan Valley is the leaders in X-ray metrology for semiconductors and thin films, with a range of products to suit all needs. Our products range from fully automated systems for specialist semiconductor fabs (JVX range) through to diffractometers for compound semi manufacturers (QC3, QC-Velox and QC-RT) and state of the art general research diffractometers (D1).

With the acquisition of Bede Scientific in 2008, Jordan Valley has over 30 years experience in a wide range of X-ray metrology methods including X-ray diffraction (XRD), X-ray reflectivity (XRR), high resolution XRD (HRXRD), X-ray Fluorescence (XRF) and X-ray topography (XRT). The systems are designed to be simple to use yet powerful enough to perform the most demanding measurements. Automation of the alignment, measurement and analysis is available on all systems to remove the necessity of highly trained operators being required for routine measurements. The simulation software (RADS, REFS) is generally regarded as the industry leader for HRXRD and XRR analysis.

Jordan Valley systems are installed in major semi manufacturers production lines, R&D labs, LED manufacturers, GaAs and InP production lines as well as many universities and research institutes worldwide.

Company Descriptions

Kempe International **Booth #315**

Kempe is the largest provider of asset and maintenance services in the aluminium smelting industry and has the most extensive product range for the aluminium smelting industry and is one of the top five global suppliers.

Kempe is currently supplying the Anode Rodding Shop and Anode Handling System for Ma'aden Aluminium and the Bath Treatment Plants for Hindalco Mahan & Aditya Smelters. We have recently installed the CBF4 Anode Handling & Transfer System at Boyne Smelters.

Kempe works for 30 smelters in 21 countries across 7 regions – Australasia, Middle East, Africa, Asia, Europe, North America, and South America. Kempe has in-house manufacturing in Australia, China, UAE & Mozambique.

Kempe has more than 2,000 employees globally, which includes in-house construction crews & equipment.

Kempe will be available at TMS to discuss potential client requirements in the various areas of aluminium smelting including – Anode Handling & Cleaning, Rodding Shops, Bath Removal (hot & cold), Bath Cooling & Processing, and other Carbon, Potroom and Casthouse equipment.

Light Metal Age **Booth #216**

Light Metal Age is the pre-eminent magazine of the light metal world. In 2012, we are pleased to celebrate our 70th anniversary of publication, covering primary production and semi fabrication of the light metals aluminum, titanium, and magnesium. Circulation is international and goes to primary and secondary smelters; casthouses; extrusion operations; rolling mills; sheet, rod, and wire mills; and foundries. Coverage of associated metal processes and equipment includes DC casting, surface technologies such as anodizing, furnaces and melting, degassing and filtration, automation and instrumentation, and handling. Recipients are executives, general managers, plant managers, technicians, metallurgists, chemists, and engineers responsible for fabrication, production, and operations.

Light Metal Age also produces select article archive content on CDs, including the Titanium Article Archive (Nov. 1945 – Aug. 2009) and the Magnesium Article Archive (May 1943 – August 2011), as well as the Aluminum Extrusion Article Archive (July 1943 – April 2011). For more information, visit Light Metal Age on the web at www.lightmetalage.com.

Linde LLC **Booth #120**

Linde, a leading global industrial gases company, provides industry-leading portfolio solutions for the aluminum industry ranging from gases and equipment to process consulting and services. These solutions enable our customers to increase productivity, lower fuel consumption and other costs and reduce emissions.

We offer dedicated applications for every step in the aluminum process chain, all designed to help you reduce fuel consumption and emissions, and improve quality:

- Low-temperature oxyfuel melting technologies to increase the melt rate, cut energy costs and reduce emissions
- Refining to improve the quality of the final product by purging the melt with gases to remove hydrogen, non-metallic inclusions and unwanted trace elements
- Heat treatment in the form of annealing in a protective nitrogen atmosphere to reduce oxidation and discoloration
- Extrusion cooling and shrouding with liquid nitrogen to raise production rates, improve surface finish and increase die lifetime.

LP Royer, Inc. **Booth #204**

For all workers in the metallurgical industry, L.P. Royer is your "one stop" supplier for specialized and innovative safety footwear since 1934, visit us and see "THE SMELTER BOOT". The XPAN® soling technology, unique to L.P. Royer in North America, adds to the mix to bring you a lighter dual density rubber sole that protect from heat and extreme cold and offer superior traction, shock absorption and durability. With our wide range of adapted protection including internal and external metatarsal protection, nonmagnetic toe protection you will find the best style for you. L.P. Royer products meet CSA, ASTM CE marking quality standards.

Maney Publishing **Booth #232**

Maney delivers a personalized service to authors, societies, readers and libraries for the publishing and international dissemination of high quality, peer-reviewed scholarly research.

Specializing in print and electronic journal publishing, Maney is committed to technical and editorial innovation combined with traditional values of quality and collaboration.

Maney publishes an impressive collection of highly regarded, peer-reviewed journals covering both niche and general topics in materials science and engineering. Coverage ranges from fundamental research to engineering application and from the extraction and refining of minerals to the characterization, processing and fabrication of materials and their performance in service.

Company Descriptions

Materials Innovation Gallery Booth #441

Welcome to TMS's showcase of ideas on how the techniques and principles that form the foundation for Materials Innovation @ TMS—the Society's exciting new strategic initiative—can revolutionize the design, development and deployment of advanced materials.

Browse the gallery of scientific and technical posters and displays that present "materials innovation in action." Network with individuals and companies who offer tools, support, and services that can enable you to implement these approaches within your own organization or team. Learn about the array of resources and opportunities that are being offered as part of Materials Innovation @ TMS. A special feature of the TMS 2012 Exhibition, the Materials Innovation Gallery will be open throughout the conference during regular exhibit hours, so stop by often!

Materials Innovation @ TMS is focused on significantly reducing the time and costs associated with materials development through the advancement of a seamless and dynamic innovation infrastructure that unifies and streamlines design and manufacturing processes. The Materials Innovation Gallery has been designed to provide a visually compelling glimpse of how these concepts can potentially transform the future of materials and manufacturing innovation.

Mecfor Booth #430

For the last 15 years, we have design and manufactured specialized equipment for the Aluminum production sector. We are present in many countries worldwide and part of the 4 or 5 worldwide manufacturers, thus the only one in America. Our main products are, crucible carries, anode carriers, anode grooving, descaling robots, skimming stations, mobile equipment for loading, custom made specialized equipment.

Metallurgical & Materials Society of CIM Booth #230

We are a world class Canadian organization that serves society and the needs of professionals in the global metallurgy and materials community. The purpose of MetSoc is to serve our members, society and others involved in the research, development and application of the science and technologies for the environmentally responsible extraction, fabrication, utilization and recycling of metals and materials

Company Descriptions

Micro Materials Ltd Booth #432

Micro Materials Ltd (MML) - A wealth of mechanical property measurements in one instrument: The NanoTest Vantage system carries out a range of nanomechanical property measurements:

- Nanoindentation
- Nano-scratch and wear
- Nano-impact and fatigue
- Nano-fretting

Optimize material properties under true "in-service" conditions: The instrument can operate under a range of environmental conditions: high temperature up to 750°C, in liquids, and under non-ambient gases.

Unique capability: The high temperature testing module allows testing of a sample heated up to temperatures of 750°C. The patented MML nano-impact and fatigue system affords unrivalled information on fracture and fatigue behavior.

A trusted manufacturer: Established in 1988, MML's global customer base includes leading research institutes such as MIT, Cambridge and Oxford Universities.

Details from: Denise Hoban, International Business Development Director, denise@micromaterials.co.uk or www.micromaterials.co.uk

Moduloc Ltd, a Rotalec company Booth #434

- Engineered Solutions for the Metals Industry
- Industrial Sensors and Measurement Systems
- Laser Based Measurement Systems of hot or cold product for length, width or positioning
- Industrial Part Marking and Reading Solutions
- Digital Laser Level Counters
- Industrial Vision Systems
- Hot Metal Detectors
- Wireless Safety and Radio Remote Control
- Material Handling Solutions

MTI Corp Booth #330

MTI Corporation, founded in 1994 by a group of material researchers from MIT and UC Berkeley, has now become the leading manufacturer of oxide crystals and substrates in the world, thanks to venture capital from Silicon Valley. MTI continues to develop new crystal substrates and maintain high quality of its single crystal substrates. MTI is equipped with the latest state of the art instruments, which allow achievement of the highest standard. We strive continuously to keep pace with customers' increasing demands on super-smoothness, super-flatness, and super-cleanliness. In 2000, by popular demand, MTI started to manufacture precision bench-top machines for material processing, analysis, and crystal wafer containers.

MTI currently operates three production factories in China. This allows for the possibility of providing high quality and low cost precision machines for material research and R&D Labs, including: low speed cutting saw, wire diamond saw, auto polishing machine, high temperature oven, tube furnace, X-Ray crystal orientation machine, and Mini XRD, as well as complete set of equipments for research of rechargeable battery materials. Simple to operate, low cost, and commitment to our customers is our priority. MTI strives to become the world's leader in bench-top machines for material lab.

MTS Systems Corp Booth #331

Engineers and researchers worldwide rely on MTS for the testing technology and expertise required to support the research, development and production of advanced metals, composites and ceramics. Reliable, high-performance MTS solutions are deployed across a diversity of industries such as aerospace, power generation, civil engineering and automotive, accurately and efficiently meeting the most demanding materials testing requirements.

The MTS portfolio is engineered to address a full spectrum of materials testing requirements - from tension/compression to fracture mechanics to complex multi-axial fatigue studies at elevated temperatures. This portfolio features: high-performance servohydraulic, static-hydraulic and electromechanical testing systems; versatile, high-resolution controls; proven application software; precision accessories; robust environmental simulation systems; and unmatched service and support.

Explore the MTS booth and discover how innovative MTS test solutions and decades of industry expertise can optimize the effectiveness and efficiency of your materials research, development and production programs.

Nanovea Booth #511

Nanovea designs and manufacture Profilometers, Mechanical Testers & Tribometers to combine the most advanced testing capabilities in the industry: Scratch Adhesion, Indentation Hardness, Wear Friction & 3D Non-Contact Metrology at Nano, Micro & Macro range. Unlike other manufactures Nanovea also provides Laboratory Services, offering clients availability to the latest technology and optimal results through improvements in material testing standards.

Company Descriptions

National Filter Media Corporation Booth #519

At National Filter Media we take pride that we are one of the world's oldest and largest providers of air pollution control and liquid filtration products. NFM has achieved success by adhering to the same business principles practiced since the firm was founded in 1906. We believe in building partnerships with our customers and in earning their business every day. The technology has changed since 1906, but our commitment remains the same. We want to be long term partners with our customers.

Nederman Booth #339

Nederman has been in business since 1944 and is one of the world's leading companies supplying products and services to protect our environment. The new headquarters in Thomasville, NC and sales/manufacturing in Westland, MI and Reno, NV bring even greater capabilities to design, manufacture, install and service our products nationwide, providing you with complete turnkey solutions.

Our new product offering includes systems for the extraction and filtration of dust, gas, smoke, and automobile exhaust fumes, equipment for industrial cleaning, as well as at source extraction equipment and clamp-together ducting.

Netzsch Booth #327

Thermal analysis, calorimetry, thermal properties, & contract testing services; DSC, DTA, TGA, STA (Simultaneous DSC/DTA-TGA) from cryogenic to +2400C, evolved gas analysis by coupled FTIR, MS, and a new GC-MS system, adiabatic reaction calorimeters (ARC & APTAC) to measure thermal & pressure properties of exothermic chemical reactions, new MMC 274 tabletop reaction calorimeter, dilatometers, thermal conductivity, thermal diffusivity by laser flash & xenon flash to +2800C, DMA, TMA, and DEA - dielectric analysis for in-situ thermoset cure monitoring.

NFC - China Nonferrous Metal Industry Booth #425

China Nonferrous Metal Industry's Foreign Engineering & Construction Co., Ltd. (NFC) was founded in 1983. It is a state-controlled holding company listed on Shenzhen Stock Exchange in 1997. As a China leading enterprise engaged in general contracting of overseas nonferrous metal (particularly aluminum, copper, zinc and etc.) projects and resources development, it covers a wide spectrum from technical assistance, engineering design, equipment manufacturing, construction, supervision, installation and training to mining, beneficiation, smelting, processing and etc. It is also listed on ENR as one of the top 225 international contractors for consecutive years. With competitive edges in technology and rich experience in EPC contracting, NFC has consistently been dedicated to global nonferrous metal industry. NFC is capable and willing to work with world partners by providing a portfolio of services including technologies, equipment supply and management.

NIST/Measurement Services Division Booth #222

NIST Standard Reference Materials supports accurate and compatible measurements by certifying and providing over 1300 Standard Reference Materials with well-characterized composition or properties, or both. SRMs are used to perform instrument calibrations as part of overall quality assurance programs, verify the accuracy of specific measurements and support the development of new measurement methods. The Standard Reference Data Group has provided well-documented numeric data to scientists and engineers for use in technical problem-solving, research, and development. The Calibration Services are designed to help the makers and users of precision instruments achieve high levels of measurement quality and productivity.

NKM Noell GmbH Booth #306

NNSC has built a strong technical force based on specialists who individually have up to 25 years experience in Primary Aluminium Industry for Potroom as well for Carbon Area, being the only independent equipment supplier.

For more than 40 years on the market through its constitutive companies, with more than 1,000 cranes in operation worldwide, NNSC is developing its mission for the Primary Aluminium Smelters and Nuclear plants:

- To be a global supplier of handling systems, process equipment and solutions,
- To integrate the client's process objectives in the design of the products through a continuous flow of mutual exchange.

Olympus Innov-X Booth #422

Olympus Innov-X provides portable handheld X-Ray Fluorescence (HHXRF) analyzers for simple, non-destructive sorting of challenging grade separations, alloy chemistry and grade ID in seconds. They provide highly specific material chemistry to rapidly and accurately identify pure metals and alloy grades. HHXRFs allow for testing of literally thousands of types of materials anywhere, anytime. For scrap recycling applications, our HHXRFs provide reliable ID in 1-2 seconds for most grades. They are designed for durability – to withstand the tough processing environment. Our HHXRFs are used for fast, reliable alloy sorting and analysis for a wide variety of ferrous and non-ferrous material. We provide optimized HHXRF configurations for cost-effective analysis when time is of the essence and when materials cannot be transported, damaged, or altered. Our X-5000 Mobile XRF analyzers offer maximum portable power with a closed beam configuration and large touch screen interface.

Opsis **Booth #419**

Opsis is a worldwide supplier of gas monitoring systems for process control applications, industrial continuous emission monitoring and ambient air quality and fence-line monitoring.

Systems use open path UV-DOAS, FTIR and laser diode TDL technologies. Monitoring solutions are provided as integrated systems including gas measurements, additional sensors such as flow and temperature and software applications for reporting and networking.

Opsis systems have been implemented in applications in a wide range of industries globally, including aluminum smelters, power plants, incinerators, cement plants and sulfuric acid production plants.

The Opsis system does not need to extract any sample of the gas making it effective to measure reactive components such as ammonia, and strong acids. Same is applicable in case gas condition is either extremely corrosive or hot, or both.

Gaseous components that can be measured include, for example: SO2, SO3, NOx, CO, CO2, H2O, NH3, HCL, HF, CL2, CLO2, HCHO, BTX, O3, Hg, HgTot. Measurements are certified under TUV, MCERTS and EPA.

A worldwide network of skilled distributor companies is available for sales and support. Opsis is a ISO 9001 and ISO 17025 certified company.

Outotec Ltd. **Booth #309**

Outotec develops and provides technology solutions for the sustainable use of Earth's natural resources. As the global leader in minerals and metals processing technology, Outotec has developed several breakthrough technologies. Outotec serves the light metals industries including the provision of cutting-edge alumina refineries and aluminum smelters. The company has over 50 years experience helping customers worldwide in both segments of the aluminum process to reach their goals. What sets Outotec apart from its competition?

They are there to help their customers from start to finish in terms of plant design, and they customize solutions to fit a client's specific needs. Outotec's processes and equipment have become industry standards and their references stretch back decades – a track record that has lead to their current reputation as a leading innovative technology partner. The company also offers innovative solutions for the chemical industry, industrial water treatment and the utilization of alternative energy sources.

Parker Hannifin **Booth #206**

Parker is the world's leading diversified manufacturer of motion and control technologies and systems. Parker provides precision engineered solutions for a variety of commercial mobile, industrial and aerospace markets. We design and manufacture optimal systems using fluid connectors, hydraulics, pneumatics, instrumentation, refrigeration, filters, electromechanical components, and seals required in motion control systems. Parker's experience in the aluminum industry spans more than 40 years. Parker has equipped machinery in all phases of aluminum production including smelters, casters and extruders through grinders, rolling mills and strip processing lines, etc.

Photron Inc. **Booth #335**

Photron offers a wide range of high-speed cameras; from HD resolution to 2,000 frames per second (fps), through dual miniature heads providing 2K fps for real time image processing, to the world's fastest mega pixel high speed camera providing reduced resolution to over one and a half million fps.

Precision Light and Air Ltd. **Booth #105**

Precision Light and Air (PLA) is an Australian based industrial instrumentation manufacturer specializing in process analyzers for mining and metals industries. These analyzers are particularly suited for high temperature and high scale applications as in alumina and nickel refineries. Our flag ship Smartdiver is regarded as the industry standard for measuring mud level, clarity, interface and tank profiles in the most hostile operating environments. Other analyzers supplied globally by PLA include non-nuclear density gauges, slurry liquor phase density refractometers, inline ceramic conductivity meters and suspended solids meters. With a support team ranking second to none, PLA remains a premier solution provider in industry.

Company Descriptions

Proto Manufacturing **Booth #123**

PROTO Manufacturing is a leading provider of portable and laboratory based x-ray diffraction systems and services including:

- X-ray diffraction residual stress measurement
- X-ray diffraction retained austenite and nitride analysis
- Laue single crystal orientation systems
- Custom powder diffraction systems
- Fine focus and micro focus x-ray tubes
- Electropolishers

PROTO Manufacturing also provides measurement services through its laboratories in the United States, Canada and Japan. Visit online at http://www.protoxrd.com or by e-mail at xrdlab@protoxrd.com.

RHI AG **Booth #516**

Refractory competence for the non ferrous metals industry: RHI is the world´s leading supplier of high-grade ceramic refractory products and services. As a reliable and competent partner it is our constant aim to add value to the process of our customers by achieving the best price/performance ratio with our refractory system solutions.

The comprehensive program of products and services ranges from basic and non-basic mixes and bricks to prefabricated products, slide gate plates, purging plugs, as well as computer simulations like CFD or FEM. We also offer special machines, repair systems and technical equipment used to install refractory products into the various production units of the non ferrous metals industry. Our metallurgists are active around the globe and cooperate with renowned research facilities and universities to support the improvement of metallurgical processes and furnace integrity.

Riedhammer GmbH **Booth #513**

Since 1924 dedicated to the design and construction of furnace plants for carbon products (OPEN as well as CLOSED type), RIEDHAMMER is presently the only independent supplier worldwide being able to deliver complete solutions and technology for baking of anodes, cathodes, electrodes and special carbon products. More than 85 years of experience and know-how guarantee a high economic efficiency and reliability of the plants. In total RIEDHAMMER has executed more than 300 bake furnace projects in 25 countries. Our reference list includes major global players in the production of primary aluminum with pre-baked technology as well as top suppliers of cathodes and electrodes respectively for the aluminum and steel industry.

Rio Tinto Alcan **Booth #301**

Global leader in the aluminium industry

Building on more than a century of experience and expertise, Rio Tinto Alcan is a global leader in the aluminium industry. We supply high quality bauxite, alumina and aluminium worldwide and our AP smelting technology is the industry benchmark. Our enviable hydroelectric power position delivers significant competitive advantages in today's carbon constrained world. Rio Tinto Alcan is the aluminium product group of Rio Tinto, a leading international business involved in each stage of metal and mineral production. The Group is listed on the London Stock Exchange and Australian Securities Exchange under the symbol RIO. Rio Tinto's major products are aluminium, copper, diamonds, coal, iron ore, uranium, gold and industrial minerals.

Sente Software Ltd. **Booth #338**

We offer materials-focused software products for modeling the behavior and properties of complex alloys. The thermodynamic databases produced by Thermotech set the standard for the prediction of equilibrium and non-equilibrium structures in multi-component commercial alloys. Our latest product, JMat-Pro, is a unique software program for predicting phase transformations, physical/mechanical properties and solidification properties for complex alloys. It provides fast and robust calculations that have been extensively validated to ensure sound predictions of the properties. Our software combines industrial relevance with realistic physical models and user-friendly interfaces that work with "real" materials which are multi-component in nature and exhibit complex behavior. www.jmatpro.com.

SLM Co., Ltd **Booth #240**

We are an Aluminium Master Alloys Manufacturer located in Korea. Our company is specialized in Grain Refiners(AlTiB Alloys), Modifiers(AlSr Alloys) and Other Aluminium Alloys such as AlTi, AlB, AlV, AlMg, AlMn etc. We produce aluminium alloys in various forms such as Rod in coil, Cut Rod, Bar and Plate.

We have been producing high quality of Aluminium Master Alloys for 19 years and we export to over 20 countries. We supply high quality materials at competitive price.

We are looking for distributors now. Please visit our stand!

Company Descriptions

STAS **Booth #302**

STAS is a Canadian based company specialized in the fabrication of process technologies for the aluminium industry.

The company has over 20 years experience, with clients on all continents. Most of STAS' sales activities are managed from STAS' head office in Canada, with a network of well known agents in specific countries or geographical areas. STAS is a world leader in providing various equipment designed to improve productivity and the quality of molten aluminium.

Three main product lines are available:
1. Casthouse technologies, which include the Alcan Compact Degasser (ACD), the Rotary Flux Injector (RFI), the Inert Gas Dross Cooler (IGDC), the Deep Bed Filter (DBF) and the Treatment of Aluminium in Crucible (TAC).

2. Crucible cleaning shops, which include crucible cleaning systems, crucible preheating systems, and siphon tube cleaners and preheaters.

3. Pot room and rodding shop equipment, which include fume hoods to reduce HF emissions, anode positioning systems, anode stub inspection systems and anode butt inspection systems.

Sunstone **Booth #215**

Sunstone Development Co., Ltd. ("Sunstone") is the largest anode exporter and one of the largest merchant anode manufacturers in China. It owns and operates two anode production facilities with an annual capacity of 520,000 metric tons. More than half of Sunstone's annual capacity is exported to more than 20 aluminium smelters in as many countries. Sunstone provides anodes to aluminium smelters in North America, Europe, Russia and the Middle East. The company holds ISO 9001, ISO 14001 and OHSAS 18001 certifications.

Other products and services supplied by Sunstone include calcined petroleum coke, cathode blocks, anode paste, cold ramming paste, anode slot sawing machinery, anode cleaning machinery, pot shells, anode yokes and other various equipment used by the aluminium industry.

Our company's mission is:
- To be the world's largest merchant anode manufacturer and supplier. To provide the highest quality integrated solutions and project management for the global electrolytic aluminium industry.
- To be recognized as the company with the "Best Practice" in the comprehensive utilization of resources in the prebaked anode industry.
- To be recognized as the company with the most environmentally friendly and energy efficient process that produces innovative and technologically superior anodes.

Techmo Car **Booth #413**

Techmo is an Italian independent company focused in the engineering and production of special mobile and stationary equipment for the aluminium and non ferrous metals industry. The full range of purpose designed machines covers different types of equipment performing a large number of operations in pot-rooms, rodding shops and cast-houses. The Company's aim is to provide the most innovative, rational, cost effective and user friendly technical solutions. Among the most significant families of mobile equipment are the Tapping Vehicles, Anode Transporters, Crucible Transporters and Tilters, Alumina/ AlF3 Feeding Vehicles, Furnace Charging Vehicles and Furnace Tending Vehicles, Multipurpose Anode Changers and Crust Breakers. Beside its line of purposed designed vehicles, Techmo provides a number of stationary equipment such as Crucible Cleaning Machines, the Crucible Tilting stations and the Anode Butts Cleaning Stations.

Tenova Core **Booth #334**

Tenova Core is a worldwide leader in the supply of loose carbonaceous material calciners based on rotary hearth technology. These furnaces are used for the processing of petroleum coke, coal, formed coke briquettes and various other carbon based products. Tenova Core also provides a wide range of heat treating, reheating and specialty furnaces as well as technical and spare parts services. Booth Personnel: Thomas Walsh, Bill Barraclough, Bert Mangold; visit Tenova Core online at www.tenovacore.com.

Thermo Scientific **Booth #423**

Thermo Scientific product portfolio provides world-class solutions for analytical microscopists. See the QuasOr EBSD system and experience the seamless integration of EDS, WDS and EBSD in the NORAN System 7 X-ray microanalysis system. Also see our EDXRF, WDXRF/XRD and OES products for materials characterization in terms of qualitative and quantitative elemental/phase composition.

Thermo-Calc Software **Booth #223**

Thermo-Calc Software is a leading developer of software and databases for calculations involving computational thermodynamics and diffusion controlled simulations. Thermo-Calc is a powerful tool for performing thermodynamic calculations for multicomponent systems. Calculations are based on thermodynamic databases produced by expert evaluation of experimental data. Databases are available for Al, Mg, steels, Ni-superalloys, Ti, solders and other materials. Programming interfaces are available which enable Thermo-Calc to be called directly from in-house developed software or MatLab. DICTRA is used for accurate simulations of diffusion in multicomponent alloys. TC-PRISMA is a new software package for the simulation of precipitation kinetics in multicomponent alloys.

Company Descriptions

Tri-State Refractories Corp. **Booth #239**

Tri-State Refractories is a full service contractor specializing in the Aluminum Industry. We offer turn key projects for Carbon Bake Furnaces, Aluminum Holding and Melters, De Laq Furnaces, Rotary Furnaces, Pot Lining, and most other requirements for plant operations. We also have maintenance contracts in place with Rio Tinto Alcan and Alcoa doing multi task type work throughout these facilities.

UES, Inc. **Booth #108**

UES, Inc. is an innovative science and technology company that provides its industry and government customers with superior research and development expertise. We create products and services from our technology breakthroughs and successfully commercialize them.

RoboMet.3D™ is a fully automated, serial sectioning system that generates two-dimensional data for three-dimensional reconstruction. Robo-Met.3D enables more time for data analysis and characterization and ensures repeatable and accurate data is collected in an efficient and cost-effective manner.

Additional areas of expertise for UES include materials science, metallurgy, ceramics, processing science, modeling and simulation, surface engineering, materials characterization, biotechnology, sensor development and nanomaterials.

University of Central Florida AMPAC **Booth #119**

The Advanced Materials Processing and Analysis Center (AMPAC) located at the University of Central Florida is an interdisciplinary research and education center for materials science and engineering. AMPAC excels in the development, processing and characterization of advanced materials, addressing a broad range of civilian and defense applications including energy, microelectronics, nanotechnology, sensors and actuators, biomaterials, lasers and propulsion. AMPAC administers the Materials Science and Engineering Graduate Program, a nationally ranked academic program. AMPAC is also home to the Materials Characterization Facility (MCF), a user facility with state-of-the-art electron microscopy, ion spectroscopy, x-ray analysis and much more. AMPAC also maintains the Advanced Microfabrication Facility, a class 1000 cleanroom facility for the fabrication and testing of semiconductor devices, thin films and more.

Westmoreland Advanced Materials, LLC **Booth #325**

Westmoreland Advanced Materials manufactures a full line of premium refractory castables. In addition, the company provides innovative refractory technology for the aluminum industry. WAM® AL II is a truly unique, non-wetting corundum resistant refractory castable developed specifically for the aluminum industry. This family of products provides for all metal contact needs including a non-penetrable insulating product, a high strength/high density product, a gunning product and maintenance and repair products. Customers using this technology in aluminum metal processing applications have measured and documented energy savings up to 46%, maintenance savings of at least 50% and have reduced down times to 8% of typical.

If you process aluminum metal come visit us at booth #325 and learn how we can improve your processing efficiency and your cost to produce product.

York Linings Intl. Inc. **Booth #401**

York Linings Inc. is a market leader in the design and installation of refractory linings in all major industries. We incorporate our own in- house experience and technology with that of the major refractory suppliers to provide our clients with an installed product that will provide the best lining performance in their specific industry.

YLI have been involved in many major Aluminum smelting plants in the United States and Overseas. Major projects include New Carbon Bake Furnaces, Reduction Cells, Cathode Sealing, Metal Holding Furnaces and Plant maintenance.

YLI are committed to deliver a quality Refractory project, meeting the high levels of design criteria, safety standards and schedule requirements for today's industrial climate, providing best results for the future of your facility.

TECHNICAL PROGRAM

TMS2012

141st Annual Meeting & Exhibition

	Day	AM or PM	Room (D) Dolphin / (S) Swan	Page
Characterization of Minerals, Metals, and Materials				
Characterization of Ferrous Metals I	Mon	AM	Asia 2 (D)	24
Characterization of Non-Ferrous Materials	Mon	PM	Asia 2 (D)	81
Characterization of Minerals and Ceramics	Tues	AM	Asia 2 (D)	156
Characterization Technologies	Tues	PM	Asia 2 (D)	233
Characterization of Environmental and Construction Materials	Wed	AM	Asia 2 (D)	310
Characterization of Energy, Electronic and Optical Materials	Wed	PM	Asia 2 (D)	388
Characterization of Carbon and Soft Materials	Thurs	AM	Asia 2 (D)	459
Characterization of Light Metals	Thurs	AM	Europe 6 (D)	461
Characterization of Ferrous Metals II	Thurs	PM	Europe 6 (D)	508
Computational Thermodynamics and Kinetics				
In honor of Dr. Long-Qing Chen, EMPMD Outstanding Scientist: Session I	Mon	AM	Australia 3 (D)	26
In honor of Dr. Long-Qing Chen, EMPMD Outstanding Scientist: Session II	Mon	PM	Australia 3 (D)	83
Thermodynamics	Tues	AM	Australia 3 (D)	160
Phase-field Simulations in Alloys I	Tues	AM	Asia 5 (D)	158
Diffusion Coefficients	Tues	PM	Australia 3 (D)	235
Phase-field Simulations in Alloys II	Tues	PM	Asia 5 (D)	237
Molecular Dynamics: Potentials and Simulations	Wed	AM	Australia 3 (D)	312
Oxides, Steels, and Nuclear Materials	Wed	AM	Asia 5 (D)	314
Cluster Expansion, Kinetic Monte Carlo, and First-principles	Wed	PM	Australia 3 (D)	390
Interfaces	Thurs	AM	Australia 3 (D)	462
Defects and Properties of Cast Metals				
Metal Cleanliness	Mon	AM	Oceanic 4 (D)	27
Porosity	Mon	PM	Oceanic 4 (D)	84
Hot Tearing	Tues	AM	Oceanic 4 (D)	162
Solidification Structure and Segregation	Tues	PM	Oceanic 4 (D)	239
Ductility, Creep, Stress and Cracks	Wed	AM	Oceanic 4 (D)	316
Novel Processes and Applications	Wed	PM	Oceanic 4 (D)	392
Deformation, Damage, and Fracture of Light Metals and Alloys				
Session I	Mon	PM	Northern A2 (D)	86
Session II	Tues	AM	Northern A2 (D)	163
Session III	Tues	PM	Northern A2 (D)	241
Session IV	Wed	AM	Northern A2 (D)	317
Session V	Wed	PM	Northern A2 (D)	393
Electrode Technology for Aluminium Production				
Paste Plant Design and Improvement	Mon	PM	Americas Seminar (D)	87
Bake Oven Design and Improvement	Tues	AM	Americas Seminar (D)	164
Carbon Materials for Anode and Cathode	Tues	PM	Americas Seminar (D)	242
Characterization of Anode Materials	Wed	AM	Americas Seminar (D)	318
Characterization of Cathode Materials	Wed	PM	Americas Seminar (D)	394
Inert Anode and Wettable Cathode Materials	Thurs	AM	Americas Seminar (D)	464
Electrometallurgy 2012				
Session I	Mon	PM	Europe 5 (D)	88
Session II	Tues	AM	Europe 5 (D)	165
Session III	Tues	PM	Europe 5 (D)	244
Session IV	Wed	AM	Europe 5 (D)	320
Emeritus Professor George D.W. Smith Honorary Symposium				
Atom Probe Tomography	Mon	AM	Mockingbird 2 (S)	29
Novel Materials and Aluminium Alloys	Mon	PM	Mockingbird 2 (S)	90
Steels I	Tues	AM	Mockingbird 2 (S)	167
Steels II and Superalloys	Tues	PM	Mockingbird 2 (S)	245

	Day	AM or PM	Room (D) Dolphin / (S) Swan	Page
Magnesium Technology 2012				
Plenary Session	Mon	AM	Southern IV (D)	36
High Temperature Processing and Properties	Wed	PM	Southern V (D)	404
Alloy and Microstructural Design	Wed	AM	Southern V (D)	328
Processing-Microstructure-Property Relationships I	Thurs	AM	Southern IV (D)	472
Energy and Biomedical/Primary Production	Thurs	PM	Southern V (D)	513
Casting and Solidification	Wed	AM	Southern IV (D)	330
Primary Production	Mon	PM	Southern V (D)	103
Corrosion and Coating	Wed	PM	Southern IV (D)	402
Deformation Mechanisms	Mon	PM	Southern IV (D)	101
Advanced Processing and Joining	Thurs	AM	Southern V (D)	470
Processing-Microstructure-Property Relationships II	Thurs	PM	Southern IV (D)	514
Magnetic Materials for Energy Applications II				
Permanent Magnets for Energy Applications	Tues	AM	Europe 10 (D)	175
Magnetocaloric and Magnetostrictive Materials	Wed	AM	Europe 10 (D)	331
Power Conversion and Microstructural Effects	Thurs	AM	Europe 10 (D)	473
Materials and Fuels for the Current and Advanced Nuclear Reactors				
Nuclear Fuels - Modeling	Mon	AM	Swan 2 (S)	37
Nuclear Fuels - Characterization	Mon	PM	Swan 2 (S)	104
Nuclear Fuels	Tues	AM	Swan 2 (S)	176
Structural Materials I	Tues	PM	Swan 2 (S)	254
Structural Materials II	Wed	AM	Swan 2 (S)	333
Structural Materials - Characterization	Wed	PM	Swan 2 (S)	407
Modeling I	Wed	PM	Swan 4 (S)	405
Structural Materials - Irradiation Studies I	Thurs	AM	Swan 2 (S)	476
Modeling II	Thurs	AM	Swan 4 (S)	475
Structural Materials - Irradiation Studies II	Thurs	PM	Swan 2 (S)	517
General	Thurs	PM	Swan 4 (S)	515
Materials Design Approaches and Experiences III				
Material Design Tools	Mon	PM	Europe 11 (D)	106
High Strength High Toughness Steels	Tues	AM	Europe 11 (D)	178
Non-ferrous Alloys and Processes	Tues	PM	Europe 11 (D)	256
Superalloys	Wed	AM	Europe 11 (D)	334
High Strength Steels	Wed	PM	Europe 11 (D)	409
Joining and Microstructure-Property Relationships	Thurs	AM	Europe 11 (D)	478
Materials in Clean Power Systems VII: Clean Coal-, Hydrogen Based-Technologies, and Fuel Cells				
Fuel Cells	Tues	AM	Europe 8 (D)	179
Materials for Hydrogen Production, Separation, and Storage	Tues	PM	Europe 8 (D)	257
Materials for Clean Coal Technologies, Turbines	Wed	AM	Europe 8 (D)	335
Materials Processing Fundamentals				
Process Metallurgy of Metals	Mon	AM	Oceanic 8 (D)	39
Physical Metallurgy of Steel	Mon	PM	Oceanic 8 (D)	107
Application of Microwave, Magnet, Laser and Plasma Technology	Tues	AM	Oceanic 8 (D)	181
Metallurgy of Non-Ferrous Metals	Tues	PM	Oceanic 8 (D)	259
Materials Research in Microgravity				
Session I	Mon	AM	Asia 3 (D)	40
Session II	Mon	PM	Asia 3 (D)	109
Session III	Tues	AM	Asia 3 (D)	182
Session IV	Tues	PM	Asia 3 (D)	260
Session V	Wed	AM	Asia 3 (D)	337
Session VI	Wed	PM	Asia 3 (D)	410

	Day	AM or PM	Room (D) Dolphin / (S) Swan	Page
Symposium Poster Sessions				
2012 Functional and Structural Nanomaterials	Mon	PM	Atlantic Hall (D)	523
Alumina and Bauxite	Mon	PM	Atlantic Hall (D)	526
Aluminum Alloys: Fabrication, Characterization and Applications	Mon	PM	Atlantic Hall (D)	526
Biological Materials Science Symposium	Mon	PM	Atlantic Hall (D)	528
Computational Thermodynamics and Kinetics	Mon	PM	Atlantic Hall (D)	530
Deformation, Damage, and Fracture of Light Metals and Alloys	Mon	PM	Atlantic Hall (D)	532
Magnesium Technology 2012	Mon	PM	Atlantic Hall (D)	533
Materials Processing Fundamentals	Mon	PM	Atlantic Hall (D)	539
Materials Research in Microgravity	Mon	PM	Atlantic Hall (D)	540
Mechanical Behavior at Nanoscale I	Mon	PM	Atlantic Hall (D)	542
Mechanical Behavior Related to Interface Physics	Mon	PM	Atlantic Hall (D)	547
Nanocomposites	Mon	PM	Atlantic Hall (D)	548
Neutron and X-Ray Studies of Advanced Materials V	Mon	PM	Atlantic Hall (D)	549
Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies	Mon	PM	Atlantic Hall (D)	550
Radiation Effects in Ceramic Oxide and Novel LWR Fuels	Mon	PM	Atlantic Hall (D)	551
Randall M. German Honorary Symposium on Sintering and Powder-Based Materials	Mon	PM	Atlantic Hall (D)	552
Recycling General Sessions	Mon	PM	Atlantic Hall (D)	552
Refractory Metals 2012	Mon	PM	Atlantic Hall (D)	552
Solid-State Interfaces II	Mon	PM	Atlantic Hall (D)	553
T.T. Chen Honorary Symposium	Mon	PM	Atlantic Hall (D)	554
Ultrafine Grained Materials VII	Mon	PM	Atlantic Hall (D)	557
General Poster Session	Mon	PM	Atlantic Hall (D)	562
Student Poster Contests				
Biological Materials Science Student Poster Contest	Mon	PM	Atlantic Hall (D)	578
EMPMD Student Poster Contest	Mon	PM	Atlantic Hall (D)	579
EPD Student Poster Contest	Mon	PM	Atlantic Hall (D)	581
LMD Student Poster Contest	Mon	PM	Atlantic Hall (D)	582
MPMD Student Poster Contest	Mon	PM	Atlantic Hall (D)	584
SMD Student Poster Contest	Mon	PM	Atlantic Hall (D)	585

About TMS Poster Sessions

The TMS 2012 Annual Meeting & Exhibition is pleased to provide a central area for all poster presentations at the conference. This area, located in the Atlantic Hall in the Dolphin Hotel near Registration, will include:

- Individual symposium poster sessions
- General poster session
- Student poster sessions (by division)

Presentation times:
Presenters should plan to be available to discuss their posters on **Monday, March 12**, from **5:30 to 6 pm** in conjunction with the **President's Welcoming Reception in the exhibition hall.**

Poster installation and removal:
Presenters may install their posters on **Sunday, March 11**, from **12 to 6 pm** and on **Monday, March 12**, from **7 to 8 am**.

Presenters may remove their posters beginning at **noon on Wednesday, March 14**. All posters must be removed **before 5 pm on Wednesday**.

2012 Aluminum Plenary: "Aluminum Industry Technology 2020, A Look Ahead ": Aluminum Industry Technology 2020, A Look Ahead

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee
Program Organizer: Carlos Suarez, Alcoa Maaden JV

Monday AM — Room: Southern III
March 12, 2012 — Location: Dolphin Resort

Session Chair: Carlos Suarez, Alcoa

8:30 AM Introductory Comments

8:35 AM
Acceleration of Cell Technology through Breaking Barriers: A Closer look at Innovation by High-Tech Sensor Technology and Energy Recovery Solutions: *Stephan Broek*[1]; [1]Hatch Ltd

Today's cell technologies are pushed harder and harder. However, to make the advancement necessary in the future technologies are needed that enables us to look in more detail in how a cell performs. Technical advances in sensor techniques help us learn more of the intimate behavior of cells. Developments today lay the foundation of even more intelligent cell operation in the future. A different trend is advances in the energy recovery potential. As cell become more powerful the opportunity to utilize the waste energy becomes more and more realistic. A brief overview is presented in the status and potential of energy recovery.

9:05 AM
Alumina Technology – Present and Future: *Ender Suvaci*[1]; [1]Anadolu University

Alumina has been one of the most widely utilized engineering materials. Besides its use as a precursor for aluminum production, it has been used as an advanced ceramic material which can be tailored to fulfill technological needs. In this presentation, firstly current status of the alumina technology in terms of production methods and material characteristics will be discussed, secondly the current status will be compared with the alumina technology roadmap which was prepared in 2001. In the final part, future of the alumina technology and alumina's possible roles on development of innovative bio and/or nano-technological products will be discussed.

9:35 AM
A Sustainable Production of Primary Aluminum: *Claude Vanvoren*[1]; [1]Rio Tinto Alcan

In a carbon and energy constrained world, with dramatically escalating power costs, ever increasing environmental regulations and where access to large power blocks and multi billion capital investments required to build the most competitive smelters becomes increasingly difficult to source, producing Aluminum in a sustainable way, which is already a challenge, will become an industry threat if innovative solutions delivering step change performance improvements are not developed in due time. Presentation will review options which the primary Aluminum industry critically needs to be available for a smelter built in the 2020s.

10:05 AM Break

10:15 AM
Driving Business Technology to Remain Competitive in the Aluminum Business: *Roberto De Andrade*[1]; [1]Alcoa Inc

With the slowdown of the economy, aluminum companies respond by delaying technology development and asset expenditures to offset the lower metal prices and lower demand. Prior to these times companies must have strategies in place that will allow them to understand the risks the businesses are taking and prioritizing what equipment expenditures and the technology development programs which must continue on. The future of the industry will also depend on the competence of the organization to advance the production process while driving the aluminum cost down. On the talent front, this will occur through strategic workforce planning, modified selection profiles, accelerated development and organization designs to help facilitate succession planning. The purpose of my paper is to show how technology innovation combined with a vision of being a failure mode driven organization and talented employees can enable aluminum companies to improve operations and remain cost competitive even in tough times.

10:45 AM
Achieving Carbon Neutrality in the Global Aluminum Industry: *Subodh Das*[1]; [1]Phinix LLC

The current carbon foot print of the global aluminum industry is estimated at 500 million metric tonnes of carbon dioxide equivalents (CO2eq), representing about 1.7 % of global emissions from all sources. This paper outlines an integrated and quantifiable plan for achieving "carbon neutrality" in the global aluminum industry by advocating several steps such as : using "greener" energy grids, reducing energy intensity of manufacturing processes, deploying products in energy saving applications , diverting material from landfills and urban mining from " aluminum - rich landfills ".

11:15 AM
The Aluminum Story – The Positive Contribution of the Aluminium Industry and its Products to Sustainable Development: *Chris Bayliss*[1]; [1]International Aluminium Institute

By working continuously to minimize its environmental impacts and maximize the benefits that its products offer to the world, the aluminium industry is committed to ensuring that aluminium is part of the solution for a sustainable future. The International Aluminium Institute's Aluminium for Future Generation initiative seeks to demonstrate: 1. that the aluminium industry produces responsibly, by mitigating environmental impacts and positively impacting the communities in which it operates; 2. that its products bring a net benefit to society in terms of energy efficiency & emissions reduction, quality of life, health and sustainable development; 3. that at the end of product life, the value of the material, the energy that went into its production and the socio-economic benefit is retained and realised as another product, through collection and recycling or energy recovery.

11:45 AM Panel Discussion

12:05 PM Concluding Comments

2012 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: Carbon Nanomaterials

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Nanomaterials Committee
Program Organizers: Jiyoung Kim, University of Texas; David Stollberg, Georgia Tech Research Institute; Seong Jin Koh, University of Texas at Arlington; Nitin Chopra, The University of Alabama; Terry Xu, UNC Charlotte

Monday AM Room: Pelican 1
March 12, 2012 Location: Swan Resort

Session Chairs: Jiyoung Kim, University of Texas at Dallas; Nae Eung Lee, SungKyunKwan University

8:30 AM Introductory Comments

8:45 AM Invited
Graphene -The Route Toward Applications: *Wonbong Choi*[1]; [1]Florida International University

Graphene has revolutionized the scientific frontiers in nanoscience and condensed matter physics due to its exceptional electrical, physical and chemical properties. This talk will focus on engineering of graphene and its applications in transparent and flexible display and flexible solar cells. The graphene film was grown by the thermal CVD. Further, the graphene film was functionalized with reactive ion plasma. The doped graphene was characterized as a counter electrode in a dye sensitized solar cells showing ~3.5% efficiency. The graphene film was spin-coated using carbon nanotubes to form the cathode of the field emission device. A phosphor coated graphene-PET film was used as the anode. The device showed good transparency and flexibility apart from offering appreciable emission current. Our efforts on the strategies of manipulation of carbon nanomaterials' interface, growth of large scale graphene and its characterization at nanoscale will be reviewed and critical issues will be highlighted.

9:20 AM
Growth of Low Dimensional Carbon Nanomaterials: *John Boeckl*[1]; Weijie Lu[1]; William Mitchel[1]; [1]Air Force Research Laboratory

Low dimensional carbon nanostructures have attracted significant interest due to promising applications ranging from high-speed electronics, thermal management, sensing, multi functional structures and beyond. Insight into the growth mechanism of low-dimensional carbon nanomaterials remains a challenge. Metal-free nanocarbon/SiC structures offer an excellent platform to gain a fundamental understanding of carbon nano-materials. In this talk, metal-free nanocarbon/SiC structures are used as a platform to gain a fundamental understanding of the growth mechanisms of CNTs and graphene. We focus on graphene growth on SiC (0 0 0 1) (Si-face) as a model system in comparison with aligned CNT growth on SiC. The experimental growth aspects for graphene growth, including vacuum and ambient growth environments, and growth temperature will be presented, then, proposed decomposition and growth mechanisms are discussed. Example structures based on the growth model for specific applications will be presented.

9:40 AM
Piezoelectric Coated Carbon Nanotubes for Electronic Applications: David Stollberg[1]; *Austin Mohney*[2]; [1]Georgia Tech Research Institute; [2]Lock Haven University

As electrical devices continue to decrease in size the desire grows to eliminate the need for batteries as power sources. Piezoelectric nanogenerators have proven themselves as a viable means for ambient energy harvesting: Zinc oxide (ZnO) has this the unique property of producing a voltage difference when subjected to mechanical strain. The objective is an energy harvesting piezoelectric generator that transduces ambient mechanical vibrations into electrical energy. Carbon nanotubes (CNTs) are used as a structural backbone for a ZnO piezoelectric coating and a silver electrode coating. CNTs are chosen for their strong, flexible, and conductive properties. A Schottky diode is created at the interface of the silver electrode and the ZnO coating, rectifying the current output of the piezoelectric-coated nanotubes. Previous devices yielded a maximum current output of 1.2microA. SEM was used to characterize the fabrication process. A Keithley 4200 SCS was used to characterize the power output.

Engineering Improved Strain Capacity Carbon Nanotube Electrodes on Shape Memory Polymers for Cortical Brain Probes, Cochlear Implants, Flexible Antennas and Multi-Electrode Arrays: Dustin Simon[1]; Taylor Ware[1]; Yael Hanein[2]; Moshe David-Pur[2]; Edward Keefer[3]; *Walter Voit*[1]; [1]UT Dallas; [2]Tel-Aviv University; [3]Plexon

A current limitation in the field of flexible electronics is the ability to achieve complex 3-D structures using cost-effective, well-studied photolithographic approaches. A class of dynamic, smart materials called shape memory polymers has been used for interfacing with metallic conductors, to create devices that change in stiffness as a function of temperature or environmental condition. Using the shape memory effect enables standard lithographic processing on these (temporarily) flat surfaces, which then can recover (permanently) to new complex shapes. However, these devices are limited by the strain capacity of the metal electrodes. This work explores the effectiveness of photolithographically patterned carbon nanotube electrodes to scale up and integrate these nanomaterials into functional device architectures and bulk shape memory polymer systems for a variety of engineering applications such as neural brain probes, flexible transistors, flexible antennas, cell culture dishes, cochlear implants and flexible prosthetics.

10:50 AM
Photo-Ignition of Liquid Fuel Spray and Solid Fuel by Carbon Nanotubes: *Alireza Badakhshan*[1]; Stephen Danczyk[2]; [1]Jacobs Technology Inc.; [2]Air Force Res. Lab

We have studied the ignition of fuel sprays and solid rocket fuels by the photo-ignition of single wall carbon nanotube (SWCNT) with a camera flash. Our investigation includes the effects of O2 concentration and the presence of solid oxidizers such as ammonium perchlorate (AP) on the minimum ignition energy (MIE) as well as the duration and temperature of the reaction. We have shown that by mixing CNT with other nanoparticles and powdered material, the ignition parameters such as ignition delay, burn temperature, and burn duration can be tailored to meet ignition requirements. This approach in photo-ignition of fuel spray and solid fuel provides a suitable method for ignition of liquid rocket engines and solid rocket motors that is scalable from very small to large rockets. Among the advantages of this photo-ignition approach are; very low weight, low power, robust system, with volumetric distributed ignition capability.

11:10 AM
Boron Carbide Nanowires: Low Temperature Synthesis, Structural and Thermal Conductivity Characterization: *Zhe Guan*[1]; Timothy Gutu[1]; Juekuan Yang[2]; Yang Yang[2]; Deyu Li[2]; Terry Xu[1]; [1]UNC Charlotte; [2]Vanderbilt University

Boron carbide nanowires are synthesized by co-pyrolysis of diborane and methane in a low pressure chemical vapor deposition system at relatively lower temperatures such as 879 °C. Both transverse twins and axial twins are observed from as-synthesized nanowires, which provide additional measures to tune their transport properties for better thermoelectric performance. The thermal conductivity of as-synthesized nanowires is found to be diameter-dependent. The room temperature thermal conductivity of a 55 nm diameter nanowire is 3.78 W m^{-1} K^{-1}, which is about eight times lower than that of bulk boron carbides.

11:30 AM
Electrical and Mechanical Response of CNT Turfs under Normal Loads: *Anqi Qiu*[1]; David Bahr[1]; [1]Washington State University

Carbon nanotube turfs; arrays of multiwalled carbon nanotubes with unique electrical and mechanical properties, have potential for dry, electrically conductive adhesives. Nanoindentation and electrical contact resistance testing was used to characterize the properties of CNT turfs. The rate of unloading during nanoindentation impacted the stiffness, while longer time in contact leads to a higher perceived modulus and larger adhesion between the tip and the turf, but also accentuates creep. Electrical properties, such as current density and conductivity, were also evaluated. The electrical conductance stays constant when the tip is held at constant depth. Sweep test determined the turf behaved as a heavily doped semiconductor. The combination of testing methods is used to demonstrate that time dependent behavior is due to movement of tubes beneath the tip, and not relative motion of CNTs to the contact surface. This suggests conductive adhesive applications are viable and will improve over time.

2012 Symposium on Surfaces and Heterostructures at Nano- or Micro-Scale and Their Characterization, Properties, and Applications: Heterostructure Growth and Characterization

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS: Energy Conversion and Storage Committee, TMS: Nanomaterials Committee, TMS: Surface Engineering Committee, TMS: Young Leaders Committee, TMS: EMPMD Council

Program Organizers: Nitin Chopra, The University of Alabama; Ramana Reddy, The University of Alabama; Arvind Agarwal, Florida International University; Sandip Harimkar, Oklahoma State University; Jiyoung Kim, University of Texas at Dallas; Christopher Matranga, National Energy Technology Laboratory

Monday AM — Room: Pelican 2
March 12, 2012 — Location: Swan Resort

Session Chairs: Nitin Chopra, The University of Alabama; Christopher Matranga, National Energy Technology Laboratory (NETL)

Defining Nanoscale Structure-Property Relationships in Nanowire Heterostructures: *Lincoln Lauhon*[1]; [1]Northwestern University

The discovery of new nanoscale structure-property relationships in heterogeneous nanostructures is enabled by techniques that spatially correlate structure/composition with electronic and optical properties. Towards this goal, we pursue correlated imaging studies involving electron microscopy, atom probe tomography (APT), Raman microspectroscopy, and scanning photocurrent microscopy. I will discuss applications of correlated imaging of form and function to nanowire heterostructures and hybrid nanowire-nanoparticle structures of interest in energy harvesting applications. The non-uniform distribution of dopant atoms in Si and Ge nanowires and heterostructures, measured by APT, strongly influences the distribution of majority and minority carriers under electrical biasing and photoexcitation, which are key inputs to models of devices including solar cells. Nanowire and hybrid metal-semiconductor heterostructures strongly influence the absorption of light and the distribution of charge carriers with excess energy that can be extracted for power generation in photovoltaic applications. The talk will highlight recent results from our group and collaborators.

Challenging the Trade-Offs in Synthesis and Application of Core/Shell Nanocrystal Fluorophores: *Andrew Greytak*[1]; [1]University of South Carolina

Core/shell heterostructures have been widely used to increase the brightness of nanocrystal quantum dots (QDs) as fluorophores in two ways: (1) maximizing the quantum yield (QY) through electronic and chemical isolation of the core; and (2) increasing the excitation rate by building a high density of states at energies above the shell bandgap. These two roles for the shell present a potential trade-off in terms of shell material. A wide bandgap shell imposes large barriers for carrier access to the surface but will be less able to contribute to absorption, while a narrower gap shell could participate in light harvesting but may make it harder to achieve high QY. I will present recent work on the development of core/shell QDs with modest band offsets that nonetheless maintain high QY in aqueous solution, and new experiments that explore the limits of alternating layer addition approaches to core/shell nanostructures.

9:45 AM
Anisotropic Evaporation of GaN Nanowires Analyzed Using Atom Probe Tomography: *James Riley*[1]; Rodrigo Bernal[1]; Qiming Li[2]; Horacio Espinosa[1]; George Wang[2]; Lincoln Lauhon[1]; [1]Northwestern University; [2]Sandia National Laboratories

GaN is a promising material for light-emitting diodes (LEDs) but GaN films exhibit numerous dislocations when grown on inexpensive, but lattice-mismatched substrates such as Si. Dislocation-free nanowire heterostructures can be grown at high lattice mismatch, but measurement of dopant incorporation and interface uniformity becomes substantially more challenging in this 3D geometry. We have used atom probe tomography (APT) to analyze the 3D composition of Metal Organic Chemical Vapor Deposition (MOCVD) grown GaN nanowires. Post-APT SEM imaging was used to correlate evaporation features with crystallographic poles. Regions of low Ga+N detection were associated with trajectory effects caused by surface faceting. Furthermore, an area of enhanced N detection was attributed to evaporation from a semipolar surface. The increased N detection in this region causes the overall measured composition to deviate from the expected stoichiometric ratio. This knowledge of spatial variations in apparent stoichiometry is essential to correctly interpret APT data from heterostructures.

10:05 AM
Fabrication of Silicon Nanowires by Metal Nanoparticles Assisted Anisotropic Etching and Their Electron Microscopic Studies: *Wenwu Shi*[1]; Laura Phillips[1]; Nitin Chopra[1]; [1]The University of Alabama

Silicon nanowires possess unique optical and semiconducting properties, and show great potential as solar cell, biological/chemical sensor, and batteries. Anisotropic chemical etching inside strong acids using noble metal nanoparticles could produce large amount, properly aligned silicon nanowires at ambient temperature and pressure within short duration. However, detailed understanding of the growth process is warranted. This study examined the effects of etching duration, temperature, salt type, and acid concentration on the length, morphology, uniformity, and density of nanowires. This fundamental understanding was developed using scanning electron microscopy (SEM), transmission electro spectroscopy (TEM), Raman spectroscopy, and X-ray diffraction (XRD). Of the salt types used, only gold and silver salts produced high quality nanowires after etching, with the silver being the best. This method also allowed for the growth of various morphologies of the Si nanowires with in-situ nanoparticle coatings.

Hybrid Nanowires for Functional Applications: *Pelagia Gouma*[1]; [1]SUNY Stony Brook

Electrospun nanofibers of hybrid materials (polymers, ceramics, metals, biomolecules) are a class of bio-nano-composites that also allow for versatile design, ease of manufacturing, and diversity of applications. Both the nanoelectronics and nanomedicine fields will eventually require the integration of protein nanofibers-based design and manufacturing (e.g. nanocircuitry templating, protein structures such as those binding bone to collagen in tissue scaffolding, etc.) and electrospun nanofiber-based synthesis and processing (active components in sensing, actuation, nanocues in templating, drug delivery systems, etc.). This paper provides an overview of the author's research related to hybrid nanowire synthesis and use in specific functional applications. The solution and process parameters that control the morphology and structure of the nanofibrous materials will be discussed and emphasis will be paid on the electrostatic interactions between different types of materials (e.g. organic vs inorganic components) during the electrospinning process.

Tuning Color by Pore-Depth of Metal-Coated Nanostructured Porous Alumina: *Dongxian Zhang*[1]; Xulongqi Wang[1]; Haijun Zhang[1]; Yi Ma[1]; Jianzhong Jiang[1]; [1]Zhejiang University

A simple and effective color-tuning method has been developed by controlling pore-depth of metal-coated porous alumina (PA) template. The mechanism for color tuning in this method was uncovered, which can be used to design colorful complex pattern. A colorful 'World Map' was exhibited on PA template by this method. Such vivid color tuning is predominately due to the interference enhancement of nanostructure. This method has the potential for tuning colors and being widely applied in the fields of nanotechnology, physics and photonics.

11:40 AM Invited

In-Situ TEM Controlled Growth of Silicide in Si Nanowires: *Yi-Chia Chou*[1]; Mark Reuter[2]; King-Ning Tu[3]; Eric Stach[4]; Frances Ross[2]; [1]IBM/Purdue University; [2]IBM T. J. Watson; [3]University of California Los Angeles; [4]Purdue University/BNL

Silicides are important for microelectronics, but compared to bulk or thin film reactions, mechanisms and kinetics can be dramatically different in nanoscale structures. In order to quantify these effects, we have used in situ transmission electron microscopy to observe silicidation in Si nanowires. Movies recorded during silicidation show at atomic resolution that homogeneous nucleation of silicide takes place at the center of each Si atomic layer; heterogeneous nucleation is suppressed due to the native oxide. We compare with Si nanowires grown in a UHV transmission electron microscope where metal is deposited without breaking vacuum. Silicidation was observed in real time during annealing and the kinetics measured from movies. The presence of a surface oxide can lead to striking changes in the silicide morphology. We will discuss the degree to which silicide structures can be controlled using oxygen, in particular to form nanowires with silicide at controlled positions along the nanowire.

12:15 PM

Development of ZnO/MgO/p$^+$-Si Heterostructures for Pure UV Light Emitting Diode with Carrier Blocking Layer: *Byung Oh Jung*[1]; Ju Ho Lee[2]; Hyung Koun Cho[1]; Jeong Yong Lee[2]; Ho Seong Lee[3]; [1]Sungkyunkwan University; [2]KAIST; [3]Kyungpook National University

ZnO has been considered as candidate material for optical devices alternative to GaN. However, due to the difficulty in obtaining p-ZnO, ZnO emitters utilized the heterojunctions, including p-GaN and SiC. However, ZnO/GaN heterojunction LEDs are economically infeasible. However, the Si substrates based LEDs have stable p-type and cost effective. ZnO can be easily synthesized, leading to the formation of high quality single crystal nanostructure on the Si. For the ZnO/Si, the interface has large band offset because the ZnO has larger band gap energy than Si. Such band offset provides effective hole carrier tunneling effect to the ZnO under forward bias. In this research, the ZnO based UV LEDs including dielectric MgO layers with proper thickness were fabricated on the p$^+$-Si substrates. We focus on the thickness effect of inserted MgO layer on the blocking of the carrier flow and the UV emission intensity in the ZnO nanowires.

12:30 PM

The Temperature and Excitation Intensity Effects on the Photoluminescence Spectra of InAs /InP Quantum Dots: *Fatiha Besahraoui*[1]; [1]Oran University

The optoelectronics properties of InAs /InP quantum dots (QDs) are investigated by means of photoluminescence (PL) measurements. The mechanisms of electron-heavy/light hole recombination which is responsible of the PL peaks appearance are explored in this study. The electron-hole recombinations are influenced by the temperature and the laser excitation intensity. The PL signal and its yield are reduced with the increase of temperature. Especially, in high energies range.The PLE measurements are very sensitive to the excitation intensity. From an appropriate value of Laser excitation, the energies levels will be saturated, which favors the light emission.The bands filling is translated by a widening in the PL spectrum towards the high energies range.

3rd International Symposium on High Temperature Metallurgical Processing: High Efficiency New Metallurgical Technology

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Energy Committee, TMS: Pyrometallurgy Committee

A Laboratory Investigation of the Reduction of the Siderite Iron Ore to Iron Nugget: *Nikolay Panishev*[1]; Eugene Redin[1]; Vladimir Pilshchikov[2]; [1]Magnitogorsk Iron & Steel Works; [2]Hares Engineering GmbH

The Bakal (South Ural, Russia) deposit of iron ore bearing iron carbonate (siderite) with the capacity of more than 1 billion tones belongs to the MMK. This ore cannot be fully processed via blast furnace technology because of high content of MgO. According to the investigations carried out in the USA and Japan in 1999-2004 the ITmk3 technology is a breakthrough in Ironmaking. Reduction, melting and slag removal can be achieved in just 10 min. The main objective of the investigation is to establish optimum operation conditions for the production of iron nuggets from iron carbonate bearing ore via the ITmk3 by means of the lab scale testing. Green pellets were processed via a lab tube (chamber) furnace to simulate RHF conditions. This preliminary test work provides valuable information which may be used for large-scale testing in a commercially sized RHF.

9:00 AM

Composite Agglomeration Process of Iron Ore Fines: *Tao Jiang*[1]; Youming Hu[1]; Guanghui Li[1]; Yufeng Guo[1]; Zhengwei Yu[1]; Xiaohui Fan[1]; Yuanbo Zhang[1]; Yongbin Yang[1]; [1]Central South University

Composite agglomeration process (CAP), as an innovative method for preparing blast furnace burden, was developed and has been put into operation in China. CAP is different from traditional agglomeration processes of iron-bearing materials involving sintering and pelletizing. Compared to the traditional agglomeration processes, CAP is characterized by several strengths such as permission of diverse iron-bearing materials in production, obvious improvement of permeability in the feed bed, decreasing the fuel consumption and remarkably increasing the productivity of sintering machine. Furthermore, the use of the composite agglomerates prepared with CAP is capable of obviating the negative effects caused by the differences in quality of sinter and pellets on the operation of blast furnaces. This paper mainly presents an overview of the principle and applications of CAP.

9:20 AM

Investigation of Pyrometallurgical Nickel Pig Iron (NPI) Production Process from Lateritic Nickel Ores: Onuralp Yucel[1]; *Ahmet Turan*[1]; Halil Yildirim[1]; [1]Istanbul Technical University

Nickel is mainly used in stainless steel production as ferronickel. In recent years, low grade ferronickel or nickel pig iron (NPI) is used in stainless steel production to reduce expenditure of nickel price. In this study, Turkey East Anatolian region lateritic nickel ores were directly processed by using carbothermal reduction to produce NPI. Firstly the raw lateritic ore that contains 0.9% Ni, 0.054% Co and 2.3% Cr was mixed with metallurgical grade coal at different stoichiometric ratios. The samples were smelted at 1600-1650°C temperature range in a induction furnace for 25 min. In the second experimental set, different process times were investigated varying from 15 to 35 min. Effect of different flux additions to the smelting charge also were examined. The raw material, obtained alloys and slags were analyzed by using XRD (X-Ray Diffractometer), XRF (X-Ray Fluorescence Spectrometer), AAS (Atomic Absorption Spectrometer) and EPMA (Electron Probe Micro Analyzer) techniques.

9:40 AM

Novel Process for Utilizing Low-Grade Manganese Oxide Ores by Sulfur-Based Reduction Roasting-Acid Leaching: Tao Jiang[1]; Zhixiong You[1]; *Yuanbo Zhang*[1]; Daoxian Duan[1]; Guanghui Li[1]; [1]Central South University

Manganese is mainly consumed by steel and battery industries. In recent years, high quality manganese oxides are becoming less and less with development of steel and battery industries. It is essential to utilize the low-grade manganese oxides with total manganese below 25%. Conventional pyrometallurgical and hydrometallurgical processes for utilizing pyrolusite are characterized as high production cost and energy consumption, low productivity, serious environmental pollution, etc. In this study, reduction thermodynamic by sulphur of MnO2 was firstly carried out. Then, a new process of reduction roasting with sulphur followed by acid leaching was developed to recover manganese from very low-grade pyrolusite. Effects of reduction time, S/Mn ratio and leaching parameters were investigated, and a high leaching efficiency above 95% was obtained under optimal conditions.

10:00 AM Break

10:10 AM

Silicon Process Pilot Scale Experiment in a Semi Closed in a 440 kVA Furnace Furnace: *Ingeborg Solheim*[1]; [1]SINTEF Materials and Chemistry

SINTEF Trondheim has carried out several pilot scale silicon process experiments in the past, but always with an open off gas system. In order to test the possibilities in running a semi closed furnace operation, a new off gas hood has been designed and tested. The off gas hood is designed to collect all off gases to gain insight into the phase compositions in the off gas and at the same time have the opportunity to monitor and maintain the charging/stoking of the furnace. The furnace hood has regulation and control of the air inlet into the combustion zone in two different heights. The off gas temperature and composition was continuously monitored and analyzed during the experiment. The presentation will give a description of the pilot scale experiment with setup, equipment and results.

10:30 AM

Slide Gate Systems for Copper Tapping: Klaus Gamweger[1]; *Andreas Schmid*[1]; [1]RHI AG

This paper introduces an innovative solution to open and close the tap hole of different furnace types in the copper industry with a slide gate system. Two plates with defined drilled holes are slid against each other, which enables effective starting and stopping of the copper flow as well as throttling. Typically, the copper is poured via a tap hole into a launder system by rotating the furnace into an appropriate position. Control of the casting rate is also performed in this manner. Or, in case of stationary furnaces the tap hole is opened by oxygen lancing and closed manually with a clay- or copper-cone. These procedures show a lot of disadvantages including splashing, oxygen pick-up, and energy losses as well as a severe danger for the working staff. All these problems can be overcome with an appropriate slide gate system.

10:50 AM

Recovery of Huangmei Limonite by Flash Magnetic Roasting Technique: *Wen Chen*[1]; Xinghua Liu[1]; Zeyou Peng[1]; Qiulin Wang[1]; [1]Changsha Research Institute Of Mining And Metallurgy

Limonite is a collective for iron hydroxide argillaceous materials. It is very difficult to treat due to the wide variation in specific gravity and magnetism and the high argillization rate in the course of grinding and beneficiation. The iron ore in Huangmei, Hubei, China is the typical representative of limonite. If the limonite is processed using conventional physical beneficiation methods (e.g. magnetic separation, gravity separation, flocculation-desliming-flotation, or a combined process of the three), can only be obtained an iron concentrate grade of 51.98% and an iron metal recovery of 86.64%. However, using the technique of flash magnetic roasting—magnetic separation can improve the concentrate grade to 61.03%, iron recovery to 91.17%. This paper describes the tests of recovering limonite by flash magnetic roasting in detail.Key words: limonite; flash magnetic roasting; recovery

11:10 AM

Studies on Alternative Blast Furnace Burden Structure with High Proportion Sinter: Jianjun Fan[1]; Guanzhou Qiu[1]; Tao Jiang[1]; Yufeng Guo[1]; *Yongbin Yang*[1]; Meixia Cai[2]; [1]Central South University; [2]Taiyuan Iron and Steel (Group)Co. Ltd

The experiments were conducted on optimizing the blast burden structure so as to replace the original low quality sinter with basicity being around 1.4-1.5. A series of sintering and metallurgical experiments was carried out, the results indicated that the sinter disintegrated seriously with basicity being around 1.4, and after this “turning point”, the sintering properties get improved steadily with the increase of sinter basicity. Based on the results ,a bold idea was put forward which focused on producing two kinds of sinter with different basicity .Finally an alternative BF burden structure was proposed as following:44% sinter(Basicity being 1.05)+44% sinter(Basicity being 1.87)+12% pellet, which exhibited better technical indices compared with the original burden structure of 85% sinter(Basicity being 1.4-1.5)+15% pellet .

11:30 AM

Hydrothermal Sulfidation of Carbonate-Hosted Zinc-Lead Ore with Elemental Sulfur: Cunxiong Li[1]; *Chang WEI*[1]; [1]Kunming University of Science and Technology

Direct flotation of carbonate hosted zinc-lead ore is characterized by recovery of zinc and lead only around 55% and 50%, respectively. Mineralogical analysis shows that the sample used in the present study is a carbonate hosted zinc-lead ore, with a zinc and lead carbonate content that accounts for 80.14% and 75.63% of the total minerals, respectively. The carbonate hosted zinc-lead ore was hydrothermally sulfidized with elemental sufur and the experimental data indicated that under the conditions employed up to 75% zinc and 82% lead sulfidation extent were achieved. As a result of pre-sulphidation followed by flotation, the recoveries of zinc and lead into flotation concentrate were over 90%. A flotation concentrate was obtained with 52% Zn and 37% Pb from the materials which was treated by sulphidation.

Advances in Surface Engineering: Alloyed and Composite Coatings: Session I

An Overview of Dry Sliding Wear of Two-Phase FeNiMnAl Alloys: *I. Baker*[1]; [1]Dartmouth College

This paper presents an overview of the dry sliding wear behavior of two-phase FeNiMnAl alloys tested in different environments, i.e. air, dry oxygen, dry argon and a 5% hydrogen/nitrogen mixture. Pin-on-disk wear tests were performed using FeNiMnAl pins against an yttria-stabilized zirconia counterface. The worn pins and the counterface were examined using a variety of techniques: the near-surfaces of the worn pins were examined using transmission electron microscopy on cross-sectional specimens produced by focused ion beam (FIB) milling; scanning electron microscopy was used to examined the FIBbed pits and the worn surfaces of the pins; debris collected from all the tests was characterized using X-ray diffractometry; and the worn zirconia disk was examined using both optical microscopy and profilommetry. Using this combination of techniques it has been possible to understand the wear rates and wear mechanisms for the different alloys in the various test environments.

9:00 AM Invited
CrN-Ag Nanocomposite Coatings: High-Temperature Lubrication through Nanopore Channels: *Daniel Gall*[1]; Christopher Mulligan[2]; Paul Papi[1]; Thierry Blanchet[1]; [1]Rensselaer Polytechnic Institute; [2]Benet Laboratories

A promising approach to achieve high-temperature lubrication and wear protection is the inclusion of a soft noble metal in a hard wear-resistant matrix. Our prototype nanocomposite material system is CrN-Ag, which is co-deposited by reactive sputtering onto steel substrates. A detailed study of the atomistic processes during deposition allows control of the microstructure. In particular, surface diffusion and atomic shadowing effects are exploited to create 1-nm-wide pores (nanopipes) within the CrN matrix which act as channels for Ag lubricant flow during high temperature operation. The key parameter that determines the lubricant transport is the difference in the temperature of layer deposition Ts = 300-700 °C and testing temperature Ta = 425-800 °C. This is attributed to the Ag agglomerate size which increases with increasing Ts, reducing the thermodynamic driving force for surface segregation. Ball-on-disk testing against alumina counterfaces shows sustained friction coefficients =0.2 at 450-650 °C.

9:25 AM Invited
Micromechanisms of Failure in Multilayered Hard Coatings of ZrN-Zr and TiAlN-TiN: *Vikram Jayaram*[1]; Nisha Verma[1]; [1]Indian Institute of Science

Contact damage in hard coatings is a function of coating microstructure, residual stress and the mechanical properties of the constituents as well as the film thickness and substrate's mechanical properties. This talk will describe how multilayering with either similar phases (TiN-AlTiN) or with ductile interlayers (ZrN-Zr) can modify damage modes under indentations. Interfaces between similar phases are able to provide additional modes of deformation that reduce stress concentrations that lead to fracture. On the other hand, soft layers need to be an optimum thickness which appears to be ~ 30-50 nm to avoid interfacial delamination or nitride cracking that is induced by metal plasticity. These observations will be supported by a combination of analytical and finite element modeling of axisymmetric indentations.

9:50 AM
Advances in Surface Engineering for Amorphous Coatings: *Sandip Harimkar*[1]; [1]Oklahoma State University

Amorphous alloys represent a new class of advanced materials exhibiting attractive combinations of properties such as high strength/hardness and excellent wear/corrosion resistance. While bulk processing of amorphous alloys is difficult, various binary and multi-component amorphous alloys can be coated using various rapid solidification, solid-state sintering, and electrochemical processes. In this presentation, an overview of processing approaches for coating wear and corrosion resistant amorphous coatings will be presented.

10:10 AM Break

10:25 AM
Metal Matrix Composite Hardfacing by Additive Friction Stir: *Jeffrey Schultz*[1]; [1]Schultz-Creehan Holdings, Inc

Additive friction stir (AFS) is a solid-state coating method in which wrought metal is deposited onto metallic substrates. AFS uses shear-induced interfacial heating and plastic deformation to deposit metal and metal matrix composite (MMC) coatings, and the mechanical shearing that occurs at the interface results in a metallurgical bond between the substrate and coating. Al alloys are relatively soft in comparison to other materials used for wear surfaces. However, if the wear resistance of Al alloys can be improved by local surface modification then significant weight reductions could be realized by replacing iron-based materials with Al. Deposition of Al-50 vol% SiC coating onto a MIC 6 substrate was demonstrated using AFS. The deposited MMC coating is approximately twice as hard the base metal. The MMC-coated surface showed an almost three-fold improvement in the reciprocal wear rate as compared to the base casting when tested under ASTM G65 abrasion testing.

10:45 AM
Multiscale Mechanical and Tribological Behavior of Plasma Sprayed Carbon Nanotube Reinforced Aluminum Composites: *Srinivasa Bakshi*[1]; Arvind Agarwal[2]; [1]Indian Institute of Technology Madras; [2]Florida International University

Mechanical and Tribological Properties of CNT reinforced Aluminium have been evaluated at the macro- and nano-scale. Nanoindentation indicated an increase in the elastic modulus by 19% and 39% by the addition of 5 wt.% and 10 wt.% CNTs respectively. Macro-scale compression tests indicated no improvement in the elastic modulus but an increases in the compressive yield strength by 27% and 77% respectively, by addition of 5 wt.% and 10 wt.% CNTs. Nanoscratch testing carried out on the Al-Si matrix with dispersed CNTs indicated a decrease in scratch volume by 34% and 71% for 5 wt.% and 10 wt.% CNTs coating respectively. Macro-scale wear tests indicated a decrease in the wear volume by 68% in case of 5 wt.% CNT coatings but an increase in the wear volume by 15% for the 10 wt.% CNT coating. The variation of the properties at nano and macro scales are discussed.

11:05 AM
Microstructures and Wear Properties of $(Ti_{1-x}Mo_x)N_y$ Hard Coatings: *Shoko Komiyama*[1]; Yuji Sutou[1]; Junichi Koike[1]; Mei Wang[2]; Takaomi Toihara[2]; [1]Tohoku University; [2]OSG Corporation

TiN films have been widely used in cutting tools and molds. It is recently found by Komiyama et al. that the hardness of Ti-Mo-N films can be increased by precipitation hardening by soft bcc particles [1]. In this study, the effects of the film composition on the microstructures and wear properties of $(Ti_{1-x}Mo_x)N_y$ films were investigated. The films with various compositions were deposited on AISI304 and WC-Co by

RF reactive sputtering using $Ti_{25}Mo_{75}$, $Ti_{50}Mo_{50}$ and $Ti_{75}Mo_{25}$ targets. To deposit nitrides, the mixture of Ar (7.5ccm) and N_2 (0-2.0ccm) gases were introduced. From wear test using carbon steel (S45C) as a counterpart, it was found that a $(Ti_{0.51}Mo_{0.49})N_{0.72}$ film deposited on WC-Co shows excellent wear properties. Transferred materials from the counterpart were hardly observed on the surface of the film. These results suggest that the film has an excellent adhesion resistance. [1] S. Komiyama et al., Materials Transactions, 51 (2010) 1467.

11:25 AM
Wear Resistance of Spray Formed Stainless Steels: *Claudemiro Bolfarini*[1]; Leamar Beraldo[1]; Conrado Afonso[1]; Claudio Kiminami[1]; Walter Botta[1]; [1]Universidade Federal de São Carlos

This work investigated the microstructure and wear resistance of two spray formed stainless steels, ferritic-AIF with 29% Cr and a superduplex- SDM modified with boron (3.5wt%).The rapid solidification process promoted the formation of a new structure with refined grains and metastable phases. The deposits, weighing about 3.5 kg, were characterized by a combination of optical microscopy, scanning electron microscopy (SEM), hardness test and abrasion test according to ASTM G65-07. The deposits of AIF and SDM presented finer microstructure and higher hardness values when compared to conventionally cast materials. The abrasion resistance of the SDM was higher than the materials tabulated in ASTM G65-07, namely, Stellite 1016 and AISI D2, while the AIF presented an intermediate value between these two materials.

11:45 AM
Use of Thermo-Mechanical Simulator in Studying the Cyclic Oxidation of NiCrAlY Coatings: *Nidhi Rana*[1]; R. Jayaganthan[1]; Satya Prakash[1]; [1]Indian Institute of Technology, Roorkee, India

The MCrAlY coating system has been used in the gas turbine engines to provide the resistance against oxidation and corrosion at the operating temperature of the engine. The cyclic oxidation test of the coatings has been carried out by heating the samples at temperature of 900°C and subsequent cooling so as to simulate the actual operation of the engine. In present work an attempt has been made to use the Thermo-mechanical Simulator for the above study. Various characterisation techniques like X-ray diffraction, Electron microscopy and X-ray elemental mapping has been used to study the presence of different oxide phases, their morphology and elemental composition.

Aluminum Alloys: Fabrication, Characterization and Applications: Development and Application

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Processing Committee
Program Organizers: Subodh Das, Phinix LLC; Tongguang Zhai, University of Kentucky; Zhengdong Long, Kaiser Aluminum

Monday AM — Room: Northern E1

Session Chair: Steven Long, Kaiser Aluminum

8:30 AM
Aluminum Welded Blank Applications in the Automotive Industry: *Susan Hartfield-Wunsch*[1]; Ravi Verma[1]; Blair Carlson[1]; [1]General Motors

Aluminum welded blanks (AWB's) are of interest to the automotive industry for applications such as door inner panels to achieve mass reduction over current production steel doors, leading to improved fuel economy. Using an AWB instead of a multi-piece aluminum door inner design provides not only part consolidation, but also improved dimensional performance, and improved door stiffness. In this study, AWB's were evaluated for a midsize car door inner, including laboratory testing and full-scale forming trials. Blanks were fabricated using friction stir welding and laser welding, joining 1.1mm AA5182 to 2.0mm AA5182. The blanks were stamped into door inner panels where local strains and thinning measurements were compared to formability simulation predictions. Weld quality was evaluated with microstructure and microhardness data. Forming results and weld quality evaluation were used to create specification guidelines for AWB's.

8:50 AM
Influence of Stress on Sensitization in Al-Mg Alloys: *William Golumbfskie*[1]; Jennifer Gaies[1]; Mitra Taheri[2]; [1]Naval Surface Warfare Center, Carderock Division; [2]Drexel University

5xxx aluminum alloys are considered sensitized when magnesium precipitates out of solution forming a deleterious ß-phase (Mg2Al3) around grain boundaries. Current research uses accelerated heat treatments at elevated temperatures in a laboratory setting to simulate sensitization that occurs naturally at lower temperatures and longer times. This approach neglects contributions of stress on the kinetics of ß-phase precipitation. Understanding how stress affects sensitization is necessary to ensure that laboratory samples reflect the microstructure and phase stability of naturally sensitized specimens.Test specimens will be loaded at incremental stress levels and exposed to elevated temperatures. Their microstructure and degree of sensitization will be characterized using microscopy coupled with the ASTM G67 test. The findings will be compared to aluminum samples that were sensitized via natural exposure. A key deliverable of this effort is the determination of a combination of time, temperature, stress and environment that best replicate naturally sensitized Al.

9:10 AM
Material Performance of Naturally Sensitized Aluminum 5xxx Alloys: *Angela Whitfield*[1]; Daniel Stiles[1]; William Golumbfskie[1]; [1]Naval Surface Warfare Center

Current understanding of the effect of sensitization on 5xxx aluminum mechanical property performance is limited. Sensitization of aluminum in-service has lead to severe cracking in marine structures. Degree of sensitization measurements taken near cracks in naturally-sensitized aluminum plates have shown high (>40 mg/cm^2) levels of sensitization. This effort will examine the degree of sensitization, microstructure, tensile, and fracture toughness of several specimens of naturally sensitized aluminum in an attempt to correlate degree of sensitization with material performance. The resulting data can be used to understand how degree of sensitization degrades performance of aluminum ship structures and can influence maintenance or repair decisions. This study is unique, in that it examines the performance of naturally-sensitized aluminum in lieu of artificially (laboratory) sensitized materials.

9:30 AM
Precipitation of the θ′ (Al_2Cu) Phase in Al-Cu-Ag Alloys: *Julian Rosalie*[1]; Laure Bourgeois[2]; Barrington Muddle[2]; [1]National Institute for Materials Science; [2]Monash University

Precipitation of the θ′ (Al_2Cu) phase was examined in Al-(1.75-x) at.%Cu-x at.%Ag alloys. In alloys containingtrace Ag the θ′ precipitates formed T- or cross-shaped arrays of sympathetically-nucleated arrays similar to those reported in binary Al-Cu alloys. However, in alloys with equal atomic levels of copper and silver such arrays were not formed and the θ′ plates formed at specic sites on dislocation loops alongside pre-existing γ′ ($AlAg_2$) precipitates. The dislocation loops appeared to dissociate at these sites in a manner which would provide a stacking fault that was isostructural with the θ′ precipitate. Energy dispersive X-ray (EDX) mapping showed that the dislocation loops were silver-enriched at the sites where the θ′ phase eventually precipitated and that a silver atmosphere remained after precipitation of the θ′ plates.

9:50 AM
Using High-Resolution Topographic Imaging to Characterize the Hemming Performance of Automotive Aluminum Alloys: *Mark Stoudt*[1]; Joseph Hubbard[1]; John Carsley[2]; Susan Hartfield-Wünsch[3]; [1]National Institute of Standards and Technology; [2]General Motors R&D Center; [3]General Motors Technical Center

Flat hemming of aluminum alloys can be problematic due to a lower ductility and fracture resistance that promotes intense strain localization and crack initiation near the apex of the bend. The performance of two-6xxx series aluminum hemming alloys, with and without a ten percent uniaxial pre-strain, was evaluated after bending to a 180-degree angle in a simulated hemming operation. Since the deformed surface is highly dependent on the local microstructural and strain conditions, detailed examinations of the morphologies of the bend apexes from these surfaces revealed substantial details about the character of the deformation produced during hemming. The topographical data were also used to construct high-resolution maps of the strain localization magnitudes. These maps directly quantified the surface conditions required for crack initiation and revealed the specific locations of the most intense surface deformation. The techniques and the observed relationships between the microstructure and the deformed surface shall be discussed.

10:10 AM
Characterization of Electron Beam Deposited Aluminum Alloy 2139: *Milo Kral*[1]; Karl Buchanan[1]; Craig Brice[2]; Marcia Domack[2]; Ravi Shenoy[2]; William Hofmeister[3]; [1]University of Canterbury; [2]NASA Langley Research Center; [3]UT Space Institute

Aluminum 2319 is a Cu-Mg-Ag bearing alloy designed to have a desirable combination of strength and fracture toughness through a large range of plate thicknesses. Electron beam freeform fabrication (EBF3) is an additive manufacturing technique that allows for the creation of near net shape directly from a computer model. Alloy 2139 is an excellent candidate material for EBF3 due to its insensitivity to section size and low mechanical work requirements necessary to achieve peak strength and toughness. This study aims to characterize EBF3 deposited 2139, in the as-deposited state as well as in various heat-treated states. Characterization methods include scanning electron microscopy with electron backscatter diffraction for phase identification and orientation mapping, analytical transmission electron microscopy, differential scanning calorimetry and microhardness mapping. The results of this study will identify the ideal heat treatment for achieving peak strength in EBF3 2139 aluminum alloy.

10:45 AM
Near Net Shaped Casting of 7050 Al Wrought Alloy by CDS Process: Microstructure and Mechanical Properties: *Seyed Giaasiaan*[1]; Abbas Khalaf[1]; Xiaochun Zeng[1]; Sumanth Shankar[1]; [1]McMaster University

Controlled diffusion solidification (CDS) involves mixing two precursor alloys at different thermal mass and subsequently casting the resultant mixture into ner net shape cast components. The process enables casting of Aluminum wrought alloys into near net shaped components by circumventing the problem of hot tearing by obtaining a non dendritic morphology of the primary Al phase. The study presents the favorable process and alloy parameters to enable sound shaped casting of 7xxx Al wrought alloys (Al-Zn-Mg-Cu) by the CDS process along with the mechanical tensile properties under various heat treatment conditions. The tilt pour gravity casting process was used for this study and the ability to obtain high integrity casting of these alloys with significantly superior strength and ductility of the cast components. In depth microstructure analysis outlining the phased in the cast and heat treated microstructure would also be presented.

11:05 AM
A Study of Stress Effects on eta-Phase Precipitation in Al-Mg Alloys Using In-Situ TEM: *Daniel Scotto D'Antuono*[1]; Jennifer Gaies[2]; William Golumbfskie[2]; Mitra Taheri[1]; [1]Drexel University; [2]Naval Surface Warfare Center

The 5xxx series aluminum-magnesium alloys are non-heat treatable metals commonly found in structural applications due to excellent corrosion resistance and weldability. Despite these strong characteristics these systems are prone to sensitization which leads to failure. Here, magnesium segregates toward grain boundaries and precipitates as Al3Mg2 (ß-phase). This ß-phase renders the alloy susceptible to intergranular and stress corrosion cracking (IGSCC). Aging exposure to medium/high temperatures, corrosive environments, and load contribute to the overall failure. Current studies on 5xxx sensitization have neglected to examine the effects of stress along with temperature on ß-phase formation. In this work, the ß-phase precipitation mechanism is observed by conducting simultaneous heating and straining experiments using in-situ TEM. This will allow for the determination of the time, temperature, and stress that give rise to the sensitization. Understanding the precipitation of ß-phase is necessary to mitigate and prevent its formation and thus reduce the susceptibility of these alloys.

11:25 AM
Effect of Heat Treatment on Silicon in Hypereutectic Al-Si Alloy: *Ying Zhang*[1]; [1]Zhengzhou Research Institute of CHALCO

Heat treatment is an efficient way to refine the second-phases in alloys. Refinement is very important to hypereutectic Al-Si alloy, a type of outstanding wear-resistant material, which mechanical properties are always badly damaged by coarse silicon. In this article, morphology and orientation changes of primary and eutectic silicon caused by solution treatment were studied. Integrated thermal analyzer, high temperature metallographic microscope, optical microscope, scanning electronic microscopy and transmission electron microscopy were used. The result shows that the heat treatment can smooth and refine silicon phases, thus increases the tensile strength and elongation. The orientation relationship between silicon and matrix is also changed.

Atomistic Effects in Migrating Interphase Interfaces - Recent Progress and Future Study: Interfacial Structure with Small Misfit

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS/ASM: Phase Transformations Committee

Topological Modelling of the Growth and Accommodation of Plate-Shaped Products Formed in Displacive Transformations: *Robert Pond*[1]; John Hirth[2]; [1]University of Exeter; [2]Private individual

Both diffusionless (martensitic) and diffusional-displacive transformations can be modelled using the topological method. Here, interfaces are considered to be semi-coherent, with a network of disconnections and dislocations (slip or twinning) superposed on the underlying coherent terrace. The mechanism of transformation is the motion of disconnections along the interface, so transformation kinetics depend on the mobility of these defects, and the extent of long-range diffusion, if any. The 3-D morphology of a product is determined by the configuration of disconnection loops encircling it. On the broad faces, the defect network compensates the coherency strains, but, towards the edges, longer-range stresses arise. These stresses can be ameliorated by, for example, plastic deformation in the vicinity of the edges, or the coalescence of plate variants in self-accommodating groups. In cases where the matrix and product exhibit common symmetry, internal dislocation walls may be present. Experimental observations consistent with these accommodation mechanisms are discussed.

Application of Edge-to-Edge Matching Model to Surface Transformation in a Titanium-Chromium Alloy: *Mingxing Zhang*[1]; Dong Qiu[1]; Patrick Kelly[1]; [1]The University of Queensland

The success in applications of the edge-to-edge matching (E2EM) model to crystallography of diffusion-controlled phase transformations in solids, to understanding of the grain refinement mechanism in light metals and to study of the epitaxial growth, quantum dots and nanowires, shows particular importance of the actual atomic matching along the matching rows. However, previous work was done in bulk materials. Phase transformations occurred on the free surface differ from those in the bulk materials because there are less restriction to the formation of new phases, which facilitates the release of strain energy, and surface relief appears on the free surface. The present work reports the recent crystallographic results of surface transformation in a Ti-Cr alloy. The E2EM model is used to understand the formation of surface reliefs. The role of the edge-to-edge atomic matching in reduction of interphase interfacial energy between two phases is also discussed.

9:35 AM
Crystallographic Morphology Evolution in a FCC/BCC System via a Discrete Atom Method: *Dai Fu-Zhi*[1]; Wen-Zheng Zhang[1]; [1]THU

Phase transformation crystallography evolution in a FCC/BCC system is studied with a discrete atom method proposed by Lee [1995, Scripta Metall.] Isotropic elastic constants and interfacial energy were adopted in the simulation. Morphologies and orientation relationships (ORs) were computed for different precipitate sizes. Small precipitates show a rhombus shape with the N-W OR, while big precipitates are elongate along the invariant line direction,with the direction and OR in a full agreement with the values determined by Dahmen's [1982,Acta Metall.] 2D invariant line model. Application to a Cu-0.20mass%Cr alloy shows the evolution from the N-W OR for small particles to a near K-S OR for big precipitates, which can account for the observations of OR in the early stage of ageing of the same alloy reported in literature.

9:55 AM
Characterization of Alpha/Gamma Interfaces in a Bainitic Microstructure: *Sherri Hadian*[1]; Gary Purdy[1]; Gianluigi Botton[1]; [1]McMaster Univrsity

The cementite free bainitic microstructure in a 0.5%c, 1.8% Si and 5% Ni steel, was used to study the interfacial structure of fcc/bcc interfaces. Several facets and their dislocation structure were characterized. Based on observations, the transformation was recognized as an invariant line transformation and consequently the interfacial structure and the mobility of interfaces were discussed as they might be affected by this observation.

Crystallography, Shape Change and Their Relationship in the Formation of Precipitate Plates/Laths: *Jian-Feng Nie*[1]; [1]Monash University

The approach that is based on commensurate edge-on matching of lattice planes is used in the present work to examine the crystallography, shape change and their relationships in the formation of precipitate plates/laths. It is found that many precipitations of the plates/laths, including those that have been conventionally classified as non-displacive, exhibit a significant shear component of the shape strain. In all such precipitations, a shear strain is inevitably associated with interface motion if the coherent or commensurate edge-to-edge matching of lattice plane is to be preserved in the planar interface separating the two lattices. This finding provides some insights into the transformation mechanisms and the nucleation and growth behaviours of precipitate plates/laths. It is conceivable that minimisation of this shear strain, via either self-accommodation or external lattice defects, could be a critical factor in dictating the formation of such precipitates.

11:00 AM
Modelling Morphologies of ß' Precipitates in Mg-RE Alloys: *Hong Liu*[1]; Yipeng Gao[2]; Zhe Liu[1]; Yunzhi Wang[2]; Jian-Feng Nie[1]; [1]Monash University; [2]The Ohio State University

The metastable phase ß' is a key strengthening precipitate phase in Mg-RE alloys. Its morphology changes from a nearly spherical shape in Mg-Y-Nd alloys to a lenticular shape in Mg-Gd-Y alloys. In the latter, the broad surface of the lenticular precipitates is nearly parallel to the prismatic planes of the matrix phase and is therefore more effective in strengthening. In this work, we aim to understand the various morphologies of the ß' phase in the Mg-RE alloys. The lattice parameters and elastic constants of the ß' phase and the interfacial energy of the coherent ß'/Mg interface are calculated for various Mg-RE systems by the first-principles approach. Using these parameters as inputs, the equilibrium shape of and the stress field around the ß' phase are then determined by the phase field approach. The strengthening effect of ß' precipitates having different morphologies are also investigated by phase field model of dislocation-precipitate interactions.

11:20 AM
HRTEM Investigations on Austenite/Ferrite Interfacial Structure in the 2205 Duplex Stainless Steel: *Hung-Wei Yen*[1]; Jer-Ren Yang[1]; [1]National Taiwan University

The ferrite/austenite interfacial structure always plays a critical role in diffusional austenite-to-ferrite transformation in steels. Unfortunately, undecomposed austenite in the corresponding alloys with diffusional ferrite will transform into bainite or martensite as the alloys cooled down so that it causes difficulty to study the previous interfacial structure. The present study attempts to investigate, by using HRTEM, the interfacial structure of intra- and intergranular austenite form in delta ferrite matrix by diffuiosnal transformation in the 2205 stainless steel. The TEM results indicates the transformation is associated with ledge structure for austenite with and without rational orientation relationship with neighboring ferrite. It is proposed that these ledged interfacial configurations can also occurs in diffusional austenite-to-ferrite transformation.

Biological Materials Science Symposium: Bio-Inspired Materials: Mechanics and Design

Bioinspired Ceramic Coatings: Durability and Potential for Self-Lubricity: *John Nychka*[1]; Nathan Lun[1]; [1]University of Alberta

Ceramic coatings have been produced on metallic substrates with varying wettability through process optimization of temperature and time. Hydrophillic or near super-hydrophobic coatings are possible, and this presentation will report on investigations of the wettability, durability, and potential for self lubricating qualities when oils are introduced on the surface.

8:55 AM
Structure-Property Relationships of the Natural Multi-Layered Material Systems: *Wayne Hodo*[1]; Paul Allison[1]; Mei Chandler[1]; John Peters[1]; Allan Kennedy[1]; Rogie Rodriguez[2]; [1]ERDC; [2]University of Puerto Rico - Mayaguez

In this investigation, experiments and modeling were conducted to study the structure and mechanical properties of the alligator gar fish scales to ascertain the possible design principles of the biological armor system. Optical microscope and scanning electron microscope (SEM) images of the cross section of garfish scales revealed a multi-layered structure. Nanoindentation tests correlated to SEM with energy dispersive X-ray (EDX) analysis show that the hardness and modulus exhibit a gradient across the scale's layers when transitioning from one layer to the next instead of discrete variations in mechanical properties between each layer. Microindentation tests were performed at quasi-static loading conditions to examine the fracture and deformation mechanisms of the individual scales due to penetration loading condition. Finite element analysis of garfish scale under microindentation loading shows that the scale's overall property gradient across the layers spreads the deformation which provides delamination resistance at the interfaces.

9:10 AM
Quantum Effects in Interfacial Mechanics of Polymer-Ceramic Hybrid Biomaterials: Devendra Dubey[1]; *Vikas Tomar*[1]; [1]Purdue University

In hierarchical nanocomposite materials (eg. bone, nacre), interfacial interactions between the organic phase (eg. tropocollagen (TC)) and the mineral phase (eg. calcium hydroxyapatite (HAP)) as well as the structural effects arising due to the staggered arrangement, TC mutations, and varied HAP textures significantly affect the strength of such biomaterials. In the present investigation, different idealizations of TC-HAP composite biomaterial system under tensile and compressive loadings are analyzed using explicit three dimensional (3-D) quantum mechanical simulations to develop an understanding of these factors. Analyses show that maximizing the contact area between the TC and HAP phases result in higher interfacial strength as well as higher fracture strength. Analyses based on strength scaling as a function of structural hierarchy reveal that while peak strength follows a multiscaling relation, the fracture strength does not. The peak strain for failure was found to be independent of the level of structural hierarchy.

Nonlinear Behavior of Silk Minimizes Damage and Begets Spider Web Robustness from the Molecules Up: *Markus Buehler*[1]; Steven Cranford[1]; Nicola Pugno[1]; Anna Tarakanova[1]; [1]Massachusetts Institute of Technology

The behavior of spider webs, ranging from its protein sequence to spiral geometry, has intrigued scientists for centuries. How the role of silk's material behavior, architecture, as well as its failure behavior altogether serve to benefit the integrity of a spider web formation, however, remains unknown. Here we show that the nonlinear material behavior of silk fibers, softening at the yield point to dramatically stiffen during large deformations until point of failure, is what allows for localization of deformation upon loading, and is precisely what makes spider webs robust and extremely resistant to defects, as compared to other linear-elastic or elastic-plastic materials. Through in situ experiments on webs of a European garden spider, we confirm the prediction that locally applied loading results in minimal damage. We further show that under global loads such as wind, the material behavior of silk under small-deformation is crucial to maintaining the web.

Mechanics of Hierarchical Structures in Bone: Shashindra Pradhan[1]; Dinesh Katti[1]; *Kalpana Katti*[1]; [1]North Dakota State University

Collagen is the most abundant protein in the human body and provides structural integrity to tissues. A hierarchical organization of collagen exists in bone. The collagen molecule is about 300 nm long and 1.5 nm in diameter. It consists of a triple helical molecular structure consisting of three polypeptide chains. We have studied the role of nonbonded interactions between mineral and collagen on collagen mechanics. We have also investigated molecular level deformation mechanics of full length collagen (300 nm) using steered molecular dynamics (SMD). We report that nonbonded interactions of collagen with mineral as well as with water molecules play significant role on mechanics of collagen. Also, new hierarchical morphologies of collagen are observed in the full length collagen, not seen in short collagen. Multiscale models of fibril level structures are developed using finite element methods. These multiscale simulations provide the necessary framework for robust prediction of human tissue mechanics.

10:40 AM
Phase Field Model of Fracture for Inhomogeneous Materials: *Mark Jhon*[1]; Qian Xiao Li[1]; [1]Institute of High Performance Computing

Hard biological tissues such as nacre contain many levels of structural hierarchy. One challenge for predicting the mechanical behavior of these materials involves incorporating different levels of structural hierarchy into a mesoscale model. In the present study, we present a phase field model of fracture that incorporates disorder at fine length scales. This is intended to account for randomness in the brick-and-mortar structure of nacre. We find that by introducing disorder in the local stiffness, the apparent toughness of the composite is increased. If spatial correlations in the stiffness are sufficiently large, crack deflection can also be observed.

11:00 AM
A Study of Latrogenic Fracture Risk in Reduction of Pipkin Fracture-Dislocations of the Hip: Michael Duffy[1]; *Samar Kalita*[2]; Gerald Bertetta[2]; Mark Munro[1]; [1]Orlando Regional Medical Center; [2]University of Central Florida

Hip fracture-dislocations are serious injuries that require emergent orthopedic treatment. Iatrogenic femoral neck fracture during closed reduction of hip fracture-dislocations is an unappreciated occurrence. This study evaluated the risk of such fractures during closed reduction of Pipkin fracture-dislocations. 20 specimens (12 male and 8 female), age 54.3-42.4 years, were obtained, radiographed, and prescreened for abnormalities and bone mineral density (BMD). 18 screened femurs were tested in a tensile tester by randomly assigning them to three groups: native femora, simulated Pipkin I fracture, and simulated Pipkin II fracture. Most specimens failed at the neck. The average failure loads of the native, Pepkin I and Pepkin II specimens were 2501, 2750 and 2787 N, respectively. Statistical analysis, performed with ANOVA, showed no correlation between failure load, BMD, and fracture-type. Closed reduction should be gentle and be attempted under appropriate relaxation to apply the least force to the proximal femur.

Bulk Metallic Glasses IX: Alloy Development and Application

Progress in Engineering Applications of Bulk Metallic Glasses: William Johnson[1]; [1]University of Tennessee

Bulk metallic glasses with unique combinations of strength, toughness, ductility, and other properties are of increasing interest for a variety of engineering applications as structural and functional materials. Emerging approaches to fabrication of precision net-shape metallic glass hardware such as the recently developed Rapid Discharge Forming method enable fabrication of high performance metallic glass components using methods that parallel those employed to produce widely used polymer plastic parts. The evolution of this processing technology combined with the discovery and optimization of lower cost, high performance, and processable glass forming alloys is expected to lead to accelerated adaption of bulk metallic glasses in a variety of commercial products. The talk presents an overview of this emerging materials/processing technology.

9:00 AM
Glass Formation in a Laser-Glazed Zr-Cu-Ni-Al-Nb Alloy: *Brian Welk*[1]; Hamish Fraser[1]; Mark Gibson[2]; [1]The Ohio State University; [2]CSIRO

The present work explores the practical possibilities of using the LENS\8482 (laser engineered net shaping) deposition technique, combined with laser-glazing, to evaluate the formation-properties-production of bulk metallic glasses. A Zr-Cu-Ni-Al-Nb alloy was subjected to a number of laser glazing experiments to remelt and rapidly solidify a thin layer. Detailed SEM evaluation was conducted to investigate the microstructural evolution from the base alloy through a semi-solid region to the re-solidified melt pool. A marked transition in the microstructure was observed as a result of phase selection. This provided valuable insight into the scope for microstructure manipulation with alteration of the processing variables. The results obtained thus far indicate that the technique described herein provides a powerful tool for rapid screening of the glass forming potential of compositionally graded alloy bars. Additionally, this technique provided insight into alloy compositions that may produce amorphous matrix composite microstructures for a variety of functional applications.

9:10 AM Invited
Bulk Metallic Glasses: From Fundamentals to Applications: *Atakan Peker*[1]; [1]Washington State University

During the past two decades, Bulk Metallic Glasses (BMG) received an increasing attention from academia and industry. Researchers developed several new alloy formulations, performed extensive structure and property characterization, and end-user engineers explored creative ways to use BMG in various products. Despite all these efforts, the commercial success of BMG is still quite limited. This presentation will give a concise review of these efforts and will consider the underlying issues key to broader success and applications of BMG. Some of these issues are inherent to BMG fundamentals and are difficult challenges to address in the near term. There are also issues, which can be resolved in the near term with better awareness and focused effort by the BMG community. This presentation will focus on these issues and review recent attempts to address such challenges with particular attention to structural applications.

9:30 AM
Fabrication of Microchannels for Micro-Fluidic Applications Using High Frequency Micromachining on an Amorphous Material: *Vivek Jain*[1]; Apurbba Sharma[1]; Pradeep Kumar[1]; [1]Indian Institute of Technology Roorkee

Developments of micron-sized channels and cavities through micromachining techniques have contributed immensely towards advancements in the area of micro-fluidic systems. These microchannels are typically made of silicon, metal, or glass with the size ranging from 1 µm to 1000 µm and often feature circular, rectangular or trapezoidal cross sections. However, precision machining of any feature on an amorphous material is challenging. A high frequency low amplitude micromachining technique is capable of machining high aspect-ratio features on these materials without significantly changing metallurgical, chemical, or physical properties of workpiece material. In the present work, micro ultrasonic machining (micro USM),is employed to create microchannels on glass. The channels produced in the dimensions of 300 µm × 400 µm × 500 µm are ideally suited for micro-fluidic applications. The performance of the method while fabricating the microchannels has been evaluated in terms of dimensional errors, flatness, straightness, and surface roughness.

9:40 AM Invited
Development of Porous Metallic Glass Compacts: *Ki Buem Kim*[1]; [1]Sejong University

In this report, a single pulse of 0.1kJ-0.5kJ/0.5g spherical three kinds of metallic glass powder (Cu-Ni-Zr-Ti, Zr-Ti-Cu-Ni-Be and Zr-Al-Ni-Cu alloys) in size range of 90-150µm at a constant capacitance of 450µF, was applied to produce the porous metallic glass compacts. Microstructural investigation reveals that fully porous structure was obtained at low input energy (0.1 kJ ~ 0.3 kJ) as similar to pure Ti porous compacts. Moreover, the metallic glassy powder (Zr-Ti-Cu-Ni-Be alloy) with larger supercooled region maintains an amorphous phase without crystallization at higher input energy than metallic glassy powders (Cu-Ni-Zr-Ti and Zr-Al-Ni-Cu alloys). These results suggest that the melting point and supercooled region of the metallic glassy powders are critical factors to fabrication of porous metallic glass compacts without crystallization.

Bulk Metallic Glasses Form Like Plastics: *Jan Schroers*[1]; [1]Yale University

The metastable nature of BMGs has imposed a barrier to broad commercial adoption, especially where the processing requirements of these alloys conflict with conventional metal processing methods. Research on the crystallization of BMG formers has uncovered novel processing opportunities using thermoplastic forming (TPF), which utilizes the dramatic softening exhibited by a BMG as it approaches its glass transition temperature. This talk introduces such techniques that are unique among metals. Due to the absence of an intrinsic size limitation, BMGs can be precision net-shaped on the micro, nano, and even atomic length scale. Furthermore, these length scales can be combined even on complex surfaces. Within TPF, BMGs can be considered high strength material that can be processed like plastics, whereby previously mutually exclusive attributes of materials -processability and performance – can be combined.

Mechanistic and Thermodynamic Origins of Toughness in Metallic Glasses: *Marios Demetriou*[1]; William Johnson[1]; Robert Ritchie[2]; [1]California Institute of Technology; [2]University of California, Berkeley

Over the recent years, metallic glasses have evolved at an unusually high rate, far surpassing the development rate of other standard metallic materials used currently in engineering applications. The attributes contributing to their rise are fairly obvious: stronger, harder, and more elastic metal hardware compared to any of the incumbent metals like steel, titanium, and aluminum alloys. Other aspects of their engineering performance however are not quite as universal, and not necessarily as favorable. One such aspect is toughness. Their fracture toughness varies over two orders of magnitude between alloys, from values corresponding to brittle ceramics to tough metals. The acceptance of metallic glasses as widespread engineering materials hinges on our ability to understand and control such broadly-varying fracture toughness. In this presentation, the current understanding of the mechanisms of fracture toughness in metallic glasses will be reviewed, and the chemical and topological origins of these mechanisms will be discussed.

Recent Research Efforts in Bulk Metallic Glass Matrix Composites at NASA JPL/Caltech: *Douglas Hofmann*[1]; [1]NASA JPL/Caltech

In this talk we will review some of the recent research efforts funded by NASA and the Jet Propulsion Laboratory which work towards implementation of metallic glasses and composites into spaceflight hardware. These projects include studying dendrite growth in bulk metallic glass (BMG) composites in the low-gravity environment of the International Space Station, developing BMG shielding for protection from micrometeorites and orbital debris, and fabricating high-performance BMG composite mirrors and structural hardware. The talk will also give a historical perspective of NASA spaceflights performed by the Caltech group and how that relates to industrial development of BMGs as well as currently funded programs and future programs. Processing capabilities at JPL/Caltech will be discussed.

11:15 AM
Glass Forming Ability of the Multi-component Bulk Metallic Glasses: *Anupriya Agrawal*[1]; Logan Ward[1]; Katharine Flores[1]; Wolfgang Windl[1]; [1]The Ohio State University

Bulk Metallic Glasses (BMGs) represent a new class of metallic alloys with a wide range of potential applications. Our current work encompasses the development of reliable modeling methods to create realistic multicomponent glass structures, examine their glass forming ability (specifically, the glass transition temperature), and study their mechanical properties as a function of composition using Molecular Dynamics. We studied the glass forming ability in the Cu-Zr-Ti system in the composition ranges Cu60ZrxTi40–x (x = 5, 10, 20, 30) and Cu50ZrxTi50–x (x = 5, 7.5, 10, 15, 20, 35, 40) using Embedded Atom Method potentials. The fragility, which we find to be a better measure of glass forming ability, is also calculated within the Green-Kubo formalism. The results predict that a low Ti concentration favors good glass forming ability, which is in excellent agreement with experiment, where an upper limit of ~6-7% of Ti is found for glass formation.

11:25 AM Invited
Effect of Casting Technique on Glass Formation of Bulk Metallic Glasses: *Tao Zhang*[1]; [1]Beihang University

The glass-forming ability (GFA) is significant for both scientific research and industry application of bulk metallic glasses (BMGs). However, the experimental evaluation of GFA for an alloy is still a confusable and arguable problem although the critical diameter (dc) has been provided for a long time as an evaluation parameter of GFA. Recently, we found dc of a certain alloy can be strongly influenced by casting factors, e.g. casting temperature (overheating), casting time (speed) and casting atmosphere (trace gas elements). The proper and careful adoption of optimal casting factors is important for the corrective evaluation of GFA of alloys. Furthermore, we combined some traditional casting techniques with rapid solidification techniques to develop new casting technique for the fabrication of BMGs with special dimension, like super-long bulk glassy rods and micron-scale inner holes, which provide new potential applications of BMGs.

New Ti-Based Bulk Metallic Glasses for Biomedical Application: *Xidong Hui*[1]; Xialiang Zhou[1]; Xiaohua Chen[1]; Xiongjun Liu[1]; Yuan Wu[1]; Zhaoping Lu[1]; [1]University of Science and Technology Beijing

In this work, new Ti-Zr-Cu-Pd-Sn, Ti-Zr-Cu-Pd-Sn-Hf and Ti-Zr-Cu-Pd-Sn-Hf-Si BMGs were successfully fabricated by copper mold casting method. The compositional feature of this kind of Ti-based BMGs is that they don't contain elements which are harmful to human body (e. g. Be and Ni etc), and the content of Cu is lower than that in Ti40Zr10Cu34Pd14Sn2. It is shown that these glassy alloys have good thermal stability and wide supercooled liquid regions, resulting in relatively high glass forming ability. The compressive strength and plastic strain of this kind of BMGs reach as high as 2600 MPa and 3.6%. The electrochemical corrosion measurements and immersion tests show that the corrosion resistance properties of these Ti based BMGs are superior to those of Ti40Zr10Cu34Pd14Sn2, Ti6-Al4-V and 316L stainless steel in NaCl, HCl, NaOH and PBS solutions. It is believed that these Ti-based BMGs are competitive candidates for future biomedical materials applications.

12:05 PM
Effect of Tungsten Reinforcement Particle Sizes on the Fabrication of Hf-Based Metallic Glass Matrix Composites: *Min Ha Lee*[1]; Daniel Sordelet[2]; Jürgen Eckert[3]; [1]Korea Institute of Industrial Technology; [2]Caterpillar Advanced Materials Technology Group; [3]IFW Dresden

Due to limitations in decreasing the reinforcement size as well as processing complications, most composites have not achieved uniform nanometer-size scale homogeneity. We investigated the effect of tungsten metal particle sizes from nanometer scale to micrometer scale on the thermal stability and reactivity of uniformly dispersed metal particles in Hf-based metallic glass alloy melt at elevate temperature (1673K). The effect of particle size on solubility is significant for particles less than about 100 nm in radius. In case of fine metal particle with 20 nm in diameter, the solubility of metal remarkably increases around 700% compare to that of coarse metal particle. The mechanisms and kinetics of this dynamic growth of particle are discussed and developing techniques to obtained freezing microstructure of particle reinforced composites using by rapid solidification process was presented.

12:15 PM Invited
Ferromagnetic Fe-Based Bulk Metallic Glasses with Low Glass Transition Temperature and Large Supercooled Liquid Region: *Wei Zhang*[1]; Canfeng Fang[2]; Akihiro Makino[2]; Akihisa Inoue[3]; [1]School of Materials Science and Engineering, Dalian University of Technology; [2]Institute for Materials Research, Tohoku University; [3]WPI, Advanced Institute for Materials Research, Tohoku University

Fe-based bulk metallic glasses (BMGs) have gained considerable attention due to their low material cost and many unique properties, such as excellent soft magnetic properties, high strength, viscous flow workability in the supercooled liquid state, high corrosion resistance, etc. However, most of these Fe-based BMGs show high glass transition temperatures (Tg) or narrow supercooled liquid region (ΔTx), which hinder their thermoplastic formability. In present work, new ferromagnetic Fe-based BMGs have been synthesized in the (Fe, Ni, Co)-Mo-(P, C, B, Si) alloy system. The BMGs possess low Tg below 720 K, wide ΔTx of over 90 K, and high GFA with critical sample diameters of ~4 mm. The alloys also exhibit rather high saturation magnetization of 0.66–0.93 T, low coercive force of 1.47–5.34 A/m, and high compressive yield strength of over 3000 MPa with a distinct plastic strain. In addition, the thermoplastic formability of the BMGs is investigated.

12:35 PM
New Fe-C-Si-B-P-Cu Amorphous and Nanocrystalline Alloys Concurrently Possessing High Glass Forming Ability and Good Soft Magnetic Properties: *Jingen Gao*[1]; H.X. Li[1]; Y. Wu[1]; Z.P. Lu[1]; [1]University of Science and Technology Beijing

In order to improve energy saving needed for conservation of environment, the soft magnetic amorphous ribbons applied in the electrical power supplies demand to have high saturation magnetization and large thickness simultaneously. However, obtaining large glass-forming ability (GFA) is always at expense of the saturation magnetization due to alloying nonmagnetic elements substituting Fe. Here we reported our surprising finding that the optimum minor additions of the Cu element which have positive enthalpy of mixing with the main constituent could not only dramatically enhance the GFA but also improve the soft magnetic properties. This surprising finding was realized by tuning formation of the nanosized □-Fe clusters and annealing conditions. Moreover, the underlying mechanisms for the beneficial effects of the minor Cu doping are also presented.

CFD Modeling and Simulation in Materials Processing: CFD Modeling in Materials Processing I

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS Materials Processing and Manufacturing Division, TMS: Process Technology and Modeling Committee, TMS: Solidification Committee
Program Organizers: Laurentiu Nastac, The University of Alabama; Lifeng Zhang, Missouri University of Science and Technology; Brian Thomas, University of Illinois at Urbana-Champaign; Adrian Sabau, Oak Ridge National Lab ; Nagy El-Kaddah, The University of Alabama; Adam Powell, Metal Oxygen Separation Technologies, Inc.; Hervé Combeau, Institut Jean Lamour

Monday AM — Room: Asia 4

Fluid Flow, Solidification and Inclusion Entrapment during Steel Centrifugal Casting Process: *Lifeng Zhang*[1]; Edith Martinez[1]; Kent Peaslee[1]; [1]Missouri University of Science and Technology

The current study investigated the multiphase fluid flow, heat transfer, solidification of the steel, and the motion and entrapment of inclusions during centrifugal casting process using FLUENT software. User-defined functions (UDFs) were developed to add a speed with a value related to the rotation speed and radial distance to the solidified steel, to exert a centrifugal force to the motion of inclusions, and to add the entrapment condition of inclusions at the solidifying shell and export the entrapment locations of inclusion. The calculation shows that there are two peaks of inclusions along the thickness of the produced tube: one at close to outer surface and another one close to the inner surface of the tube. With larger rotation speed, inclusions tend to be entrapped more towards the inner surface. The calculation agrees well with the industrial measurement.

A Coupled CFD-Thermodynamic-Kinetic Model to Simulate a Gas Stirred Ladle Refining Process: Raj Venuturumilli[1]; *Pavan Shivaram*[2]; [1]ANSYS, Inc.; [2]U.S. Steel Corporation

Dynamics between molten metal and slag in a ladle is of immense interest to the steel industry during steel conditioning through desulphurization and reoxidation reactions in a ladle. Over the years, studies have shown that these processes can be optimized by controlled metal-slag stirring or mixing. For this purpose, argon gas stirring is commonly used. A three dimensional multiphase computational fluid dynamics (CFD) model is developed to study fluid stirring in the ladle. Furthermore, the CFD model is coupled to a thermodynamic and kinetic model to predict the slag-metal interactions. Argon, molten metal and slag are modeled as three separate phases in an Eulerian framework. Desulphurization process in a ladle furnace is among the phenomena studied. The model provides an understanding of the kinetics of the process as well as a means to predict the extent of desulphurization after a given process time.

A Micro-Macro Model of a PEM Fuel Cell System: *Thiyagarajan Paramadhayalan*[1]; Hrushikesh Pimpalgaonkar[1]; Suresh Sundarraj[1]; [1]General Motors

In this paper, a model of the fuel cell system has been proposed to account for the membrane physics at the micro level which is coupled with the macroscopic flow and mass transport phenomena occurring in a single channel of a PEMFC system. We have developed a novel approach to model the catalyst layer electrochemical processes in a Membrane Electrode Assembly and coupled it with mass transport and fluid flow calculations at the channel level using STAR-CD commercial software. This micro-macro model results of the cell voltage and the current density have been validated with previous literature data. A sensitivity analysis has been carried out to study the effect of the model parameters such as catalyst loading, width of the catalyst layer as well as the channel dimensions and fuel mass flow rate on the overall performance of the PEMFC.

9:50 AM
Mathematical Modelling of Welding Process of Al/Al2O3 Nanocomposites Produced by Solidification Route: *Payodhar Padhi*[1]; France Behera[1]; [1]Konark Institute of Science & Technology

The present study proposes to model of the thermo fluid dynamics of the molten pool created during an arc fusion welding process of aluminium metal matrix Nano composites (MMNCs)produced through solidification rout.The aluminium metal matrix nano composites (MMNCs) has been developed by Padhi et al. using solidification process. The said nano composites are subjected to MIG welding. The volume of fluid method and the heat transfer models have been applied using ANSYS R12 to study the welding process.Heat affected zone is not very large compared to the general aluminium alloy welding because of the presence of nano particles.Here nano particles play a major role. During welding, the nano particles present in the weld pool did not settle down since the particles are very fine. The welding joints are very strong compare to the general welding as it behaves like composite.

Modeling the Effects of Tool Geometries on the Temperature Distributions and Material Flow of Friction Stir Aluminum Welds: Hrusikesh Mohanty[1]; *Manas Mahapatra*[1]; Pradeep Kumar[1]; P K Jha[1]; [1]Indian Institute of Technology Roorkee

During friction stir welding, the tool geometries affect the weld together with the process parameters like welding speed, vertical pressure and tool rotational speed. The present investigation deals with the three dimensional computational fluid dynamics modeling of friction stir welding process considering material flow around the tool, welding speed with respect to tool geometries. Friction stir welding tools with different tool geometries were used for the experiments to achieve acceptable aluminum welds. The temperatures near the welds for each tool were experimentally observed. In three dimensional computational fluid dynamics model, temperature dependent material properties of the aluminum alloy was used.Thermal analysis was carried out considering rotational speed, vertical pressure and traverse speed for the tool geometries. The numerically predicted stirring patterns and temperature profiles closely matched with the experimental ones.

10:50 AM
Determination of Heat Transfer Coefficient Distribution at Part Surface during Press Quenching Process Using CFD: Morgan Guardino[1]; Soraya Benitez[2]; *Liang He*[1]; Richard D. Sisson[1]; [1]Wocester Polytechnic Institute; [2]Sikorsky Aircraft

A computational fluid dynamic (CFD) analysis of a gear within a press quench was performed to investigate the effect of oil flow on the heat transfer coefficient (HTC) distribution at the gear surface. A CFD model, built in Fluent within ANSYS Workbench, used an energy and a viscous flow model to calculate the HTC values between the gear and the oil. The results showed where uneven cooling, due to HTC variation, was likely to occur and indicated that a slower oil velocity in this situation caused a larger HTC distribution when compared to a faster flow rate. The results of this model provided insight into the press quenching process and could potentially be used to help improve the heat treatment of the gear.

11:10 AM
Fuzzy Extraction Separation Optimized Process of Tm, Yb and Lu Enriched Oxides by Computer Simulation: Fengli Yang[1]; *Sh Yang*[1]; Mingzhou Li[1]; Changren Tong[1]; [1]Jiangxi University of Science and Technology

According to characteristics of Tm, Yb and Lu enriched oxides composition and problems in its traditional extraction separation process, the computer simulation of a optimized fuzzy extraction separation process, in which three products with high purity(>99.99%) could be obtained at same time, was carried out. Distributing curves of every element in both organic and aqueous phases were worked out. Distribution rules of rare earth elements in every stage of the optimized extraction process were studied. The computation results of economical and technical index showed the consumption of the acid and base chemical reagents in the optimized process would be saved more than 30%.

11:30 AM
Understanding Fuming during Metal Refining by CFD: *Jan Erik Olsen*[1]; Mari Naess[2]; Gabriella Tranell[2]; [1]SINTEF Materials & Chemistry; [2]NTNU

Fume produced during metal refining exposes plant operators for disease and health issues. With the motivation to reduce the risk for exposures a CFD model has been developed to better understand the underlying mechanisms and make predictions of potential design modifications. The process considered is gas stirred refining of silicon metal. The model accounts for conservation of mass, momentum and energy by the classical CFD approach. Additionally radiation of heat and species conservation with reactions are included in the model. Results are compared with measurements. It is shown that understanding the flow pattern is important for reducing the fuming rate.

11:50 AM
CFD–Based Modelling on Interfacial Heat Transfer for Water Quenching: *Gang Wang*[1]; Yiming Rong[1]; [1]Tsinghua University

Water quenching is one of common heat treatment processes with complex physical phenomenon which involves vaporizing, bubbling and convection. The current simulations of liquid quenching processes are conducted by using an average value of heat transfer coefficient obtained from experimental measurement under a strong assumption. A preliminary model for water quenching has been presented in this paper based on multiphase flow theory. The conjugate heat transfer method is used to describe thermal conduction in the simplified workpiece, and generation, growth and flow of bubbles are modeled by using Eulerian-Eulerian method for the gas-liquid multiphase flow. The simulation result shows the intense variation of heat exchange through the interface between workpiece and liquid and unsteady distribution around the solid surface.

12:10 PM
Mathematical Model of Purges Process at a Heat Treatment Furnace: *Irma Hernández*[1]; Jacobo Vargas[2]; [1]Universidad Autónoma del Estado de México; [2]UAEMex

In this work a mathematical model of the purges process at an industrial cylindrical furnace was constructed using CFD, a bi-dimensional nitrogen jet was ejected in the contained air of the furnace. The evolution at the outlet gas composition of the furnace was computed using the commercial software PHOENICS to solve Navier Stokes and the classical k-e turbulence equations for both, nitrogen and air phases. The results were compared with plant measurements, founding a good agreement. A new geometry for the nozzle was computationally proved with a different velocity profile in the nitrogen purging gas , the computed results presented a major jet expansion for a minor distance from the nozzle and a quickly displacement in the initially contained air at the furnace, it might produce a faster purging process.

Characterization of Minerals, Metals, and Materials: Characterization of Ferrous Metals I

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Materials Characterization Committee
Program Organizers: Jiann-Yang Hwang, Michigan Technological University; Sergio Montero, State University of North Rio De Janeiro; Chenguang Bai, Chongqing University; John Carpenter, US Department of Energy; Donato Firrao, Politecnico di Torino; Byoung-Gon Kim, Korea Institute of Geoscience & Mineral Resources; Mingdong Cai, Schlumberger

8:30 AM
Characterization of the Microstructure of Compacted Graphite Cast Iron: *Vahid Rastegar*[1]; [1]Dalarna University

Characterization of microstructure and revealing dendrites in microstructure and also measuring DAS and distribution of silicon were studied in various pieces of CGI with different mishmetal percentage. Quantitative and qualitative metallography were carried out on various steps of cast samples. Distribution of silicon was studied quantitatively using spot analysis with SEM. Furthermore, effects of two variables (cooling rate and mishmetal percentage) on DAS were investigated. In order to color metallography, samples were plunged into boiling solution of 18% KOH, 9% NaOH and 9% picric acid. It was inferred that the microstructure coloration varies according to the sequence: green, red, yellow, blue, dark brown, light brown as silicon content decreases. After observing dendrites, DAS was measured. In this method, it seems to be possible to predict mechanical properties of CGI by knowing DAS and without any destructive testing. It was concluded that DAS decreases as mishmetal amount increases and it increases as the cooling rate increases.

8:50 AM
EBSD Analysis of Complex Microstructures of CSP® Processed Low Carbon Micro-Alloyed Steels: *Carl-Peter Reip*[1]; Reinhard Flender[2]; Matthias Frommert[2]; [1]SMS Siemag AG; [2]Salzgitter Mannesmann Forschung GmbH

Today there is a growing demand for strip of superior steels with specifically tailored technological properties. Especially strips of high-strength, micro-alloyed steel grades applied to manufacture longitudinally and spiral-welded pipes are a growth market. Tubes are generally required to have high strength and sufficient toughness values and thus favour specific hot strip microstructures. The correlation of chemical analysis, process parameters and mechanical properties with microstructural features is still a challenging task. During the last decades, scanning electron microscopy (SEM) and electron backscatter diffraction (EBSD) have become useful tools for the characterization of complex microstructures. The EBSD data provides an immense variety of post-processing possibilities, e.g. related to grains, grain boundaries, misorientations or texture. This paper highlights the results of an advanced analysis of microstructures representing industrial produced hot-rolled strips and presents an approach to define and quantify some essential microstructural parameters.

9:10 AM
Empirical Models of Cold Working Effect in Steel Tube Production: *Robert Batson*[1]; Jing Zhang[1]; [1]University of Alabama

Carbon steel is purchased in coils, slit to width, and fed into electrical resistance welding mills that convert it into round, square, or rectangular structural tubing. The objective of this project was to establish relationships between certain properties (yield, tensile, elongation) of the tube after cold working and those of the flat coil before cold working, and build empirical predictive models from a data base of before-and-after properties provided to us by a tube manufacturer. Using multiple regression analysis, a set of three regression models was built with tube geometry and flat steel properties as the independent variables, and tube physical properties as the dependent variables. These regression models can be used by the manufacturer for prediction of results when coil properties are known, and for computation of ideal coil steel specifications. We provide a sample solution of the latter "inverse problem" using the three equations and Excel Solver.

9:30 AM
Correlation of Cu Precipitation with Austenite Decomposition in a Continuously Cooled Multicomponent Steel: An Atom Probe Tomography Study: *Qingdong Liu*[1]; Wenqing Liu[1]; Shijin Zhao[1]; Qifeng Zeng[2]; [1]Shanghai University; [2]Shanghai Nuclear Engineering Research & Design Institute

The Cu precipitation in continuously cooled multicomponent steel is examined by atom probe tomography. During austenite decomposition, the solutes partitioning behaviors at the migrating ferrite / austenite interphase and the micro-constituents such as dislocation and cementite in the ferrite have a great effect on the nature of Cu precipitation. Both the actual sizes of Cu precipitates and austenite decomposition process correlate with the compositional evolution of Cu precipitates with the different level of Ni and Mn segregation. The partitioning behaviors of solutes atoms at ferrite / austenite interface have an effect on the kinetics of ferrite formation and its final microstructure. The micro-constituents such as dislocation, cementite in ferrite and ferrite / austenite hetero-phase boundary determines the compositional changes of Cu precipitates. The transition bcc Cu precipitates are considered to nucleate through interphase precipitation and grow at crystal defects after being embedded within ferrite.

9:50 AM
Effect of Epsilon Martensite on Low Temperature Tensile Properties of Fe-12Mn and Fe-14Mn Steels: *Jung-Su Kim*[1]; Jong Bae Jeon[1]; Joong Eun Jung[1]; Young Won Chang[1]; [1]POSTECH

High manganese steels containing 10 ~ 14% of Mn are now known to exhibit excellent combination of tensile strength and ductility. Their mechanical properties are strongly affected by the deformation-induced martensitic transformation (DIMT) of metastable phases. The present Fe-Mn alloys contained ε-martensite formed during prior thermal treatments, which transforms into α'-martensite during the plastic deformation. It is thus important to study the DIMT kinetics of ε-martensite in relation to the mechanical properties of these alloys. The transformation kinetics of ε->α' has therefore been investigated in this study using the recently proposed kinetics equation by one of the authors to evaluate the stability of ε-martensite. The stability of ε-martensite phase was found to increase as the test temperature was decreased, contrary to the case of retained austenite being more stable at higher temperatures. This reversed stability-temperature relationship appears to provide an enhanced ductility at lower temperatures exhibited in the present alloys.

10:10 AM Break

10:20 AM
Microstructural Investigation of Carbon Steel after Hot Rolling to Optimize Complex Hot Forming of Thick Plates: *Gerhard Tober*[1]; Okechukwu Anopuo[2]; Petra Maier[1]; [1]University of Applied Sciences Stralsund; [2]CORTRONIK GmbH

In this study, an investigation on the microstructure of hot rolled steel S355 was conducted to optimize process parameters of complex forming, which combines rolling and bending. The best sets of parameters are worked out based on homogeneous mechanical properties and microstructure within the varied deformation degree with maximum at f = 1.14 on a 25 mm thick plates. Mechanical properties, especially of heavy plates, are strongly influenced by the local deformation degree, strain rate and temperature. Detailed microstructural analyses showed that the ferrite-pearlite band structure recrystallizes near the surface, while maintaining homogeneous microstructure within the deformed work piece. Surface decarburization was also observed and this leads to decrease in hardness. To minimize iron oxide formation which could lead to side cracking, reduction in exposure time to temperature was suggested. One the other hand, temperature reduction below a critical value would risk the accurate forming process.

10:40 AM
Microstructural Characterization of Fe-Mn-C Ternary Alloy under Near-Rapid Solidification: *Wenbin Xia*[1]; Rong Yang[1]; Changjiang Song[1]; Qijie Zhai[1]; [1]Shanghai University

This paper focus on the influence of carbon content and cooling rate on the microstructure and phase formation of Fe-Mn-C alloys under near-rapid solidification. When manganese content is about 11wt.%, more e-martensite can be obtained with cooling rate increasing when carbon content is 0.14wt.%, the formed phase changed from a phase to □ phase when 0.74wt.% carbon is added to the samples, and when carbon content up to 2.1wt.%, carbide can be obtained in the sample. A host of stacking fault, which attributes to the strain-induced martensite, can be observed in the sample. The microhardness increased with cooling rate increasing, and under the same cooling rate, the microhardness of samples with 0.14wt.% carbon is highest.

11:00 AM
Effects of Surface Modifications on SCW Corrosion Resistance: *Jian Li*[1]; Penttila Sami[2]; Wenyue Zheng[1]; [1]CANMET-MTL; [2]VTT

Materials selection for Gen IV supercritical water reactor in-core components faces major challenges due to severe operating condition. Beside high-temperature mechanical properties, SCC and general corrosion resistance of commercially available materials are also major focuses in recent research. Recent reports suggest that certain types of surface modifications are beneficial to SCW corrosion resistance. In this study, the effects of surface modifications are investigated, and possible mechanisms for improved corrosion performance are discussed.

11:20 AM
Interface Mass Transfer during the Tribofinishing Process: *Isaias Hilerio*[1]; Dulce Medina[2]; Victor Cortes[2]; Juan Muñoz[2]; [1]UAM AZCAPOTZALCO; [2]UAM Azcapotzalco

Tribofinishing process is investigated as a means to reach a quality state for the surface treated. For obtain this result is utilized the following combination: Machines, Additives, Abrasives and Pieces to be treated. The machines determines the energy utilized in the process. The additives are utilized to create a superficial tension that permits withdraw material. The abrasives are the components that make the work. During the commented process there occurs a mass transfer at the interface of the piece to be treated and the abrasive charge. It is mentioned the interaction between piece treated and abrasives as an interaction of three bodies. It is shown the evolution of surface roughness to evaluate their quality. This situation is studied for Titanium as a possibility for application in prosthesis. With these results is intended to produce a model of the mass transfer that would allow to have further control in the process.

11:40 AM
Martensitic Meso- and Nanostructures in High-Carbon Low-Alloyed Steels: *Albin Stormvinter*[1]; Peter Hedström[1]; Annika Borgenstam[1]; [1]KTH Royal Inst. of Technology

The martensite morphology of high-carbon low-alloyed steels is commonly described as plate-like and has been studied extensively in the past. However, recently not much attention has been given to characterization of high-carbon martensite. In the present work the SEM-EBSD technique was applied to steels with carbon contents: 0.86, 1.20 and 1.67 mass% C. In contrast to previous works, SEM-EBSD enables characterization through both apparent morphology and crystallography simultaneously. This seems suitable, since although ferrous martensite may appear irrational, it is known to have well-defined crystallographic relationships. In addition, the substructure of the martensite units in the 1.20 and 1.67 mass% C steels was studied by TEM. The results demonstrate that even though the apparent morphology seems plate-like, several unexpected features are found when the meso- and nanostructure are studied in depth. This study has been part of a project to establish a good characterization procedure for martensitic steels.

Phase-Field Modeling of Microstructure Evolution in Elastically Inhomogeneous Systems: *Long Qing Chen*[1]; Saswata Bhattacharyya[1]; Taewoo Heo[1]; Jianjun Wang[1]; Qun Li[1]; [1]Pennsylvania State University

Essentially all materials in applications are elastically inhomogeneous, i.e., the elastic constants are different in different locations of a solid material. Although for some cases in which the elastic inhomogeneity is small homogeneous modulus approximation is adequate for predicting microstructure evolution during phase transformations, many others require the solution to an elastically elastic inhomogeneous system. Examples include solid materials that contain voids, cracks, and polycrystals. This presentation will provide a brief review of various numerical treatments and their efficiencies of elasticity inhomogeneity within the context of phase-field method, starting from the Khachaturyan's theory of microelasticity. Examples of applications to be presented include phase transformations and microstructure evolution in polycrystalline materials, grain boundary motion under the influence of an applied stress, deformation twinning in structural materials, morphology of lithium-rich and lithium-depleted two-phase mixtures in Li-intercalation compounds, and evolution of voids/cracks or crack/domain interactions.

9:05 AM Invited
Phase Field of Prototyping Structural Transformations and Properties in Systems with Long-Range Interaction: *Armen Khachaturyan*[1]; [1]Rutgers University

Structural transformations in solids results in a strong long range interaction between transformed finite elements. This is the long-range character of this interaction that is responsible for the nano- and submicron heterogeneous structure and for important properties of material. In the structural materials the long-range interaction has a dipole-dipole character. It can be the strain-induced interaction, electrostatic, and manetostatic dipole-dipole interaction or their combination in structural,ferroelectric and ferromagnetic materials. The use of the Phase Field approach, which integrates these interactions, allows us to realistically prototype a spontaneous microstructure evolution and the structure-property relations. It does not require any ad hoc assumptions about a transformation path that would diminish the predicting power of the modeling. This talk presents a review of a current status of the Phase Field of modeling of systems with a long-range interaction.

9:30 AM Invited
Diffusive Molecular Dynamics Simulation of Displacive-Diffusional Coupling in Solid State Processes: Sanket Sarkar[1]; William Cox[1]; Ju Li[2]; *Yunzhi Wang*[1]; [1]Ohio State University; [2]MIT

In solid processes displacive-diffusional coupling is a rule rather than an exception. For example, curvature driven grain growth may involve coupled tangential (displacive) and normal (diffusional) migration of grain boundaries. Creep deformation often involves conservative and non-conservative motion of dislocations. Mechanistic studies of these processes require modeling capabilities at atomistic length scales but diffusional time scales. In this presentation we review a new computational method called Diffusive Molecular Dynamics (DMD) developed recently, which captures diffusional-displacive evolution of complex microstructures at atomic scale by coarse graining over atomic vibrations and evolving atomic density clouds. Derived in grand canonical ensemble, DMD is a chemical mean-field extension of the variational Gaussian method coupled with master equation for diffusion solved on a moving atomic grid. Several examples involving simultaneous diffusional and displacive processes will be presented, with which we show the importance of sampling the free-energy landscape along coupled displacive-diffusive reaction coordinates.

Origin of Negative Thermal Expansion Phenomenon in Solids: *Zi-Kui Liu*[1]; Yi Wang[1]; Shun Li Wang[1]; [1]The Pennsylvania State University

We show that the negative thermal expansion (NTE) phenomenon originates from the existence of high pressure, small volume phases with higher entropy, with their configurations present in the stable phase matrix through thermal fluctuations, thus exists frequently. Consequently, it extends the platform for designing structures with desired thermal expansion properties whether positive, negative, or zero. The theory is validated for a range of pure elements and compounds and utilized to provide insights to the NTE phenomenon in INVAR and ZrW2O8.

Coherent Precipitation in Ternary Al Alloys: Colin Ophus[1]; Maarten de Jong[2]; *Mark Asta*[2]; Marcel Sluiter[3]; Ulrich Dahmen[1]; Velimir Radmilovic[4]; [1]Lawrence Berkeley National Laboratory; [2]University of California, Berkeley; [3]Delft University of Technology; [4]University of Belgrade

This talk will discuss recent studies obtained in combining advanced electron microscopy techniques and first-principles calculations in the study of coherent precipitation phenomena in ternary Al-based alloy systems. The studies have been motivated by observations in the Al-Si-Ge and Al-Sc-Li systems. In the former system, it is observed that the precipitation of stable diamond-cubic precipitates are preceded by coherent precipitation of nano-scale coherent precipitates that have a mixed Si-Ge content. The results are analyzed in the framework of a first-principles statistical-thermodynamics treatment that explicitly accounts for elastically-mediated interactions. We further discuss results obtained by combining first-principles-based thermodynamics methods with mean-field models for diffusion-limited precipitate growth in the Al-Sc-Li system. The results explain that the observed, highly monodisperse size distributions for core-shell precipitates in this system arise from capillary effects that can be readily exploited in conventional thermal processing.

Interplay between Surface Segregation, Ordering, and Adsorption Behavior of Pt-Alloy Surfaces: Wei Chen[1]; *Chris Wolverton*[1]; David Schmidt[2]; William Schneider[2]; [1]Northwestern University; [2]Univ. of Notre Dame

Bimetallic surface alloys are considered a promising type of catalyst for improved activity and selectivity. Understanding surface structure and its effect on catalytic performances plays a critical role in designing catalysts from surface alloys. We have studied the surface structure and ordering of Pt alloys surfaces, such as Pt-Au(111) and Pt-Ti(111), using a first-principles cluster expansion (CE) based method. Even though the Au-Pt system is phase-separating in the bulk, we find a series of thermodynamically stable, laterally ordered striped structures of AuPt(111) surfaces. In contrast, Pt-Ti(111) subsurface alloys show a strong ordering tendency, in analogy with bulk Pt-Ti alloys. A series of stable ordered Pt-Ti(111) subsurface structures are identified from the two-dimensional (2D) CE. In both cases, we calculate the interplay between metal ordering and segregation at the surface and lateral interactions between adsorbates (O, S, H, and NO) on these surfaces.

Twin Boundary Behaviors of Magnetic Shape Memory Alloys: *Yongmei Jin*[1]; [1]Michigan Technological University

Twin boundary behaviors of magnetic shape memory alloys are investigated by phase field micromagnetic microelastic model. The simulations show coupled magnetic and elastic domain evolutions under magnetic field, and reveal various aspects of twin boundary behaviors, including pinning effects of twin boundary to magnetic domain wall motion, varying twinning stress with twin volume fraction, different domain evolution pathways depending on the magnitude and direction of external magnetic field, and time-dependent twin boundary motion. The respective contributions from magnetocrystalline anisotropy, twinning strain, magnetostrictive strain, long-range magnetostatic and elastostatic interactions, and twin boundary mobility are analyzed. The findings help explain peculiar domain processes and magnetic field-induced strain behaviors observed in magnetic shape memory alloys.

Defects and Properties of Cast Metals: Metal Cleanliness

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Solidification Committee
Program Organizers: Mark Jolly, University of Birmingham; Brian Thomas, University of Illinois at Urbana-Champaign; Carl Reilly, University of British Columbia

Monday AM	Room: Oceanic 4

8:30 AM Introductory Comments

8:40 AM
Films and Bifilms – An Update: *John Campbell*[1]; [1]University of Birmingham

It is proposed that bifilms are the only source of cracks generally known as Griffith cracks. Failure modes of cast products involving the creation of porosity, hot tears, cracks and failure modes of solid metals in room temperature tension and high temperature creep (together with cavitation failure in superplastic forming) all appear to be explicable assuming the presence of bifilms. Furthermore, their control over cast microstructures of metals and alloys is profound as a result of the favored precipitation of intermetallics and second phases on the wetted exterior faces of bifilms. Modification of Al-Si alloys and even possibly the structure of cast irons becomes explicable for the first time. The discovery of bifilms promises to revolutionize our understanding of the behavior of cast and wrought engineering metals. Conversely, bifilm-free metals promise unprecedented properties.

9:00 AM
Fluid Flow and Inclusion Entrapment in the Runner Steel During Ingot Casting: *Lifeng Zhang*[1]; Yongfeng Chen[1]; Shufeng Yang[1]; [1]Missouri University of Science and Technology

This paper studied the nonmetallic inclusions in the steel of an ingot runner. Thermodynamic modeling was performed to study the formation mechanism and sources of inclusions. CFD modeling on fluid flow, heat transfer, solidification of molten steel was carried out and the entrapment of inclusions in runner steel was predicted and compared with the measurement. Al2O3-based inclusions were the main ones in the steel samples. MgO\149;Al2O3 mainly stemmed from the lining refractory. The high MnO inclusions in the runner steel came from the runner slag. The effect of natural convection was very important for the cooling and solidification of the steel in the runner. Both the observation and the modeling show that > 50 μm inclusions more accumulated on the upper area in the runner and < 50 μm inclusions dispersed well and more accumulated on the lower area of the runner.

9:20 AM
Modeling of Mould Filling of Low-Pressure Die-Cast Aluminum Alloy Wheels: *Jianglan Duan*[1]; Daan Maijer[1]; Steve Cockcroft[1]; Carl Reilly[1]; Ken Nguyen[1]; Dominc Au[1]; [1]University of British Columbia

As part of a program to understand the influence of die filling on defect formation in low-pressure die-cast aluminum wheels, work has been ongoing toward the development of a thermal-fluid model of the filling process. A transparent planar die section has been built, instrumented and tested using water to explore the role of pressure and venting on the free surface behavior of water and to produce data for validation of the flow aspects of the model. Comparison to the experimental data confirms the model's ability to accurately predict the filling in a planar die and that fill pressure and venting influences the free surface behavior significantly. To examine conditions more similar to the industrial process the material properties of aluminum were input to the model and flow in a periodic section of the production die has been simulated. Once again the fill pressure and venting are found to be critical.

9:40 AM Break

10:00 AM
Quench Sensitivity of 2024, 6063 and 7075: *Engin Tan*[1]; Ali Tarakcilar[1]; Derya Dispinar[2]; [1]Pamukkale University; [2]University of Istanbul

The influence of quenching temperature during solution heat treatment of 2024, 6063 and 7075 was investigated by means of tensile testing. SEM analyses were carried out on the fracture surfaces. In addition, reduced pressure tests were carried out to correlate the mechanical test results with metal quality. The alloys were received as extruded. SIMA process was applied to achieve spherical grain structure. T6-solution heat treatment was carried out and quenching was done in temperature controlled water bath. Two different quenching temperatures were selected: 20°C and 80°C. The results were analysed by Weibull statistics. It was found that Weibull moduli of all test results were similar for all the alloys and there was a good correlation between bifilm index. Ultimate tensile strengths were high when samples were quenched at 20°C. On the other hand, elongations at fracture were high for the samples quenched at 80°C.

10:20 AM
Effect of Different Casting Parameters on the Cleanliness of High Manganese Steel Ingots Compared to High Carbon Steel: *Petrico von Schweinichen*[1]; Zhiye Chen[1]; Dieter Senk[1]; Alexander Lob[1]; [1]RWTH Aachen University, Department of Ferrous Metallurgy, Intzestrasse 1, 52072 Aachen, Germany

Nowadays, the demand of excellent steel properties leads to the birth of new steel grades such as high manganese TWIP and TRIP steels which are scientifically investigated in the framework of the SFB 761 "Steel - *ab initio*" in Germany. However, this demand brings new challenges to steel producers with regard to the production of these high-technology products, which are mostly produced by ingot casting. The major defects of casted ingots like cavity, macro segregation, surface quality and cleanliness as well as as-cast structure and the position of CET are systematically investigated at the RWTH Aachen University. One low alloyed steel and one high manganese alloyed steel with different casting parameters with regard to superheat, casting atmosphere, pouring rate, hot top and stirring conditions have been studied in this paper. The main focus of this research is the investigation of the cleanliness of the ingots of both steel grades.

10:40 AM
Tensile Properties, Porosity and Melt Quality Relation of A356: *Derya Dispinar*[1]; Shahid Akhtar[2]; Arne Nordmark[1]; Freddy Syvertsen[1]; Marisa Di Sabatino[2]; Lars Arnberg[2]; [1]SINTEF Materials and Chemistry; [2]NTNU

The movement of liquid aluminium in mould cavity plays a significant role in determining the cast part's quality. Turbulence and entrained defects lower melt quality. What has usually been disregarded is the melt quality of the starting material. If the charge material is of bad quality, the effectiveness of the casting method losses its importance. Therefore, in this work, gravity and counter gravity casting methods were used to cast A356 in a step mould die. Reduced pressure test samples were collected to assess melt quality by means of bifilm index. It was found that although the measured porosity level was lower in LPDC castings, the tensile properties were lower than GDC. In fact, LPDC melt had higher bifilm index than GDC which was the indication of low melt quality. Thus, this investigation has shown that the metal quality has a dominant effect over the mechanical properties than the porosity content.

11:00 AM
Investigation on Non-metallic Inclusions of Q420 Ingots Cast by Bottom Teeming: *Yanzhao Luo*[1]; Jiongming Zhang[2]; Chao Xiao[2]; Jin Yang[2]; [1]University of Science & Technology Beijing ; [2]University of Science & Technology Beijing

For analyzing the composition and morphology of inclusion in the bottom pouring mold cast ingot of Q420 steel, the experimental samples sampled separately at different locations of the ingot were investigated using optical microscope observation, SEM analysis and slim electroanalysis extraction methods. The results showed that the average T.O. in the ingot is about 10ppm at a lower level, indicating that ingot is high purity. The index of microscopic inclusions in the ingot is between 2.09~4.98/mm2, the microscopic inclusions in the middle of ingot are less than other parts. The contents of large sized inclusions in the ingot were between 5.7 and 22.5mg/10kg, which composed mainly by SiO2, Al2O3 and a small amount of Na2O and K2O. The large sized inclusions were mainly from the mold slag during bottom pouring and its content in the bottom of the ingot is much higher than that in the other parts.

11:20 AM
Tracking the Formation and End Location of Oxides in Orthopaedic Investment Casting Running Systems: *Mark Jolly*[1]; Alan Kavanagh[2]; [1]University of Birmingham; [2]Depuy Johnson &Johnson

This work was an investigation into a specific defect identified during the casting of Co-Cr-Mo for human prostheses. A leading cause of such scrap is the presence of sub-surface oxides that are exposed during post-casting machining operations. Their presence on the articulating surface and possible impact on wear and fatigue characteristics of the final product results in the casting being scrapped. Researchers at Birmingham have developed an Oxide Film Entrainment Model (OFEM) tracking algorithm capable of predicting the entrainment of oxides and tracking their movement and final location within simulations performed in the CFD package Flow3D. Validation of the model has been performed using DePuy's existing tree. The number of oxides each casting contained was shown to be dependent on the location of the castings. Metallurgical evaluation of the castings supported this finding. Modifications were made to the tree to reduce possible oxide formation and entrainment events during metal filling.

Emeritus Professor George D.W. Smith Honorary Symposium: Atom Probe Tomography

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS/ASM: Phase Transformations Committee

8:45 AM Keynote
Look Back in Wonder: A Partial View of a Lifetime's Developments in Atom Probe Technology: *Alfred Cerezo*[1]; [1]University of Oxford

In the early 80s, atom probe instruments existed in a few specialist laboratories, mainly for metallurgical studies. All-metal designs had been developed, with specimen exchange facilities, and computer data-logging systems. Early experiments with laser pulsing promised to expand the technique to semiconductor materials. Thirty years on, fully-automated 3-dimensional atom probes (3DAPs), which can switch easily between laser and voltage pulsing, are routinely being used in a wide range of laboratories to study an equally wide range of materials. What caused this massive leap forward? The seeds of change were already present in the 2-D elemental maps produced by the imaging atom probe (IAP) which, though less accurate, hinted at the vastly greater information that could be made available. It was using simple position-sensitive detectors in an IAP configuration that produced the first 3DAP data, and encouraged a wave of instrument development that led to our modern instruments.

9:15 AM Keynote
Prospects for Atomic-Scale Tomography: *Thomas Kelly*[1]; Michael Miller[2]; Krishna Rajan[3]; Simon Ringer[4]; Albina Boresevich[2]; [1]Cameca Instruments, Inc.; [2]Oak Ridge National Laboratory; [3]Iowa State University; [4]University of Sydney

Atomic-scale tomography (AST) may be defined as any technique that provides the precise three-dimensional position and identity of every atom in a "large" structure. Major breakthroughs in microscopy, condensed matter physics, and materials science will occur when this information becomes readily available. In the ultimate expression of AST, vacancies and interstitial atoms would be resolved which would enable a host of dynamic materials processes to be studied. Several experimental approaches are possible that may lead to AST. For example, by combining APT and (S)TEM, the limitations of each technique may be overcome and a robust synergy results. This 3D data could be used to generate many other types of knowledge, such as mechanical, magnetic and electrical properties, through the use of computational modelling techniques. A plan for achieving this goal will be described. Research sponsored by the U.S. DOE- Office of Basic Energy Sciences SHaRE user program [AYB and MKM].

Recent Developments in Atom Probe Microscopy: From Data to Information and through to Knowledge: *Simon Ringer*[1]; [1]The University of Sydney

During public scientific discussion at the 2008 meeting of the international field emission society, Prof. G.D.W. Smith hinted at an analogy between the notion of 'data mining', such as may be done in the context of extracting information from atom probe data, and the actual endeavour of minerals processing, where the technological stages of geological survey, mining, mineral separation, refinement and smelting processes operate in tandem to create valuable metals and alloys. We use this analogy to explain the impact of Prof. Smith's teaching and research on the research agenda around atom probe microscopy at The University of Sydney. My lecture will focus on our efforts to develop more precise approaches to the tomographic reconstruction, data analysis and recent successes in using atom probe data in first principles calculations that unravel controversies on the origins of certain behaviour in materials.

APT Applied to MgO-Based Magnetic Tunnel Junctions: *Amanda Petford-Long*[1]; Daniel Schreiber[2]; David Seidman[2]; [1]Argonne National Laboratory; [2]Northwestern University

The novel properties of magnetic tunnel junctions (MTJs) depend critically on their microstructure and composition, with variations on the atomic scale leading to variations in their properties. In its simplest form a MTJ consists of two ferromagnet layers separated by a nanoscale oxide tunnel barrier. The magnitude of the tunneling electrical current crossing the oxide barrier is a function of the relative orientation of the magnetization in the two ferromagnetic layers, an effect known as tunnel magnetoresistance (TMR). The nature of the oxide / ferromagnetic electrode interfaces is one of the critical parameters that control the magnetotransport properties of the MTJ, such as the spin polarization, tunnel barrier height, and indeed the shape of the tunnel barrier. We have used atom probe tomography and transmission electron microscopy to characterize the buried layers and their interfaces within MTJs to help explain their transport properties.

11:10 AM Invited
Atom Probe Tomography of Thin Films and Interfaces: *David Larson*[1]; [1]Cameca Instruments, Inc.

Field ion microscopy and atom probe tomography has been applied to thin films since the early development of each of these instruments. However, a fundamentally limiting problem has always been the capability of fabricate specimens contains thin film regions of interest. Over the past decade or so, specimen fabrication techniques using focused-ion beam instruments with in-situ manipulation has revolutionized preparation of such specimens. Today, a variety of nanoscale thin films (including oxides) with site-specific features may be prepared and analyzed in arbitrary directions using atom probe tomography. APT data reconstruction of such structures, however, is quite complicated and significant work remains in this area. This talk will address the current status of atom probe analysis of thin films and interfaces, using a variety of materials types as examples, and include comparison to simulated structures.

11:35 AM
Atom Probe Studies of Nitride Multilayer Hard Coatings: *Darius Tytko*[1]; [1]Max-Planck Instutut für Eisenforschung

CrN/AlN multilayers having a bilayer thickness in the nanometer range are highly promising as hard coating materials for cutting tools due to their outstanding hardness, wear and oxidation resistance. The hardness of such multilayer hard coatings can be as high as 40 GPa by controlling the interface sharpness and the bilayer period of the multilayers. However, during operation at elevated temperatures such hard coatings undergo significant microstructural changes, which can cause a decrease in hardness. The aim of this study is to elucidate the nanostructural changes of CrN/AlN multilayers upon various thermal treatments and relate them to the mechanical properties. Using RF – magnetron sputtering, CrN/AlN multilayer superlattices with different bilayer periods and compositions were produced. The basic characterization of as-sputtered and annealed multilayers was done using Atom Probe Tomography in conjunction with X-ray diffraction and transmission electron microscopy.

Modelling Image Formation in Atom Probe Tomography: *François Vurpillot*[1]; [1]GPM UMR 6634

The understanding of image formation in Atom probe Tomography is the direct consequence of the processes of field evaporation, emission and projection of ionised atoms from the "Muller" field emitter (a sharply pointed needle). Basic models of field evaporation are now more than 50 years old. The models are extremely simple and ion trajectories are known to be governed by simple electrostatic relationships. Nevertheless, because since 30 years the complexity of materials analysed with the instrument has gradually increased (from simple metals to heterogeneous materials), these simple ingredients could give rise to various image artefacts. The comprehension of these artefacts and aberrations requires the use of numerical model to improve the fidelity of image reconstruction. This paper will show how the modelling approach could be used to understand the image deformations observed experimentally in alloys, multiphase samples, multilayer samples, or more complex devices.

12:15 PM
Coupled Modeling and Observation of Morphological Change in APT of Multicomponent Materials: *Daniel Haley*[1]; George Smith[1]; [1]Univeristy of Oxford

We apply combined numerical methods to register and evolve Transmission Electron Microscopy (TEM) observations of interrupted evaporations of Al-Ge alloys. Through multiple tilt-series TEM observation of the morphology of interrupted atom probe evaporated samples, we couple TEM observations to a numerical solution of the boundary motion equations using level set methods. These methods are subsequently used to form the foundation of an experimentally driven, temporally-resolved solution to the electrostatic equation in the tip region. Such a solution allows for the computation of the projection function that occurs as a result of near-atomic scale specimen geometry during the modelled morphological change. This work is conducted with a view to providing and validating a framework for experimentally driven reconstruction of atom probe datasets from inhomogeneous materials.

Advanced Materials for Energy Storage Application: *Ilias Belharouak*[1]; [1]Argonne National Laboratory

As lithium-ion batteries continue to be developed for energy storage applications with increasing energy demands, such as electric vehicles, new materials have been developed in efforts to increase the energy density and lower the cost. Lithium-and manganese-enriched oxides recently have received much attention. These materials have overall lithium to transition metal stoichiometry of greater than 1.0 and have greater than half of the relative transition metal composition manganese. These materials are composites of layered LiMO2 (R m) (M = Ni, Co) and Li2MnO3 (C2/m) structures. The paper will provide insights into the structure of the family of Li-and Mn-enriched cathode materials that have shown promise for high capacity Li-ion battery applications.

8:55 AM
Nanoscale Testing of Low Dimensional Materials for Energy Harvesting and Storage: *Reza Shahbazian-Yassar*[1]; Hessam Ghassemi[1]; Anjana Asthana[1]; Yoke Yap[1]; [1]Michigan Technological University

Low dimensional materials have received considerable attention for their unique properties in energy storage (batteries) and energy harvesting (nanogenerators) devices. In this presentation, we cover the in-situ studies of Boron Nitride nanotubes (BNNTs), Zinc Oxide nanowires (ZnO NWs), and Silicon nanorods (Si NRs). Size scale effects were observed in ZnO nanowires and were explained by the modification of atomic structure at the nanowire surface. In addition, the rippling and bifurcation of multiwalled BNNTs were observed upon buckling and were quantified in terms of number of walls and nanotube's diameter. We also studied the mechanics of lithiated Si NRs to understand the effect of lithium intercalation into the structure of NRs.

9:10 AM
Nanostructured 3.9 V Triplite Cathode Materials for Li-Ion Batteries: *Prabeer Barpanda*[1]; Jean Marie Tarascon[2]; [1]The University of Tokyo; [2]Universite de Picardie Jules Verne

Li-ion batteries empower consumer electronics to (hybrid) electric vehicles. Here, the 3.45 V LiFePO4 is the most outstanding cathode for its low cost and safety. Benchmarking against LiFePO4, new cathode materials with higher energy density can be realized by designing novel polyanionic compounds having higher Fe2+/Fe3+ redox potential. The current work reports a novel 3.9 V (vs Li/Li+) triplite nanostructured polyanionic material, namely Li(Fe1-xMnx)SO4F [x=0.01~0.20]. It is a quantum leap in the field of battery showing the highest Fe2+/Fe3+ redox voltage ever-reported, exceeding that of LiFePO4 by 450 mV. This novel triplite phase offers excellent reversible capacity of 130 mAh.g-1 with lowest volume change of 0.3%. The local atomic disorder induced by Mn is believed to be at the origin of the triplite structure and 3.9 V Fe redox activity. This recent breakthrough in the Li-ion battery technology [Nature Materials, In Press 2011] will be described in detail.

9:25 AM Invited
A Nanofiber Approach to Advanced Lithium-Ion Battery Materials: *Xiangwu Zhang*[1]; [1]North Carolina State University

Among the various existing energy storage technologies, rechargeable lithium-ion batteries have been considered as effective solution to the increasing need for high-energy density electrochemical power sources. Novel electrospun nanofibers with functional properties can dramatically alter surface reaction and charge transport throughout the batteries, causing significant improvement in energy storage efficiency. The design of functional nanofiber materials for alternative energy systems is, therefore, a way to develop a wide range of new technologies for a healthy future. Here, we present our work on the development of advanced functional nanofibers and the integration of these materials into rechargeable lithium-ion batteries to achieve high system performance.

Carbon-Containing Nanocomposite Materials for Energy Storage: *Gleb Yushin*[1]; [1]Georgia Institute of Technology

High power energy storage devices, such as supercapacitors and Li-ion batteries, are critical for the development of zero-emission electrical vehicles, large scale smart grid, and energy efficient cargo ships and locomotives. The energy storage characteristics of supercapacitors and Li-ion batteries are mostly determined by the specific capacities of their electrodes, while their power characteristics are influenced by the maximum rate of the ion transport. The talk will focus on the development of nanocomposite electrodes capable to improve both the energy and power storage characteristics of the state of the art devices. Advanced ultra-high surface area carbons, carbon-polymer, and carbon-metal oxide nanocomposites have been demonstrated to greatly exceed the specific capacitance of traditional electrodes for supercapacitors. Rationally designed Si-C composites showed up to 8 times higher specific capacity than conventional anodes in Li-ion batteries, and stable performance for over 1000 cycles.

10:35 AM
Nanostructured Metals and Metal Oxides for Hgh Capacity Anodes of Li-Ion Rechargeable Batteries: *Ming Au*[1]; Thad Adams[1]; [1]Savannah River National Laboratory

The electric vehicles with 300 miles driving range require new batteries with capacity 4-5 times high than today's Li-ion batteries. The metals and metal oxides have the higher theoretic anodic capacity. However, the large volume changes during charge and discharge causes materials pulverization resulting in quick capacity decay. To accommodate the volume change and increase lithium ion mobility in the anodes, the aligned metal nanorods and the nanoporous hollow spheres of the metal oxides were developed. Our anodes made by aligned Al and Si nanorods demonstrated 1000-2000 mAh/g of capacity. By tuning the composition of Si nanorods, their electrochemical cycling life was improved significantly. Our batteries made by the hollow nanoporous spheres of SnO2 demonstrated 400 mAh/g of capacity in multiply cycles. The good cyclability is contributed to the unique hollow spherical structured of these metal oxides. We will report the details in this presentation.

10:50 AM
Nano-Crystalline Sn/Co-C Alloys Prepared as a High Stable Anode for Lithium Ion Batteries: *Youlan Zou*[1]; Xiangyang Zhou[1]; Juan Yang[1]; Jie Li[1]; Jingjing Tang[1]; [1]Central South University

A simple hydrolysis synthesis method, united with carbothermal reduction using phenolic resin coated mixed oxides of CoO and SnO2 as precursor, has been exploited to produce nano-sized Sn/Co-C alloys for lithium ion batteries. Physical and electrochemical properties were investigated by XRD, EDS, SEM, potential-sweep cyclic voltammetry, and galvanostatic charge and discharge tests. The results show that Sn/Co-C alloys with the size range from dozens of to hundreds of nanometer distribute evenly in the carbonaceous substrate. The morphology and granulometric distribution of the Sn/Co-C composites can be controlled by adjusting the heating schedule during carborthermal reduction. It was found that when the activated temperature is 600□, the Sn/Co-C composite exhibits an initial reversible capacity of 829.4mAh/g at first cycle, decayed to a stable value of 555.9mAh/g after 30 cycles, and coulomb efficiencies of 96% were obtained after the first cycle at 100 mA/g.

11:05 AM
Transmission Electron Microscopy Studies on Lithium Battery Materials III: Effect of Aluminum Substitution in Layered Oxides: *Alpesh Shukla*[1]; Thomas Conry[1]; Marca Doeff[1]; Thomas Richardson[1]; [1]Lawrence Berkeley National Laboratory

Layered mixed transition metal oxide materials such as LiNixCo1-2xMnxO2 (x=0.33, 0.4) have been extensively investigated as Li-ion battery cathodes to replace LiCoO2 in consumer electronics and, especially, for potential electric vehicle applications. A further reduction of the Co-content is desirable for cost and environmental reasons. To this end, Al-substitution for Co has been shown to improve both cost and safety aspects of the cathode materials while, notably, enhancing the cycling stability for reasons that are not explicitly known. This work explores the structural effects of Al-substitution in a nanoscale LiNi0.45Co0.1-xAlxMn0.45O2 (0=x=0.1) model system through transmission electron microscopy studies. Electron diffraction is used to resolve the unit-cell distortion observed upon Al-substitution in the as-made materials with an average particle size ~50nm. Additionally, the structural changes occurring throughout the cycling life of the parent and substituted cathode materials will be discussed.

11:20 AM
The Effects of Annealing on the Charge-Discharge Characteristics of Eutectic Al-Si Thin Film with Pre-Deposited Al Layer: *Chao-Han Wu*[1]; Fei-Yi Hung[1]; Truan-Sheng Lui[1]; Li-Hui Chen[1]; [1]Department of Materials Science and Engineering, National Cheng Kung University

In this study, radio frequency magnetron sputtering was used to prepare 400nm eutectic Al-Si film anodes and the effect of annealing in vacuum on the charge-discharge capacity characteristics at different temperatures are discussed. For the purpose of letting Al-Si film possess the lowest crystallization temperature, the eutectic composition was adopted. The pre-sputtered 40nm Al thin film not only reduced the resistivity of the composite anode film, but also diffused to prevent peeling between the Al-Si films and Cu foils after annealing in the vacuum. The morphology transformation at samples' surface and cross section resulted from annealing at different temperatures and cycling was examined by Focus Ion Beam. Besides, the relationship between cycling performances and other electrochemical characteristics of the Al-Si film anodes was also investigated in this study by Cyclic Voltammetry and Electrochemical AC Impedance Spectroscopy.

Fatigue and Corrosion Damage in Metallic Materials: Fundamentals, Modeling and Prevention: Fundamentals of Fatigue Damage and Modeling

Fatigue Modeling - Linking Microstructure to Predictions of Fatigue Crack Initiation: *Michael Sangid*[1]; Huseyin Sehitoglu[2]; [1]Purdue University; [2]University of Illinois, Urbana-Champaign

Excessive scatter is observed in the fatigue response of a nickel-based superalloy, U720, which is partly attributed to the variability in the microstructure. There is great interest in linking the microstructure to fatigue properties using a multi-scale approach that focuses on integrating the results of atomic simulations to the continuum level. Our approach is to model the energy of a persistent slip band (PSB) structure and use its stability with respect to dislocation motion as our failure criterion for fatigue crack initiation. Through this methodology, the fatigue life is predicted based on the energy of the PSB, which inherently accounts for the microstructure of the material. From this framework, we construct simulated microstructures based on the measured distributions of grain size, orientation, neighbor information, and grain boundary character, which allows us to calculate fatigue scatter using a deterministic approach. Excellent agreement is shown between the model predictions and experimental data.

9:00 AM Invited

A FIB Study of the Resistance of Grain Boundaries to Short Fatigue Crack Propagation in Three-Dimensions in High Strength Al Alloys: *Wei Wen*[1]; A. H. W. Ngan[2]; Tongguang Zhai[1]; [1]University of Kentucky; [2]University of Hong Kong

Based on the early discovery that the twist component of crack plane deflection across a grain boundary (GB) was the key factor controlling the crack growth in high strength Al alloys, the resistance of the GB to short fatigue crack growth was quantified. Micro-cracks were made with a focus ion beam (FIB) before GBs which have a wide range of a. The measured growth rates of these cracks demonstrated that the resistance of the GB, following a Weibull-type function, increased with a. The study of the crack front advance in 3-D with the aid of the FIB illustrated that the GB could still drag the crack front under the sample surface, though the crack tip on the surface already passed a GB.

On Crack Initiation and Early Growth of Very-High-Cycle Fatigue for High Strength Steels: *Youshi Hong*[1]; Aiguo Zhao[1]; Chengqi Sun[1]; [1]Institute of Mechanics, Chinese Academy of Sciences

In the regime of Very-High-Cycle Fatigue (VHCF) for high strength steels, crack initiation and early growth dominate the fatigue life. The process of crack initiation and early growth of high strength steels at VHCF regime almost originates from the interior of the material with fish-eye embracing FGA or ODA. In this paper, fatigue tests on two high strength steels, i.e. a high carbon chromium steel and a medium carbon chromium steel, were performed with rotating bending and ultrasonic fatigue testing machines. The results show the dimensions of FGA and fish-eye as a function of inclusion size and reveal the correlation of the dimensions for FGA and fish-eye with fatigue failure cycles. The results also show the values of stress intensity factor ranges for FGA and fish-eye keep constant with fatigue failure cycles, which was used to estimate the fatigue life of high cycle and VHCF for high strength steels.

9:50 AM

Quantification of Fatigue Weak-Links in 713 Cast Al Alloys: *Zhiqiang Xu*[1]; Xinliang Zang[1]; Yanguang Liu[1]; Yuanbin Zhang[2]; Bin Xu[2]; Tongguang Zhai[3]; [1]College of Mechanical Engineering, Yanshan University; [2]Materials Science and Engineering Department, Shandong Jianzhu University; [3]Chemical and Materials Engineering Department, University of Kentucky

By taking into account the effects of pore position in depth and size, the average shear plastic strain amplitude for an applied cyclic stress over a region of 8 mm away from the pore on surface was calculated in 713 cast Al alloys using a finite element analysis method. The pore distribution in the alloy was reconstructed on computer by randomly placing the pores, measured with an optical microscope, in a cube. The average shear plastic strain amplitude around each pore in the surface which was randomly selected in the cube could be subsequently quantified for an applied cyclic stress. Fatigue crack initiation sites were identified from all the pores in the surface by calculating the life of fatigue crack initiation from each of the pores, using an improved Manson-Coffin law. The fatigue weak-link density and strength distribution were obtained and could be regarded as materials properties.

Fundamental Principle of Cyclic Deformation and Dislocation Evolution in fcc Single Crystals: *Peng Li*[1]; Shouxin Li[1]; Zhongguang Wang[1]; Zhefeng Zhang[1]; [1]Institute of Metal Research

This paper systematically summarized the cyclic deformation behaviors of different kinds of face-centered cubic (fcc) single crystals, including Cu, Ni, Ag, Au, Al, as well as Cu-Al, Cu-Zn and Cu-Ni alloys in attempt to provide a historical perspective of the developments over the last several decades. Combined with plenty of previous research results, the influencing factors of cyclic deformation behaviors can be listed as follows: temperature, frequency, orientations and stacking fault energy (SFE). Among them, the orientation and SFE are the core factors. Compared with the above two factors, temperature and frequency can be regarded as the extrinsic factors. As the testing temperature increases, the plateau of the cyclic stress-strain (CSS) curves gradually disappears and the saturation resolved shear stress decreases distinctly at low strain amplitudes. However, the increase in frequency does not affect the appearance of the plateau behavior, but the corresponding plateau stress slightly increases.

10:50 AM

Fatigue Interrogating 3D Synthetic Microstructures of Ni-Based Alloys: *Joseph Tucker*[1]; Clayton Stein[1]; Lisa Chan[2]; Albert Cerrone[3]; Anthony Rollett[1]; Anthony Ingraffea[3]; [1]Carnegie Mellon University; [2]EDAX; [3]Cornell University

Determining the root cause of decreased fatigue life in Ni-based alloys is a complex problem. Processing, part shape, and application environment all contribute to significant variations. Crack initiation and propagation is first microstructural, leading to a study on grain character. Grain size, orientation, misorientation, NN, substructure, and inclusions collectively affect the likelihood of slip. For instance, forging and heat treating a Ni alloy resulting in as large as grains with little substructure would provide a long dislocation mean free slip length with few obstructions. These types of scenarios are injected into Ni alloy statistical volume elements and tested with crystal plasticity models.

11:10 AM

Modeling Intergranular Crack Growth in a Nickel Based Superalloy: *Kimberly Maciejewski*[1]; Hamouda Ghonem[1]; [1]University of Rhode Island

A mechanistic based crack growth model has been developed to simulate intergranular cracking in a polycrystalline Nickel based superalloy at elevated temperatures. The model considers the interactions between creep, fatigue and environment. The bulk material is modeled using a microstructure explicit crystal plasticity model surrounded by an internal state variable type of model. The crack path is described using a cohesive zone approach in which the grain boundary dislocation network is smeared into a Newtonian viscous fluid element. The cohesive laws consider deformation and damage through grain boundary sliding and dynamic embrittlement mechanisms based on the grain boundary dislocation mobility and its evolution due to Oxygen diffusion. The model, in conjunction with experimental results, is utilized to obtain the critical sliding length in both air and vacuum as a function of temperature. This model is then used to study the sensitivity of environment, temperature, precipitate microstructure and grain boundary morphology.

11:30 AM

Investigating Deformation Mechanisms Under Dwell-Fatigue in a Ni-base Superalloy: *G. B. Viswanathan*[1]; Dan Huber[2]; Sushant Jha[1]; Sara Knox[3]; Ken Bain[4]; Hamish Fraser[2]; C Woodward[1]; [1]Air Force Research Laboratory; [2]The Ohio State University; [3]Southwestern Ohio Council for Higher Education; [4]GE Aviation

The ability to resist crack growth at high temperature under hold times is an important design criterion for the new generation superalloys. While the crack nucleation is still an intensely debated issue in these alloys, the mechanism by which stable crack growth occurs also remains unclear. In this study, hold-time stable crack growth studies are conducted in notched samples of Rene104 Ni-base superalloy tested at 1300 with a stress concentration factor 1.7 and a 90 seconds dwell to failure. Thin foils were extracted from specific grains from the fracture surface via focused ion imaging (FIB). TEM analysis showed that depending on the local stress condition (Δk), the deformation substructure within the grains varied from dislocations and stacking faults within the γ matrix to APB coupled dislocations within the γ' precipitates. Based on these observations an attempt is made to elucidate possible operating mechanisms under dwell fatigue conditions in this alloy.

From Macro to Nano, Understanding Mechanical Behavior across Length Scales: A Structural Materials Division Symposium in Honor of Robert Ritchie: Biological and Bioinspired Materials Science

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Biomaterials Committee
Program Organizers: Jamie Kruzic, Oregon State University; Brad Boyce, Sandia National Labs; Reinhold Dauskardt, Stanford University

Monday AM — Room: Mockingbird 1
March 12, 2012 — Location: Swan Resort

Session Chairs: Marc Meyers, University of California, San Diego; Markus Buehler, MIT

8:30 AM Introductory Comments

8:35 AM Keynote
Studies of Mechanical Properties of Materials across Length Scales: Subra Suresh[1]; [1]Department of Materials Science and Engineering, Massachusetts Institute of Technology

This presentation will provide an overview of research into mechanical properties of materials over the past several decades with a view to assess key advances and remaining challenges. Attention will be devoted to major advances in (a) bridging length scales from the nano- to the macroscopic structures, (b) bringing transformative research from other disciplines, such as genetics and computation, to gain a better understanding of mechanistic processes underlying the mechanical signatures of engineered and living systems, and (c) guiding experiments and engineering practice through advances in computational modeling and simulations. The presentation will also address the unique perspectives that materials science and engineering offer to the coupled mechanical, biochemical and biomedical phenomena in the context of human health and diseases.

9:15 AM
Structural Hierarchies Define Toughness and Defect-Tolerance Despite Simple and Mechanically Inferior Brittle Building Blocks: *Markus Buehler*[1]; [1]Massachusetts Institute of Technology

Mineralized biological materials such as bone, sea sponges or diatoms provide load-bearing and armor functions and universally feature structural hierarchies from nano to macro. Here we report a systematic investigation of the effect of hierarchical structures on toughness and defect-tolerance based on a single and mechanically inferior brittle base material, silica, using a bottom-up approach rooted in atomistic modeling. Our analysis reveals drastic changes in the material crack-propagation resistance (R-curve) solely due to the introduction of hierarchical structures that also result in a vastly increased toughness and defect-tolerance, enabling stable crack propagation over an extensive range of crack sizes. Over a range of up to four hierarchy levels, we find an exponential increase in the defect-tolerance approaching hundred micrometers without introducing additional mechanisms or materials. This presents a significant departure from the defect-tolerance of the base material, silica, which is brittle and highly sensitive even to extremely small nanometer-scale defects.

9:30 AM
Enhanced Energy Dissipation through Size-Dependent Nanoscale Heterogeneity in Bone: *Ming Dao*[1]; [1]MIT

Various mechanisms have been identified in the literature that enhance the strength and toughness of bone. An earlier study showed that nanoscale heterogeneity in bone promotes inelastic energy dissipation during deformation. On the other hand, it is well known that heterogeneity in composite materials may introduce stress concentration and strain localization that can degrade mechanical properties. So, is nanoscale heterogeneity found in bone good or bad? We have recently quantified both elastic and inelastic heterogeneities of bovine cortical bone with a spatial resolution as low as 100 nm. A characteristic length scale was identified at about 200 nm. Below this length scale, heterogeneity was found to be high and strongly size-dependent; whereas above this length scale, heterogeneity is much less pronounced. Such an size dependence can effectively take advantage of damage tolerance at the nanoscale while limiting stress concentration or strain localization caused by heterogeneity at higher length scales.

9:45 AM
Multiscale Modeling of R-Curve Behaviors in Bone Tissue: *Kwai Chan*[1]; Daniel Nicolella[1]; [1]Southwest Research Institute

The risk of bone fracture increases with age because of a variety of factors that include, among other, decreasing bone quantity and quality. Experiemtnal evidence has indicated that changes in bone microstructure and trace mineralization with age can result in different crack-tip strain field and fracture response, leading to different fracture mechanisms and R-curve behaviors. Age-related embrittlement of bone fracture is associated with higher near-tip stains by lamellar shear and crack deflection at lamellar interfaces in young bone and their absence in the old bone. The different near-tip deformation and fracture behaviors may be related to changes of mineralization in bone tissue with age. In this paper, a multiscale modeling approach is developed to predict the R-curve response of bone tissues by delineating fracture mechanisms that lead to microdamage and ligament bridging. The effects of age and trace mineralization on bone fracture are then examined via the multiscale fracture model.

10:00 AM Break

10:15 AM Keynote
Scale Effects and Hierarchy in Biological Materials: *Marc Meyers*[1]; Po -Yu Chen[2]; [1]UCSD; [2]National Tsing Hua U.

One of the principal differences between biological and synthetic materials is that biological materials are constructed from the bottom up, whereas many synthetic materials are produced in a top-bottom sequence. Synthetic materials benefit from a cornucopia of high temperature synthesis methods not available to biological materials. The ubiquitous presence of water in the extra and intracellular materials is of primary import and dictates, ofetn, the mechanical response. This, and the multifunctionality of biological materials requires structures that often exceed in complexity and hierarchical levels their synthetic counterparts. We illustrate the hierarchical levels, from the nano to the structural scale, for a few biological materials studied by our group: abalone shell, crab exoskeleton, fish scales, and toucan beak and feathers. Funding: NSF DMR Biomaterials and Ceramics Programs

10:55 AM
On the Exceptional Facture Toughness of Elk Antler Bone: *Po-Yu Chen*[1]; Maximilien Launey[2]; Joanna McKittrick[3]; Robert Ritchie[4]; [1]National Tsing Hua University; [2]Lawrence Berkeley National Laboratory; [3]University of California, San Diego; [4]University of California, Berkeley

We investigate the fracture toughness of a non-structural bone, namely the elk antler, which has a primary function in combat and is designed for high impact loading without fracture. Antler has lower mineral content compared to mammalian limb bones and consists mainly of young primary osteons due to limited remodeling. In situ mechanical testing under ESEM and micro-CT scans are performed to examine crack propagation in the longitudinal and transverse orientations in compact antler. We find that antler in the transverse orientation is one of the toughest biological materials known, reaching 60 kJ/m^2. Its resistance to fracture is achieved extrinsically during crack growth by crack deflection/twisting and crack bridging via uncracked ligaments and collagen fibrils. We present an assessment of the toughening mechanisms acting in antler as compared to human cortical bone, and identify an enhanced role of inelastic deformation in antler which further contributes to its intrinsic toughness.

11:10 AM
Aging-Related Changes in the Plasticity and Toughness of Human Cortical Bone at Multiple Length-Scales: *Elizabeth Zimmermann*[1]; Eric Schaible[1]; Hrishikesh Bale[1]; Holly Barth[1]; Simon Tang[2]; Peter Reichert[1]; Bjorn Busse[1]; Tamara Alliston[2]; Joel W Ager III[1]; Robert O. Ritchie[1]; [1]Lawrence Berkeley National Lab; [2]University of California San Francisco

The structure of human cortical bone evolves over a range of length-scales; as this hierarchical structure provides the basis for bone's mechanical properties, each level's contribution to the fracture resistance (from plasticity to crack-tip shielding mechanisms) needs to be evaluated. Although an important reason for the decreased fracture resistance is the loss of bone mass with age (bone quantity), aging-related changes in the structure can occur at multiple length-scales to deteriorate the fracture resistance (bone quality). This study mechanically characterizes different length-scales via small- and wide-angle x-ray scattering/diffraction and fracture toughness measurements of different age groups. On the same bones, structural changes are quantified via crosslinking measurements and x-ray computed tomography. Our results show how aging-related structural changes at differing size-scales can degrade the intrinsic toughness by increased cross-linking suppressing plasticity, as well as the extrinsic toughness of bone by an increased osteonal density limiting the potency of crack-bridging mechanisms.

11:25 AM
Mechanical Behavior in Human Cortical Bone Across Multiple Length Scales: Investigations of Elastic Anisotropy and Damage Accumulation: *Ryan Roeder*[1]; Andrew Baumann[1]; Travis Turnbull[1]; Joshua Gargac[1]; David Rudy[1]; Justin Deuerling[1]; Glen Niebur[1]; [1]University of Notre Dame

Elastic properties and fatigue microdamage accumulation in human cortical bone both vary with age, disease, gender, and anatomic location, as governed by complex structure-property relationships across multiple length scales. Variability in experimental measurements of elastic constant magnitudes and anisotropy was shown to be governed primarily by the apatite crystal volume fraction and orientation distribution, respectively, using a specimen-specific, multi-scale micromechanical model. A subsequent multi-scale framework combining specimen-specific micromechanical and micro-finite element models showed that the apatite crystal orientation distribution accounts for the dominant overall transverse anisotropy, while the architecture of intracortical porosity accounts for more subtle variations in tissue orthotropy. Nondestructive and three-dimensional detection of fatigue microdamage was recently enabled using contrast-enhanced micro-computed tomography. Damage initiation and accumulation was shown to be non-uniform, occurring in preferentially in regions of tissue experiencing elevated tensile principal strains due to the whole bone morphology, mode of loading, and intracortical porosity.

Integrative Materials Design: Performance and Sustainability: Processing and Properties of Traditional and Novel Materials at Ambient and High Temperatures I

Sponsored by: The Minerals, Metals and Materials Society, TMS/ASM: Mechanical Behavior of Materials Committee
Program Organizer: Diana A. Lados, Worcester Polytechnic Institute

Monday AM — Room: Europe 2
March 12, 2012 — Location: Dolphin Resort

Session Chair: Diana Lados, Worcester Polytechnic Institute

Nanostructured Metals: Synergy between Multiple Scales: *Enrique J. Lavernia*[1]; [1]University of California, Davis

Bulk nanostructured materials have matured into a new class of materials with potential structural applications. Successful synthesis of large-scale nanostructured materials is of technological and scientific significance. Technologically, it will be feasible to obtain engineering materials that retain structural and chemical attributes in the nanometer size range. Scientifically, large-scale nanostructured materials will permit systematic investigations of physical and mechanical behavior, as well as novel phenomena. Results from various groups around the world reveal considerable improvements in physical performance as well as interesting deformation phenomena in a variety of nanostructured materials. Increases in strength are commonly documented, ductility, however, appears to scale inversely with strength in these materials. This challenge has been addressed via the introduction of additional size scales that facilitate plasticity during deformation. In this lecture, deformation behavior and underlying mechanisms of several nanostructured metals are discussed to shed light into the fundamental behavior of nanostructured materials.

9:00 AM Invited
Optimization of Mechanical Properties in Ultrafine Grained Lightweight Alloys: *Rajiv Mishra*[1]; [1]Missouri University of Science and Technology

For engineering applications, structural materials must possess a balance of static and dynamic properties. Strength, ductility and fatigue life are often critical properties. While ultrafine grained materials (UFG) invariably possess high strength, the level of ductility and fatigue life often limit the applicability. To obtain balanced mechanical response in UFG lightweight alloys, consideration must be given to the details of the microstructure and the microstructure/mechanics intersection. Some examples of change in overall mechanical response in UFG aluminum, magnesium and titanium alloys will be highlighted. The relative role of microstructure and mechanics will be discussed.

9:25 AM Invited
Friction Stir Welding in Aluminum and Magnesium Alloys: Effects of Processing Parameters on Microstructure and Mechanical Properties: *Andrew Biro*[1]; Diana Lados[1]; [1]WPI

Friction stir welding is a solid-state joining process used in structural and transportation applications where low-density and high-strength requirements dictate the use of light metals including aluminum and magnesium alloys. This study focused on two themes. The first was to optimize processing parameters for welding similar alloys, wrought 6061-6061 aluminum and cast ZE41A-ZE41A magnesium, and to determine the effect of post-weld heat treatments on the microstructures and properties of the welds. The second was to investigate processing parameters for welding dissimilar alloys, wrought aluminum to cast aluminum and magnesium alloys, specifically 6061-A356 and 6061-ZE41A. In addition, post-weld heat treatments were conducted on the dissimilar welds to determine if and to what degree mechanical properties could be improved over those obtained in as-welded conditions. Fatigue crack growth studies were also conducted on base and welded samples using compact tension specimens, and microstructural effects were analyzed and related to weld performance.

9:50 AM
Sequential Approximate Optimization Based Robust Design of SiC-Si3N4 Nanocomposite Microstructures: Gilberto Mejia-Rodriguez[1]; *Vikas Tomar*[2]; John Renaud[3]; [1]San Luis Potosí; [2]Purdue University; [3]University of Notre Dame

A simulation-based robust design optimization methodology to predict the most suitable microstructures of SiC-Si3N4 nanocomposites for desired high temperature toughness is presented. The focus is on finding robust nanocomposite microstructures with maximum toughness at two temperatures: 1500°C and 1600°C. Within this context a sequential approximate optimization algorithm under uncertainty is applied to six different test problems addressing different aspects of robust microstructure generation. During optimization, statistical uncertainties inherent to the computational microstructural generation are quantified and introduced in the optimization framework. The results show that the SiC volume fraction, the number of Si3N4 grains, the grain size distribution of the Si3N4 grains, and the grain size of the SiC grains have varied effects on the microstructure toughness at different temperatures.

10:35 AM Invited
Bulk Metallic Glasses: Highly Processable, High Performance Materials: *Jamie Kruzic*[1]; [1]Oregon State University

Bulk metallic glasses (BMGs) are a class of materials with both novel processing characteristics and mechanical properties. Accordingly, BMGs are poised to make major inroads into the design and manufacture of a wide variety of commercial products. The possibility of processing via thermo-plastic forming (TPF) makes BMGs attractive over traditional metals. Advantages of TPF include the ability to process net-shaped components with high dimensional accuracy at low temperature and pressures; thus, there is a large potential for energy and cost saving in manufacturing. The high specific strengths of BMGs coupled with reasonable fracture toughnesses make them attractive for many applications; however, questions of fatigue resistance and durability have slowed their application. More recent research has demonstrated that BMGs can be engineered with good fatigue resistance. This presentation reviews some of the advantageous processing characteristics and mechanical properties of BMGs and explains some of the misconceptions regarding fatigue resistance and durability.

11:00 AM
Characterization of Nickel Rich NiTiHf Shape Memory Alloys for Use as High Temperature Actuators: *Daniel Coughlin*[1]; Glen Bigelow[2]; Anita Garg[2]; Ronald Noebe[2]; Michael Mills[1]; [1]Ohio State University; [2]NASA Glenn Research Center

The use of shape memory alloys (SMAs) as "smart" structures to eliminate hydraulic and pneumatic actuators can reduce weight, moving parts, and energy cost in many industrial applications, but the need for high temperature SMAs still exists. NiTiHf ternary system exhibit attractive high temperature shape memory properties, including relatively high transformation temperature, and small irrecoverable strain during load-biased and thermal-cycling tests at moderate to high stresses. Two distinct nickel rich compositions, both containing 20at.% Hf and Ti concentrations of 29at.% and 29.7at.%, have been analyzed using TEM in the as-extruded condition and several aging conditions that range from 3hrs at 400ºC to 3hrs at 700ºC. The strengthening effects due to precipitates formed during aging was measured using isothermal, constant strain rate testing at several temperatures above the austenite finish temperature. A comparison of the mechanical response and precipitate structure between these NiTiHf alloys and other NiTiX SMAs will be discussed.

11:20 AM Invited
Design of Smart Metal-Matrix Composites for Sustainability and Advanced Performance: *Charles Fisher*[1]; Michele Manuel[1]; [1]University of Florida

In an effort to increase reliability and sustainability in complex systems, smart metal-matrix composites with the ability to self-heal are currently under development. Self-healing has the potential to greatly increase the life-cycle of specific components. Designing systems which possess the appropriate processing-structure-property relationships for self-healing, however, can be a difficult undertaking. The multifaceted interaction across multiple length scales yields a very complex issue for composite development. To combat this issue, a systems design approach governed by thermodynamics and empirical models was utilized to aid in the selection of materials with potential for self-healing. This study will present the alloy selection process for a high-specific strength matrix utilizing shape-memory alloy wire reinforcements to aid in self-healing in addition to initial tensile and microstructural characterization of the metal-matrix composite. The authors would like to gratefully acknowledge the support of the National Science Foundation under grant number CMMI-0824352.

11:40 AM
Multi-Scale Design of Open-Cell Aluminum Alloy Foam: *Daeyong Kim*[1]; Ji Hoon Kim[1]; Myoung-Gyu Lee[2]; Jong Kook Lee[3]; [1]Korea Institute of Materials Science; [2]Pohang University of Science and Technology; [3]Hyundai Motor Company

Metal foam inserts in the crash member are expected to reduce vehicle weights while maintaining or even increasing the crashworthiness. Due to its complex structure and behavior, however, few works have been reported to design and optimize its structure and performance. In this work, multi-scale methods are used to design the metal foam structures. The 3D structure of an open-cell foam is obtained and analyzed using the X-ray microtomography. Based on the structure information, virtual foam structures are generated by changing the length and orientation of the cell struts. The optimum structure for maximizing the energy absorption is obtained and tested numerically for crashworthiness.

International Smelting Technology Symposium (Incorporating the 6th Advances in Sulfide Smelting Symposium): Plenary Session

Sponsored by: The Minerals, Metals and Materials Society, The Metallurgy and Materials Society of CIM, TMS Extraction and Processing Division, TMS: Pyrometallurgy Committee

8:30 AM Introductory Comments

8:40 AM Keynote
2012 EPD DISTINGUISHED LECTURER: Conservation & Development: Industrial Learning in Non-Ferrous Smelting: *Theo Lehner*[1]; [1]Boliden Mineral AB

The 2012 TMS Annual Meeting hosts The International Smelting Technology Symposium. This makes a metallurgist happy and interested – in at least 4 ways! Our business is truly International: not only by ownership, but also by localizations, global competition, international treaties regulating our operations and not least: friends around the Globe. Smelting calls awake – also after a long life with metallurgy – the curious spirits dancing above red hot liquids: whispering sometimes, shouting at other occasions: why don't you understand what is going on in the molten phases below, what is explaining the phenomena observed? Technology allows the engineer to emerge and divide reality quickly into ample boxes to grasp and control. Finally Symposium describes the avenue ahead of us: a forum for continued learning, and it is always equally astonishing how much more there is to be learnt. Our industry has demonstrated impressive industrial learning curves.

9:25 AM
Modernization and New Copper Smelter Project Developments on the Central African Copperbelt: *Timothy Smith*[1]; [1]SNC Lavalin

Recent global copper supply and demnad factors have, in part, helped to drive a surge of new copper projects within the central African Copperbelt. High copper prices along with issues such as location, by-product cobalt and a regional shortage of sulphuric acid, have provided impetus to investment and rapid development of a cluster of both new and modernized copper smelters to serve local mines. This paper descibes these smelter projects and technology developments in the context of the special local factors.

9:55 AM Break

10:10 AM
Developments in DC Arc Smelting Technology in Southern Africa: *Rodney Jones*[1]; Isabel Geldenhuys[1]; Glen Denton[1]; [1]Mintek

DC arc furnaces are well suited to a number of reductive smelting processes. This technology has been used (initially in southern Africa, but now also elsewhere in the world) for the commercial production of ferrochromium from chromite, the production of titania slag and pig iron from ilmenite, and for the recovery of valuable metals from slags. A further process, currently undergoing commercialisation involves reductive smelting for the production of platinum group metals (PGMs). Some of these processes require the use of other enabling technologies, both for pre-treatment of feed materials, and for making the product more easily handled. An example of this is the use of water atomisation for the production of a powdered metal product for further downstream treatment. This paper describes the development and application of DC arc furnace technology, with a particular emphasis on recent developments.

10:40 AM
Aluminothermic Smelting: A Versatile Process Serving Demanding Markets: *James Robison*[1]; [1]Reading Alloys, Inc., an Ametek Company

Aluminothermic ("Thermite") smelting became commercial with the develop-ment of tonnage aluminum, and prospered producing metals and alloys with higher cleanliness, consistency and elemental control than competing technologies. We explore the scope of thermite smelting, and metallothermic smelting in general; the thermochemistry of the process, and its advantages and limitations as applied to industrial production. We review currently-produced products of thermite smelting in several forms and a wide range of heat sizes. As these products serve several industries, we will relate the demands of those industries to the require-ments imposed on the thermite process, leading to process dynamics and mechanisms to control/alter those dynamics. We review ways to lower the costs of the process by altering process stoichiometry, using other energy sources, and utilizing less costly raw materials while considering effects on product quality and customer requirements. Finally, we examine overall emissions control and waste disposal.

11:10 AM
The Blast Furnace: What Was, What Is, and What Will Be: *Mark Schlesinger*[1]; David Robertson[1]; [1]Missouri University of Science and Technology

The blast furnace is the oldest type of reactor for the production of molten metal from mineral ores. Over eight centuries of development it has become a primary tool for production of metals from oxide ores, and from sintered sulfides. It is particularly important in the production of pig iron, but is still used to produce other metals, and for the treatment of secondary materials. This presentation will review the development and use of the blast furnace for production of pig iron and other metals, the current state of the art for this technology, and its advantages and limitations.

Magnesium Technology 2012: Plenary Session

8:45 AM Keynote
Magnesium Alloy Development Using Phase Equilibria Computation and Microstructure Validation: *Alan Luo*[1]; Raja Mishra[1]; Bob Powell[1]; Anil Sachdev[1]; [1]General Motors Corporation

This paper summarizes the development of new cast and wrought magnesium alloys using computational thermodynamics and experimental methods. The work illustrates the role of calculated phase diagrams, solidification paths and phases in predicting and interpreting the final microstructure of Mg-Al-Ca and Mg-Al-Sn cast alloy systems and Mg-Al-Mn and Mg-Zn-Ce wrought alloy systems. The Mg-Al-Ca alloys show excellent creep resistance due to the formation of high-temperature (Mg,Al)2Ca phase. The Mg-Al-Sn alloys are designed for mechanical properties and corrosion resistance by optimizing the Mg17Al12 and Mg2Sn phases in the microstructure. AM30 (Mg-3Al-0.3Mn) alloy was developed to have significantly improved extrudability and slightly improved mechanical properties compared to AZ31 alloy, due to the absence of low eutectic-point Mg-Al-Zn ternary phases existing in the AM30 alloy. In the Mg-Zn-Ce system, Zn provides strength through solid solution strengthening, while Ce increases the ductility by creating a favorable texture.

9:15 AM Keynote
Research and Application of Mg Alloys for Aerospace: *Donald Shih*[1]; [1]The Boeing Company

This keynote presentation will address my perspectives on research, development, and application of Mg alloys in aerospace. Specific focus will be given to the Boeing products.

9:45 AM Keynote
Atoms-to-Grains Corrosion Modeling for Predictive Design of Mg-Alloys: *Santanu Chaudhuri*[1]; Jie Xiao[1]; Hyunwook Kwak[1]; [1]Washington State University

Development of new Mg-alloys needs greater efforts in systematic evaluation of corrosion protection methods under service environments. A deeper understanding of microscale and nanoscale metallurgy is needed to slow down corrosion. Results from our multiscale model will be presented to demonstrate the power of first-principle theories in predicting the composition-dependent kinetics of corrosion reactions. Our recent results show that the corrosion prevention properties of Mg-alloys can be significantly enhanced by doping rare-earth elements such as Cerium that protects the oxide layer from rapid hydrolysis. Furthermore, we are developing kinetic Monte Carlo and finite-element analysis (FEA) based models to extend the predictions from the atomic length scales to nano-and microscale models that will include grains and alloy microstructure. The potential for incorporating mechanical and corrosion performance in continuum length scale combined with the insights from first-principles based surface chemical models can have powerful impact on the development of Mg-alloys.

10:15 AM Break

10:30 AM Keynote
Solid State Joining of Magnesium to Steel: *Yuri Hovanski*[1]; Michael Santella[2]; Saumyadeep Jana[1]; Hao Yu[3]; David Field[3]; Tsung-Yu Pan[2]; Siva Pilli[1]; [1]Pacific Northwest National Laboratory; [2]Oak Ridge National Laboratory; [3]Washington State University

Friction stir welding and ultrasonic welding techniques were applied to join automotive magnesium alloys to steel sheet. The effect of tooling and process parameters on the post-weld microstructure, texture and mechanical properties was investigated. Static and dynamic loading were utilized to investigate the joint strength of both cast and wrought magnesium alloys including their susceptibility and degradation under corrosive media. The conditions required to produce joint strengths in excess of 75% of the base metal strength were determined, and the effects of surface coatings, tooling and weld parameters on weld properties are presented.

11:00 AM Keynote
Grain Evolution During High Temperature Necking of Magnesium Alloys: *Paul Krajewski*[1]; [1]General Motors

Magnesium sheet materials AZ31, AZ61, AM50, ZM21, ZK10, and ZK30 were tested to failure at 350C and 450C at strain rates between 0.001 and 0.3/s. Each of these materials exhibit significant changes in grain structure during deformation, especially in the necked regions of the failed samples. Grain size in the neck is shown to vary with thickness strain and strain rate. At the fastest strain rates, grain size decreases as the strain in the neck increases. At the slower strain rates, very coarse grains are observed at the highest strains. The effect of temperature and alloy will also be presented. The results of this work can be used to help validate models for dynamic recrystallization in magnesium.

11:30 AM Keynote
Production of Wide Shear-Rolled Magnesium Sheet for Part Forming: *David Randman*[1]; Bruce Davis[1]; Martyn Alderman[1]; Govindarajan Muralidharan[2]; Thomas Muth[2]; Thomas Watkins[2]; William Peter[2]; [1]Magnesium Elektron North America; [2]Oak Ridge National Laboratory

In recent years the process of shear rolling has seen considerable study, particularly for heavily textured materials such as magnesium. The goal of this work has been to produce more formable sheet to form parts for industries such as automotive and aerospace. To date, almost all work has been carried out on small strips that are not large enough to produce many useful parts. The current work will discuss the scaling-up of the shear rolling process to generate wider sheet. A mill at the Magnesium Elektron North America plant has been modified to allow shear rolling at a ratio of 1:1.35 on sheets up to 36" wide. Elektron 717 sheets of size 36"x72" have been shear rolled and demonstration automotive parts have been formed by General Motors and Superform USA.

Materials and Fuels for the Current and Advanced Nuclear Reactors: Nuclear Fuels - Modeling

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Corrosion and Environmental Effects Committee, TMS/ASM: Nuclear Materials Committee

Program Organizers: Ramprashad Prabhakaran, Idaho National Laboratory; Dennis Keiser, Idaho National Laboratory; Raul Rebak, GE Global Research

Monday AM — Room: Swan 2
March 12, 2012 — Location: Swan Resort

Session Chair: Ramprashad Prabhakaran, Idaho National Laboratory

8:30 AM Invited
3-Dimensional, High-Resolution Modeling of Nuclear Fuel Performance: Pellet Clad Interaction: *Brian Wirth*[1]; Derek Gaston[2]; Jason Hales[2]; Richard Martineau[2]; Robert Montgomery[3]; Y.R. Rashid[4]; Chris Stanek[5]; [1]University of Tennessee; [2]Idaho National Laboratory; [3]Pacific Northwest National Laboratory; [4]Anatech Corp.; [5]Los Alamos National Laboratory

The nuclear fuel operating environment is among the most extreme encountered by any functioning materials system. Fission processes generate high temperatures and high fluxes of energetic particles. The zirconium alloy cladding is exposed to a highly corrosive environment, in addition to numerous mechanical and chemical interaction forces as it serves as the first engineered barrier against the release of radioactive fission products. This presentation will introduce the inherently multiscale nature of irradiation effects in nuclear fuels and cladding materials and then describe an engineering-scale, 3D framework for modeling nuclear fuel performance, with an emphasis on pellet clad interaction. Following a description of the important materials degradation phenomena and the current best effort models to describe them, the presentation will focus on an example demonstrating the capability to the model stress state in a Zirconium alloy fuel clad surrounding a fuel pellet with a missing pellet surface during an operational transient.

9:00 AM
Multiscale Modeling of Reactor Fuel Restructuring: *Michael Tonks*[1]; Paul Millett[1]; Bulent Biner[1]; Liangzhe Zhang[1]; Xianming Bai[1]; [1]Idaho National Laboratory

Due to temperature and stress gradients, as well as radiation effects, the grain and pore structure of reactor fuel changes significantly during its lifetime. This restructuring in the fuel has a significant impact on thermal conductivity and fission gas release, and therefore is of critical importance when predicting fuel performance. To gain a better understanding of fuel restructuring, we use a combination of atomistic and mesoscale phase field simulations to investigate GB and pore migration and how the two interact. We also compare the effects of stress and temperature gradients. Finally, we demonstrate how this information can be used to improve existing fuel performance materials models.

9:20 AM
Phase-Field Modeling of Pore Migration in Nuclear Fuels Due to a Temperature Gradient: *Liangzhe Zhang*[1]; Michael Tonks[1]; Paul Millett[1]; Bulent Biner[1]; Yongfeng Zhang[1]; Karthikeyan Chockalingam[1]; [1]Idaho National Laboratory

Sintered UO2 nuclear fuel materials undergo a unique microstructural evolution process during operation. The evolved microstructure is usually characterized by the columnar grains surrounding a large central void, which mainly results from the migration of the initial pores towards the high temperature regions. A quantitative description of the pore migration process is therefore desirable for better understanding and accurate predictions of the fuel performance. For this purpose, a phase-field model is developed; in which the kinetics of the migration due to both bulk and surface diffusion is formulated by utilizing fourth order Cahn-Hillard (CH) equations. The results indicate that the porosities migrate towards the high temperature region owing to the temperature gradient as the driving force, which are consistent with the experimental observations. Furthermore, it is also seen that a pore can also changes its shape due to the small variations of temperature profile at its surrounding regions.

9:40 AM
Computational Crystal Plasticity with the Jacobian-Free Newton Krylov Method: *Karthik Chockalingam*[1]; Micheal Tonks[1]; Paul Millett[1]; Bulent Biner[1]; [1]Idaho National Laboratory

The primary objective of this work is to study the interaction between grain growth and plastic deformation, focusing on dislocation glide along preferred slip planes. Implicit implementations of crystal plasticity finite element method (CPFEM) are usually solved using Newton's method. However, the inherent non-linearity in the flow rule model that characterizes the crystal slip system deformation makes it difficult to form the exact analytical Jacobian needed by Newton's method. Here we analyze how to circumvent this problem by using Jacobian Free Newton Krylov (JFNK), as it does not require a Jacobian. JFNK is used to solve the system of fully coupled implicit non-linear PDEs by using an approximation to the jacobian, in contrast to the traditional Newton solve thus significantly reducing the computational time. Further studies will be aimed at extending this work in simulating the effects of plasticity on 3-D microstructural evolution to characterize performance of nuclear fuels.

10:00 AM
Thermomechanical Properties Prediction of Complex Heterogeneous Irradiated Nuclear Fuel: *Dongsheng Li*[1]; Yulan Li[1]; Fei Gao; Ram Devanathan; Xin Sun[1]; Mohammed Kahleel[1]; [1]Pacific Northwest National Laboratory

Spatial structure and chemical information of irradiated nuclear fuel were obtained by multiple chemical imaging modalities. Synthetic microstructure was reconstructed from metadata set with different signal and resolution. The synthetic microstructure is statistically stable with high resolution and enough components to represent the local and global structure. Simulated behavior from this synthetic microstructure is stable and accurate, comparing with simulation using microstructure information obtained by discrete chemical imaging modality. Correlation function and other statistical representation functions are used in microstructure reconstruction. Efficiency and accuracy in microstructure representation and property prediction were investigated.

10:30 AM
Effect of Di- and Quad-Interstitials on the Diffusivity of Oxygen in UO_{2+x}: *Rakesh Behera*[1]; Taku Watanabe[1]; David Andersson[2]; Blas Uberuaga[2]; Chaitanya Deo[1]; [1]Georgia Institute of Technology; [2]Los Alamos National Laboratory

Both due to synthesis conditions as well as the evolution of the fuel during burnup, fuels based on urania can be hyper-stoichiometric (UO_{2+x}) during operation. Previously, we characterized the thermophysical properties, in particular diffusivity of oxygen in UO_2, due to mono- and di-interstitials as a function of stoichiometry. Using density functional theory (DFT), we have predicted that quad-interstitial clusters are more stable than di-interstitials. Thus, this presentation will address the effect of mono-, di-, and quad-interstitials on oxygen transport in UO_{2+x} using kinetic Monte Carlo with inputs from DFT. The predicted diffusivities are compared with the available experimental results. Diffusivity of oxygen interstitials exhibits a non-linear relationship with oxygen non-stoichiometry which can be explained by the formation of defect clusters, their interaction, and their motion. This research is being performed using funding received from the DOE Office of Nuclear Energy's Nuclear Energy University Programs.

10:50 AM
First-Principles Theory of Magnetism, Crystal Field and Phonon Spectrum of UO2: *Fei Zhou*[1]; Vidvuds Ozolins[1]; [1]UCLA

The properties of UO2 result from rich f-electron physics, including electronic Coulomb interactions, spin-orbit and crystal-field effects, as well as interionic multipolar coupling. However, first-principles modeling of nuclear fuel materials such as UO2 is often plagued by the problem of inconsistency and disagreement among different theorists and between theory and experiment. In an attempt to address this issue and achieve consistent and accurate theoretical modeling of nuclear fuel materials, we present a comprehensive theoretical study [PRB 83, 085106] of the electronic and structural properties of UO2 using a combined application of self-consistent LDA+U calculations and a model Hamiltonian. The crystal-field ground states and excitation energies, non-collinear 3-k magnetic ground state and associated lattice distortion are all reproduced in excellent agreement with experiment. Our method also predicts the phonon spectrum of UO2 with reasonable accuracy. Application of our approach to other oxide fuels such as PuO2 also shows promising results.

11:10 AM
Investigation of the Stability and Energies of Defect and Defect Clusters In bcc-U Using Atomic Level Simulations: *Priyank Shukla*[1]; Benjamin Beeler[1]; Erin Haywar[1]; Chaitanya Deo[1]; Michael Baskes[2]; Maria Okuniewski[3]; [1]Georgia Institute of Technology; [2]University of California, San Diego; [3]Idaho National Laboratory

Metallic nuclear fuel (U-Zr) exhibits swelling and formation of inert gases during burn-up cycle. We use molecular dynamics simulations to understand the energetics of the vacancy and vacancy cluster formation and arrangement using a recently developed modified embedded atom method interatomic potential for Uranium. First, we vary the number of vacancies in pure bcc Uranium from 1 to 10, and calculate the formation energy for these vacancy clusters. Also, we investigate the effect of inert gases on the physical properties of bcc-U. This work provides fundamental insight with regard to the swelling of bcc-U based nuclear fuel.

11:30 AM
A Semi-Empirical Interatomic Potential for bcc U: *Benjamin Beeler*[1]; Chaitanya Deo[1]; Michael Baskes[2]; Sergey Rashkeev[3]; Maria Okuniewski[3]; [1]Georgia Institute of Technology; [2]University of California-San Diego; [3]Idaho National Laboratory

A Modified Embedded-Atom Method potential is presented for the high temperature body-centered cubic (gamma) phase of U. The calculated volume and elastic constants at 0K are in close agreement with previous work. Thermodynamic properties calculated include the melting point, heat capacity, enthalpy of fusion, thermal expansion and volume change on melting. The low temperature mechanical instability of gamma U is correctly predicted and investigated as a function of pressure. The mechanical instability is suppressed at pressures greater than 17.23 GPa. Energetics of self-defects in gamma U are also investigated at 0K. The vacancy formation energy is calculated to be 1.39 eV and the most energetically favorable interstitial is the <100> dumbbell, both results in close agreement with previous work. The vacancy formation energy is analyzed as a function of pressure and shows a linear trend, allowing for the calculation of the extrapolated zero pressure vacancy formation energy.

11:50 AM
Influence of Zn on the Thermodynamic Stability in the FeO-Fe2O3-NiO System: *Dongwon Shin*[1]; Theodore Besmann[1]; David Andersson[2]; [1]Oak Ridge National Laboratory; [2]Los Alamos National Laboratory

Phase equilibria will play a controlling role in defining the nature of the Chalk River Unidentified Deposits (CRUD) that form on the surfaces of fuel rods in LWR systems. The deposits are the result of corrosion products of iron, nickel, chromium and other alloying elements dissolved in reactor cooling water from piping and heat exchangers as well as coolant additives i.e., zinc, lithium, and boron. This work aims to add zinc into an existing thermodynamic model of Fe-Cr-Ni-O within the framework of the Compound Energy Formalism (CEF). Thermodynamic descriptions for constituent systems with zinc have been obtained from the literature and integrated into the existing model. Energetics of Zn containing hypothetical CEF end-members have been calculated from first-principles calculations. Phase diagrams of FeO-Fe2O3-NiO with the various ZnO content were computed from the thermodynamic model to illustrate the effect of zinc on the CRUD deposits of nickel ferrites and other phases.

Materials Processing Fundamentals: Process Metallurgy of Metals

Session Chairs: Lifeng Zhang, Missouri S&T; Antoine Allanore, MIT

8:30 AM Introductory Comments

8:35 AM
A Critical Review of the Modified Froude Number in Ladle Metallurgy: *Krishnakumar Krishnapisharody*[1]; Gordon Irons[1]; [1]McMaster University

The modeling of gas-liquid plumes in steelmaking ladles has been the subject of many investigations. In most studies, the “modified” Froude number, based on the momentum of the injected gas, has been employed to characterize two-phase plumes. This approach has several shortcomings and is critically reviewed in the present work. Based on an extensive review of previous work and theoretical considerations, it is demonstrated that the injected momentum and consequently, the modified Froude number has no significance to gas blowing operations in Ladle Metallurgy. Instead, an approach based on the “plume” Froude number, previously shown by the authors as the proper form for Froude similarity, is extended as a simpler alternative. Furthermore, the dissipation of the gas momentum in the vicinity of the injector is shown to be consistent with the present analysis.

9:00 AM
Inclusion Characteristics in Stainless Steel Ingots: Shufeng Yang[1]; *Lifeng Zhang*[1]; Yongfeng Chen[1]; [1]Missouri University of Science and Technology

Inclusions in ingots of the 316L stainless steel casted by two different upgate designs were investigated using SEM and ASPEX with automated feature analysis. The number of high SiO2 inclusions, MnS inclusions and MnO inclusions was much larger than other types of inclusions and many inclusions in the ingot contained two or three phases. There were much more high SiO2 and SiO2-Al2O3-CaO inclusions in the samples using a half upgate. The distribution of inclusions was non-uniform in the ingot: more inclusions at the top than other place in the vertical direction, and more inclusions at the side of the ingot in the radial direction.

9:25 AM
FEM Study of Centerline Defect Closure In Large Open-Die Forgings: *Jie Zhou*[1]; Joshua Blackketter[1]; Philip Nash[1]; [1]Illinois Institute of Technology

Large ingots tend to have internal defects such as shrinkage cavities, which have to be closed at the initial open die forging stage to ensure sound internal quality of forged parts. In this work, two FEM-based software packages, FORGE 3D and DEFORM 3D, were employed to investigate the void closure behavior and the impact of forging parameters on the internal quality of big billet. Several forging variables including feed ratio and reduction amount were investigated. Especially, the material studied in present work was H13 steel, known to be difficult to forge; therefore, intense attention was paid on the special properties of H13 steel to solve real world problem. Additionally, physical modeling made in selective laser sintering (SLS) machine was used to verify the numerical analysis results. At last, optimal forging practices were propose to produce square and round H13 bars.

9:50 AM
Effect of Mould Taper and Wall Thickness on Steel Ingots Soundness by 3-D Solidification Simulation: *Peng Lan*[1]; Yang Li[1]; Jiaquan Zhang[1]; Ruitian Zhang[2]; Jingyuan Wang[2]; Hengyi Zhang[2]; [1]Department of Metallurgical Engineering and State Key Laboratory of Advanced Metallurgy, University of Science and Technology Beijing; [2]Angang Subsidiary Enterprise Company

For the determination of mould taper and wall thickness, a 3-D numerical model of ingot-mould-hot top system has been made to evaluate the related ingot solidification process and the final soundness. The effect of mould wall thickness and the taper of its hot faces on the thermal history and the as cast structure of steel ingot has been revealed through the numerical simulation. It is shown that the ingot soundness can be improved remarkably by increasing the mould wall thickness, which is possibly beneficial to the mould life as well owning to an improved mould thermal state. The mould taper is vital to the ingot soundness but much less coherent to the mould temperature profiles. Under given casting situations, a larger mould taper can lead to a less intensity of the shrinkage porosities at the top part of ingot.

10:25 AM
Hydrometallurgical Study of Purifying MG Silicon Feedstock for Solar Cells Production: *Yongqiang Liu*[1]; Jilai Xue[1]; Jun Zhu[1]; [1]Unversity of Science and Technology Beijing

Up-grading silicon feedstock by removing B and metal impurities can improve process efficiency and lower production cost in metallurgical processing for solar cells production. The hydrometallurgical study has been carried out in laboratory through alternative treatments of the metallurgical grade (MG) silicon (< 200 mesh) by using hydrogen peroxide, hydrofluoric acid (4 mol 10/L) and NH4Cl-NH4F (30:5) solution. The experiments were usually performed under mechanical agitation at 70°C for 5 hours. ICP-AES analysis showed that B content in MG silicon has reduced by 92.4%, and Fe, Al, and Ca contents by 98.8%, 98.0% and 81%, respectively. Kinetics of the processes was also studied for better understanding of the effects of silicon powder size, acid concentration, leaching or oxidizing time, and so on.

10:50 AM
The Effect of Fe Addition on the Activity of Si in Liquid Cu-Si Alloys: *Yuichi Kato*[1]; Takeshi Yoshikawa[1]; Kazuki Morita[1]; [1]University of Tokyo

The carbon fiber composite with Cu-Si alloy is a candidate for the next generation brake disks for high-speed trains. The composite can be prepared by vacuum infiltration of Cu-Si alloy into fibrous carbon matrix. During the process, SiC is formed by the reaction between carbon fiber and the alloy, and its excess formation results in the embrittlement of the composite. In order to suppress its formation, Si activity in the alloy should be adequately controlled. Since Fe has a strong affinity for Si, its addition is expected to decrease the activity of Si. In the present work, variation in Si activity of the alloy with Fe addition has been investigated by equilibrating a Cu-Fe-Si alloy with both SiO_2 and graphite under a controlled CO partial pressure. Addition of Fe was found to decrease Si activity in the molten alloy, which was thermodynamically evaluated in terms of the interaction parameter.

11:15 AM
Thermodynamic Properties of the Silicon Binary Melts: *Jafar Safarian*[1]; Leiv Kolbeinsen[1]; Merete Tangstad[1]; [1]Norwegian University of Science and Technology

Silicon and its binary alloys have several applications in metallurgical, chemical, photovoltaic and semiconductor industries. Silicon goes to its liquid state within its production, refining and when it is alloyed with other elements. Therefore, the characterization of silicon melts thermodynamics is important and useful. The liquidus and activities in several silicon binary systems have been recently calculated by the application of two liquidus constants, which were established using the experimentally determined liquidus data. In the present study, the thermodynamic properties of six silicon binary melts, which are simple eutectics, are calculated by analytical approaches. In this case, the changes in the partial and integral Gibbs free energies and enthalpies of mixing are calculated and compared with the experimental data in literature. The enthalpies are calculated by two methods and the calculation results are compared to the data from the literature. It is shown that thermodynamic properties of silicon binary melts can be accurately predicted without the use of complicated thermodynamic software.

11:40 AM
Minor Element Distributions in Mount Isa Copper Smelter: *Pengfu Tan*[1]; [1]Xstrata Copper

Xstrata Copper Smelter at Mount Isa in Australia has operated one copper Isasmelt furnace, two Rotary Holding Furnaces (RHFs), four Peirce-Smith P-S converters, two anode furnaces, one casting wheel, slag crushing and screening plant, and ESP dust recovery plant. During the smelting of copper concentrates, it is important to eliminate deleterious minor elements such as Pb, Zn, As , Sb and Bi, while recover valuable elements such as Au and Ag to copper. The distributions of the minor elements, such as Pb, Zn, As, Bi, Sb, Ni and Co, in Copper Smelter have been presented and discussed. The thermodynamic modeling of those minor element distributions have been compared with the plant data and discussed as well.

Materials Science Experiments under Microgravity - A Review of History, Facilities, and Future Opportunities: *Christian Stenzel*[1]; [1]Astrium

Materials science experiments have been a key issue already since the early days of research under microgravity conditions. A microgravity environment facilitates processing of metallic and semiconductor melts without buoyancy driven convection and sedimentation. Hence, crystal growth of semiconductors, solidification of metallic alloys, and the measurement of thermo-physical parameters are the major applications in the field of materials science making use of these dedicated conditions in space. In the last three decades a large number of successful experiments have been performed, mainly in international collaborations. In parallel, the development of high-performance research facilities and the technological upgrade of diagnostic and stimuli elements have also contributed to providing optimum conditions to perform such experiments. A review of the history of materials science experiments in space focussing on the development of research facilities is given. Furthermore, current opportunities to perform such experiments onboard ISS are described and potential future options are outlined.

9:10 AM
The Materials Science Laboratory
An Opportunity for Materials Processing on Board the ISS
: Petra Neuhaus[1]; *Harald Lenski*[2]; [1]Astrium ; [2]Astrium

The Materials Science Laboratory (MSL) is a multi-user facility that supports processing and investigation of materials like metal alloys, semiconductors, and ceramics under weightlessness. MSL was built under a contract of the European Space Agency and is operated since October 2009 as part of NASA's Materials Science Research Rack in the US-Laboratory of the International Space Station. MSL supports various research fields by means of dedicated Furnace Inserts which are exchanged on orbit over the ten years lifetime of the facility. MSL provides a very precise process control, several built-in diagnostics features, and the capability to add experiment specific diagnostics. A series of experiments have meanwhile been successfully executed making use of the Low Gradient Furnace and the Solidification and Quenching Furnace. Two types of experiment cartridges are currently available. However, new cartridge types are under development to broaden the application of the facility.

9:35 AM Invited
Novel Second Generation Inserts for the MSL Aboard ISS: Florian Kargl[1]; Christian Stenzel[2]; *Andreas Meyer*[1]; [1]German Aerospace Center (DLR); [2]Astriumn

The first insert is a high temperature isothermal furnace with a 68mm bore that provides an isothermal zone of 90mm length with less than +-2K temperature gradient at 1600°C. It can accommodate a large diameter shear-cell for diffusion experiments on up to six samples simultaneously. The second insert is a compact fully-protected X-ray radiography device. Its total weight is less than 43kg. It consists of a microfocus X-ray source delivering up to 20W at 100kV. It contains a szintillator-based actively-cooled 2D X-ray detector with a total sensor area of 50x50mm at a native pixel resolution of 48um at 14bit depth and a framerate of 2Hz. The X-ray insert can be used for in-situ studies of e. g. diffusion, solidification, foaming, and granular dynamics. First ground-based shear-cell experiments on metallic alloys using the isothermal furnace are discussed. The results are compared with ground-based in-situ diffusion experiments using the X-ray insert.

Results of the MICAST Experiments in MSL Onboard the ISS: *Sonja Steinbach*[1]; Lorenz Ratke[1]; Sadik Dost[2]; Robert Erdmann[3]; Yves Fautrelle[4]; Jacques Lacaze[5]; Andras Roosz[6]; Gerhard Zimmermann[7]; [1]DLR; [2]University of Victoria; [3]University of Arizona; [4]ENSHMG; [5]CIRIMAT; [6]SGMU ; [7]ACCESS

The ESA-MAP project MICAST performs the first solidification experiments on the ISS in the MSL (Materials Science Laboratory). The MICAST team systematically studies the impact of fluid flow on the as-cast microstructure of industrially relevant Al-Si cast alloys in order to deepen the theoretical understanding of those phenomena and optimize industrial casting processes. Since the influence of fluid flow on the evolution of microstructure cannot be avoided on earth, data from terrestrial experiments can hardly be used for the verification of models solely based on diffusion which in turn is the prerequisite to elaborate more sophisticated models including fluid flow. Therefore the microgravity environment of the ISS is of special importance to the project. Only there all gravity-induced convections are eliminated and experiments under well defined thermal and controlled fluid flow conditions are possible. The paper gives an overview on recent experimental results and theoretical modelling of the MICAST team.

11:05 AM Invited
Microgravity Melting Experiments:Revealing the Mechanism of Dendritic Growth: Martin Glicksman[1]; [1]University of Florida

Sharp interface theories of melting and freezing use capillarity as a boundary condition on the normal fields, which transport the latent heat and/or solute during melting or freezing. Microgravity experiments, to be briefly described, proved that capillarity acts as a real interface field during melting. When this 'missing physics' is added to the theory of dendritic growth, the capillary-–induced temperature distribution on the solid-–liquid interface provides a two-–dimensional energy field, along with appropriate interfacial gradients and heat fluxes. Energy conservation on the interface shows, surprisingly, that the local equilibrium temperature becomes instantaneously unsteady. The details of this unsteadiness depend sensitively upon the interface shape and its energy anisotropy. The LeChatelier Braun principle, a thermodynamic postulate based on the 2nd law of thermodynamics, demands that the interfacial curvature respond to these weak imputed temperature changes with 'negative feedback'. Their response initiates kinematic (deterministic) rotation points on the interface near the dendrite tip. Rotations with favorable chirality then couple with the normal transport field to form dendritic branches. A precision, noise free solver confirms that the predicted interface rotations arise dynamically exactly at the locations specified for various starting shapes. This appears to be the process fundamentally responsible for dendrite formation.

11:40 AM
Phase-Field Simulation of Dendrite Fragmentation: Maziar Aghvami[1]; *Christoph Beckermann*[1]; [1]University of Iowa

Dendrite fragmentation is an important mechanism for generating new grains during solidification of alloys. It also represents one of the main unknowns in current models of the columnar-to-equiaxed transition in the grain structure of castings. Three-dimensional phase-field simulations are performed of the directional solidification of a binary alloy. Melt convection and movement of solid are neglected so as to simulate a microgravity environment. Fragmentation of the initial dendritic structure is induced by a change in the applied thermal gradient or cooling rate. Parametric studies are performed to investigate the conditions necessary for fragmentation to occur, the rate at which fragmentation proceeds, and the yield of dendrite fragments. The present study represents a first step in developing a general fragmentation model for use in macro-scale simulations of casting processes.

Mechanical Behavior at Nanoscale I: In-situ Technique on Deformation Process

Micro-Compression Testing of Cu: About Single Crystals, Grain Boundaries and Polycrystals: *Gerhard Dehm*[1]; Peter Imrich[2]; Christoph Kirchlechner[3]; Bo Yang[4]; Christian Motz[2]; [1]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences and Materials Physics, University of Leoben; [2]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences; [3]University of Leoben, Materials Physics; [4]Materials Center Leoben GmbH

Miniaturized compression and tension tests have shed new light on plasticity of single-crystal metals with small volumes. However, the miniaturized tests permit as well to probe the mechanics of grain-boundaries. In the present talk two aspects will be analyzed: Firstly, miniaturized Cu samples with different ratios of grain size to sample diameter will be studied to obtain general information on the impact of grain-boundaries to the strengthening behavior. Secondly, the strength of individual Cu grain-boundaries will be probed. A random large angle grain boundary of a Cu bicrystal is exposed to micro- compression testing, and compared to a Cu twin boundary. Differences and similarities will be analyzed by stress-strain measurements, scanning electron microscopy and micro-Laue diffraction. Acknowledgement: X.H. An S.D. Wu and Z.F. Zhang, Shenyang National Laboratory for Materials Science, Institute of Metal Research, Chinese Academy of Sciences, are acknowledged for supplying the Cu bicyrstals.

On Atomic Resolution In-Situ Electron Microscopy Study of Abnormal Mechanical Properties of Nanowires and Ultra-Thin Layers: *Ze Zhang*[1]; X.D. Han[2]; [1]Department of Materials Science and Engineering, Centre of Electron Microscopy; [2]Institute of Microstructure and Properties of Advanced Materials

By applying a tensile or bending strain on low dimensional materials, we developed a special technique which enables an atomic resolution in-situ transmission electron microscopy study of size effects of nanowires or ultra thin layers. For Si-, SiC, and SiO2 nanowires with two dimensional size confinements, we observed a brittle to ductile transition in contrast with their bulk counterpart with intrinsic brittle nature. The unusual large plasticity appeared via a phase transition from crystalline to amorphous under direct atomic resolution observation. This indicates that these observed strain-induced ductility are diffusion controlled and is more pronounced at nanoscale in these nanowires. From ultra thin Pt metallic layer, we observed a clear evidence of dislocation role concerning the inverse Hall-Petch d dependence. Through these studies, we thus provide new routs to study dynamic mechanical properties and their corresponding microstructure evolutions of one- dimensional nanomaterials (crystalline vs. amorphous) under direct atomic scale.

9:35 AM
Deformation of Gold Nanowires: Elongation Mechanisms and Quantum Conductance: *Lyle Levine*[1]; Francesca Tavazza[1]; Douglas Smith[1]; Anne Chaka[1]; Jon Pratt[1]; [1]National Institute of Standards and Technology

In situ measurements with unprecedented mechanical stability (2 pm noise floor) combined with several years of density functional theory simulations provide the first comprehensive picture of how individual gold nanowires thin down to single atoms chains during tensile deformation. We will show that Au nanowires deform through a series of distinct transitions between metastable, highly-ordered 3D, 2D and 1D atomic configurations. Discrete jumps in the simulated conductance correlate perfectly with the structural transitions, providing a simple explanation for these previously unexplained phenomena. Excellent agreement between the conductance simulations and experimental results was observed, providing confidence that these predicted structures and transitions reflect the underlying physical reality.

Size Matters for Deformation Twinning in Single Crystal Metals: *Evan Ma*[1]; [1]Johns Hopkins University

This work was performed in collaboration with Qian Yu, Yonghai Yue, Zhiwei Shan, Ju Li, Xiaodong Han, Xiaoxu Huang and Jun Sun. Sample size (d) of deforming single crystal is known to have a major effect on dislocation slip. In contrast, for the other major mechanism of plastic deformation, deformation twinning (DT), the sample size effect is much less understood. Using (in situ) experiments, we have found that the stress required for DT increases drastically with decreasing d of a titanium alloy single crystal, in a Hall-Petch-like relationship. We use a ‘stimulated slip’ model to explain this size regime. At very small d, a new regime sets in, when dislocation activities are dominated by direct partial (twinning) dislocation emission from surfaces. This leads to an inverse sample size effect. i.e., twinning becomes pronounced while absent at larger d, as illustrated using Cu single crystals over a range of sizes.

10:35 AM
In Situ TEM Observations of Reverse Dislocation Motion upon Unloading of Ultrafine-Grained (UFG) Aluminium Strained in the Microyield Region: *Daniel Caillard*[1]; Frederic Mompiou[1]; Marc Legros[1]; Hael Mughrabi[2]; [1]CNRS; [2]University of Erlangen

Ultrafine-grained (UFG) metals produced by Equal Channel Angular Pressing (ECAP) exhibit high strength properties. When strained in the microyield region and subsequently unloaded, such materials also exhibit unusually large inelastic reverse strains. The purpose of the present study is to clarify the reasons for such behavior, by means of in situ transmission electron microscopy experiments, in UFG aluminium produced by ECAP. Sources emitting dislocations which interacted with adjacent grain boundaries (GBs) have been observed. Depending on the character of the dislocations emitted, different behaviors have been observed: i) intensive cross-slip and rapid insertions in GBs for screw and mixed dislocations, and ii) pile-up formation in front of GBs for pure edge dislocations. Upon unloading, the release of stress induces a substantial reverse motion of dislocation pile-ups in case ii). The origin of the inelastic behavior in the bulk material and the possible role of dislocation pile-ups are then discussed.

10:55 AM
Direct Observation of Deformation Behaviors in Nanostructured Ceramic Materials by In Situ Nanoindentation in TEM: *Haiyan Wang*[1]; Joon Hwan Lee[1]; Amiya Mukherjee[2]; Xinghang Zhang[1]; [1]Texas A&M University; [2]UC Davis

At room temperature, in situ nanoindentation experiments in a transmission electron microscope are conducted on nanostructured ceramic materials to reveal their deformation behaviours. The materials include bulk ceramic nanocomposites composed of Al_2O_3 : ZrO_2 : $MgAl_2O_4$ (AZM), $YBa_2Cu_3O_{7-x}$ (YBCO) thin films and other nanolayered ceramic thin films. In situ dynamic deformation studies show that the AZM nanocomposites undergo the deformation mainly through the grain boundary sliding and rotation of small grains. We observed both plastic and elastic deformations in different sample regions in these multi-phase ceramic nanocomposites at room temperature. Detailed in situ movie analysis on YBCO thin films reveals that twin structures play an important role in deformation and strengthening mechanisms in the films and result in the anisotropic mechanical properties along c-axis and a-axis. This work is funded by the Office of Naval Research (under Dr Lawrence Kabacoff; Contract number: N00014-08-0510).

11:15 AM
Localized Crystal Rotation in Gum Metal at Ideal Strength: *Shigeru Kuramoto*[1]; Tadahiko Furuta[1]; Daigo Satoyama[1]; Elizabeth Withey[2]; J.W. Morris, Jr.[3]; [1]Toyota Central R&D Labs., Inc.; [2]Lawrence Livermore National Laboratories; [3]University of California, Berkeley

Localized crystal rotation in a multifunctional Ti-36Nb-2Ta-3Zr-0.3O alloy (mass%), Gum Metal, was analyzed in the nano-pillar specimens during in situ nano-compression tests. The very small value of C11- C12 in the alloy means that the Peierls stress required for dislocation motion is small. However, the actual deformation strength of the alloy is much higher; the resolved shear stress in nanopillars of the alloy has been reported to approach the ideal shear strength during the compression test. Results of microstructural analyses in various size scales performed so far support that the key basic process of plastic deformation is localized shear deformation accompanied by inhomogeneous crystal lattice rotation. The diffraction patterns after compressive deformation in pillar specimens showed that crystal rotation of as much as 30 degrees occurs continuously in the small deformed area of the pillar specimens. Such crystal rotation will be discussed in relation to the shear orientation and the Schmid factor in the loading direction.

11:35 AM
Stress-Driven Grain Boundary Migration in Ultrafine-Grained Mg Film: *Yong Zhang*[1]; John Sharon[1]; Kevin Hemker[1]; [1]Johns Hopkins University

Stress-driven grain boundary migration and consequent grain growth has been widely observed in face center cubic (fcc) nanocrystalline metals, namely nanocrystalline Al, Ni and Cu. However, no stress-driven grain growth was reported in hexagonal close packed (hcp) nanocrystalline materials. In this work, various stress levels in ultrafine-grained Mg films with 200 nm grain size were achieved by varying the deformation parameters, i.e., strain rate and temperature. Transmission electron microscopy (TEM) studies were used to identify the evolution of grain structure. The results demonstrate that stress-driven grain growth can be activated in hcp Mg with suitable stress, and the grain growth scales with stress as observed in fcc nanocrystalline Al film.

11:55 AM
TEM Studies on Microsturcture and Mechanical Properties of Nanotwinned Metals: *Ying Zhang*[1]; James Anderegg[1]; Ryan Ott[1]; Mikhail Mendelev[1]; Matthew Kramer[1]; [1]Ames Lab

Nanotwinned fcc metals have recently emerged as a particular form of nanoscaled structural materials with uncommonly stable microstructure coupled with enhanced mechanical properties. High-purity copper foils with nano-scale growth twin lamellae are synthesized by means of the pulsed electrodeposition technique from an electrolyte of $CuSO_4$ and magnetron sputtering system. The microstructure and density of the nanoscaled twins can be controlled by setting up different cathodic square wave pulses periodically for pulsed electrodeposition technique and changing the deposition rate for magnetron sputtering method. A novel Hysitron in-situ transmission electron microscopy (TEM) tensile strain holder is used to measure the stress-strain behavior with concurrent in-situ TEM observations of evolving microstructures on nanotwinned samples. These experiments are being performed in conjunction molecular dynamic simulations to provide both realistic validation of models and a deeper understanding of fundamental deformation mechanisms in nanotwinned materials.

12:15 PM

Interface Dominated Small Scale Plasticity in a Ni-Based Superalloy: *Robert Maass*[1]; Bin Gan[2]; Sammy Tin[2]; Lucas Meza[1]; Julia Greer[1]; [1]California Institute of Technology; [2]Illinois Institute of Technology

Small-scale mechanical behavior of individual constituent phases and interphase boundary-containing nano-pillars made from a Ni-based superalloy was examined by compressive flat punch testing in a nanoindenter. Specimens containing isolated vertical γ/γ'-interfaces with systematically varying coherency were prepared by focused ion beam milling. Microstructure was characterized via side-specific high-resolution TEM and linked to mechanical response as a function of lattice misfit. Attention is focused on the role of misfit dislocations and their influence on flow behavior in two-phase nanopillars as compared with their single crystalline γand γ' counterparts. Finally, size-affected flow is investigated in the framework of precipitate and interface dominated plasticity at the micron scale.

Mechanical Behavior Related to Interface Physics: Grain Boundaries: Experiment and Modeling

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Materials Processing and Manufacturing Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Nanomechanical Materials Behavior Committee

Program Organizers: Jian Wang, Los Alamos National Laboratory; Nathan Mara, Los Alamos National Laboratory; Izabela Szlufarska, University of Wisconsin-Madison ; Zhiwei Shan, Xi'an Jiaotong University

Observations of Stress-Coupled Grain Boundary Migration: John Sharon[1]; Frederic Mompiou[2]; Marc Legros[2]; *Kevin Hemker*[1]; [1]Johns Hopkins University; [2]CEMES-CNRS

The traditional view of grain boundaries envisions them as mechanically static, immovable structures. Room temperature grain growth in nanocrystalline metals, molecular dynamics simulations, and recently proposed theories of coupled boundary migration all suggest that grain boundaries are not nearly as static as generally assumed. Observations of stress-assisted grain growth will be reviewed and linked to theories of coupled boundary migration by the importance of applied shear stress. In situ experiments designed to investigate the details associated with stress-coupled grain boundary migration will also be presented. These in situ observations are being used to quantify the effect of grain boundary character, morphology, size and connectivity on stress-assisted grain boundary migration. This work was supported by the U.S. Department of Energy under grant number DE-FG02-07ER46437.

9:00 AM Keynote

Atomistic Modeling of Grain Boundary Sliding/Migration and Related Mechanical Behavior in FCC Metals: X.M. Su[1]; *Z.H. Jin*[1]; P. Gumbsch[2]; K. Lu[3]; [1]Shanghai Jiao Tong University; [2]Karlsruher Institut für Technologie (KIT); [3]Institute of Metal Research (IMR)

Mechanical properties of materials depend on grain boundaries (GBs) or interfaces. Properly introduced GBs in metals may improve the strength, the ductility, or both. It has been long recognized that GB activities such as sliding and migration play crucial roles. However, to reveal and characterize many details of such plasticity flows, esp. down to the atomic scale, still remains interesting and challenging. With molecular dynamics modeling, we aimed to reveal how tilt and twist GBs slide and/or migrate in fcc metals. We found that, depending on GB structure and mechanical driving force, GB migration and GB sliding involving dislocation emission as well as dislocation-GB interaction may intervene. Besides, the GB mobility not only depends on the driving force but also is temperature and rate limited. These observations suggest correlated GB phenomena and help to clarify the governing deformation mechanisms of nanostructured metals.

9:30 AM

Dislocation Pileups in fcc Aluminum Bicrystals: *Steven Valone*[1]; Jian Wang[1]; Richard Hoagland[1]; Timothy Germann[1]; [1]Los Alamos National Laboratory

Materials deformation processes are increasingly approachable through atomistic methods. In one deformation process, dislocation pile-up at a grain boundary, how dislocations transmit through grain boundaries is of intense interest. Here dislocation pile-ups in aluminum bicrystals with several tilt grain boundaries are simulated. Dislocations are initially distributed according to linear elastic estimates from a far-field stress of 40 MPa. The system is propagated for different periods of time, representing different shear rates, with load being incremented every 40 ps. Depending on the details of the grain boundary, a variety of dislocation reflection, transmission and adsorption events can occur. Some boundaries can form steps that propagate to the cell boundaries from dislocation adsorption before transmission occurs. These examples are particularly helpful in understanding the importance the distribution of far-field pinning sites in determining dislocation transmission and macroscopic deformation.

9:45 AM

Molecular Dynamics Simulation of Energy Dissipation at the Liquid/Solid Interface with Slip Boundary Condition: *Kai Huang*[1]; Izabela Szlufarska[1]; [1]UW-Madison

How mechanical energy is dissipated at a vibrating solid/liquid interface is of great importance for applications in sensor technology and microfluidic devices. For the case of Newtonian liquids with no-slip boundary conditions, continuum-level models have already been developed and validated. Although a number of analytical approaches have been also proposed for the case of slip boundary conditions, it has not been established which theory provides the correct underlying physics because of the difficulty in obtaining slip information directly from experiments. To determine relationships between surface hydrophobicity and energy dissipation at the solid/liquid interface, we performed molecular dynamics simulations of a Quartz Crystal Microbalance (QCM) in the presence of water. By controlling surface chemistry we modify the amount of interfacial slip, which then is directly measured in our simulations. We test existing theoretical models and propose their generalization to relate surface hydrophobicity, slip length, and mechanical damping at the solid/liquid interface.

10:00 AM

Nucleation and Early Growth of Mechanical Deformation Twins in Hexagonal Close-Packed Metals Deformed at Extreme Conditions: *George Kaschner*[1]; Stephen Niezgoda[1]; Rodney McCabe[1]; Carlos Tome[1]; [1]Los Alamos National Laboratory

In an effort to better understand nucleation and growth of mechanical deformation twins in HCP metals, in particular Zr, we deform samples to small strains at two extreme conditions. The first condition, quasi-static loading at equilibrium liquid nitrogen temperature, has been previously explored by this research team in studies examining larger strains and in the context of strain path change tests. The second condition is more challenging experiment in that we arrest the deformation under high strain rate conditions. We perform statistical analysis of the deformation twins using EBSD and analyze the twin morphology (aspect ratio, thickness, and spacing) as a function of temperature and strain rate. We employ a cross-correlation EBSD to analyze local strain fields at the grain boundary/twin interface to determine contributing factors to twin nucleation. Finally, we compare the experimental results with the predictions of our evolving deformation model using parameters of texture, strain rate, and temperature.

10:15 AM Break

10:25 AM Keynote
Coupled Grain Boundary Motion in a Nanocrystalline Grain Boundary Network: Mario Velasco[1]; *Helena Van Swygenhoven*[1]; Christian Brandl[2]; Enrique Martinez-Saez[2]; Alfredo Caro[2]; [1]Paul Scherrer Institute; [2]Los Alamos National Laboratory

Coupled grain boundary motion to shear deformation was simulated in a 3D nanocrystalline Al sample using molecular dynamics. It is shown that in spite of the triple junction constraints around a symmetrical S75(-751)[112] (□=23.07º) tilt boundary, the GB can migrate during the microplastic regime with the same coupling factor as when simulated in a bi-crystal configuration, i.e. the geometric predictions previously seem to be also valid in nanocrystalline structures. After reaching the full plastic regime, dislocations start coming into play changing the grain boundary structure, hindering further coupled motion. The basin-hopping algorithm is used to explore further the effect of structural rearrangement in the triple junctions and the therein-lying implications on the coupled grain boundary motion before the onset of dislocation propagation. The importance of coupled grain boundary motion as a deformation mechanism will be discussed in relation to other mechanism such as dislocation pile-up and grain boundary sliding.

10:55 AM Keynote
Multi-Scale Simulation of the Mechanical Response of Metal/Metal Interfaces in Non-Equilibrium Environments: *Douglas Irving*[1]; [1]North Carolina State University

In this talk, I will present our recently developed multi-scale method that couples the solution of electrical and thermal transport equations to an underlying empirical potential molecular dynamics simulation. The method seeks to both correct for the lack of explicit electrons, which impacts the ability to simulate electrical and thermal conductivity with MD, and to also extend the length scale of the simulation. The goal in development of this method is to simulate the response of interfaces exposed to non-equilibrium conditions (Joule Heating). The capabilities of the method will be demonstrated by highlighting our efforts to simulate the complicated environment experienced by interfaces in the electrical contacts of an Au based RF-MEMS switch. Included in this presentation will be our efforts to both extend the efficiency of this method and also extend it to systems that contain non-metallic components between the interfaces. This work is supported by ONR grant N00014-10-1-0402.

11:25 AM
Atomistic Modeling of Structure and Twinning from the {112}KS Cu-Nb Interface: *Keonwook Kang*[1]; Jian Wang[1]; Irene Beyerlein[1]; [1]LANL

Recently, multi-layered Cu-Nb composites were manufactured via a severe plastic deformation technique called accumulative roll-bonding (ARB). TEM analysis showed that the stable ARB interface structure maintains the conventional Kurdjumov-Sachs (KS) orientation, but joins the Cu and Nb crystals at unconventional interface planes: {112}Cu || {112}Nb and <110>Cu || <111>Nb. We denote this newly observed ARB KS interface as {112}KS. Twin formation was experimentally observed in copper with an angle of 19.5 degrees from the {112} interface plane. This twin formation is unusual since it does not occur in rolled physical vapor deposited (PVD) nanolayered Cu-Nb composites, where the classical KS {111} Cu || {110} Nb is maintained at the interface.In this study, atomistic simulation is used to explore the atomic interface structure, the intrinsic defect network, and mechanism of twin formation from the {112}KS Cu-Nb interface.

11:40 AM
Phase Separation of Binary Alloy: Effects of Semi-Coherent Interface: *Siu Sin Quek*[1]; Rajeev Ahluwalia[1]; David Srolovitz[1]; [1]Institute of High Performance Computing Singapore

The phase separation (spinodal decomposition) of binary alloys and the effects of elasticity on the microstructure evolution with coherent interfaces had been well studied. For the semi-coherent or incoherent case, continuity of the crystal lattice across the interface is partially or completely lost. Such loss of interface coherency at the interface can occur when the interface induces a strain energy build-up due to the mismatch of lattice constants or when the crystal structures across the interface is completely different. We consider a lattice mismatch between two phases of a binary alloy and examine how plasticity mediates the phase separation and subsequent precipitate coarsening through computational simulation. Cubic anisotropy and inhomogeneous elastic properties are incorporated in our model. Through the interaction of lattice dislocations with the interface, the loss of interface coherency is observed and the microstructure evolution is inadvertently affected. The simulation is carried out via a phase field approach.

11:55 AM
Interface Bond Strength of HIP-Clad Depleted Uranium and 6061-Aluminum: *Manuel Lovato*[1]; Cheng Liu[1]; William Blumenthal[1]; [1]Los Alamos National Laboratory

An experimental study of the interfacial bond strength of thin (0.3 mm) foils of depleted uranium (DU) that were hot-isostatic-press (HIP)-clad within one-inch thick 6061-aluminum were performed as surrogates for low-enriched uranium (LEU) nuclear fuel elements. Mechanical test specimens were prepared with and without pre-cracks along the interface and were loaded under uniaxial tension, nearly pure shear, and in mixed tension-shear loading (45 degrees) at room temperature using 2-D video digital image correlation (DIC) to obtain full-field deformation mapping of the specimen surface perpendicular to the interface and pre-cracks. As expected, pre-cracks introduced using wire electro-discharge machining (EDM) reduced the load required for interface debonding. In addition, bond strength measurements were also made on specimens of 6061-aluminum HIP-clad together without depleted uranium. The high spatial resolution of the DIC strain technique allowed evaluation of local deformation near the interface and the crack growth/debonding response.

Mechanical Performance of Materials for Current and Advanced Nuclear Reactors: Mechanical Behavior of Reactor Materials

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Nuclear Materials Committee

8:30 AM
Crack Tip Deformation Mechanisms in hcp Zr with and without Dilute H Impurities: *Margarita Ruda*[1]; Graciela Bertolino[2]; Diana Farkas[3]; A. Baruj[2]; [1]CNEA and Univ. N. del Comahue,; [2]CONICET; [3]Virginia Tech

We present a study of the atomic scale deformation mechanisms occurring at the crack tip in hcp Zr with and without a dilute amount of H present. Mode I crack propagation was studied using EAM potentials and atomistic simulation techniques. The results show a variety of deformation mechanisms, including twinning and hcp to bcc phase transformations near the crack tip. H impurities were placed at different distances from the crack tip significantly affecting the competition among the various deformation mechanisms involved in the crack propagation process. In particular, the presence of H modified the extent of the hcp to bcc transformation region leading to an increase in ductility in some single crystal configurations.

8:50 AM
Fracture Toughness of 9Cr-1MoV and Thermally Aged Alloy 617 for Advanced Reactor Applications: *Randy Nanstad*[1]; Mikhail Sokolov[1]; Xiang (Frank) Chen[2]; [1]Oak Ridge National Laboratory; [2]University of Illinois

Abstract: Nickel-base Alloy 617 is being considered as a structural material for application in the secondary heat exchanger of the New Generation Nuclear Plant, a very high temperature gas-cooled reactor. Thermal aging of Alloy 617 plate and welds is being performed with tensile, Charpy impact, and fracture toughness tests conducted at temperatures to 950°C. Results of testing for thermal aging to 5,300 h have been obtained and are presented; varying effects of thermal aging temperature and time on fracture toughness are observed. The 9Cr-1MoV (Grade 91) ferritic steel is a candidate for structural applications in the sodium fast reactor. Fracture toughness testing of unaged Grade 91 steel has been performed to evaluate specimen size effects in preparation for future testing of the material in the thermally aged condition. Results for material in the mill-annealed and heat treated conditions are presented and show that this heat of Grade 91 steel does not indicate a small specimen bias on the fracture toughness Master Curve reference temperature.

9:10 AM
Influence of Cold Work and Sensitization on Stress Corrosion Cracking of Stainless Steel: *Elaine West*[1]; Nathan Lewis[1]; David Morton[1]; Bryan Miller[2]; [1]Knolls Atomic Power Laboratory; [2]Bettis Atomic Power Laboratory

The effect of cold work (CW) and sensitization on the stress corrosion cracking (SCC) susceptibility of Type 304 SS was evaluated in high temperature aqueous environments. Experiments were conducted primarily in deaerated water at 550-680°F on ring loaded and active loaded compact tension specimens with CW levels of 0-28%. Crack growth rates in deaerated water increased as a function of temperature and CW level and decreased with sensitization. In aerated water with 200 ppb sulfate, however, rapid crack growth was measured on a 10% CW sensitized specimen. Transmission electron microscopy (TEM) measurements of grain boundary chromium depletion on sensitized material indicated that the austenite (γ) grain boundaries had chromium concentrations as low as 10.4 wt%, and carbide decoration was observed at both γ/γ and γ/δ-ferrite interfaces. TEM and Electron Backscatter Diffraction analyses were used to characterize the factors promoting crack propagation in the stainless steel specimens.

9:30 AM
Time-Dependent Fatigue Crack Propagation in Ni-Based Solid-Solution-Strengthened Superalloys INCONEL 617 and HAYNES 230: *Longzhou Ma*[1]; Shawoon Roy[1]; [1]University of Nevada Las Vegas

Ni-based superalloys INCONEL 617 and HAYNES 230 were subjected to factigue crack propagation (FCP)tests with sinusoidal and hold time waveform as well as sustained loading crack growth (SLCG)tests at temperatures of 600- 800 Deg.C using the constant stress intensity factor control. The experimental results showed that both alloys displayed the time-dependent FCP behaviors, when a hold time at maximum load of fatigue was imposed. In SLCG tests, both alloys showed the incubation and steady crack growth process. The SLCG rates, da/dt, could be characterized using a thermal activation equation. Toward this end, a general model, based on thermo-dynamic equation, was employed to correlate the FCP rates of alloys at cycle/time-dependent domain.

9:50 AM
Strain Localization During Creep-Fatigue Deformation of Alloy 617: Mark Carroll[1]; *Laura Carroll*[1]; Richard Wright[1]; [1]Idaho National Laboratory

Alloy 617 is the leading candidate material for the intermediate heat exchanger (IHX) of the Very High Temperature Reactor (VHTR), which will require an alloy capable of operating at temperatures of up to 950°C. In order to provide adequate test data for design Code purposes, numerous strain controlled low-cycle fatigue (LCF) tests with hold times up to 1800 s at peak tensile strain have been conducted at 950°C. Post-test observations reveal that bulk grain boundary damage in the form of intergranular cracking was present in the interior of the creep-fatigue specimens. This bulk cracking was observed throughout the deformed material in distinct grain boundary locations, although the majority of grain boundaries were absent of any observable damage or signs of cavitation. Localized strain fields in the grains adjacent to interior cracks are being investigated using orientation imaging microscopy (OIM) techniques coupled with transmission electron microscopy (TEM) characterization.

10:10 AM Break

10:30 AM
Creep Behaviors of a Nanocluster-Strengthened Ferritic Steel: *M Brandes*[1]; G Daehn[1]; M Miller[2]; M Mills[1]; [1]The Ohio State University; [2]Oak Ridge National Laboratory

Mechanical-alloyed, nano-ferritic steels represent a class of alloys displaying radiation and creep resistances. Their excellent performance is a result nanoclusters, which have been observed to interact with glide dislocations. Post-mortem, probe-corrected scanning transmission electron imaging has revealed attractive dislocation-nanocluster interactions. The creep behavior of alloy Fe-14YWT has been investigated between 650 and 950°C through creep and monotonic strain rate testing. Significant strain accumulation occurs in the primary regime, and a varying stress dependence is measured in the steady strain regime where N ~ 1 at low stress. A new model of the creep response using a modified Kocks-Argon-Ashby model has been developed and extended to a cellular-automata model. With this approach, it is possible to explain the creep transient behaviors over a wide range of temperature and stress. This research was sponsored by the U.S. Department of Energy, Division of Materials Sciences and Engineering.

10:50 AM
Creep Deformation Mechanisms in Grade 91 Steel: *Triratna Shrestha*[1]; Mehdi Basirat[1]; Indrajit Charit[1]; Gabriel Potirniche[1]; Karl Rink[1]; Uttara Sahaym[2]; [1]University of Idaho; [2]Washington State University

Grade 91 (modified 9Cr-1Mo) steel is a candidate material for the pressure vessel of the Very High Temperature Reactor (VHTR). The creep behavior of this steel was studied in the temperature range of 873 K to 1023 K and at a stress range of 35 to 350 MPa. Threshold stress correction of the creep data in the higher stress regime yielded a true stress exponent of 5, indicating the operation of high temperature climb-controlled creep. The estimated threshold stresses displayed strong temperature dependence. The origin of the threshold stress was explained in terms of particle-dislocation attractive interaction. Creep tests in the lower stress regime resulted in a stress exponent of 1, indicating the operation of a Newtonian viscous creep mechanism. Furthermore, the rate-controlling creep mechanisms in both the stress regimes were elucidated with the help of transmission electron microscopy (TEM). The research was supported by the NEUP contract # 42246-59.

11:10 AM
High Temperature Aging Study on Long-Term Aged Alloy 617 and Alloy 230: *Yang Zhao*[1]; Kun Mo[1]; James Stubbins[1]; [1]University of Illinois at Urbana Champaign

Alloy 617 and Alloy 230 are lead structural materials for next generation nuclear power plant (NGNP). Both alloys possess good corrosion resistance and exceptional high-temperature strength. In order to gain a better understanding of the high-temperature degradation process of these materials, long-term (up to 10000 hours) aging experiments have been carried out to investigate the microstructural evolution and mechanical property development for both alloys. In the present study, focus is placed on the alloys aged for 10000 hours. Both alloys softened significantly after aging at 1000ºC for 10000 hours. In contrast, the strength of both alloys was maintained when aging at 900ºC. Carbide particle growth is known to be a dominant microstructual feature during long-term aging at elevated temperatures. The evolution of the carbide structure is also the major contributor to the changes in mechanical properties. The microstructures are related to the measured changes in mechanical properties.

11:30 AM
High Temperature Creep Studies on Nano Structured Ferritic Alloys: *E. Stergar*[1]; M. Salston[1]; K. Fields[1]; Y. Wu[1]; G. R. Odette[1]; [1]University of California-Santa Barbara

Nano-structured ferritic alloys (NFAs), which gain their excellent creep and tensile strength from nanometer-scale precipitates, are candidate materials for new generation nuclear and future fusion reactors. NFAs are thermally stable and have good creep strength up to about 800°C. These alloys also manifest remarkable resistance to radiation damage. These attributes are due to an ultrahigh density of Ti-Y-O enriched nano-features (NFs) that provide dispersion strengthening, stabilize dislocation and fine grain structures, reduce excess concentrations of radiation induced defects and trap helium in fine harmless bubbles. The presentation summarizes an extensive database on creep properties of MA957 with different heat treatments as well as other NFAs. Also the mechanical property data is complemented by detailed microstructural characterization studies using high resolution methods like TEM and atom-probe. The results show a significant impact of the thermo-mechanical treatment on the microstructure, precipitate distribution and creep behavior of NFAs.

11:50 AM
Creep Behavior of High Temperature Alloys for Intermediate Heat Exchanger in Next Generation Nuclear Plant: *Xingshuo Wen*[1]; Laura Carroll[2]; Richard Wright[2]; T. L. (Sam) Sham[3]; Vijay Vasudevan[1]; [1]University of Cincinnati; [2]Idaho National Laboratory; [3]Oak Ridge National Laboratory

Alloy 617 and 800H were selected as candidate materials for Intermediate Heat Exchanger used in the Next Generation Nuclear Plant with operating temperature in the range of 800 to 950°C and a service life of 60 years. In this work, creep behavior of alloys 617 and 800H specimens with different grain sizes was studied over the temperatures of 850 to 1050°C and stress levels ranging from 5 to 100MPa. Creep data was analyzed to decipher the various stages, the stress exponents and activation energies were determined and diffusional versus dislocation creep mechanisms were discriminated. Microstructural changes and damage processes following creep were characterized, with special attention given to grain size effects, grain boundary type and structure, second phase precipitates, dislocation structures and void formation. The various results relating the creep behavior to microstructural changes in these alloys will be presented and discussed.

Mechanomutable Nanomaterials: Multiscale Computational and Experimental Studies: *Markus Buehler*[1]; Steven Cranford[1]; Christine Ortiz[1]; [1]Massachusetts Institute of Technology

Mutable materials are found widely in biology, characterized by a material's capacity to change its properties under external cues based on directed structural changes at specific material levels. Here we focus on a class of mechanomutable materials, which change their mechanical properties such as elasticity, deformability, strength and toughness based on external signals. A hierarchical approach, implemented through coarse-grain molecular modeling, is utilized do develop a powerful framework that can successfully collaborate atomistic theory and simulations with material synthesis and physical experimentation, and facilitate the design of mechanomutable structural materials. We review studies of PAA/PAH polymer systems, where a first principles based bottom-up approach is used to predict the structure and mutability of large-scale material properties from the nanoscale up. We demonstrate hierarchical material designs, validated by experimental studies, to realize mechanomutable polymer nanotubes and films. Experimental approaches towards the design of adaptable, mutable and active nanomaterials will be presented.

8:50 AM
Compressive Strength of Epoxy- Graphite Nanoplatelets Composites: *H. A. Colorado*[1]; A. Wong[1]; J M Yang[1]; [1]University of California, Los Angeles

Epoxy matrix composites reinforced with Graphite Nanoplatelets (GNPs) at different concentrations have been fabricated in this research. The Epoxy matrix was made with Epon 828 cured with epikure 3055. GNPs were used in two conditions, as received and after being oxidized at high temperature.A planetary Thinky Mixing was used first to mix the Epoxy with the curing agent and then to mix the resulting liquid with the GNPs. The microstructure was identified by using optical and scanning electron microscopes and X-ray diffraction (XRD). Compressive strength was conducted over cylindrical samples of different length. X-ray micro tomography was used to characterize the samples after tested in compression in order to understand the failure modes.

9:10 AM Invited
Graphene Based Composite Materials: *Nikhil Koratkar*[1]; [1]Rensselaer Polytechnic Institute

Graphene is a single-atom-thick sheet of sp2 hybridized carbon atoms. In this talk, I will describe our process used to synthesize bulk quantities of exfoliated graphene sheets from graphite and the processing techniques used to disperse them in polymer matrices. I will discuss various mechanical properties of these composites including Young's modulus, ultimate tensile strength, fracture toughness, fracture energy, buckling stability, wear and fatigue resistance. Study of Interfacial load transfer at the graphene polymer-matrix interface using Raman spectroscopy will also be presented. I will show that graphene can match the performance of other competing nanofillers such as carbon nanotubes, nano-particles and nanoclays, at 1-2 orders of magnitude lower nanofiller weight fraction. I will discuss the reasons for the superiority of graphene over other forms of nanofiller reinforcement. Finally I will end by discussing the potential of graphene ceramic and graphene metal-matrix composite materials in high performance structural applications.

9:50 AM
Compressive Properties of Polymeric Syntactic Foams at Various Quasi-Static and High Strain Rates: Vasanth Chakravarthy Shunmugasamy[1]; Dinesh Pinisetty[1]; *Nikhil Gupta*[1]; [1]Polytechnic Institute of New York University

Syntactic foams (SFs) are lightweight composites synthesized by filling a matrix material with hollow particles called microballoons. The use of SFs for weight reduction in marine and aircraft structures makes it necessary to understand their compressive characteristics at various strain rates. The present study attempts to understand the quasi-static and high strain rate compressive characteristics of vinyl ester matrix SFs filled with glass microballoons. A split-Hopkinson pressure bar setup is used for high strain rate testing. The strength is found to be 50–150% higher at high strain rates when compared to quasi-static values for various syntactic foam compositions. Also, a transition in failure pattern is observed from shear cracking under quasi-static loading to failure along the direction of loading with increase in strain rate. Such observations can help in structural design in existing applications and enable new applications.

10:10 AM
Thermal Expansion of Carbon Nanofiber Reinforced Syntactic Foams: Ronald Poveda[1]; Sriniket Achar[1]; *Nikhil Gupta*[1]; [1]Polytechnic Institute of New York University

Coefficient of thermal expansion (CTE) is an important consideration in several existing applications of composite materials where temperature variations are experienced during their service life. The present study analyzes the effect of carbon nanofibers (CNFs) on the thermal expansion of hollow particle (microballoon) filled composites called syntactic foams. Different CNFs weight fractions are randomly dispersed into syntactic foams and tested using a thermomechanical analyzer. Two types of glass microballoons having wall thickness of 521 and 878 nm are used in 30 and 50 vol.% in syntactic foams. Results show that a combination of CNF and microballoon volume fraction and microballoon wall thickness can be used effectively to tailor the composites' CTE. Turner's and Kerner's models are modified to enable prediction of CTE of hollow particle reinforced composites. The theoretical estimates are in close agreement with the experimental results.

10:50 AM
Atomistic and Continuum Understanding of the Particle Clustering and Particle Size Effect on the Room and High Temperature Strength of SiCN Nanocomposites: *Vikas Tomar*[1]; [1]Purdue University

Silicon Carbide (SiC)-Silicon Nitride (Si3N4) nanocomposites are future important high temperature materials. This work presents our recent findings that analyze the effect of morphological variations in second phase SiC particle placement and grain boundary (GB) strength on the room temperature fracture strength of SiC-Si3N4 nanocomposites using continuum analyses based on a mesoscale (~50 nm) cohesive finite element method (CFEM) and using molecular dynamics (MD) based analyses at nanoscale (~15 nm). CFEM and MD analyses have revealed that high strength and relatively small sized SiC particles act as stress concentration sites in Si3N4 matrix leading to inter-granular Si3N4 matrix cracking as a dominant failure mode. However, the particle's presence does not have a significant effect on the mechanical strength of bicrystalline or nanocrystalline Si3N4 phase matrices. The strength of the structures showed an uncharacteristic correlation between the GB thickness and temperature.

11:10 AM
Mechanical Response of the PMMA-CNT Nanocomposite via Molecular Dynamics: *Yae Ji Kim*[1]; Eugenio Jaramillo[2]; Benjamin Haley[1]; Alejandro Strachan[1]; [1]Purdue University; [2]Texas A&M International University

Despite progress in incorporating carbon nanotubes (CNTs) into polymeric matrices, the expected mechanical performance enhancement of the resulting nanocomposites remains unrealized. Progress in this area is hindered by the lack of fundamental understanding of CNT-polymer interactions and the molecular mechanisms that govern the response of the composite. We use large–scale MD simulations to characterize the interface energy between CNTs and poly(methyl methacrylate) surface and bulk as well as the effect of the CNT on the polymer structure. We also characterize the mechanical response of a nanolaminate composite with CNTs at [45/-45] degrees compare their performance with that of bulk PMMA.

11:30 AM
Micromechanical Analysis of Influences of Agglomerated Nanotube Interphase on Effective Material Properties of a Three Phase Piezoelectric Nanocomposit: *Tian Tang*[1]; Paul Wang[1]; [1]Mississippi State University

The focus of the present study is to investigate influences of agglomerated nanotube interphase on effective material properties of a three phase piezoelectric nanocomposite using a recently developed micromechanics framework, namely, variational asymptotic method for unit cell homogenization (VAMUCH). The three phase nanocomposite is composed of PZT-5A fibers and polyimide matrix enhanced with single-wall carbon nanotubes (SWNT). The effects of parameters of agglomerated nanotube interphase (caused by PZT fibers) such as stiffness and volume fraction on effective material properties of nanocomposite were analyzed. For verification, the numerical results were compared with finite element method.

11:50 AM
Effect of Nano-Paper Coating on Flexural Properties of a Fire-Treated Glass Fiber-Reinforced Polyester Composite: *Jamie Skovron*[1]; Jinfeng Zhuge[1]; Ali Gordon[1]; Jan Gou[1]; [1]University of Central Florida

Planned aerospace vehicles require materials with high specific strength to withstand thermal shock associated with re-entry. Composites, such as glass fiber-reinforced (GFR) polyester, have rapidly become preferred for high value structural components requiring high specific strength and durability. Their ability to sustain high tensile, impact, etc. has allowed them to be used as light-transmitting panels, fuselages, nose cones, and combustor nozzles. As a part of service conditions, heat flux evolves mechanical properties with exposure time. The effect of including a carbon nano-paper coating on the monotonic flexural properties of a GRP polyester are analyzed. A series of three-point bend experiments was performed on specimen-sized samples of composites subjected to various levels of heat fluxes across numerous exposure times. Analysis of these experiments reveals trends in the deformation mechanisms of these materials near failure. Correlations of flexural modulus, toughness, critical couple are used to develop models for life.

12:10 PM
Finite Element Modeling of the Nanoscratching of Polymer Surfaces: *William Chirdon*[1]; Joshua Rozas[1]; [1]University of Louisiana at Lafayette
Modeling of nanoscratching phenomena is important for several material applications. In some applications, scratching is the desired effect of nanofabrication techniques. In other applications, scratching is undesired, as it causes coatings to fail, acts as a mechanism of wear, and can accelerate corrosion. This work uses finite element modeling techniques to investigate the effectiveness of various material models in their ability to model scratch experiments which have been previously published. The material models studied included viscoelasticity, deformation plasticity, elastic/plastic, strain-rate-dependent elastic/plastic, and other mechanical material models. Elastic/plastic models with and without strain-rate dependence were found to be the most robust material models. This work also highlights the importance of the scratching conditions, noting that the material properties that are desirable for resisting a scratching force are different from the desirable material properties for resisting a scratch displacement. Advantages and disadvantages of material models will be discussed.

Neutron and X-Ray Studies of Advanced Materials V: Centennial: Von Laue, Bragg and Diffraction Centennial

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Chemistry and Physics of Materials Committee
Program Organizers: Rozaliya Barabash, Oak Ridge National Laboratory; Xun-Li Wang, Oak Ridge National Laboratory; Gernot Kostorz, ETH Zurich; Lyle Levine, National Institute of Standards and Technology; Peter Liaw, Univ of Tennessee; Yandong Wang, Beijing Institute of Technology; Brent Fultz, California Institute of Technology

Session Chairs: Wolfgang Pantleon, Risoe National Laboratory; Xun-Li Wang, SNS

8:30 AM Keynote
Materials Research with X-Rays: *Gernot Kostorz*[1]; [1]ETH Zurich
The year 2012 marks the one hundredth anniversary of the discovery of X-ray diffraction. This is a good reason to look back at the development of X-ray diffraction as a tool in materials science, a discipline that emerged only several decades later. The initial notion of crystalline imperfection as ‘mosaicity’ survived as a global term even until today. However, the possibility of not only determining the unit cell of a crystalline structure, but also identifying microstructural features down to the atomic level, has inspired many researchers ever since. A few milestones that are (as a personal selection) considered relevant to the development of a deeper understanding of the properties of real materials will be highlighted. The impact of diffraction and scattering of X-rays (complemented by electrons and neutrons) on many advances in materials science is, of course, generally recognized, but may deserve a moment of celebration.

8:55 AM Invited
Diffuse Scattering Resulting from Macromolecular Frustration: *Richard Welberry*[1]; [1]Research School of Chemistry
Distinctive diffuse scattering in the form of diffuse rings around Bragg positions has been observed in the diffraction patterns of a crystal of the N-terminal fragment of the Gag protein from Feline Foamy Virus. It is shown that these are caused by geometric frustration as molecules try to pack on the triangular *bc* mesh of the space group $P6_122$. To explain the strong diffuse scattering the crystal must contain occupational disorder such that each unit cell contains one or other of two different molecular arrangements, **A** and **B**. The frustration arises because the molecular packing prefers neighbouring cells to be **AB** or **BA**. To explain the observation that reciprocal sections $h\ k\ 5nl$ where n = integer, contain only Bragg peaks **A** and **B** must be identical molecular arrangements differing only by a translation of 0.2**c**. The implications of the disorder for solving the structure of the protein are discussed.

Residual Strain Measurement by X-Ray and Neutron Diffraction: The First 100 Years: *Philip Withers*[1]; [1]University of Manchester
Almost as soon as X-ray Bragg diffraction had been developed as a tool for measuring the lattice spacings of crystals in 1913, its potential for measuring elastic strain was identified in a series of articles in the 1920’s. The opportunity to probe the state of elastic strain and hence stress deep inside the bulk of materials had to wait some 50 years until suitable thermal neutron beams became available at research reactors. In the 1990s the high flux and penetrating power of synchrotron x-rays allowed the investigation of residual strains and stresses at the micron scale or sub-second timescales. Each of these beams provided a complementary window into residual stresses for the materials scientist/engineer. In this talk a personal historical perspective of the major developments during the last 100 years is given illustrated by a range of experimental studies made across a large range of scales and engineering applications.

Inelastic Neutron Scattering Measurements and Calculations of Anharmonic Phonons in fcc Metals: *Brent Fultz*[1]; Xiaoli Tang[1]; Chen Li[1]; [1]California Institute of Technology
Anharmonicity is important in the thermodynamics of solids. Especially at elevated temperatures, anharmonic contributions to the phonon entropy can be a significant fraction of a k_B per atom. We report progress in identifying the sources of non-harmonic behavior, specifically phonon-phonon interactions in the fcc metals Al, Cu, Ag, Au, Pd, Pt. Thermal broadenings of phonon spectra were measured by inelastic neutron scattering on Al, Pd, Pt, and broadenings of individual phonons were measured on a single crystal of Al. The broadenings showed severe “damping” of phonons at moderately high temperatures. Phonon lifetimes at low and high temperatures were calculated using density functional theory combined with second-order perturbation theory, with surprising success. The dominant effects were the kinematical requirements of energy and momentum conservation, not the wavevector-dependence of the cubic anharmonicity itself. Semiquantitative results on phonon damping are possible with a simpler model of cubic anharmonicity.

Monitoring Strain Path Changes by High Resolution Reciprocal Space Mapping: Christian Wejdemann[1]; Ulrich Lienert[2]; Henning Poulsen[1]; *Wolfgang Pantleon*[1]; [1]Risoe DTU; [2]Argonne National Laboratory
The evolution of deformation structures in polycrystalline copper during strain path changes is observed in situ by high resolution reciprocal space mapping with high energy synchrotron radiation. The resolved behavior of a large number of resolved individual subgrains (complemented by conventional x-ray peak profile analysis) allows a distinction between two different regimes during the mechanically transient behavior following the strain path change: below about 0.3% strain, number and orientation of the resolved subgrains changes only slightly while their elastic stresses are significantly altered indicating a microplastic regime during which only the subgrains deform plastically and no yielding occurs in dislocation walls. After reloading to about 0.3% strain, the elastic stresses

of the individual subgrains (having reached the corresponding values of unidirectionally deformed reference specimens) increase only slightly further on - accompanied by occasional appearances of new subgrains, abundant orientation changes and removal of individual existing subgrains.

Diffraction from Vibrating Crystals: From Ultrasound to Phonons: *Klaus-Dieter Liss*[1]; Andreas Magerl[2]; [1]ANSTO; [2]University of Erlangen-Nürnberg

The excitation of ultrasonic waves in perfect crystals can lead to interesting phenomena in neutron and X-ray diffraction, such as peak broadening caused by the lattice gradient, satellite reflections due to the space and time modulated structure, inelastic scattering, and caustics of the beam paths. Furthermore, spatially resolved diffraction on ultrashort time scales leads to the characterization of standing waves and shock waves. White beam Laue section topography is very sensitive to spatial wave field arrangements and shows up the transition between the dynamical and the kinematic theory of diffraction. The presentation reviews the concepts on our older work, gives unpublished experimental results and an outlook to the state-of-the-art and future capabilities of technological development, and their applications in materials science and physics.

10:40 AM Keynote
Real Space Atomic Correlation and Elastic/Inelastic Scattering from Disordered Systems: *Takeshi Egami*[1]; [1]University of Tennessee

Traditionally the results of elastic and inelastic neutron or x-ray scattering are presented in the reciprocal space, because the measurements are made as a function of Q, the scattering vector. It also makes sense when the materials studied are crystalline. But for disordered systems it is much more useful to present the results in real space, in terms of the two-body correlation functions. For elastic scattering this is the pair-density function (PDF). For inelastic scattering it corresponds to the dynamic PDF (DPDF). The dynamic structure factor, S(Q,E), of a liquid just shows strongly damped phonons and not much else. But the same data presented as the DPDF shows the atomic dynamics is totally localized to the nearest neighbor. This superlocalization is fundamental in understanding the statistical mechanics of a liquid. This result demonstrates the usefulness of this approach. Work supported by US Department of Energy, Office of Basic Energy Sciences.

From Closed Packed Metal Structures to Monoclinic SMA and Multiphase Complex Materials: 20 Years of Rietveld Stress-Texture Analyses: *Luca Lutterotti*[1]; [1]University of Trento

Until 20 years ago the only available method for texture analysis was to collect pole figures and residual stress measurement were done using the traditional $\sin^2$(psi) on single peaks. These methodologies could be applied only to single phase materials with high symmetries. In 1992 the Rietveld method was developed also for texture and residual stresses by measuring several full patterns for a significant number of sample tilting and analyze them including a model for the texture and residual stress effects. Several different models were developed over the years and the method has been used for different scientific problems. The procedure was successfully applied to geological, cultural heritage and material science problems using neutron diffraction in bulk samples or X-ray on thin films and in transmission. Now, complex multiphase materials can be analyzed routinely even if triclinic and monoclinic compounds are present like in the case of NiTi SMA alloys.

11:25 AM Invited
Internal Strain Evolution during Thermomechanical Cycling of NiTi Shape Memory Alloys Investigated Using Neutron Diffraction: *Raj Vaidyanathan*[1]; Othmane Benafan[1]; Doug Nicholson[1]; Ron Noebe[2]; Santo Padula[2]; Bjorn Clausen[3]; Don Brown[3]; Sven Vogel[3]; [1]UCF; [2]NASA Glenn Research Center; [3]Los Alamos National Laboratory

In order to engineer stable shape memory alloys for use as actuators, there is a need to understand the internal strain evolution with thermomechanical cycling. We present such a study of the strain evolution with thermomechanical cycling in a binary NiTi alloy. The study reports on in situ neutron diffraction measurements during selected combinations of heating, cooling and loading at Los Alamos National Laboratory as well as ex situ thermomechanical cycling experiments. The in situ neutron diffraction experiments follow the micromechanical and microstructural changes, i.e., texture, strain and phase volume fraction evolution with thermomechanical cycling. Deformation of the cubic austenite phase is also investigated with increasing temperature in order to assess both reversible stress-induced martensite and irreversible retained or residual martensite and plasticity contributions to the strain. The implications of these results for engineering stable shape memory alloys for aerospace applications is presented.

Small-Angle Scattering with Synchrotron Radiation and Neutrons - Precise Experimental Techniques for Quantitative and Structural Analysis in Chemistry and Physics: *Guenter Goerigk*[1]; [1]Helmholtz-Zentrum Berlin

Synchrotron Radiation (SR) provides Small-Angle X-ray Scattering (SAXS) with major improvements, among others the photon flux, allowing the study of samples with only weak small-angle X-ray scattering like diluted chemical solutions or amorphous alloys. Additionally the continuous energy spectrum of SR provides energy tunability in the vicinity of the K- and LIII-absorption edges of most of the elements giving access to an element specific structural and quantitative analysis. From this technique - known as Anomalous Small-Angle X-ray Scattering (ASAXS) – crucial chemical parameters like volume fractions and chemical concentrations can be obtained, which can be correlated to macroscopic or physico-chemical properties. Complementary, Small-Angel Neutron Scattering (SANS) gives access to systems build up by lighter elements especially polymers, suspensions, membranes and moreover by Very Small-Angle Neutron Scattering the structural analysis of Large Scale Structures can be assessed. Different examples from amorphous alloys, soft matter and membrane science are presented.

12:05 PM Keynote
Hard X-ray Microscopy and its Application to Energy Science – Current Studies and Next-Generation Capabilities: *Jörg Maser*[1]; Barry Lai[1]; [1]Argonne National Laboratory

The success of the application of high-resolution, penetrating techniques to the study compositional and structural properties at the nanoscale has spawned the development of a next-generation nanoprobe beamline, the In Situ Nanoprobe, as part of the Upgrade of the Advanced Photon Source. This system provide in-situ capabilities such as heating and cooling, enable study of energy systems such as batteries and processes such as defect formation during materials processing in operando, at currently unavailable spatial resolution. The In-Situ Nanoprobe will provide 1000-fold increased photon flux at a spatial resolution of 50 nm, provide a highest resolution of 20 nm or below, and provide full spectroscopy capabilities for study of most elements in the periodic system. We will present recent materials studies using the Hard X-ray Nanoprobe (Fig. 1), discuss development of our next-generation capabilities, and outline our approach towards APS' goal for hard X-ray focusing to 5 nm.

Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Studies of Mechanical Properties and Effects of Current I

Impact of Sn Grain Orientation and Isothermal Aging on Pd Added Sn-Ag-Cu Solder Interconnect Board Level Mechanical Shock Performance: *Tae-Kyu Lee*[1]; Bite Zhou[2]; Thomas R. Bieler[2]; Kuo-Chuan Liu[1]; [1]Cisco Systems; [2]Michigan State University

The mechanical stability of solder joints with Pd added to SnAgCu alloy with different aging conditions was investigated in high G level shock environment. A test vehicle, which has three different strain and shock level condition couples in one board, was used to identify the joint stability and failure modes. The results revealed that the Pd provided stability at the package side interface with an overall shock performance improvement over 40% compared to the SnAgCu alloy without Pd. There is also a dependency on the pad structure on the board side, which implies that the intermetallic at the board side and the package interface have different fracture/failure mechanisms. The effect of Sn grain orientation on shock performance, interconnect stability, and crack path with and without Pd added was investigated and compared with the effect of tin grain orientation in thermomechanical cycling conditions.

8:55 AM Invited
Effect of Temperature Dependant Deformation Characteristics on Thermomechanical Fatigue Reliability of Eutectic Sn-Ag Solder Joints: Deep Choudhuri[1]; Andre Lee[1]; *K.N. Subramanian*[1]; [1]Michigan State University

Results from the monotonic shear loading at different temperatures in the range of -55 to 150°C of eutectic Sn-Ag solder joints with a simple shear strain rate of 10-3 s-1 provide a clear explanation for the differences in the thermomechanical fatigue response of such joints subjected to temperature excursions ranging between -55°C to 125°C, and -15°C to 150°C. At very low temperatures regimes the strength of the interfacial Cu6Sn5 intermetallic compound layer and the Sn matrix control the montonic deformation and TMF behavior. However, at higher temperatures the failure mode in both monotonic loading and in TMF is dominated by the Sn-Sn grain boundary sliding/decohesion within the solder matrix. Such observations also explain why significant reduction in the residual shear strength is noted from the very early stages of low temperature regime TMF as compared to that at high temperature regime TMF.

9:20 AM
Stress-Strain Behavior of Lead Free Solder Joints Determined by Digital Image Correlation Techniques: *Golta Khatibi*[1]; Martin Lederer[1]; Brigitte Weiss[1]; Herbert Ipser[1]; [1]University of Vienna

Previous investigations on miniaturized solder joints showed a strong increase in their yield and tensile strength with decreasing the gap size. In this study using digital image correlation techniques and FEM simulations the influence of geometrical constraints on stress-strain response of lead-free solder joints was analyzed. Solder joints of Cu-Sn3.5Ag-Cu with thicknesses between 50µm to 500µm were subjected to tensile loading and the sequences of local strain build-up in the joint area was measured using a VIC3D system. With decreasing the gap size a shift of strain localization from the center of the joints towards the interface region was observed. FEM analysis showed that the interface between the solder and substrate introduces a high triaxiality of stress which reduces the deviatoric stress inside the solder. This effect was more prominent in highly constrained solder joints leading to an increase of strength and a decrease of ductility.

9:40 AM
Effect of Continuous Recrystallization on Pb-Free Solder Joints in Thermo-mechanical Fatigue(TMF): *Liang Yin*[1]; Babak Arfaei[2]; Peter Borgesen[2]; [1]Universal Instruments Corp; [2]Binghamton Univeristy

The performance of Pb-free solder joints in TMF depends on the initial microstructure and its subsequent evolution. The fatigue failure of a typical Sn-Ag-Cu joint is commonly observed to involve the recrystallization of beta-Sn across the high strain region of the joint. Recent studies showed the recrystallization occurred through the formation of low-angle grain boundaries and the continuous increase of their misorientations. Random high angle grain boundaries provide sites for damage accumulation, such as grain boundary cracking and cavitation. In this study, the microstructure evolution of Sn-Ag-Cu solder joints was characterized quantitatively by using scanning electron microscopy, polarized light microscopy and imaging processing techniques. The effect of TMF testing parameters, e.g. peak temperature and dwell time, on the levels of recrystallization and strain-enhanced coarsening of secondary precipitates were evaluated and correlated to fatigue crack propagation. Discussions on subgrain/grain rotation and its effect on fatigue crack propagation are presented.

10:00 AM
Influence of Aging on Fatigue Behavior of SnAgCu Solders: *Jonathon Tucker*[1]; Dennis Chan[1]; Ganesh Subbarayan[1]; Carol Handwerker[1]; [1]Purdue University

In our prior research we developed the Maximum Entropy Fracture Model (MEFM), a thermodynamically consistent and information theory inspired (non-empirical) damage accumulation theory for ductile solids. Since fracture in SnAgCu solder alloys is known to be highly dependent on grain orientation, the model maximally accounts for uncertainty in the knowledge of the microstructure to describe the risk of fracture for a given applied energy (inelastic dissipation). The model utilizes theoretical arguments from statistical mechanics and continuum thermodynamics to relate probability of fracture to accumulated entropic dissipation. Here, we investigate the effects of isothermal aging on damage accumulation in fatigue cycling testing. A custom-built microscale mechanical tester capable of approximately 10 nm displacement resolution was utilized to carryout isothermal cycling fatigue tests on carefully designed assemblies. The resultant relationship between load drop and accumulated entropic dissipation was used to extract the geometry-independent MEFM damage accumulation parameter for different aging conditions.

10:20 AM Break

10:30 AM
Influence of Solder Microstructure and Intermetallic Layer Thickness on Mechanical Shock Resistance of Pb-free Solder Joints: *K. Yazzie*[1]; H. Fei[2]; H. Jiang[2]; N. Chawla[1]; [1]Materials Science and Engineering, School for Engineering of Matter, Transport, and Energy, Fulton Schools of Engineering, Arizona State University; [2]Mechanical and Aerospace Engineering, School for Engineering of Matter, Transport, and Energy, Fulton Schools of Engineering, Arizona State University

Pb-free solder alloys are routinely subjected to mechanical shock and drop conditions in service. These solder alloys are susceptible to dynamic loading. Quantifying the contributions of intermetallic layer thickness and solder microstructure to the mechanical shock behavior of the solder specimen is extremely important and needs to be studied. In this study, dynamic strength of Sn-3.9Ag-0.7Cu solder joints was quantified as a function of strain rate, solder microstructure, and intermetallic layer thickness. High-speed video and nanoindentation of Sn grains in solder joints was used to measure constitutive data for high-fidelity finite element models. The mechanisms for deformation and the interplay between solder-controlled and intermetallic controlled fracture will be discussed.

10:50 AM
Effects of Crystal Orientation on Recrystallization and Damage in Lead-Free Solders during Thermal Cycling in Low and High Stress Package Designs: *Bite Zhou*[1]; Thomas Bieler[1]; Tae-Kyu Lee[2]; Kuo-Chuan Liu[2]; [1]Michigan State University; [2]Cisco Systems, Inc

The stress levels imposed on lead-free solder joints during thermal cycling vary in different package designs. With the same thermal history, solder balls in higher stress packages failed earlier compared to low stress packages. More significant recrystallization and big opening cracks were observed in high stress packages. The effects of Sn crystal orientation on cracking during thermal cycling are compared with packages with different stress levels and discussed in relation to the strain history. A diverse range of Sn crystal orientations were correlated with cracking in high stress packages. Even joints with Sn orientations resistant to cracking during thermal cycling in low stress package (with [001] perpendicular to the interfaces) developed cracks in the high stress package design. Sn crystal orientation evolution in selected solder balls are evaluated using electron backscatter diffraction (EBSD) and differential aperture X-ray microscope (DAXM) for surface and subsurface characteristics.

11:10 AM
Study on Fatigue Mechanism in Pb-Free Solder Joint using Isothermal Shear Fatigue: *Huili Xu*[1]; Choong-Un Kim[1]; Tae-Kyu Lee[2]; Hong-Tao Ma[2]; Kuo-Chuan Liu[2]; [1]The University of Texas at Arlington; [2]Cisco System Incorporation

Prediction of solder joint failure under temperature cycling is a difficult and persisting task in electronics packaging industry because of the continuously changing of solder property caused by dynamic changing of microstructure. To overcome such a difficulty, we conducted series of shear fatigue testing on solder joint and attempt to model the failure rate using known theories. Our investigation reveals that shear fatigue can be successfully modeled by frequency modified Coffin-Manson fatigue theory. However, the success of the model is found to be limited only to a given temperature and cannot be extended to include temperature term. This is related to the change in microstructure dynamics that alters mechanical constraint as well as change in failure location. This paper presents summary of our data, supporting the fatigue model but showing its limitations, along with discussion on their implications especially on the model for thermal cycle fatigue.

11:30 AM
Retarding Electromigration on Lead-Free Solder Joints by Micro-Sized Metal Particle Reinforcements: Limin Ma[1]; Yong Zuo[1]; Guangchen Xu[1]; *Fu Guo*[1]; [1]Beijing University of Technology

Although the failure induced by Electromigration(EM) can trigger a large void across the entire cathode interface of solder joints, no effective solutions are presented throughout years of effort on this problem. Here, the composite solder joints are addressed to demonstrate their potential roles on solving the EM issue in the eutectic lead-free solder joints. Micro-sized Ni or Co particles were selected to intentionally add into the solder matrix due to their extensive application as a barrier layer in the under-bump-metallization (UBM) of flip chip solder joints. The ultimate results illustrated that the phase segregation of solder joints induced by EM was significantly inhibited in the composite solder joints during the current stressing, demonstrating the Sn–Ni or Sn-Co IMCs can act as the obstacles to obstruct the movement of dominant diffusion entity along the phase boundaries.

11:50 AM
Effect of Thermomigration on Redistribution and Growth of Intermetallic Compounds in the Sn0.7Cu Solder Bump under Current Stressing: *Wei-Yu Chen*[1]; Kwang-Lung Lin[1]; [1]National Cheng Kung University

The dissolution and redistribution of Cu6Sn5 in the Sn0.7Cu solder bump were observed consecutively with various time intervals under 150°C, 1.0×104 A/cm2 of current stressing. The thermal gradients in the vertical (parallel to electron flow) and horizontal directions (normal to the electron flow) were considered to combine the electromigration, induced by electron flow, in a current stressed solder joint. The combined effect of electromigration and thermomigration induces dissolution of Cu6Sn5 at the hot side and polarized flux of Cu in the solder bump from the hot side to the cold side. Consequently, the Cu6Sn5 recrystallized at the cold side of the solder bump and thus a behavior of the redistribution of the compound. Kinetic analysis indicates that the dissolution of Cu6Sn5 at the hot side is dominated by reaction control, while the growth of Cu6Sn5 at the cold side follows diffusion control.

Phase Stability, Phase Transformations, and Reactive Phase Formation in Electronic Materials XI: Solder-related Reliability Issues

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Alloy Phases Committee

Effect of Crystal Orientation on Mechanically Induced Sn Whiskers of Sn-Cu Platings: *Yukiko Mizuguchi*[1]; Yosuke Murakami[2]; Shigetaka Tomiya[2]; Tadashi Asai[3]; Tomoya Kiga[3]; Katsuaki Suganuma[4]; [1]Sony Corporation, Osaka University; [2]Sony Corporation; [3]Sony EMCS Corporation; [4]Osaka University

Mechanically induced Sn whiskers were examined by means of scanning electron microscopy (SEM) and electron backscatter diffraction (EBSD) patterns. The analyses revealed that Sn-Cu grains grew by recrystallization under mechanical stress. The notable feature was frequent twin formations. Most of the twin planes were {301}, and the number of {301} twin boundaries increased about twenty times as many as that of as-deposited platings. The present study clearly shows the first evidence that the mechanically induced Sn whiskers nucleate from twin grains of Sn. The authors will show twin formation plays a key role in the whisker formation. The details are discussed in the presentation.

8:50 AM
Effects of Cu-Bearing Flux on Joint Reliability and Microstructure of Sn-3.5Ag/ENIG Joint: *Hitoshi Sakurai*[1]; Youichi Kukimoto[2]; Chang-Jae Kim[1]; Katsuaki Suganuma[1]; [1]Osaka University; [2]Harima Chemicals, Inc

The demand for powerful BGA package accelerates the reduction in size of both BGA ball and pad. Therefore, control of the interfacial reaction is important to realize high reliability of small solder joints. In this study, the effects of Cu-bearing flux on joint strength and microstructure of Sn-3.5Ag/ENIG joints with additional heat treatment were investigated. The results of joint strength tests for as-reflowed solder joints showed that Cu-bearing fluxes gave higher joint strength than did flux without

Cu compound. Additionally, the use of flux containing high concentration of Cu compound provided the small reduction rate in joint strength in regard to additional heat treatment. According to the observation of the joint interface obtained by the use of Cu-bearing flux, the growth of a P-rich layer was well suppressed during thermal treatment. The Cu barrier effect by Cu-bearing flux had a significant impact on joint reliability of Sn-3.5Ag/ENIG joint.

9:05 AM
Gold and Palladium Induced Embrittlement Phenomenon in Microbumps Using Au/Pd(P)/Ni(P) Metallization Pads: *Wei-Hsiang Wu*[1]; Chia-Ming Li[1]; Yen-Chen Lin[1]; Cheng-En Ho[1]; [1]Yuan Ze University

Thermal reliability of the Au/Pd(P)/Ni(P) tri–layer utilized in microbumps (85 micrometer diameter) was investigated in this study. We found that the surface Au/Pd films would quickly alloy with molten Sn3Ag0.5Cu during soldering and then precipitated significant amounts of AuSn4 and PdSn4 in the solidified Sn matrix, respectively. In the subsequent isothermal aging, these two intermetallic species together with Cu6Sn5 gradually migrated to the solder/Ni(P) interface, forming a mixture layer(s) of AuSn4 + PdSn4 + Cu6Sn5. The driving force for their resettlement is that they can acquire specific amounts of Ni from the Ni(P) substrate, becoming more thermodynamically stable phases. The formation of the multi–compound layer(s) at the interface substantially weakened the interfacial strength, deteriorating the mechanical/electrical reliability of the solder joints. More details regarding the microstructural evolution of AuSn4, PdSn4, and Cu6Sn5 in microbumps will be presented in this talk.

9:20 AM
Inhibiting Cu-Sn Intermetallics by a Pre-Heat Treatment: *Chih-Chia Hu*[1]; Hsiang-Yao Hsiao[1]; Chih Chen[1]; [1]National Chiao Tung University

Copper serves as the most popular under-bump-metal (UBM) in microelectronic packaging industry. During soldering reaction, copper reaction with Sn-based solders to form Cu_6Sn_5 and Cu_3Sn intermetallic compounds (IMCs) very quickly and thus thousands of solder joints form simultaneously in one reflow. Yet, the IMCs are brittle in nature. It will be very beneficial if the Cu-Sn reaction could be inhibited after jointing. We discover a effective approach to inhibit the growth of the Cu-Sn IMCs. By depositing a thin layer of solder on a Cu film and a liquid-state metallurgical reaction at 260 ^oC for few minutes, the channels between Cu_6Sn_5 IMCs might be closed up. When the sample was jointed to solder afterwards, this layer-type Cu_6Sn_5 IMCs becomes a diffusion barrier for Cu dissolution during additional reflowing, and the growth of the IMCs was retarded.

9:35 AM
Rare-Earth Containing Lead-Free Solders with Enhanced Ductility: *Huxiao Xie*[1]; Nikhilesh Chawla[1]; [1]Arizona State University

We have previously shown that small additions of the rare-earth (RE) elements to Sn-Ag-Cu alloys (La, Ce, and Y) significantly increase their ductility, without significant loss in the overall strength or creep resistance. We have shown that the unique RE-Sn soft intermetallic (IMC) particles play and important role in the ductility enhancement. Based on these mechanisms, calcium was selected as a potential candidate to increase the ductility of Sn-Ag-Cu lead-free solder. Doping Ca into Sn-rich solder resulted in the formation of CaSn3 that has the same crystal structure as CeSn3 and LaSn3, but possesses a lower melting point. Nanoindentation was used to measure Young's modulus and hardness of CaSn3.The modulus and hardness are significantly lower than that of RE-Sn and Cu-Sn IMCs formed in Pb-free solders. Finally, the monotonic shear behavior of reflowed Ca-containing Sn-Ag-Cu/Cu lap shear joint was studied and compared to the SAC and RE-containing SAC solder joints.

9:50 AM
Study of Orientation of Solder Grains in Microbumps for 3D IC Packaging: *Han-wen Lin*[1]; Chih Chen[1]; [1]National Chiao Tung University

As the trend of portable devices strikes the whole world, people want to have more functions on their portable devices. Thus, microprocessors with better performance within the smaller size of packagings are required. So far, the most possible way to fulfill this requirement is 3D IC packaging with Pb-free solder microbumps and through-Si-vias. Many researches have shown that the BCT structure of tin makes different mechanical, electrical properties and failure mechanisms along different axis. However, There are few researches studying the orientation of tin of microbumps, in scale of 20 – 40 μm or even smaller. In this paper, the orientation of Sn and intermetallic compounds (IMCs) in microbumps are examined by EBSD. It is found that when SnAg solder jointed to Cu metallization on both sides, the orientation of Cu_6Sn_5 IMCs is random in the beginning. However, after longer time of reflowing, the merged IMCs became the same orientation.

Effect of External Strain on Growth of Interfacial Intermetalic Compounds between Sn on Cu Substrate: Yu-Ting Wang[1]; Shin-Nan Li[1]; *Ming-Tzer Lin*[1]; [1]National Chung Hsing University

A four point bend experiments were conducted to study on the effect of substrate strain related to Cu-Sn IMC growth. Two kinds of Tin samples (Matte and Bright) were prepared. 400μm Cu sheet were cut into strips with 27mm in length and 5mm in width as test samples. 35μm tin (Matte or Bright) was deposited on top of copper sheet using electroplating. A set of samples were put into furnace at 200°C and bending strain were applied under tension, compression and no strain. The results on intermetallic formation affected by different strain levels and reflow time were presented. Both of tension and compression strain would affect the Cu-Sn IMC formation. The thickness of IMC was increased when sample under strain and the trend is Compression > Tension> Control. The growth rate of IMC was faster in Bright tin under strain .The IMC structures from different Tin sources present very differently.

10:35 AM
Development and Evaluation of Direct Deposition of Au/Pd(P) Bilayer on the Cu Metallization in Soldering Applications: *Cheng-En Ho*[1]; T. T. Kuo[1]; H. G. Wang[1]; C. W. Fan[1]; [1]Yuan Ze University

The Ni-based thin film(s), such as Au/Ni(P) or Au/Pd(P)/Ni(P), is a very common surface finish to treat over the Cu pads in microelectronic packaging applications. The thickness of the Ni(P) usually exceeds 5 μm, and thereby hinders the application in the fine-pitch components. Additionally, there are several reliability concerns induced by the Ni(P), such as black pads and Au- (or Pd-) embrittlement. In order to avoid such reliability concerns, direct deposition of the Au/Pd(P) bilayer on the Cu substrate is being considered and adopted by industry very recently. This study systematically investigates the metallurgy of the solid-state reactions and intermetallic growth kinetics between Sn3Ag0.5Cu and Au/Pd(P)/Cu trilayer with various Pd(P) thicknesses. To quantify mechanical response of the interfacial microstructures, a high-speed ball shear (HSBS) test was conducted in this study. More details regarding the microstructural evolution and mechanical response of various Au/Pd(P) layers will be presented in this talk.

10:50 AM
Effective Suppression of Electromigration-Induced Cu Dissolution by Using a Ag Barrier Layer in Lead-Free Solder Joints: *Chao-hong Wang*[1]; Han-ting Shen[1]; Wei-han Lai[1]; [1]National Chung Cheng University

Electromigration-induced failures are a crucial reliability issue for solder joints in flip-chip technology. The main failure modes are void formation and fast Cu dissolution, leading to a rise in resistance. Under current stressing, electromigration causes a large amount of Cu_6Sn_5 formation in the solder matrix and the considerable consumption of Cu substrate. In this work, Ag is used as a barrier layer at the solder/Cu interface to inhibit Cu dissolution. The test specimen structure was prepared as Sn/2µm Cu/1µm Ag/Cu substrate. Without current stressing, the interfacial products were Cu_6Sn_5, $AgSn_3$, Cu_6Sn_5 and Cu_3Sn. As electron currents passed from Cu substrate to solder, the 2µm Cu layer was completely consumed and the formed Cu_6Sn_5 phase dispersed in the solder matrix. The observation of $AgSn_3$ layer and Cu substrate was similar to that of without current. Hence, Ag can act as an effective diffusion barrier against the Cu dissolution induced by electromigration.

11:05 AM
Driving Force of EM-Induced Cu Dissolution in Cu-Sn Compound: *Cheng Tse Lu*[1]; Cheng-Yi Liu[1]; [1]National Central University

Upon current-stressing a Cu/Sn cathode joint interface, the Cu atoms in the Cu-Sn compound layer would experience two major driving forces, which are EM force and difference of Cu chemical potential in the Cu-Sn compound layer and in the Sn solder with deficient Cu solubility. Both forces would simultaneously result in Cu dissolution fluxes from the Cu-Sn compound layer into the Sn joint. In this study, we design a special T-shape solder joint structure to separate this two driving force of EM-induced Cu dissolution in Cu-Sn compound. The current work has demonstrated that the EM-induced deficient Cu solubility in Sn solder is the dominant driving force for the dissolution in the cathode Cu-Sn compound layer under current density of 104 A/cm2 at 150 °C.

11:20 AM
Reactive Wetting of Heterogeneous Substrates by Sn-based Solders: Q. Lai[1]; L. Zhang[1]; *J. Shang*[2]; [1]Institute of Metal Research; [2]University of Illinois

Reactive wetting of heterogeneous substrates by Sn-based solders were investigated to clarify the mechanisms of reactive wetting in these systems. It was found that the wettability of dual-phase alloys could be made better than that of each component. Over a wide composition range, reactive wetting on dual-phase alloys was shown not to follow the classical Cassie equation. Instead, the contact angle vs. area fraction of the second phase showed a "V"-shape variation and there was an inverse relationship between the contact angle and the phase boundary density. From the observations of wetting processes, it was shown that the excellent wettability of dual-phase alloys resulted from the sharp difference in the dissolution rate between the two phases, which promotes phase boundary grooving at the triple junction and enhances wetting.

11:35 AM
The Cross-Interaction in the Ni/Sn/Cu Sandwich-Type Solder Joint with Electroless Pd Surface Finish: *Chi-Pu Lin*[1]; Chih-Ming Chen[1]; [1]National Chung-Hsing University

In modern integrated circuit (IC) packaging, the under bump metallization (UBM) used in flip-chip technologies is often composed of two different types of metal pads. Cu is commonly used as a metallization layer on the printed circuit boards (PCB). Ni has good solderability and is also a good diffusion barrier. Sn is the primary element of the Pb-containing and Pb-free solders, hence the Ni/Sn/Cu sandwich-type structure is often formed in the flip-chip solder joints. Electroless Pd surface finish also has good wetting property and gradually replaces immersion Au in recent years. In this study, the quaternary Ni/Pd/Sn/Cu and Ni/Sn/Pd/Cu systems were prepared by thermal compression and then solid-state aging were performed at 200□ up to 240h. Cross-interactions in the multi-layered structure were investigated. Morphological evolution, formation, and kinetic behavior of the intermetallic compounds formed by the interfacial reactions were discussed.

11:50 AM
Grain Boundary Penetration of Various Types of Ni Layers by Molten Pb: *Chia Yuan Chang*[1]; C. Robert Kao[1]; [1]National Taiwan University

In this study, we investigated the penetration of grain boundary by molten Pb into different Ni-based substrates, including pure Ni, electroplating Ni, and electroless Ni-P. Penetration was observed for all three types of substrate when these substrates were inserted into molten Pb at 360 oC. Since electroplated Ni has a very small grain size than bulk Ni, liquid Pb not only penetrated the grain boundaries but also resulted in fragmented interface. Molten Pb also penetrate electroless Ni-P even though it is amorphous structure originally, and the penetration depth are more than that of electroplated Ni. This result shows that electroplating Ni exhibits best penetration resistance.

Randall M. German Honorary Symposium on Sintering and Powder-Based Materials: Sintering Theory and Practice

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Powder Materials Committee
Program Organizers: K. Morsi, San Diego State University; Fernand Marquis, Naval Postgraduate School; John Meyer, Iowa State University; Ahmed El-Desouky, San Diego State University; Eugene Olevsky, San Diego State University

Monday AM	Room: Oceanic 2
March 12, 2012	Location: Dolphin Resort

Session Chair: Eugene Olevsky, San Diego State University

8:30 AM Introductory Comments

8:40 AM Keynote
History of Sintering: *Randall German*[1]; [1]San Diego State University

Sintering has been used for thousands of years and rediscovered several times. The modern era traces to the early 1900s and is close coupled to basic discoveries in atomic and crystal structure, defect migration, surface energy, and microstructure evolution. This converged in the late 1940s to generate the accepted concepts on how materials sinter. This presentation organizes the timeline for sintering literature to show early concepts were too restrictive. Starting with sintering observations it is possible to sort out how models emerged to explain those observations. Comments are offered on who generated the greatest impact, what applications were most significant, and how a few inspirational leaders and organizations clearly dominated the emergence of sintering theory. Commercial developments were far ahead of theory and that is seen today with the emergence of novel electronic products relying on sintering.

9:10 AM Invited
Grain Growth during Sintering of Nanosized Particles: *Zhigang Fang*[1]; Hongtao Wang[1]; Vineet Kumar[2]; [1]University of Utah; [2]Kennametal Inc.

Grain growth during sintering of nanosized powders is an issue that is critical for manufacturing of bulk nanocrystalline materials by sintering nanosized powders. In general, it has been found that grains grow rapidly during sintering and it is very difficult to achieve nanoscaled grain sizes in as-sintered state. Although the thermodynamic driving forces for grain growth for nanosized particles are the same as that for micron-sized particles, the kinetics and mechanisms of the grain growth of nano particles during sintering deviate from that of the conventionally known power law relationship. This paper examines the grain growth of nanosized tungsten particles during the early stage of sintering when the relative density of the material is still less than 90%. Linear kinetic behavior of grain growth will be discussed.

9:35 AM Invited
Distortion in a 7xxx Aluminium Alloy Sintered in Nitrogen under Different Flow Patterns: Xini Yuan[1]; *Ma Qian*[1]; Saiied Aminossadati[1]; Graham Schaffer[1]; [1]The University of Queensland

This paper presents an experimental and numerical study of the effects of sample position and gas flow pattern on the distortion that occurs during sintering of a 7xxx aluminium alloy, Al-7Zn-2.5Mg-1Cu. The experimental study examines the distortion of three equally spaced compacts during sintering in flowing nitrogen at separation distances ranging from 2 mm to 40 mm. The microstructural evolution in each compact during sintering was characterized using optical and scanning electron microscopy. The surface compositions of the sintered samples were analysed using X-ray photoelectron spectroscopy (XPS) depth profiling. A computational fluid dynamics (CFD) model was developed to investigate the flow pattern surrounding each sample by streamlines corresponding to the experimental conditions. The mechanism of distortion in the Al-7Zn-2.5Mg-1Cu alloy sintered under different sample separation distances is discussed in light of the microstructural observation, composition analysis and CFD modelling results.

10:00 AM Invited
Challenges and Further Developments in Modeling of Sintering: *Eugene Olevsky*[1]; [1]San Diego State University

Six possible directions of further developments in modeling of sintering are pointed out, including multi-scale modeling of sintering, development of on-line sintering damage criteria, modeling of nano-powder sintering, modeling of sintering with phase transformations or chemical reactions, modeling of field-assisted sintering, and the development of sintering optimization approaches. Existing theories require a link between the micro-, meso- and macroscopic descriptions of sintering. Certain events occurring at the micro-structure level are not accounted for; those include the phenomena, which are, in particular, important in nano-powders' sintering. Usually, factors of a non-thermomechanical nature are not incorporated in sintering models. Such factors include phase transformations, chemical reactions, influence of sintering atmospheres, and influence of electro-magnetic fields. Rigorous optimization tools are missing in modeling approaches, which could enable the determination of the most favorable initial properties and geometry of the sintered specimen as well as the most advantageous parameters of sintering regimes.

10:40 AM Keynote
Stereological Analysis of Microstructural Evolution during Sintering: *Burton Patterson*[1]; [1]University of Florida

Microstructural evolution during sintering is the net result of a number of interacting processes with different driving forces and controlling effects. Following the paths of evolution of 3D microstructural descriptors such as pore and grain boundary surface area per volume and their triple-line of intersection provides insight and shows relationships that may not otherwise be apparent. In liquid phase sintering, growth path envelope analysis of the evolving particle size distribution provides growth and shrinkage rates as a function of initial size class, enabling testing of coarsening models and controlling mechanism. All in all, numerous microstructural characteristics are amenable to quantification via stereological methods for understanding numerous aspects of sintering. This presentation will review useful examples of these analyses.

11:10 AM Invited
A Review on Alloying in Tungsten Heavy Alloys: *Animesh Bose*[1]; Rajendra Sadangi[2]; Randall German[3]; [1]Materials Processing, Inc.; [2]Rutgers University; [3]San Diego State University

This paper will review some of the developments in the area of alloying of tungsten heavy alloys. The review will concentrate on the alloying additions that have been made to the classic liquid phase sintered tungsten heavy alloys primarily based on W-Ni-Fe compositions. The effects of these alloying elements on the microstructure and properties of tungsten heavy alloys will be discussed in this paper. The review will also touch on some of the advantages that these additive modified tungsten heavy alloys yield over conventional tungsten heavy alloys (without the alloying additions), especially the ability to form near net-shaped, high strength, high hardness, heavy alloys without the additional thermo-mechanical treatments needed to attain higher strength and hardness.

11:35 AM Invited
Development of Alternate Materials to Cemented Carbides without Tungsten: *Ken-ichi Takagi*[1]; [1]Tokyo City University

Paucity of scarce and unevenly distributed resources such as tungsten has become a crucial issue all over the world. In the field of wear resistant hard materials, development of alternative materials with less or no tungsten is a current research topic. Borides, especially transition metal borides show high hardness, high melting point, etc. and hence borides are well-suited to wear resistant applications. A unique reaction sintering technology named reaction boronizing sintering to form multiple borides coexisting with a metallic binder during liquid phase sintering has been successfully developed as world's first ternary boride base cermets with excellent mechanical properties such as Mo2FeB2 and Mo2NiB2 base cermets. These boride base cermets containing no tungsten have already been applied to wear resistant applications such as injection molding machine parts, etc. This paper focuses on resent development of alternate materials to cemented carbides without tungsten, especially on the ternary boride base cermets.

Science and Engineering of Light Metal Matrix Nanocomposites and Composites: Metal Matrix Nanocomposites

A Unified Theoretical Model for Nanoparticle and Microparticle Capture by Metal Solidification Front: *Jiaquan Xu*[1]; Lianyi Chen[1]; Xiaochun Li[1]; [1]University of Wisconsin-Madison

Effective capture of nanoparticles by solidification front is extremely challenging for solidification processing of metal matrix nanocomposites (MMNCs). But there is little theoretical study on nanoparticle capture during metal solidification. This article is to establish a unified theoretical framework for fundamental understanding of nanoparticle and microparticle capture during metal solidification. Nanoscale interactions among particles (micro- and nanoparticles), molten metal, and solidification front were analyzed. Van der waals and viscous forces were especially studied. Plasma frequencies were introduced to approximate Hamaker constants for various metals. Factors such as thermal conductivity, Gibbs Thomson effect, varying viscosity and possible gas film on surface of nanoparticle were considered. Critical velocity and critical distance for nanoparticle capture were determined. While further study is needed, theoretical predictions from this new model shows promises for particle captures in solidification processing.

8:55 AM
Characterization of Solidification of Nanoparticle enforced Al Using In Situ TEM: *Jorg Wiezorek*[1]; Hasso Weiland[2]; Andreas Kulovits[1]; Can Liu[1]; [1]University of Pittsburgh; [2]Alcoa

Establishing the processing-structure-property relationships in Aluminum matrix nano-composite (Al-NC) requires microstructural analysis methods that can robustly and quantitatively detect the dissimilar nanoparticle reinforcements. This proves challenging for conventional electron microscopy methods, for instance, due to the low contrast resulting in Al-NC for typical reinforcement species, such as Al2O3 and SiC nanoparticles or carbon nanotubes. Using transmission electron microscopy (TEM) studies, inclusive of novel orientation imaging microscopy (OIM), enabled successful analyses of the morphology, size, phase fractions of the Al-matrix grains and the nano-particle dispersions in SiC and Al2O3 based Al-NC. In-situ TEM heating studies have been used to monitor effects of the nanoparticles on the microstructural transformations, including melting and solidification, in the Al-NC due to thermal stimulation.

9:15 AM
Interfacial Analysis of CNT Reinforced AZ61 Mg Alloy Composites: *Katsuyoshi Kondoh*[1]; Hiroyuki Fukuda[1]; Junko Umeda[1]; Bunshi Fugetsu[2]; [1]Osaka University; [2]Hokkaido University

In AZ61 Mg alloy composites with multi-walled carbon nanotube (CNT) reinforcements, in-situ formed Al2MgC2 compounds at the interface between Mg matrix and CNTs effectively reinforced the interfacial bonding, and enabled tensile loading transfer from the Mg matrix to nanotubes. As a result, the heat treatment at 550°C was obviously effective to synthesis Al2MgC2 needle-like compounds and improve the mechanical tensile strength of the composites. It was also clarified that the microstructures and grain orientations of the composite matrix were not significantly influenced by CNT addition.

9:35 AM
Magnesium Nanocomposites Processed by Electromagnetic Acoustic Transduction: *Hunter Henderson*[1]; Zachary Bryan[1]; Orlando Rios[2]; Gail Mackiewicz-Ludtka[2]; Alexander Melin[2]; George Lopp[2]; Yu-Min Su[2]; Michele Manuel[1]; [1]University of Florida; [2]Oak Ridge National Laboratory

Magnesium (Mg)-based alloys reinforced with ceramic nanoparticles have attained interest for their improvement in strength and ductility, compared to traditional Mg alloys. Among several methods of fabrication, sonication shows promise for scalability to industrial applications. A specialized technique known as Electromagnetic Acoustic Transduction (EMAT), magnetically induced sonication, is evaluated with regard to the dispersion of several particle types in Mg. This technique potentially offers several advantages over traditional melt sonication, including non-contact, higher intensity, and smoother energy distribution. The present study explores the effect of processing parameters on the composite's microstructure. Additionally, radiographic and microscopic techniques are used to evaluate microstructural parameters such as dispersion, particle morphology, and grain size The authors would like to acknowledge the support of the National Science Foundation (DMR 0845868), National High Magnetic Field Laboratory User Program, and Department of Energy's Energy Efficiency and Renewable Energy Industrial Technologies Program.

9:55 AM
Properties of Aluminum-Graphene Nanocomposites: *Stephen Bartolucci*[1]; Joseph Paras[1]; Mohammad Rafiee[2]; Sabrina Lee[1]; Javad Rafiee[3]; Deepak Kapoor[1]; Nikhil Koratkar[3]; [1]US Army ARDEC; [2]Rice University; [3]Rensselaer Polytechnic Institute

Carbon nanotubes have been studied recently as reinforcement additives for lightweight metal matrices, such as aluminum and magnesium, in order to increase mechanical properties. With the exponential increase in attention given to graphene in current research arenas, we have chosen to study the addition of graphene platelets to an aluminum matrix. Our results have shown a decrease in the mechanical properties performance of the graphene-aluminum nanocomposites as compared to composites made with multi-walled carbon nanotubes. It is believed that aluminum carbide formation plays a central role in the behavior of our graphene composites. Characterization of the composites and explanation of the results will be discussed.

10:15 AM Break

10:30 AM
Biodegradability and Mechanical Performance of Hydroxyapatite Reinforced Magnesium Matrix Nanocomposite: *Chao Ma*[1]; Lianyi Chen[1]; Jiaquan Xu[1]; Axel Fehrenbacher[1]; Yan Li[1]; Frank Pfefferkorn[1]; Neil Duffie[1]; Jing Zheng[1]; Xiaochun Li[1]; [1]UW-Madison

Magnesium and its alloys have gained significant attention recently in the field of biodegradable medical implant due to its combination of good biodegradability, biocompatibility and mechanical properties. However, magnesium implants are not able to maintain the mechanical integrity under physiological conditions because of the high corrosion rates. In this study, hydroxyapatite (HA) nanoparticles reinforced magnesium matrix nanocomposites are fabricated by friction stir processing (FSP). The microstructure, mechanical properties of the nanocomposites and their in-vivo corrosion properties in simulated body fluid (SBF) were investigated. The results suggest that the mechanical and corrosion properties of the nanocomposites could be effectively controlled by the percentage of HA nanoparticles and the processing parameters.

10:50 AM
Mechanical Properties of A356-CNTCast Nano Composite Produced by a Special Compocasting Route: Benyamin Abbasipour[1]; *Behzad Niroumand*[1]; Sayed Mahmoud Monirvaghefi[1]; [1]Isfahan University of Technology

A356 aluminum alloys reinforced with CNTs were produced by stir casting and compocasting routes and their microstructural characteristics and mechanical properties were examined. In order to alleviate the problems associated with poor wettability, agglomeration and gravity segregation of CNTs in the melt, CNTs were introduced into the melts by injection of CNT deposited aluminum particles as well as raw CNTs. Nickel- phosphorous electroless coating process was employed for uniform co-deposition of CNTs into a Ni-P matrix coated on Aluminum powder. The slurries were subsequently cast at temperatures corresponding to full liquid as well as 0.15 and 0.30 solid fractions. The results showed that addition of CNTs to A356 matrix could significantly refine both fully liquid and semi-solid cast microstructures. Mechanical properties of the samples were also significantly increased by addition of CNTs in the form of CNT deposited aluminum particles.

11:10 AM
Production of Cast AZ91-CNT Nano-Composite by Addition of Ni-P-CNT Coated Magnesium Powder to the Melt: Mahan Firoozbakht[1]; Behzad Niroumand[1]; *Behzad Niroumand*[1]; Sayed Mahmoud Monirvaghefi[1]; [1]Isfahan University of Technology

High agglomeration tendency and poor wettability of CNTs with metallic matrices are the main challenges for using this unique material as the reinforcement in magnesium based composites. In this study, nickel-phosphorous electroless coating process was employed for uniform co-deposition of CNTs into the Ni-P coating on the magnesium powder for the first time. The magnesium powder with the optimum composite coating was then used as the reinforcement and was introduced into the molten AZ91 alloy using stir casting method. Similar composites were also produced with untreated as-purchased CNTs for comparison. It was observed that addition of CNTs dispersed in the electroless coating resulted in refinement of the grain size, reduction in the porosity content and improvement of the hardness and flexural strength. Untreated CNTs were not able to improve the structural and mechanical characteristics of the cast composites to the same extent. This is believed to be due to the more agglomeration, less uniform distribution and poor wettability of the untreated CNTs with the melt compared to those introduced to the melt through the Mg-Ni-P-CNT composite powder.

11:30 AM
Wear Behavior of Magnesium Matrix Nanocomposites at Room and Elevated Temperature: *Wenzhen Li*[1]; [1]Tsinghua University

Magnesium matrix nanocomposite reinforced with nano-sized SiC particles was fabricated by mechanical stirring and high intensity ultrasonic dispersion processing. The dry sliding wear behavior of the magnesium alloy and its nanocomposites were investigated using a ball-on-disc CETR wear testing machine. The test results show that the addition of SiC nanoparticles increased the wear resistance of composites at room and elevated temperature. The wear loss increase as the load increasing as expected and the wear loss of AZ91D is higher than those of its composites at all the loads. The dominative wear mechanisms vary with different load and the load occurring delamination wear can be improved due to SiC nanoparticles strengthening function. Wear test results also showed that the worn stages of AZ91D and its composite include running and stable worn stages, however the acutely worn stages occurs in one hour sliding time.

11:50 AM
Influence of Nanodispersions on Metallurgical Properties and Performance of Cast AlSi Alloys
: *Iman El Mahallawi*[1]; Yehia Shash[1]; Hoda Abdelkader[2]; Laila Shehata[3]; Mohamed Abdelaziz[4]; Asmaa Amer Abdelmegeed[3]; Joachim Mayer[5]; Alexander Scwedt[5]; [1]Cairo University; [2]Helwan University; [3]Scientific & Technology Centre of Excellence; [4]The British University in Egypt; [5]Gemeinschaftslabor fuer Elektronmikroskopie

The present study aims at developing nano-dispersed cast Al-Si hypo and hyper eutectic alloys with optimised properties and performance in automotive applications. In this work a number of cast samples of A356 and A390 were prepared by rheo-casting in a specially designed and built furnace unit allowing for the addition of the nano-particles into the molten Al-Si alloy with mechanical stirring. The microstructural features and the mechanical properties of the cast samples were investigated, as well as resistance to wear and corrosion in laboratory tests. The results obtained in this work showed improved wear and corrosion resistance of the nano-dispersed alloys, as well as enhancement in the mechanical strength of the nano-dispersed alloys, accompanied by significant increase in the elongation percentage, supported by evidence of refined dendrite arms length, and inter-lamellar spacing.

12:10 PM
Grain Refinement and Mechanical Property Enhancement in As-cast Al-Mg Nanocomposites: *Dake Wang*[1]; Michael De Cicco[1]; Xiaochun Li[1]; [1]University of Wisconsin-Madison

The microstructure and mechanical property after ultrasonic processing were studied in an Al-9Mg matrix with TiC0.7N0.3 nanoparticles. The Al-9Mg + TiC0.7N0.3, which had significant nanoparticle incorporation, showed more significant grain refinement and mechanical property enhancement than the Al-9Mg + Al-5Ti-1B alloys. This grain refinement and mechanical property enhancement in 0.2% yield strength, ultimate tensile strength and ductility were maintained when pieces of the original 1.5 vol.% TiC0.7N0.3 nanocomposites were added to additional Al-9Mg for the 0.5 vol.% and 0.2 vol.% TiC0.7N0.3 nanocomposites. This illustrates the potential of a master nanocomposite approach for metal matrix nanocomposite (MMNC) processing. The nanoparticles probably perform as nucleant catalyst for the a-Al and ß-Al3Mg2 phase and restrict the grain growth for a refined microstructure. The unusual ductility enhancement is also the result of suppression of pore formation as well as morphology alternation of the intermetallic phase by the nanoparticles.

Solid-State Interfaces II: Toward an Atomistic-Scale Understanding of Structure, Properties, and Behavior through Theory and Experiment: Atomic Level Structures, Compositions, and General Methods

Grain Boundary Complexion Conformations (Equilibrium Interface-Stabilized Phases) in Materials: *Martin Harmer*[1]; [1]Lehigh University

A grain boundary complexion is a "phase" that is thermodynamically stabilized by its adjoining grains (Science, 332, 182, 2011). It is chemically and structurally distinct from any bulk phase. Complexion phases can interconvert between well-defined equilibrium structures, which can be represented on complexion phase diagrams analogous to bulk phase diagrams. A progressive series of six possible complexion conformations has been proposed, whereby the discrete number of atomic layers, the layer thickness and the degree of structural/chemical ordering defines the stability of each type of complexion. One well-studied complexion conformation is the equilibrium thickness (1-2nm) intergranular film (IGF). Newly revealed thinner layer complexion conformations include bilayers and trilayers. This talk will present direct evidence obtained by aberration-corrected scanning transmission electron microscopy for the existence of various complexion conformations in metals, ceramics and semiconductors. The findings have important implications to the development of new materials with improved performance by mechanism-informed design.

9:00 AM Invited
Defect Structures of Interphase Boundaries in Metallic Nano-Composites: *Amit Misra*[1]; Qiangmin Wei[1]; Richard Hoagland[1]; Xiang-Yang Liu[1]; Dhriti Bhattacharyya[2]; [1]Los Alamos National Laboratory; [2]ANSTO

In nano-composites as the length scale of the constituent phases decreases to below approximately 5 nm, the interphase boundaries begin to dominate the mechanical behavior and radiation damage tolerance. It is therefore crucial to understand the atomic arrangements and defect structures of interphase boundaries in nano-composites. This presentation will review several unusual interface structures that were observed in model systems such as V-Ag and Al-TiN using high-resolution transmission electron microscopy. Atomistic modeling has helped elucidate the mechanisms that give rise to unusual interface structures such as Al layers in twin orientation in Al-TiN, and multiple orientation relationships and tetragonal distortions in V-Ag. This research is supported by DOE, Office of Science, Office of Basic Energy Sciences.

Structural and Compositional Transitions Across Interfaces in Titanium Alloys (Invited): Soumya Nag[1]; Arun Devaraj[1]; Robert Williams[2]; Gopal Viswanathan[3]; Jaimie Tiley[3]; Hamish Fraser[2]; *Rajarshi Banerjee*[1]; [1]University of North Texas; [2]The Ohio State University; [3]Air Force Research Laboratory

The atomic-scale study of solid-solid interfaces in multi-phase multi-component titanium alloys is a challenging but important endeavor. This presentation highlights the coupling of advanced characterization techniques, such as aberration-corrected high resolution transmission electron microscopy (HRTEM and HRSTEM), and atom probe tomography, to address the structural and compositional transition at the atomic scale across solid-solid interfaces in titaniums alloys. The specific interfaces to be discussed include the interface between the hcp α precipitates and the bcc ß matrix as well as that between the metastable hexagonal ω precipitates and the bcc ß matrix. Possible implications of such detailed interface analyses on the solid-solid transformation mechanisms leading to the formation of these precipitates in titanium alloys will also be discussed.

Gradient Energy, Interfacial Energy and Interface Width: an Example from Ni-Base γ/γ' Alloys: *Alan Ardell*[1]; [1]National Science Foundation

A method is presented for calculating the gradient energy, χ, and interface width, δ, from concentration profiles across precipitate-matrix interfaces. This is accomplished provided the interfacial free energy, σ, is known. The relationship between these quantities is $s = 2\chi\Delta X^2/3d$, where ΔX is the difference between the solute concentrations in the precipitate and matrix phases. Interfaces between γ and γ' phases from 2 sources are examined. One originates from Monte Carlo simulations of a planar γ/γ' interface in binary Ni-Al alloys and the other from experimental APT measurements across γ/γ' precipitate interfaces in a ternary Ni-Al-Cr alloy. The analysis involves fitting the concentration profiles using the sigmoid function. Meaningful values of χ and δ are obtained even for incomplete profiles, and the magnitudes of χ, (typically 10^{-8} to 10^{-10} J/m) compare favorably to those used in phase-field simulations. Free energy is not needed in the analysis.

10:30 AM

Modeling Nickel Surfaces and Grain Boundaries with the Fragment Hamiltonian Model: Helen Telila[1]; Susan Atlas[2]; *Steven Valone*[1]; [1]Los Alamos National Laboratory; [2]University of New Mexico

Modeling multiple phases, surfaces, and grain boundaries of even an elemental material like nickel within a single atomistic model continues to present challenges. For instance, two separate modified embedded atom method potentials must be invoke to model the pressure and temperature axes of the phase diagrams of iron and zirconium. Here we present a new method of generating atomistic potentials, the Fragment Hamiltonian (FH) model that is aimed at producing a unified model. The FH model holds many similarities to second-moment tight-binding and embedded atom models. In contrast to those two models, the FH model has a second embedding term that contains an effective gap energy that recognizes differences in metallic character among different defects and phases. Both embedding terms contain important coordination dependencies that play an equally important role as the effective gap. Both of these properties are essential for unifying atomistic models.

10:50 AM

Grain Boundary Diagrams: A New Materials Science Tool: *Jian Luo*[1]; Xiaomeng Shi[1]; Naixie Zhou[1]; [1]Clemson University

Recent research to develop grain boundary (GB) "phase" (complexion) diagrams [Shi & Luo, PRB 2011] and relevant experiments are reviewed. HRTEM studies revealed the stabilization of impurity-based, nanometer-thick, quasiliquid, intergranular films below the bulk solidus lines [Luo, Crit. Rev. Solid State Mater. Sci. 2007]. Enhanced diffusion in these films explained a long-standing mystery regarding the origin of "solid-state activated sintering". Thermodynamic models were developed to construct a preliminary type of GB diagrams – "lambda diagrams". A computed GB diagram predicted that a retrograde solubility in a binary alloy could lead to a decrease in the GB diffusivity with increasing temperature, and this counterintuitive prediction was experimentally verified [Shi & Luo, PRL 2010]. The correctness and usefulness of these computed GB diagrams were demonstrated. Most recent efforts on (1) extending our models and methods from binary to ternary alloys and (2) modeling discrete GB phases (complexions) are also present and discussed.

11:10 AM

Twin Boundary Structure in Bismuth Telluride: *Douglas Medlin*[1]; Q. Ramasse[2]; C. Spataru[1]; N. Yang[1]; [1]Sandia National Labs; [2]SuperSTEM Laboratory, STFC Daresbury, UK

We investigate the atomic structure of the basal twin boundary in bismuth telluride (Bi_2Te_3), an important thermoelectric material. The basal planes in the perfect Bi_2Te_3 structure are arranged in a repeating sequence of 5-layer wide $Te^{(1)}$-Bi-$Te^{(2)}$-Bi-$Te^{(1)}$ packets. Thus, it is possible for the twin interface to be located at one of three distinct locations: the $Te^{(2)}$ layer, the Bi layer, or the $Te^{(1)}$ layer. Through HAADF-STEM observations, we show that the twin boundary is terminated at the Te(1) layer, where the stacking forms a double-layer of Te. Our observations are consistent with *ab initio* calculations. We also analyze the structure of an interfacial step at the basal twin. Through a discussion of the defect crystallography and its relationships to analogous features in face-centered-cubic metals, namely the {112}-type interfaces that commonly terminate {111} growth and annealing twins, we provide insight concerning the mechanisms of twin formation in Bi_2Te_3.

11:30 AM

A Dislocation-Based Model for Design of Radiation-Tolerant Nanocomposites: *Aurélien Vattré*[1]; Michael Demkowicz[2]; [1]CEA; [2]MIT

A crystallographic model extended by analytical calculations of the elastic energies is used to predict the dislocation structures and energies of heterophase interfaces. Misfit dislocation networks are characterized by accommodating long-range strain with the coherency strain fields in the frame of the anisotropic elasticity. Applying uncertainty quantification and using atomistic simulations, the model is validated for selected interfaces and applied to designing interface interactions with extrinsic point defects. Unexpected interfaces for extreme radiation environment are discussed. This material is based upon work supported as part of the Center for Materials at Irradiation and Mechanical Extremes, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number 2008LANL1026.

Symposium in Memory of Patrick Veyssière: Understanding the Mechanisms Controlling Plastic Flow: Dislocations Organization

Defect Kinetics on Experimental Timescales Using Atomistic Simulations: Hao Wang[1]; *David Rodney*[1]; Dongsheng Xu[2]; Rui Yang[2]; [1]INP Grenoble; [2]Institute of Metal Research
In his last few years, Patrick Veyssière got involved in molecular dynamics simulations that give access to the full atomistic details of dislocation/defect interactions. Such simulations are however limited in time and do not allow studying diffusional processes like vacancy migration. For such processes, one needs to explore the configuration space in search of activated states whose energy barriers control the thermally-activated kinetics of defects. We present here a work performed in the context of a project initiated by Patrick Veyssière, where we studied the long-term evolution of vacancy supersaturations in FCC metals. We employed the Activation-Relaxation Technique in conjunction with kinetic Monte Carlo simulations to reach experimental timescales while retaining atomistic fidelity. Two cases are considered: severe plastic deformation and rapidly quenched metals. The simulations reveal in particular the central role of a specific and so far unidentified cluster, the pentavacancy.

Atomistic Simulation of the Breaking and Reaction of Dipolar Dislocations under Shear Deformation: *Dongsheng Xu*[1]; Hao Wang[1]; Rui Yang[1]; David Rodney[2]; Patrick Veyssière[3]; [1]Institute of Metal Research, Chinese Academy of Sciences; [2]SIMAP-GPM2, INPG; [3]LEM, CNRS-ONERA
The deformation of materials depends not only on the glide of single dislocations, but also on their group behaviors, among which dipolar dislocations play important roles. Molecular dynamics simulations were carried out to investigate the shear deformation of crystals containing dislocation dipoles of various height and density in Al and Cu with fcc and Ti with hcp structure. It was found that the passing and breaking of the dipole depend strongly on its height, and that the corresponding stress for low dipoles exceeds largely the elastic estimation, due to the dislocation reaction. Analysis shows that the resultant structures vary with dipole height, temperature and strain rate. Repeated reactions complicated the defect configuration forming faulted dipoles with 120° zigzagged configuration and loops of various size and shape. The long term evolution of the debris has been investigated with the activation relaxation technique, and the implications to further deformation discussed.

Mechanical Behavior and Dislocation Self-Patterning in Fatigued Single Crystalline Silicon: *Marc Legros*[1]; [1]CEMES-CNRS
Fatigue structures and associated mechanical behavior were widely studied in fcc metals, leading to the well known Winter and Mughrabi composite model: characteristic dipolar walls arrange themselves in persistent slip bands (PSBs), that accommodate increasing applied strain at constant stress by invading more crystalline volumes. Dislocation walls produced in fatigued single crystal Si at intermediate temperatures (800-900 °C) combine features resembling those of fcc metals and some that have never been observed before: dense dipolar walls separated by low density channels, but a very organized patterning from the early stages of hardening to stress saturation. The associated mechanical behavior is also original, as no stress plateau is observed for a given temperature. Indeed, a softening is observed when the strain amplitude is increased. The thermal activation glide of dislocations in Si and the evolution of wall patterns are combined to explain the link between mechanical behavior and underlying dislocation structures.

10:45 AM Invited
Mechanisms Controlling Plastic Flow of Silicon High Stress: *Jacques Rabier*[1]; [1]CNRS
Patrick Veyssière has been involved in the study of plastic properties of brittle material under confining pressure below the usual brittle to ductile transition temperature. This includes materials such as semi conductors and oxides with spinel structure. Following one of the first attempts to obtain information about the plasticity of silicon under pressure (1), this paper aims at reviewing how our understanding of the plasticity of silicon has beneficed from high pressure experiments, transmission electron microscopy, deformation under pressure in synchrotron beam as well as atomistic and ab initio calculations. Such high stress plasticity experiments have put forward plastic deformation mechanisms involving dislocations with compact core structures rather than expected twinning mechanisms. These mechanisms are likely to control the plasticity of silicon nanostructures as suggested by computer simulations. (1) Plastic deformation of silicon between 300°C and 600°C, J. Castaing, P. Veyssière, L.P. Kubin, J. Rabier, Phil. Mag. A, 44 (1981) 1407.

An Extended Kocks-Mecking Approach with an Explicit Role of Cross-Slip on the Balance between Isotropic and Kinematic Hardenings: First Application to Solutes in Ferrite: *Olivier Bouaziz*[1]; David Barbier[1]; J. D. Embury[2]; Guillaume Badinier[3]; [1]ArcelorMittal; [2]McMaster University; [3]University of British Columbia
Recently, a steel obtained by adding 8% of aluminium in ferrite have been characterized using: - TEM for dislocation structure, - Tensile and Bauschinger tests. By comparison with ferrite without alloying addition, the effects of solutes are: - Increase of the total strain-hardening, - More important Bauschinger effect (kinematic hardening), - Promotion of dislocation slips planarity.If solid solution hardening is one of the most common ways to increase the yield stress of metallic materials, solutes can also change obviously the intensity and the nature of strain-hardening. Surprisingly this last aspect has been poorly discussed in literature and no approach is available to explain completely our observations. An extension of the Kocks-Mecking's approach is proposed taking into account explicitly the role of cross-slip on the balance between isotropic and kinematic hardening and describing the evolution of the planarity of slip. Validations of the new approach are finally presented.

11:20 AM Invited
Low Cycle Fatigue of Copper Single Crystals under Alien Distribution of Dislocations: *Marek Niewczas*[1]; [1]McMaster University

Latent hardening experiments have been carried out on copper single crystals under conditions of low cycle fatigue at 298K, to study behavior of the flow stress and the dislocation substructure in parent and daughter samples. The presaturation region in secondary samples exhibits stage of hardening or softening, determined by the nature of interactions between dislocations of dominant slip system with the preexisting dislocations. This stage is associated with the destabilization and rebuild of old matrix and PSB structure, leading to the collapse of new matrix and formation of new PSB's characteristic of a saturation stage. The flow stress at saturation is a function of crystallographic orientation of single crystals and it is independent on the fatigue history or the type of the preexisting dislocation substructure. Dislocation mechanisms, which may operate under these fatigue conditions that build on Patrick's Veyssière models for refinement and annihilation of prismatic loops will be discussed.

Titanium: Advances in Processing, Characterization and Properties: Processing and Process Modeling I

The Evolution of "Beta–Titanium Alloys" for the Aerospace Industry: *Rodney Boyer*[1]; James Williams[2]; John Fanning[3]; [1]Boeing Company; [2]The Ohio State University; [3]TIMET

Beta and metastable-beta titanium alloys have been in production since the early 1960's – an early alloy (Ti-13V-11Cr-3Al) was used extensively on the SR-71 Blackbird. There are two types of metastable beta-alloys, the lean beta–alloys such as Ti-17 and Ti-6-2-4-6 and numerous alloys that are richer in β-stabilizer content such as Ti-15-3. These types may require different processing to optimize their properties. The beta-alloys sometimes offer significant processing advantages, such as the capability for cold rolling. In some instances the forging flow stresses and temperatures are lower. In addition, beta-alloys offer a significant strength advantage over alpha– and alpha/beta- alloys, which has been the primary driver for their use in aerospace applications – where weight savings are a prime consideration. The advantages and disadvantages of beta–alloys will be discussed along with some of their unique characteristics, and the evolution of their applications in the aerospace industry.

Integrated Computational Materials Engineering: Recent Progress in the Advanced Titanium Microstructure and Modeling Program: *Michael Glavicic*[1]; Rod Boyer[2]; Tom Broderick[3]; Fred Cohen[4]; Yunzhi Wang[5]; Fan Zang[6]; Donald Boyce[7]; Wei-Tsu Wu[8]; Ayman Salem[9]; Ron Wallis[10]; Vikas Saraf[11]; Vasisht Venkatesh[12]; Lee Semiatin[13]; [1]Rolls-Royce Corporation; [2]The Boeing Company; [3]General Electric Aviation; [4]Pratt & Whitney; [5]The Ohio State University; [6]Computherm; [7]Cornell University ; [8]Scientific Forming Technologies; [9]Materials Resources LLC; [10]Wyman-Gordon; [11]ATI Ladish Forging; [12]TIMET; [13]Air Force Research Laboratory

A summary of the progress achieved in the Advanced Titanium Microstructure Modeling program funded under the Metals Affordability Initiative (MAI) will be presented. The goal of this program is to develop computational models that predict location specific microstructure and mechanical properties for wrought titanium alloys through the integration of phase field, crystal plasticity, variant selection, thermodynamic and neural net models into the commercially available finite element software DEFORM. Other topics to be discussed include the use of 2-point statistics in the separation of electron backscatter data (EBSD) into its primary and secondary alpha components and the incorporation of Kearns numbers for the representation of crystallographic texture into neural net models.

9:30 AM
Microstructural Evolution and Mechanical Properties of ß-Titanium Ti-10V-2Fe-3Al during Incremental Forming: *Sven Winter*[1]; Sebastian Fritsch[1]; Martin F.-X. Wagner[1]; [1]Chemnitz University of Technology

Forming of high-strength beta titanium alloys is technologically and scientifically demanding and expensive. One approach to reduce costs is incremental forming by spin extrusion. The advantage of this process is the high utilization of material (80 %) in comparison to deep-hole drilling (40 %). In this study, we investigate the microstructural evolution and the mechanical properties of a Ti-10V-2Fe-3Al hollow shaft formed by spin extrusion, which results in varying stress-strain behavior across the wall thickness. Grain refinement from >1 µm (edge) to 100 µm (center) is observed. Subsequent heat treatments can be used to achieve homogeneous properties throughout the shaft's cross section. Even higher strengths are associated with the precipitation of primary a-phase. Our results for the high-strength beta titanium alloy Ti-10V-2Fe-3Al illustrate the potential of spin extrusion, combined with suitable heat treatments, to produce hollow shafts with improved properties at lower costs.

9:50 AM
Low-cost Ultrafine Grained Titanium Sheet Production by Extrusion-Machining: Kayla Calvert[1]; Wilfredo Moscoso[2]; Mert Efe[3]; Dinakar Sagapuram[3]; Srinivasan Chandrasekar[3]; *Kevin Trumble*[3]; [1]University of California San Francisco; [2]Pontificia Universidad Catolica Madre y Maestra; [3]Purdue University

Large Strain Extrusion Machining (LSEM), a single-step deformation technique that exploits large strains of machining and dimensional control of extrusion, is introduced as a low-cost method for the production of commercially pure Grade 2 titanium strips (~2 cm wide and 0.3 mm thick). Cost analysis indicates that LSEM is cost-efficient especially in producing sheet forms of metallic materials having limited workability like titanium, compared to the conventional rolling. TEM investigations revealed that the process is also capable of achieving equiaxed ultrafine grain structures (~200 nm grain size). Crystallographic texture studies suggest that the final deformation texture can be controlled in LSEM through the process parameters. The application of the process to produce superplastic titanium sheet, for which very fine grain size and possibly certain textures are essential factors, looks promising. Economic aspects and scalability of the process to produce wider/thicker sheets will be addressed.

10:10 AM
Microstructure Evolution during Different Thermal Processing in Billet of High-Strength Titanium Base Alloy VT43: *Anatoliy Yakovlev*[1]; Nadezhda Nochovnaya[1]; [1]All-Russian Scientific Research Institute of Aviation Materials

In the report the new high-strength constructional titanium alloy VT43 based on system Ti-Al-Mo-V-Cr-Nb-Zr-Fe intended for application in welded constructions of hydroaccumulators and capacities is considered. VT43 has high manufacture properties and profitability. Charge for VT43 costs over 20% less than pseudo ß alloy VT22 and over 30% less than Ti-10V-2Fe-3Al. The electric power expense while heat treatment (a+ß)-alloy VT43 over 30% less than for VT22 and over 50% for Ti-10V-2Fe-3Al. Processing titanium alloy VT43 in comparison with VT22 and Ti-10V-2Fe-3Al less for 20% and 30% accordingly. Influence of different thermal processing (quenching + aging, high temperature processing + aging) on billets microstructure and mechanical properties of VT43. In this report is shown how high temperature processing + aging at 430-

520 0C for 10 hours and air cooling provides the best combination of mechanical properties (fine-dispersed intergranular structures), also this processing less county duty (exception of operation of preliminary quenching).

10:40 AM
Crystal Plasticity Finite Element Analysis of Hot Deformation of Ti-6Al-4V with Lamellar Microstructure: *Ayman Salem*[1]; Surya Kalidindi[2]; Jaimie Tiley[3]; S. Semiatin[3]; [1]Materials Resources LLC; [2]Drexel University; [3]Air Force Research Laboratory

A computationally efficient homogenization technique is described to incorporate slip transmission across alpha/beta interfaces in physics-based constitutive modeling of high temperature deformation of Ti-6Al-4V with lamellar microstructure. Each two phase alpha/Beta colony was simulated by a pseudo HCP grain with the orientation of the colony's alpha-phase. Plastic deformation within the HCP grains was assumed to be accommodated by seven independent slip systems. Model parameters were calibrated using measurements from uniaxial compression testing of single colonies at 815 oC. The proposed constitutive equations were incorporated into a Taylor-type crystal plasticity model with a fully implicit time integration scheme implemented in a finite element program (ABAQUS) to predict mechanical behavior and texture evolution under hot working conditions. The methodology provided a practical technique to incorporate slip transmission in physics-based constitutive models that account for anisotropic mechanical behavior and texture evolution in alpha/beta titanium alloys.

11:00 AM
Modeling Superplastic Forming and Diffusion Bonding of Titanium Alloys: *Weiqi Luo*[1]; Jae-Bong Yang[1]; Ravi Shankar[1]; Wei-Tsu Wu[1]; Vasisht Venkatesh[2]; Yoji Kosaka[2]; Phani Gudipati[2]; Daniel Sanders[3]; Larry Hefti[3]; [1]Scientific Forming Technologies Corporation; [2]Titanium Metals Corporation; [3]The Boeing Company

Superplastic Forming/Diffusion bonding processes facilitate near-net shape forming of complex aerospace titanium components with considerable cost and weight savings. Optimizing the process variables such as temperature, pressure, time duration, etc., to achieve the desired part configuration and mechanical properties without defects can be challenging.Alpha particle coarsening occurs during this slow process. The particle size affects the flow stress behavior and consequently the stability of the superplastic deformation. The bonding time and contact pressure at the joint are the two important diffusion bonding process parameters. They are, however, location dependent as the contact condition between the sheets and applied pressure continuously evolve during the process. For better predictive capability to address these challenges, the process modeling system DEFORM has been further enhanced under a program funded by the Metals Affordability Initiative. This paper presents the methodology and model validation against the laboratory and shop floor observations.

11:20 AM
Finite Element Analysis of the Anisotropic Behavior of Ti6AL4V during Incremental Sheet Metals Forming: Kazeem Sanusi[1]; Emad Uheida[1]; *Tiaan Oosthuizen*[1]; [1]University Of Stellenbosch,

Incremental sheet forming is a manufacturing process that uses a standard smooth–end tool mounted on a numerical controlled multi-axis machine. The tool rotates and follows a circular tool path to progressively deform the clamped metal sheets into the required shape. Titanium alloys have found wide applications in the aerospace and bio-medical industries due to their good strength-to-weight ratio and superior corrosion resistance. It also has good mechanical properties.This paper deals with the finite element analysis of Ti6AL4V based on elastoplastic model using an anisotropic yield criterion and hardening model for the plastic behaviour of titanium alloy. The anisotropic constitutive model is embedded in ABAQUS for its numerical implementation based on the derivation of the implicit integration algorithm and consistent tangent modulus. The paper will help in understanding the anisotropic behaviour of Ti6AL4V during incremental sheet metals forming since most of the condition and parameter depends on the direction of anisotropic.

11:40 AM
Study on Hot Deformation Behavior of TC4 Titanium Alloy: *Yanling Lu*[1]; Sihai Jiao[2]; Xingtai Zhou[1]; Anping Dong[3]; [1]Shanghai Institute of Applied Physics,Chinese Academy of Sciences; [2]Baoshan Iron & Steel Co., LTD.; [3]Shanghai Jiao Tong University

Hot compression deformation behavior of TC4 titanium alloy was studied on Thermecmaster-Z simulator in the temperature range 850°C~1150°C and strain rate range 0.5~30s-1. The results show that deformation temperature and strain rate both have significant influence on the flow stress. The flow stress decreases with the increase of deformation temperature, while increases with the increase of strain rate. The deformation mechanism of TC4 alloy exhibit dynamic recovery feature in high temperature. However, in lower temperature, dynamic recrystallization and grain boundary slip behavior may take place. Deformation activation energy values are 862.5 kJ/mol in (α + ß) phase region, and 200.6 kJ/mol in ß region respectively. Constitutive equations of TC4 alloy described by Zener-Hollomon parameter were formulated. Therefore, a scientific basis is provided for the reasonable choice of thermal parameters of TC4 titanium alloy.

12:00 PM
Evolution of Microstructures and Properties of Ti-44Al-6V-3Nb-0.3Y Alloy after Forging and Rolling: *Yuyong Chen*[1]; Hongzhi Niu[1]; Shulong Xiao[1]; Ping Sun[1]; Changjiang Zhang[1]; [1]Harbin Institute of Technology

Generally, beta γ-TiAl alloys possess excellent hot deformability and good mechanical properties. In this paper, the evolution of microstructures and tensile properties of Ti-44Al-6V- 3Nb-0.3Y (at. %) alloy after hot forging and rolling were investigated systematically. SEM results indicated that the cast microstructure of current TiAl alloy was completely broken down and refined by forging and rolling. By SEM and TEM measurements, the detailed microstructures and phase composition in the as-forged and as-rolled conditions were characterized and compared. Fully lamellar microstructures of the deformed alloy were obtained by heat treatment of 1330°C/1h/FC + 900°C/10h; Additionally, to assess the effect of microstructure variation on mechanical properties, tensile properties were measured at room temperature and 700°C. It is an extremely effective mean to optimize the microstructures and enhance the mechanical properties of TiAl alloy by hot forging and rolling.

12:20 PM
Effect of Forging on Microstrutural Characteristic and Tensile Properties of In-Situ (TiB+TiC)/Ti Composite: *Yuyong Chen*[1]; Changjiang Zhang[1]; Shulong Xiao[1]; Dezhong Wu[1]; Hongzhi Niu[1]; [1]Harbin Institute of Technology

In this work, 2.5vol. % (TiB+TiC)/Ti composite was prepared by in situ casting route then 1-D forging. The microstructure and tensile properties were presented and discussed. The results indicate that the as cast microstructure can be significantly modified by 1-D forging. After forging, TiB and TiC segregated at the prior ß grain boundaries within the as-cast composite tend to fracture and align perpendicular to forging direction. Reduction in aspect ratio of reinforcements and a lath is also observed. 1-D forging can enhance the strength and elongation of as cast composite significantly. However, the increment in strength is quite limited as strain temperature increases to 700 oC. Additionally, Room temperature and high temperature fracture mechanisms are also discussed as well.

T.T. Chen Honorary Symposium on Hydrometallurgy, Electrometallurgy and Materials Characterization: Plenary Session

Monday AM Room: Northern A4
March 12, 2012 Location: Dolphin Resort

Funding support provided by: Rio Tinto Kennecott Utah Copper, ASARCO, and Freeport McMoRan

Session Chair: Shijie Wang, Rio Tinto Kennecott Utah Copper

8:30 AM
In Honor of Dr. Tzong T. Chen: John Dutrizac[1]; *Shijie Wang*[2]; [1]CANMET-MMSL; [2]Rio Tinto Kennecott Utah Copper

A Brief Summary of Dr. T.T. Chen's Career and Accomplishment Will Be Presented.

8:45 AM
A Review of the Behavior and Deportment of Lead, Bismuth, Antimony and Arsenic in Copper Electrorefining: *Michael Moats*[1]; Shijie Wang[2]; Daniel Kim[2]; [1]University of Utah; [2]Rio Tinto Kennecott Utah Copper

The behavior and deportment of lead, arsenic, antimony and bismuth can significantly affect the production of high quality cathode by copper electrorefining. A critical review of research related to these elements is presented along with comparison to industrial data where appropriate. These elements exist predominantly in the anode as complex oxides along the grain boundaries. Upon dissolution, Group 15 elements report both to the electrolyte and slimes while lead essentially enters the slimes. The deportment of the Group 15 elements appear to be influenced by several chemical interaction which are discussed. The effect of these elements on floating slimes and anode passivation is reviewed. Under normal electrorefining conditions, lead, antimony and bismuth are thought to enter the cathode through the encapsulation of slime particles. The literature indicates that arsenic enters the cathode predominately by electrolyte entrainment. Finally, areas for future research regarding these elements are presented.

9:20 AM Plenary
Technological Overview of Zinc Industry – Now and Future: *Takashi Yoshida*[1]; [1]Mitsui Mining & Smelting Co., Ltd

This paper will discuss about recent situation and future of zinc industry from the technical point of view. It includes recent problems faced on zinc industry and technological developments. One of the biggest problems of zinc industry is row materials. Traditional zinc concentrate becomes much complicated chemical and physical properties. Thus each process faced on various problems. Also secondary resources generated so called recycling process become much important. Recycling is of course very important aspect for sustainable development of society. Secondary raw material includes also very variety of impurities not included or very low level in traditional zinc concentrate. Some problems cause by these impurities. To overcome these problems some technological challenges have been taken place. Details will discuss in the symposium.

9:55 AM Break

10:15 AM Plenary
The Next Decade in Cu, Ni, Co and Platinum Group Metal Extraction: *Bill Davenport*[1]; [1]University of Arizona

Based on recent visits to industrial smelters, refineries, and recycle plants in Africa, Asia, Europe and North America – this paper looks forward to the next decade in Cu, Ni, Co and Pt group metal extraction. It looks specifically at environmental impacts and water and energy requirements – and at technologies for reducing them.

10:50 AM Plenary
The Development of China's Molybdenum Metallurgical Technologies: *Kaixi Jiang*[1]; Wang Haibei[1]; Zou Xiaoping[1]; Zhang Lei[1]; Bangsheng Zhang[1]; [1]Beijing General Research Institute of Mining and Metallurgy

China plays an important role in the world's molybdenum industry, because both China's mine output and smelter production ranked first in the world. The characteristics of China's molybdenum resources are complex, and molybdenum-nickel ores with carbon, copper-molybdenum ores and wulfenite ores can be found only in China. This paper firstly introduces China's molybdenum resource/reserve situation. Secondly, the status of molybdenum smelting technologies, especially roasting using rotary kilns and multiple-hearth furnaces, is discussed. The practices and the development of some new technologies, such as pressure leaching, solvent extraction, ion exchange and carbon adsorption for molybdenum-nickel ores and low grade molybdenite concentrates are also introduced.

11:25 AM Invited
Some Applications of Molecular Recognition Technology (MRT) to the Mining Industry: *Steven Izatt*[1]; Ronald Bruening[1]; Neil Izatt[1]; [1]IBC Advanced Technologies, Inc.

IBC's Molecular Recognition Technology (MRT) processes selectively extract, recover, and purify a wide range of metals from a variety of process streams. The incorporation of MRT into process flow sheets greatly improves the economics of the processes. MRT separations are effective even at low metal concentrations and in the presence of much greater concentrations of competing species. MRT processes are sustainable, being economically viable, energy efficient, and environmentally friendly as well as having a low carbon footprint. Examples of MRT processes will be presented and discussed involving rhenium, gold, platinum group metals, and other metals of interest to the mining community.

Ultrafine Grained Materials VII: Plenary Session

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Nanomechanical Materials Behavior Committee, TMS: Shaping and Forming Committee
Program Organizers: Suveen Mathaudhu, U.S. Army Research Office; Xiaoxu Huang, Risø National Laboratory for Sustainable Energy, Technical University of Denmark; Hyoung Seop Kim, POSTECH; Terence Langdon, University of Southern California; Terry Lowe, Manhattan Scientifics, Inc. ; Ruslan Valiev, Ufa State Aviation Technical University; Xiaolei Wu, Institute of Mechanics, Chinese Academy of Sciences; Michael Zehetbauer, University of Vienna

Monday AM | Room: Swan 5
March 12, 2012 | Location: Swan Resort

Session Chairs: Xiaoxu Huang, Risoe National Laboratory for Sustainable Energy, Technical University of Denmark; Suveen Mathaudhu, U.S. Army Research Office; Terry Lowe, Manhattan Scientifics, Inc.; Michael Zehetbauer, University of Vienna

8:30 AM Introductory Comments

8:35 AM Keynote
Physics of Grain-Size Effect on Twinning in Nanostructured fcc Metals: *Yuntian Zhu*[1]; Xiaolei Wu[2]; Xiaozhou Liao[3]; [1]North Carolina State University; [2]Institute of Mechanics; [3]The University of Sydney

Deformation twinning is an effective approach for enhancing the ductility while at the same time also improves the strength. In this talk, I will present the physics and modeling on the effect of grain size on deformation twinning in nanocrystalline fcc metals. An analytical model based on observed deformation physics, i.e. grain boundary emission of dislocations, will be first presented. The result will be then compared with experimental observation of an optimum grain size range for the formation of deformation twins and the inverse grain-size effect. The physical origin of the observed grain size effect will be delineated.

8:55 AM Invited
Deformation Mechanisms in Nano and Ultrafine Crystalline Nickel: *Marisol Koslowski*[1]; [1]Purdue University

Deformation of polycrystalline materials includes mechanisms in the grain interior as well as in the grain boundaries. The competing grain-boundary and dislocation-mediated deformation mechanisms in crystalline Nickel with grain sizes in the range 4 nm to 128 nm are investigated with numerical simulations. We present a three dimensional phase field model that tracks the evolution of grain boundaries and individual dislocations, including the elastic interaction, the core and the stacking fault energies. Our model shows that the transition from Hall-Petch to inverse Hall-Petch as the grain size is reduced cannot be characterized only by the average grain size, but it is also affected by the grain boundary energetics, the grain size distribution and the initial defect concentration. We find that the grain size corresponding to the maximum yield stress (the transition from Hall Petch strengthening with decreasing grain size to inverse Hall Petch) decreases with increasing grain boundary energy.

9:15 AM Invited
Near Surface Nanoscale Structures Produced by Plastic Deformation: *Niels Hansen*[1]; Xiaodan Zhang[1]; Yukui Gao[2]; Xiaoxu Huang[1]; [1]Risø DTU; [2]Beijing Institute of Aeronautical Materials

Hard surface microstructures produced by plastic deformation can improve the fatigue and wear resistance of industrial structures. Such structures have been produced in iron by shot peening and by surface mechanical attrition and characterized by transmission electron microscopy, electron backscattering diffraction and microhardness testing. The structure is subdivided by boundaries forming a lamellar structure. Such a structure also characterizes samples cold rolled to medium and high strains where the structure is graded with respect to the lamellar spacing with decreases with increasing strain. This dependency can be represented by a power law relationship which allows the strain to be estimated at different depths in the near surface layer and the stress strain relationship to be derived based on the microhardness data. A discussion will focus on the structural evolution in the nanoscale regime and on strengthening mechanisms.

9:35 AM Invited
Strain-Induced Phase Transformations under Compression and Shear in Rotational Diamond Anvil Cell: *Valery Levitas*[1]; [1]Iowa State University

Experimental results on phase transformations obtained under compression and large plastic shear of materials in rotational diamond anvil cell (RDAC) are presented. Multiscale (nano-, micro- and macroscales) continuum thermodynamic theory and simulations for strain-induced transformations were developed, which explain a number of mechanochemical phenomena. Specifically, the theory explains why the superposition of plastic shear and high pressure in RDAC leads to: (a) significant reduction (by a factor of 3-5) of transformation pressure and pressure hysteresis, (b) appearance of new phases (in particular, nanostructured), which were not obtained without shear, (c) substitution of reversible transformation by an irreversible one, and (d) strain-controlled kinetics. New phenomenon of phase transformation induced by rotational plastic instability is revealed. It allowed us to reduce the pressure for irreversible phase transformation from rhombohedral to cubic BN from 55 GPa under hydrostatic pressure to 5.6 GPa. Transformation-induced plasticity under pressure and shear is revealed, quantified and modeled.

9:55 AM Invited
Tailoring or Grading Sheet Materials by Using New Concepts in ARB-Processing: *Heinz Werner Höppel*[1]; [1]University Erlangen-Nürnberg

The ARB-process is well know to produce UFG sheet materials in larger quantities. Besides, this technique also allows to produce multiphase, tailored or graded sheet materials with promising properties. By an intelligent ARB-processing 3D-architectured multiphase materials can be achieved aiming for locally tailored materials properties. It is shown, that the materials properties can be tailored locally by an adopted powder spraying process via the ARB process. Moreover, by using an appropiate post ARB-heat treatment, this technique can aslo be used to strengthen the sheet material by the formation of intermatallic phases in the sheet. In the talk, microstructural and mechanical properties with respect to the processing parameters will be discussed in detail.

10:15 AM Invited
Analysis of Plastic Flow during High-Pressure Torsion: *Roberto Figueiredo*[1]; Maria Teresa Aguilar[1]; Paulo Cetlin[1]; Terence Langdon[2]; [1]Federal University of Minas Gerais; [2]University of Southern California

It is now established that high-pressure torsion is able to produce bulk nanostructured metallic materials through severe plastic deformation-SPD. This technique produces material with the finest grain structures among all SPD processes. Despite the recent rise in interest, there are many process parameters whose influence on the sample is not clear. For example, some researchers consider the distribution of deformation homogeneous while others report heterogeneity, the hydrostatic stress and the temperature rise due to plastic strain are also not clear. It is thus important to clarify these aspects in order to analyze structure and properties evolution. The present paper reviews the experimental and theoretical results on processing parameters during HPT.

10:35 AM Break

10:50 AM Invited
Microstructure and Microtexture Evolution in Pure Metals after Ultra-High Straining: *Alexander Zhilyaev*[1]; Terence Langdon[2]; [1]School of Engineering Sciences, University of Southampton, Southampton SO17 1BJ, U.K. and Institute for Metals Superplasticity Problems, Russian Academy of Science, 39 Khalturina, Ufa, 450001 Russia) ; [2]School of

Engineering Sciences, University of Southampton, Southampton SO17 1BJ, U.K. and Departments of Aerospace & Mechanical Engineering and Materials Science, University of Southern California, Los Angeles, CA 90089-1453, U.S.A.

Ultrafine-grained and even nanostructured materials can be manufactureed using ultra-high straining by ECAP, HPT, machining and their combinations, such as machining of ECAP specimens, HPT plus ECAP and HPT of machining chips The report will present recent results of investigations of the microstructure and microtexture of pure copper, nickel and aluminum subjected to different deformation processes to ultimately high imposed strain. Comparison of microstructure, dislocation density and microhardness developed during combinations of different strain paths have been performed. All characteristics have been analyzed by x-ray, transmission and scanning electron microscopy, OIM. Influence of different processing routes is discussed in terms of accumulated strain and microstructure refinement. Saturation in grain refinement is discussed in terms of recovery taking place during ultra-high strain deformation.

11:10 AM Invited

Dilatometry – A Powerful Tool for the Study of Defects in Ultrafine Grained Metals: *Wolfgang Sprengel*[1]; Bernd Oberdorfer[1]; Eva-Maria Steyskal[1]; Roland Würschum[1]; [1]Graz University of Technology

Vacancies, dislocations and interfaces are structural defects that are deliberately introduced into solids during grain refinement processes based on severe plastic deformation (SPD). Specific combinations of these defects determine the improved mechanical properties of the obtained ultrafine grained materials. High-precision, non-equilibrium dilatometry, i.e., measurement of the irreversible macroscopic length change upon defect annealing, provides a powerful technique for the characterization and the study of the kinetics of these defects. Dilatometry is applied to determine absolute concentrations of vacancies, to characterize dislocation processes, and to assess grain boundary excess volume in pure, fcc and bcc ultrafine grained metals processed by SPD.

11:30 AM Invited

The Combined Effect of Grain Boundaries and Second Phase Particles on the Flow Stress of Nanocrystalline Metals: *Krzysztof Kurzydlowski*[1]; Romuald Dobosz[1]; Malgorzata Lewandowska[1]; [1]Warsaw University of Technology

Numerical FEM simulations were made to provide an insight into the possible combination of grain boundary and second phase particle strengthening in nanocrystalline metals. Because grain boundary sliding is one of the major deformation mechanisms in these materials special attention was paid to the role of nanoparticles located at the grain boundaries. The results obtained show that second phase particles located at the grain boundaries may contribute to the strengthening process, thereby compensating for the loss of strength brought about by grain boundary sliding. However, the effect of the particles strongly depends on the relative contribution of grain boundary sliding to the overall deformation process. In addition, particles located at grain boundaries under conditions of grain boundary sliding significantly influence the distribution of plastic deformation making it more homogenous. These findings of numerical analyses are well supported by the recent results obtained on a SPD processed aluminium alloy.

11:50 AM Invited

The Super-Strength of Ultrafine-Grained SPD-Processed Alloys Due to Grain Boundary Segregations: *Nariman Enikeev*[1]; Xavier Sauvage[2]; Maxim Murashkin[1]; Ruslan Valiev[1]; [1]Ufa State Aviation Technical University; [2]University of Rouen, Groupe de Physique des Matériaux, CNRS

It is demonstrated that the strength of ultrafine-grained (UFG) alloys produced by severe plastic deformation (SPD) can be increased not only by grain refinement but also by formation of grain boundary (GB) segregations. On the example of several Al alloys it is shown that SPD-induced segregations have unusual morphology (segregation width and concentration of alloying elements) as compared to conventional GB segregations. This phenomenon is explained by influence of non-equilibrium grain boundaries typical for SPD processed materials on the segregation formation and generation of lattice dislocations from GBs, correspondingly. As result we observed super-strength in UFG alloys, when yield stress values were considerably higher than those predicted by the Hall-Petch relationship extrapolated to the ultrafine grain size range.

12:10 PM Invited

Ultrafine-Grained Shape Memory Alloys: *Thomas Waitz*[1]; Clemens Mangler[1]; Gerd Steiner[1]; Arno Kompatscher[1]; Martin Peterlechner[2]; Wolfgang Pranger[3]; Thomas Antretter[3]; Franz Dieter Fischer[3]; Peter Müllner[4]; [1]University of Vienna; [2]University of Muenster; [3]University of Leoben; [4]Boise State University

Grain size can strongly affect the unique thermomechanical properties of shape memory alloys that are based on a martensitic phase transformation. Grain size at the nanoscale can hinder the shape memory effect by suppressing the thermally induced martensitic transformation. However, ultrafine-grained shape memory alloys can show tailored functional properties and enhanced strength. NiTi shape memory alloys, NiTiHf high temperature shape memory alloys and NiMnGa high temperature ferromagnetic shape memory alloys were subjected to severe plastic deformation followed by annealing to achieve grain sizes in the range of several tens to several hundreds of nm. Different pathways of the evolution of the small grains that might involve the formation of an intermediate amorphous phase were encountered. The phase stability and the martensitic morphology of small grains were systematically investigated. Considering a size dependent energy barrier opposing the transformation the results were modelled using the general thermodynamic framework of martensitic phase transformations.

2012 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: Nanomaterials for Information Technology

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Nanomaterials Committee

Program Organizers: Jiyoung Kim, University of Texas; David Stollberg, Georgia Tech Research Institute; Seong Jin Koh, University of Texas at Arlington; Nitin Chopra, The University of Alabama; Terry Xu, UNC Charlotte

Monday PM — Room: Pelican 1
March 12, 2012 — Location: Swan Resort

Session Chairs: David Stollberg, Georgia Tech Research Institute; HyunJung Shin, Kookmin University

In-Situ Studies of High-K/Iii-V Interfaces for Advanced Electronics: *R.M. Wallace*[1]; [1]Department of Materials Science and Engineering, University of Texas at Dallas

A host of new materials are under research to enable the continuation of improved device performance through scaling. Among these, III-V alloy materials such as InGaAs, InGaP, InGaSb and GaN are being studied for advanced logic and power applications. A key component for these systems is the interface between the high-k gate dielectric and the III-V material of choice. This talk will review our recent studies of the physicochemical properties of this interface using in-situ deposition and analytical methods, as well as electrical behavior. We will examine the correlations observed between physical analysis and the electrical behavior, particularly with regard to defects which can generate states that result in Fermi level pinning. This work is supported by the NSF under award ECCS-0925844, the AFOSR/AOARD under award FA2386-11-1-4077, the FCRP Materials Structures and Devices (MSD) Center, and the SRC Nanoelectronics Research Initiative and NIST through the Midwest Institute for Nanoelectronics Discovery.

2:40 PM Invited
Stimuli Responsive Field-Effect Transistors Integrated with Nanomaterials: *Nae-Eung Lee*[1]; Nguyen Thanh Tien[1]; D.-J. Kim[1]; I.-Y Sohn[1]; Tran Quang Trung[1]; O.J. Yoon[1]; [1]Sungkyunkwan university

Stimuli-responsive field-effect transistors (FETs) that are responsive to physical, chemical or biological stimuli are very interesting for various sensing applications due to simplicity of design, fabrication and signal detection. In our work, stimuli-responsive FETs were designed and fabricated by directly incorporating various functional materials as active channel, electrode or gate dielectric layers into the FET structure. In order to enhance the sensitivity of FETs to external stimuli and obtain additional functionalities such as flexibility, transparency, and/or stretchability, nanocomposite films and two-dimensional carbon nanomaterials were employed as gate dielectrics, active channel or electrode in the FET structure. In physically responsive FETs (Physi-FETs), for example, gate dielectric materials with piezoelectricity and pyroelectricity and active channel materials with piezoresistivity were directly incorporated into the FET structure. The generalization of this concept is shown to be applicable to multi-modal sensing of pressure, strain, and IR in the form of flexible physi-FETs.

3:15 PM
Interface Engineering as a Tool to Enhance Efficiencies of Carbon Nanotube Based Devices: *Indranil Lahiri*[1]; Wonbong Choi[1]; [1]Florida International University

Carbon nanotubes (CNT) are proposed for improved performance of numerous devices – sensors to solar cells and biomedical to electronic devices. However, desired seamless integration, reliable performance and extended device lifetime of CNT-based devices necessitates great structural stability. One of the most critical issues in structural stability is interfacial bonding between CNTs and substrate. To address this vital issue, we present an interface engineered CNT based bulk structure on copper substrate. CNT-substrate boding is enforced with proper selection of interfacial layer, on various substrates. Such CNT-based structures are applied successfully in cold field emission devices as cathode and in Li-ion batteries as anode. Interface engineering, proposed in this study, is expected to enhance bonding between CNTs and the substrate, contributing towards better structural stability and device life. These newly developed CNT-based electrodes, strongly bonded to Cu current collectors, are anticipated to enhance performance of future electronic and electrochemical devices.

3:30 PM
In-Situ Electrical Studies on Ozone Functionalization of Graphene: *Srikar Jandhyala*[1]; Greg Mordi[1]; Jiyoung Kim[1]; [1]University of Texas at Dallas

It has been reported that ozone (O3) functionalization allows for conformal deposition of high-quality ALD (atomic layer deposition) Al2O3 on graphene surface without damaging it. In this study we have investigated the functionalization mechanisms theoretically using ab-initio calculations and experimentally using in-situ electrical monitoring of transport properties. It is found that the ozone molecules at 300 K are reversibly physisorbed on the surface of graphene and the physisorption bonding is removed immediately after acting as nucleation sites for dielectric deposition. We also performed in-situ studies with H2O and O2, two other common oxidants used for deposition of dielectrics using ALD technique. It was found that these species have no significant effect on the charge transport characteristics of graphene at 300 K. This suggests that unlike O3, H2O and O2 have minimal interaction with graphene, which explains the reason for the disability to deposit oxides on graphene using these oxidants.

4:00 PM Invited
Nano-Floating Gate Memory Devices: *Jang-Sik Lee*[1]; [1]Kookmin University

In recent decades, memory device technology has advanced through active research and the development of innovative technologies. Single-transistor-type flash memory device is one of the most widely used forms of memory devices because the device structure is simple and the scaling is feasible. Nano-floating gate memory (NFGM) device is a kind of flash memory devices that use nanocrystals as the charge-trapping elements. The use of nanocrystals has advantages over memory devices that rely on other methods, such as discontinuous trap sites and controllable trap levels. Nowadays considerable progress has been made in the field of NFGM devices, and novel application areas have been explored extensively. This presentation focuses on new technologies that are advancing these developments. The discussion highlights recent efforts and research activities regarding the fabrication and characterization of nonvolatile memory devices that use a nanocrystal layer as the charge-trapping element for future device applications.

4:35 PM
Fabrication and Magnetic Properties of Graded Magnetocrystalline Anisotropy Fe(Ni)Pt Nano-Dots: Bianzhu Fu[1]; Aaron Gin[2]; James Harrell[1]; *Gregory Thompson*[1]; [1]University of Alabama; [2]Sandia National Laboratories

Increasing magnetic storage densities requires a decrease in the magnetic thin film grain size that then approaches the superparamagnetic limit where the magnetization randomly fluctuates because of thermal energy considerations. The L1o phase of FePt has a high magnetocrystalline anisotropy energy, Ku, making it a candidate material for thermally stable magnetization at these nanoscale grain sizes. Unfortunately, its high Ku prevents it from being 'written' with conventional write head field strengths. This presentation will address how compositionally grading FePt with Ni provides the ability to control the Ku enabling switching of the magnetically soft end with stabilization from the magnetically hard end. The films have been epitaxially grown off of MgO substrates, e-beam patterned into an array of nano-dots and magnetically characterized to determine switching field and thermal stability advantages.

4:55 PM
Fabrication of Nanocrystalline InGaZnO Films: The Microstructure and the Device Performance of Their Thin Film Transistors: *Haseok Jeon*[1]; Hwayoul Choi[1]; Mi Ran Moon[1]; Sekwon Na[1]; Hyoungsub Kim[1]; Hoo-jeong Lee[1]; [1]Sungkyunkwan University

In recent years, transparent oxide semiconductors (TAOS) have captivated researchers by offering a combination of several technologically important features high electron mobility, high transparency, the capability for low temperature processing, etc., which makes them an excellent candidate for the active layer of thin film transistors for display applications. Among this class of materials, amorphous IGZO has been the focus of many research and development efforts after its first demonstration as the active layer of TFTs. Here, we fabricated nanocrystalline IGZO films by co-sputtering from InGaO and ZnO targets with a high Zn ratio at an elevated temperature. By combining HRTEM and XRD analysis, we unraveled that the nanocrystalline structure sensitively changed depending on the process conditions (substrate temperature and Zn ratio). Furthermore, measurement of the electrical characteristics of the transistors fabricated from the films disclosed that the microstructure changes induced by substrate heating profoundly influenced the device performance.

5:10 PM
Discovery a Frozen Nano-Domain State in Non-Metallic Ferroelastic System: Yan Ni[1]; *Zhen Zhang*[1]; Xiaobing Ren[2]; [1]Frontier Institute of Science and Technology,Xi'an Jiaotong University; [2]National Institute for Materials Science, Japan

A fansinating state which is characterized by frozen nano strain domains has been identified in ferroelastic system as strain glass. It is reported that point defect, e.g. excess Ni in TiNi alloy, drive the crossover from martensite to strain glass. However, all reported strain glass is metallic alloys. Thus, it is a question that is there a strain glass in the ferroelastic ceramics? In present work, we studied the cubic (C) to tetragonal (T) and tetragonal (T) to Orthorhombic(O) transition in $CaTiO_3$ ceramics with doping La defect. It is found that T-O transition is easier to be suppressed than C-T transition as the concentration of La increases. When the La concentration excess a critical value, a strain glass is found in tetragonal phase and random-distributed nanodomains are observed. In addition, a new phase diagram involving strain glass regime is established for $Ca_{(1-x)}La_{2x/3}TiO_3$ ceramics.

2012 Symposium on Surfaces and Heterostructures at Nano- or Micro-Scale and Their Characterization, Properties, and Applications: Carbon Nanomaterials and Heterostructures

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS: Energy Conversion and Storage Committee, TMS: Nanomaterials Committee, TMS: Surface Engineering Committee, TMS: Young Leaders Committee, TMS: EMPMD Council

Program Organizers: Nitin Chopra, The University of Alabama; Ramana Reddy, The University of Alabama; Arvind Agarwal, Florida International University; Sandip Harimkar, Oklahoma State University; Jiyoung Kim, University of Texas at Dallas; Christopher Matranga, National Energy Technology Laboratory

Application of Carbon Nanotubes – Energy to Bioelectronic Sensor: *Wonbong Choi*[1]; Indranil Lahiri[1]; Santanu Das[1]; Chiwon Kang[1]; [1]Florida International University

A wide variety of carbon nanostructures, from zero-dimensional fullerene through one dimensional carbon nanotube to two dimensional graphene, have attracted attention of scientific community worldwide for their exciting properties. C-based nanomaterials have found applications in a vast field – electronics, sensors, biotechnology, energy, structural etc. In Nanomaterials and Device Lab at FIU, we have concentrated our effort in developing new engineering nanomaterials (graphene, carbon nanotubes) and their device applications in the field of energy generation and storage, nanoelectronics, and bio-electronic sensors. This presentation aims to capture those recent research efforts in synthesis and applications of carbon nanotubes in Li-ion battery, bioelectronic sensor and high power field emission.

2:35 PM Invited
Vertically Aligned and Periodically Distributed Carbon Nanotube (CNT) Bundles Grown by a Combination of Laser Interference Ablation and Metal-Catalyzed Chemical Vapor Deposition (CVD): *Dajun Yuan*[1]; Wei Lin[1]; Rui Guo[1]; C. P. Wong[1]; Suman Das[1]; [1]Georgia Institute of Technology

Carbon Nanotubes (CNTs) offer attractive anisotropic mechanical, thermal, and electrical properties. Scalable fabrication of CNT bundles is essential to future advances in several applications. Nevertheless, the creation of geometries at sub-micron scales in CNT bundles with existing fabrication methods remains a difficult challenge. Here, we report on the development of a simple, two-step method for fabricating vertically aligned and periodically distributed CNT bundles. The method involves laser interference ablation of an iron film followed by CNT growth through metal-catalyzed chemical vapor deposition (CVD). CNT bundles with sizes ranging from 500 nm to 5 μm in width, and 50 to 200 μm in length, are grown atop the patterned catalyst over areas spanning 5 cm^2. The CNT bundles exhibit a high degree of control over size, orientation, uniformity, and periodicity. Characterization of the catalyst post-ablation of the CNT bundles is conducted through AFM and SEM.

3:10 PM
Structural Evolution and Growth Mechanism of Hierarchal Heterostructures Comprised of Carbon Nanotubes Decorated with Nanoparticles: *Wenwu Shi*[1]; Nitin Chopra[1]; [1]The University of Alabama

We report formation and structural evolution of CNT-nickel/nickel oxide (Ni/NiO) core/shell nanoparticles (CNC) through a simple and single step synthetic approach. High surface-to-volume ratio and aspect ratio of chemical vapor deposition (CVD)-grown CNTs (average diameter ~46±16.4 nm) allowed for the uniform coating with Ni/NiO core/shell nanoparticles (average diameter ~12±2 nm). The crystal structure, morphology, and phases of CNC heterostructures were characterized using high resolution SEM, TEM, XRD, and Raman. Subsequently, as-produced CNC heterostructures were incorporated into polymers and evaluated for their chemical functionality and morphology using FTIR, UV-vis transmittance, SEM, and swelling/shrinking studies. Finally, these heterostructures were further studied for their thermal stability using Raman spectroscopy and XPS studies.

3:30 PM
Synthesis of Porous Graphene Shells with Embedded Noble Metal Nanoparticles: Wenwu Shi[1]; Robert Wright[1]; *Nitin Chopra*[1]; [1]The University of Alabama

We report the formation of nanowire-nanoparticles heterostructures and their conversion into porous graphene embedded with nanoparticles. Nanowires were synthesized by chemical vapor deposition and noble metal nanoparticles were linked onto these nanowires coating the latter uniformly. These heterostructure were further utilized as catalysts for the growth of porous graphene shells in a chemical vapor deposition process. The synthesized heterostructures were fully characterized with SEM, TEM, EDX, SAED, and Raman spectroscopy. Changes of nanoparticles diameter, nanoparticle density, nanowire diameter after graphene growth were thoroughly studied. These heterostructures were further demonstrated to have unique SERS capability.

3:50 PM
Systematic Studies on the Formation of Graphene on Noble Metal Nanoparticles: *Wenwu Shi*[1]; Nitin Chopra[1]; [1]The University of Alabama

Encapsulation of metal nanoparticles into graphene layers could bring multifunctionality and enhanced stability. Herein, we report a detailed systematic study focused on fundamentally understanding the growth of graphene encapsulated noble metal nanoparticles in a chemical vapor deposition process. Different parameters (reaction temperature, duration, H2 concentration, type of nanoparticles, type of hydrocarbon, hydrocarbon feed speed, plasma oxidation of nanoparticles) were considered to understand the formation mechanism of graphene. The hybrid nanoparticles were characterized by transmission electron microscopy and Raman spectroscopy. It was found that oxidation of Au nanoparticles is a prerequisite for the formation of graphene and optimal reaction temperature, H2 concentration, and hydrocarbon feed rate were identified. It was observed that increase of reaction duration ruptures the graphene shell and result migration of nanoparticles out from graphene shell.

4:05 PM Break

4:20 PM
Evolution of Gold Nanoparticles in a High Temperature Process and Patterned Growth of Graphene Encapsulated Nanoparticles: *Junchi Wu*[1]; Larry Summerville[1]; Nitin Chopra[1]; [1]The University of Alabama

Different sizes and shapes of gold particles were organized on silicon wafer by annealing gold thin films. The nanoparticle patterning was achieved on the silicon wafer by correlating morphology, size, and structure with processing conditions. The crystal structure and optical property of annealed sample was examined by XRD and UV-DRS. Scanning electron microscopy (SEM) was used for morphology and migration study of Au film. During annealing, Au film dewetted the Si surface and migrated to reduce the surface energy, resulting into branched gold islands or particles. These patterned nanoparticles were further utilized for the patterned growth of graphene encapsulated gold nanoparticles.

4:35 PM
Growth Mechanisms of Graphene Encapsulated Nanoparticle and Effect of Catalyst Shape on the Graphene Growth: Junchi Wu[1]; *Nitin Chopra*[1]; [1]The University of Alabama

A systematic study was performed on morphological evolution of gold nanoparticles in both single-step method and seed-growth method. The size, shape, crystallinity, and sample heterogeneity for the nanoparticles were characterized to evaluate the effect of growth parameters. As a next step, gold nanoparticles were surface oxidized used as a catalyst for the growth of graphene shells in a chemical vapor deposition method, resulting in graphene encapsulated gold nanoparticles. The oxidation kinetics of gold nanoparticles was studied. These nanoparticles were characterized by high-resolution transmission electron microscopy (TEM). Oxidation behavior of gold nanoparticles was studied by scanning electron microscopy (SEM) and X-ray photoelectron spectroscopy (XPS). Morphology and aggregation of gold nanoparticles during the CVD growth affected the graphene shells and was studied here. Raman spectroscopy/microscopy were used to evaluate the quality of graphene shells produced and chemical mapping charts were generated to understand the large area growth of these hybrid nanoparticles.

4:50 PM Invited
Defects in Carbon Based Nanostructures: Applications to Novel Morphologies and Device Concepts: *Prabhakar Bandaru*[1]; [1]UC, San Diego

Defects in carbon nanotubes can be exploited for the synthesis of interesting coiled structures or in electrodes exhibiting fast electron transfer kinetics. For example, the introduction of disclinations (in terms of pentagonal and heptagonal defects) into graphene sheets can motivate helical structure. In this talk, I will review the influence of defects in determining the electrochemical properties of carbon nanostructures. We have seen that exposure of carbon nanotubes to argon and hydrogen irradiation can be used to either increase/reduce the defect density, through Raman spectroscopy. In cyclic voltammetry (CV) measurements, we have seen that only the Ar treated samples exhibit perfect reversible Nernstian behavior characteristic of ideal electrodes. The application of such studies to novel devices, sensors, capacitors, etc. will be discussed.

5:25 PM Invited
Localized Plasmon Enhancement at Dopant Sites in Graphene: *Stephen Pennycook*[1]; Wu Zhou[1]; Jaekwang Lee[1]; Jagjit Nanda[1]; Sokrates Pantelides[2]; Mark Oxley[1]; Micah Prange[1]; Juan-Carlos Idrobo[1]; [1]Oak Ridge National Laboratory; [2]Vanderbilt University

Using Z-contrast imaging combined with electron energy-loss (EEL) spectrum imaging in scanning transmission electron microscopy (STEM), combined with theoretical simulations, we show that a single point defect can act as an atomic antenna in the petaHertz (1015 Hz) frequency range. Stable point defect complexes consisting of substitutional Si and N atoms lead to localized surface plasmon resonances at the sub-nanometer scale. We show further that chains of defects could be used to form nanoscale plasmonic waveguides.

3rd International Symposium on High Temperature Metallurgical Processing: Reduction and Titanium Production

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Energy Committee, TMS: Pyrometallurgy Committee
Program Organizers: Tao Jiang, Central South University; Jiann-Yang Hwang, Michigan Technological University; Patrick Masset, TU Freiberg; Onuralp Yucel, Istanbul Technical University; Rafael Padilla, University of Concepcion; Guifeng Zhou, Wuhan Iron and Steel

Monday PM	Room: Southern II
March 12, 2012	Location: Dolphin Resort

Session Chairs: Clemens Schmetterer , TU Freiberg; Ting'an Zhang, Northeastern University

2:00 PM
Preparation of Titanium Alloy from Titania-bearing Blast Furnace Slag: *Run Huang*[1]; Chenguang Bai[1]; Xuewei Lv[1]; Songli Liu[2]; [1]College of Materials Science and Engineering, Chongqing University; [2]College of Materials Science and Engineering, Pan Zhihua University

Titanium alloy was prepared from titania-bearing blast furnace slag (Ti-BF slag) by aluminothermic process in an induction furnace. The effects of aluminum amount on the titanium silicon yield and titanium recovery ratio were studied. The phase transformation and chemical composition of the prepared alloy were investigated by X-ray diffractometry (XRD) and X-ray fluorescence (XRF) respectively. It was found that the mass fraction of silicon and aluminum increased with increasing the aluminum amount, however, the mass fraction of titanium increased first and then decreased with increasing the aluminum amount. Furthermore, both the titanium alloy yield and titanium recovery ratio increased with the increase of aluminum amount. The main phases of the alloy were TixSiy and AlTi3. The titanium alloy samples prepared in various conditions had a composition (wt.%): 38–50% Ti, 29-34% Si, 4-11 Al%, 1.6-2.2 Mn%.

2:15 PM
An Overview of Development of Rotary Hearth Furnace and Functions: *Xuefeng She*[1]; Jingsong Wang[1]; Yihua Han[1]; Qingguo Xue[1]; [1]University of Science and Technology Beijing

Rotary hearth furnace (RHF) process is summarized in domestic and overseas at the present time. Recent utilization of RHF concerning the part of ironmaking process and recycling of solid wastes have implement in China, Japan and American. In addition, the conclusions of main functions about RHF process have drawn in three aspects. The first is pretreatment of melting reduction or production of pig iron; the second is disposed of solid wastes from iron and steel plants or nonferrous plants; the last is disposed of special mineral for example vanadium-bearing titanomagnetite, paigeite, laterite etc.

2:30 PM
Basic Research of Direct Pyrolysis Performance of MgCl2 in Molten State for New Process of Titanium Sponge Production: *Zhang Ting'an*[1]; Lv Guozhi[1]; Dou Zhihe[1]; Liu Yan[1]; Niu Liping[1]; Zhao Qiuyue[1]; Sui Lianxu[1]; He Jicheng[1]; [1]Northeastern University

This paper proposed a new method of Mg and Cl2 circulation in titanium sponge production by direct pyrolysis of MgCl2 in Molten State and thermal reduction process of MgO. We aim to study the effects of pyrolysis temperature, pyrolysis time and partial pressure of oxygen on pyrolysis efficiency of MgCl2 in Molten State, and the crystallite structural transformation of pyrolysis product MgO at different pyrolysis temperature and time by XRD. The experimental results indicate that the pyrolysis temperature and time affect the pyrolysis efficiency obviously, and the reasonable pyrolysis conditions of MgCl2 in molten state are as follows: pyrolysis temperature 1100°C, pyrolysis time 60 minutes and partial pressure of oxygen 100%. Under this condition, the pyrolysis efficiency get above 95%. The dynamic analysis on pyrolysis reaction of molten magnesium chloride shows that, the reaction is controlled by chemical reaction process with the apparent activation energy Ea=70.4 kJ/mol.

2:45 PM
Chlorination of Titania Feedstocks: *Samantha Moodley*[1]; Rauf Eric[2]; Aditya Kale[3]; Cevat Kucukaragoz[2]; [1]Exxaro Resources; [2]University of the Witwatersrand; [3]Mintek

Two titania slags, rutile and synthetic rutile were chlorinated with petroleum coke and CO in a small bubbling fluidized bed reactor. The study aims to identify differences in chlorination mechanism, compare conversion rates, blowover and the chlorination of impurities for the various feedstocks. Chlorination rates were highest at 1000ºC; rutile chlorination significantly increases as temperature increases from 800ºC to 1000°C. At 1000ºC, Slag B has the highest chlorination conversion rate followed by Slag A and rutile. The mechanism for slag and rutile chlorination differs; slag becomes porous with the chlorination of FeO and MnO whilst rutile remains solid. As the porosity of slag particles increases so does its tendency to be elutriated. Ti2O3 is oxidized within the early stages of chlorination, it is argued that this takes place during the chlorination of FeO and MnO, Ti2O3 not oxidized is rapidly chlorinated.

3:00 PM
Experimental Study on the Pulverization and Reduction Behavior of Sinter in Oxygen Blast Furnace: *Yihua Han*[1]; Jingsong Wang[1]; Rongzong lan[1]; Lintao Wang[1]; Xiaojian Zuo[1]; Qingguo Xue[1]; [1]University of Science and Technology Beijing

Using the facility of reduction experiment, the low temperature reduction pulverization and reduction behavior of sinter in oxygen blast furnace (OBF) were studied. Through analyzing the results, the difference of pulverization and reduction behavior of sinter in OBF and conventional blast furnace (BF) were discussed. Furthermore, the effect laws of reduction temperature and the content of CO and H2 on reduction behavior of sinter were studied. Also the controlling step of iron oxide reduction was discussed. The results showed that compared with BF, the low temperature reduction pulverization of sinter became serious at 773K, reduction rate became faster at 1173K, reduction time became less and final reduction degree was increased in OBF. With increasing of H2 and CO contents, the reduction of sinter was promoted. The reduction process is controlled by interface chemical reaction at the earlier stage and by interface chemical reaction and internal diffusion at the final stage.

3:15 PM
Formation of Ti(C,N) in Blast Furnace Slag Bearing High TiO2: *Shiwei Ma*[1]; Guibao Qiu[1]; Qingyu Deng[1]; Hua Wang[1]; [1]College of Materials Science and Engineering, Chongqing University

The flow properties of the blast furnace slag bearing high TiO2 at high temperature like the viscocity may change a lot due to the formation of the carbonitride inside, causing serious problems on the separation between the metal and the slag. Therefore, the critical condition of the formation of Ti(C,N) in blast furnace is vital importance for the ironmaking process with iron ore bearing titania. In this study, the formation of Ti(C,N) in blast furnace and the influences of various factors on the Ti(C,N) formation are investigated by FactSage. It is found that the mass of Ti(C,N) would reach the maximum at 1480 oC, and the product is mainly TiN below 1620 oC, while it is mainly TiC above 1620 oC. The order of the factors by the importance from strong to weak was: temperature, the content of TiO2 in slag, basicity of slag, the content of MgO and Al2O3.

Modelling of the Thermochemical and Thermophysical Properties of Molten Slags in High Temperature Conversion Processes: A Multiscale Approach: Yuanyuan Zhang[1]; Patrick Masset[1]; *Aurélie Jacob*[1]; Clemens Schmetterer[1]; Ligang Zhang[1]; Arne Bronsch[1]; Angus Gray-Weale[1]; [1]TU Bergakademie Freiberg

The modeling of high temperature processes (e.g. gasification, blast furnace process) requires the knowledge of many input parameters. In this work models for slag structure, viscosity and surface tension have been developed for the Al2O3-CaO-SiO2 system with various admixtures of FexO, Na2O or K2O. Thermodynamic data were assessed together with the respective phase diagrams using the CALPHAD method, while molecular dynamics provided structural information and viscosity. The obtained information was then used for modeling of the slag surface tension according to the Butler model and a geometric model, as well as for viscosity predictions based on the Einstein-Roscoe-equation. In this contribution the results from the various modeling efforts will be presented and compared to experimental data.

3:55 PM
Research on Carbonthermal Reduction Behavior of IImenite: *Yufeng Guo*[1]; Lirong Chen[1]; Tao Jiang[1]; Wenjie Weng[1]; Feng Chen[1]; [1]Central South University

In this paper, the behavior of Panzhihua ilmenite' carbonthermal reduction and its influencing factors under the condition of carbon-burdened were systematically investigated. The results show that under the condition of carbon-burdened, the ilmenite forms into titanium nitride during the reduction process at 1200°C. Carbon-burdened is beneficial to the reduction of iron oxide, but less favorable for the growth of iron grain.

4:10 PM
Study of Reduction Kinetics of Low Grade Hematite Ore: Tiejun Chun[1]; Deqing Zhu[1]; Jian Pan[1]; *Zhao Qiang*; [1]Central South University

In this paper, the reduction kinetics of superfine low grade hematite ore was developed. Mineralogy was measured that the ROM ore is of superfine low grade hematite ore type, assaying 27.2wt%Fetotal and with main valuable minerals of hematite occurring at size between 3 to 5μm. The reduction kinetics shows that the reduction reaction rates of pellets with complex additive and without additive are all controlled by diffusion through the product layer. The calculated apparent activation energy of pellets with 12wt% complex additive is 10.15 KJ/mol, dropping 43.9% compared to that of pellets without additive.

4:25 PM
Effect of CaO Addition on Metalothermic Reduction of Strontium Oxide: *Yeliz Demiray*[1]; Onuralp Yücel[1]; [1]Istanbul Technical University

In this present study the effect of CaO addition on Aluminothermic reduction of strontium oxide was investigated. In the experiments SrO which has 99 % purity was used. Al powder addition was selected 100, 200, 300 % of stoichiometric ratio. Effects of CaO addition (100 %, 200 %, 300 % of stoichiometric ratio) on recovering of metallic strontium was investigated. The process temperatures were selected between 1050°C and 1250° C. The final residues were examined for their chemical compositions. XRD, AAS and Flame Photometer devices were used for chemical analysis.

4:40 PM
Production of ZrB2 Powders from ZrO2 Containing Dental Implant Wastes: *Samet Yilmaz*[1]; Murat Alkan[1]; Onuralp Yucel[1]; Bora Derin[1]; [1]Istanbul Technical University

Zirconia based ceramics are used as dental materials more than other ceramics because of their highest mechanical properties. This study covers information about the reuse of dental wastes containing zirconia by self propagating high temperature synthesis (SHS) process. In the first step SHS experiments, different stoichiometric amounts of ZrO2 containing waste dental implant powders, B2O3 obtained through fusing of H3BO3 and Mg powders were used. In the second step, SHS products (ZrB2, MgO, Mg3B2O6, etc.) were leached by using HCl acid solution for the removal of MgO based impurities. Raw materials and the solid products were characterized by using XRD (X-Rays Diffractometer) and AAS (Atomic Absorption Spectrometer) was employed for the analysis of the spent leach solutions. It was found that sub-micron sized zirconium diboride powders without requiring any industrial milling processes, produced by SHS process followed by acid leaching technique.

4:55 PM
Viscosity Evolution of Blast Furnace Slag Bearing Titanium: *Hua Wang*[1]; Guibao Qiu[1]; Qingyu Deng[1]; Shiwei Ma[1]; [1]Material Science and Engineering Department,Chongqing University

The flow behavior of the blast furnace slag bearing titanium, like viscosity, play an importance role during the iron-making process with the vanadium-titanium magnetite, which is a very special minerals in Panzhihua, China. The dependency of the viscosity on the chemical composition like TiO2, Al2O3, MgO, binary basicity(CaO/SiO2), temperature, reaction time were studied. The experiments showed that the viscosity decreased with the increase of TiO2, MgO content and binary basicity, and it increased with the increase of Al2O3 content and temperature. The viscosity showed a slight decrease within 60mins' reaction with graphite crucible, however, it increased rapidly afterwards with the formation of Ti(C, N).

Understanding the Origins and Evolution of Residual Stress: *Eric Chason*[1]; [1]Div of Engineering

During deposition, thin films go through a range of stress states, from compressive to tensile and back again. Understanding the origin of stress is important to enable control of the final stress in the film. We have developed simple analytical models to describe this evolution in terms of a kinetic competition between different mechanisms of stress generation and relaxation. The balance shifts as the microstructure evolves from isolated islands, through coalescence and finally into a uniform film. We will present models for both high mobility and low mobility films which show that the stress depends on the dimensionless parameter D/LR where D is the diffusivity, R is the growth rate and L is the grain size. The model results are compared with real-time measurements of stress using wafer curvature. We also will present results of stress during sputter deposition to show how surface morphology can influence the stress.

Elevated Temperature Microstructural Stability of Ni(Cr)-Chromium Carbide Composite Coatings on Stainless Steel: *Graham McCartney*[1]; Yi Ding[1]; Philip Shipway[1]; [1]University of Nottingham

Ni(Cr)-Cr3C2 composite cermet coatings, deposited by HVOF spraying are frequently, used to provide protection against erosion and oxidation at temperatures up to 800°C and are candidate coating materials for power plant components. There has been extensive research on the mechanical and tribological properties at room temperature and elevated temperature of these types of coatings. Additionally, there have been several studies on the microstructural evolution of Ni(Cr)-Cr3C2 coatings when exposed to elevated temperature for long periods of time. However, less attention has been given to quantifying the microstructural degradation that occurs due to oxidation at the free surface of the coating and/or interdiffusion between the coating and the substrate alloy. Results on both these aspects of Ni(Cr)-Cr3C2 composite coatings deposited onto type 304 stainless steel and held at temperatures in the region of 700 to 800\176C for times ranging from 1 hour to 16 days in air will be presented.

2:55 PM Invited
3-D Focused Ion Beam Serial Sectioning to Determine Solidification and Wear Mechanisms in Adaptive Composites Coatings: Jon-Erik Mogonye[1]; Hamidreza Mohseni[1]; Sundeep Gopagoni[1]; Junyeon Hwang[1]; Jamie Tiley[2]; Rajarshi Banerjee[1]; *Thomas Scharf*[1]; [1]The University of North Texas; [2]Air Force Research Laboratory

Multifunctional, adaptive composite coatings are needed that combine the properties of solid/self-lubrication, high mechanical hardness, and high fracture toughness. We have utilized a Laser Engineered Net Shaping (LENS) process to fabricate a novel Ni/TiC/graphite self-lubricating composite coating for applications that combine these three important properties: graphite phase for solid/self-lubrication and titanium carbide phase for high hardness in a high fracture toughness nickel matrix. Microstructural evolution during solidification and wear were studied with 3-D focused ion beam serial sectioning. Novel insights into surface and subsurface deformation processes and mechanisms include stress-induced tribochemical reactions and structural transformations from microcrystalline graphite to amorphous carbon as well as the formation of a nanocomposite mechanically mixed layer (recrystallized nanocrystalline Ni grains in an amorphous carbon matrix). Another insight into the self-lubricating behavior was how subsurface compressive stresses continually feed primary and eutectic graphite into the mechanically mixed layer. These processes are responsible for improved properties.

3:20 PM
Role of Yttria Stabilized Zirconia on Fracture Toughness of Plasma Sprayed Aluminum Oxide Composite Coatings: S. Ariharan[1]; Anup Keshri[2]; Arvind Agarwal[3]; *Kantesh Balani*[1]; [1]Indian Institute of Technology Kanpur; [2]Vellore Institute of Technology; [3]Florida International University

Aluminum oxide is used as wear resistant coatings, thermal liners, heaters, crucibles, dielectric systems, biomaterial, etc. But its applications are limited due to their low fracture toughness (~3.2 MPa.m0.5). In this current work, various sizes of YSZ have been incorporated through plasma spraying in Al2O3 matrix i.e. (i) pure Al2O3, (ii) Al2O3 with 20 wt.% YSZ (particle size 30-60 nm), (iii) Al2O3 with 20 wt.% YSZ (particle size 0.5µm) and (iv) Al2O3 with 20 wt.% YSZ (spray dried). The fracture toughness of plasma sprayed Al2O3 with reinforcement of 20 wt.% of nano-YSZ, micro-YSZ and spray dried-YSZ was attained to be 4.18, 3.94 and 4.28 MPa.m0.5 respectively (attaining fracture toughness enhancement of 29%, 21% and 34% respectively when compared to that of pure Al2O3 ~3.33 MPa.m0.5). Thus, the role of YSZ distribution through its varying size and distribution can strongly affect the toughening obtained in the Al2O3 composite coating.

3:40 PM

Microstructure Evolution and Corrosion Behavior in Laser Synthesized Fe-base Amorphous Composite Coating on Structural Steel: *Shravana Katakam*[1]; Sameer Paital[1]; Narendra Dahotre[1]; [1]University of North Texas

Fe-based amorphous materials due to their excellent properties like high corrosion resistance, hardness and wear resistant are promising to produce coatings on different structural materials to enhance the surface properties. In the present study, Laser surface melting was performed on 4130 steel using Fe-Cr-Mo-Y-C-B amorphous powder as a precursor material. In spite of high cooling rates obtained by laser processing, the coating revealed a composite microstructure due to substantial solute redistribution and formation of different heterogeneous nucleation sites, resulting in formation of crystalline phases in the amorphous matrix. A thermal model approach based on COMSOL multi-physics software was developed to estimate the thermal profiles and cooling rates that are responsible for evolution of different microstructures. The corrosion resistant property of the coatings is studied based on the microstructural evolution and an attempt is made to propose a mechanism for the corrosion behavior using XRD, SEM and TEM studies.

4:15 PM

Structural Coatings in Aluminum Alloy Microtruss Materials: *Bosco Yu*[1]; Glenn Hibbard[1]; [1]University of Toronto

Incorporating an internal cellular architecture of open space is one strategy to increase the potential functionality of aluminum alloys. Stretch-dominated microtruss cellular architectures, which are designed such that externally applied loads are resolved axially along the internal struts, provide enhanced strength and stiffness at low densities when compared to conventional metal foams. In this study we introduce the idea of using a structural coating to reinforce AA3003 aluminum alloy microtrusses. Because the internal surface area is large and the strut cross-sectional dimensions can be as small as hundreds of microns, only a 40 μm thick hard anodized alumina coating was needed to induce a four-fold increase in compressive strength and a six-fold increase in energy absorption at virtually no additional weight penalty. Backscatter electron microscopy was used to examine the failure mechanisms of the structural coatings and the cores in order to explain such a large change in behaviour.

4:35 PM

Understanding Plasma Spraying of Nano Crystalline Cerium Oxide for SOFC Electrolyte: *Virendra Singh*[1]; Robert Draper[1]; Shashank Saraf[1]; Sudipta Seal[1]; [1]University of Central Florida

In the present work three different techniques namely air plasma spray (APS), solution precursor plasma spray (SPPS), and suspension plasma spray (SPS) have been attempted for thin dense coating of CeO2. During internal injection high temperature and reducing condition in APS vaporizes the agglomerated nano cerium oxide feed stock and drastically reduces the deposition efficiency whereas, external injection improves deposition efficiency. The characteristics of CeO2 thin coating and challenges prepared by SPS and SPPS were compared with APS. It was found that solution- based deposition could be an alternative for dense coating. Different spray parameters were varied to optimize coating density and deposition efficiency. DSC/TG study was performed to determine the decomposition kinetics of solutions. SEM and TEM studies were carried out for microstructural characterization. XRD and X-ray photoelectron spectroscopy study was performed to understand formation of single phase fluorite structure and the change in oxidation state of cerium, respectively.

4:55 PM

Laser Cladding of High-Performance CPM Tool Steels on Hardened H13 Hot-Work Tool Steel for Automotive Tooling Applications: *Jianyin Chen*[1]; Lijue Xue[1]; [1]IMI-National Research Council Canada

This paper summarizes our work on laser cladding of high vanadium carbide CPM tool steels including CPM 3V, 9V and 15V onto hardened chromium hot-work H13 tool steel (HRc 52-55) to substantially enhance abrasive wear resistance due to their potentials for fabricating high-performance automotive tooling at affordable cost. The similarities and differences in the morphological characteristics of macro- and microstructures of the CPM coatings obtained by laser cladding were studied using X-ray diffraction (XRD), optical microscope (OM), scanning electron microscope (SEM) and microhardness tester. The implications on the resulting mechanical performance of the laser clad CPM tooling materials were discussed as well.

5:15 PM

Dynamic Annealing Effect during Filtered Cathodic Vacuum Arc Deposition of DLC Coatings: *Feng Ji Li*[1]; Sam Zhang[1]; Deen Sun[2]; [1]Nanyang Technological University/School of Mechanical and Aerospace Engineering; [2]Singapore Epson Industrial Pte Ltd/PVD Department Plating Division

Demonstrated is the fast deposition of thick DLC coatings of high hardness and yet low residual stress via introducing a titanium (Ti) interlayer. The process makes use of both the unbalanced magnetron sputtering and filtered cathodic vacuum arc (FCVA) deposition. Unbalanced magnetron sputtering is used to deposit a thin Ti layer for bonding and FCVA deposition is used for its high deposition rate of thick and hard diamond-like carbon. The surface morphology, chemistry, bonding structure and mechanical properties of the coatings are examined for such coatings deposited at different substrate bias voltage during FCVA deposition. The results showed that the neutralization effect of the Ti interlayer, back-sputtering and dynamic annealing take place at too high substrate bias voltages.

5:35 PM

Electron Beam Deposited Multilayer Optical Interference Coatings Using Oxide Composites: *Ankush Nayak*[1]; N Sahoo[2]; R Tokas[2]; Arup Biswas[2]; Nitin Kamble[2]; [1]National Institute of Technology Karnataka, Surathkal; [2]Bhabha Atomic Research Centre, Mumbai

Optical multilayer interference coatings are not only the key elements/components of the lasers, synchrotron (beam lines), and solar devices but also serve to propagate, deliver and manipulate such radiations for materials science experiments. Composite oxide thin film materials have added several promising dimensions with respect to the design, development and applications of such precision devices. Binary ZrO2-MgO and ternary ZrO2-MgO-Al2O3 oxide composite thin films have been deposited using electron beam physical vapor deposition (EB-PVD) technique and nano-metric multilayer devices utilizing such films in a regular periodic design have been developed. As a specific objective, a multilayer high-reflection (HR) laser mirror having a narrow bandwidth has been designed and developed for the Nd: YAG second harmonic laser wavelength of 532 nm. These composite thin films and multilayers have been characterized using various microstructural probing techniques.

Alumina and Bauxite: Bauxite Digestion

2:00 PM
Characterization of Bauxite and its Minerals by Means of Thermoanalytical Methods: *Ekkehard Post*[1]; Bob Fidler[2]; Dorothea Kwiryn[2]; Doreen Rapp[2]; [1]NETZSCH Geraetebau GmbH; [2]NETZSCH Instruments North America, LLC

Bauxite is the most important metallic ore for the production of aluminum and alumina. With the help of classical thermoanalytical methods such as thermogravimetry (TG), differential scanning calorimetry (DSC) or simultaneous thermal analysis (STA), information on the mineralogical composition and enthalpy values can be obtained. The gaseous products formed during the decomposition processes can be simultaneously detected and identified by means of mass spectrometry or Fourier Transform Infrared Spectroscopy. By means of dilatometry, the thermal expansion or shrinkage can be determined. The Laser Flash Technique yields the thermal diffusivity values of both the raw material and all intermediate phases to the final product. Based on the thermal diffusivity, specific heat and density, the thermal conductivity can then be calculated. With the example of thermoanalytical measurement results on bauxite as well its individual minerals, the most important possibilities of Thermal Analysis for this application field are shown in this paper.

2:20 PM
Study on Application of a New Model for the Kinetics of Diaspore Leaching Process: Li Bao[1]; *Ting-An Zhang*[2]; Anh Nguyen[1]; Guozhi Lv[1]; Zhihe Dou[1]; Yan Liu[1]; [1]Northeastern University; [2]University of Queensland

The process of leaching diasporic bauxite in sodium aluminate solution is the most popular method to produce alumina in Chinese alumina industry. A new consistent kinetic model for gibbsite leaching process model has been developed in our previous work. This paper aims to study the application of the new model for the diaspore leaching in industrial alkali solution. The model equation was numerically integrated applying the fourth-order Runge-Kutta technique. Nonlinear regression analysis was carried out to estimate the unknown model parameters by comparing numerical solutions with available experimental data. The new model which considers the fractal geometry of the shrinking diaspore particles and the residual aluminium concentration in particles, is more consistent with the leaching process of the diaspore particles distributing in a narrow size range than the particles with the wide range of the size distribution.

2:40 PM
Mechanical Activation of Al-Oxyhydroxide Minerals – Physicochemical Changes, Reactivity and Relevance to Bayer Process: Thomas Alex[1]; Rakesh Kumar[1]; Sanat Roy[2]; *Surya Mehrotra*[3]; [1]National Metallurgical Laboratory (CSIR); [2]Indian Institute of Technology, Kharagpur; [3]Indian Institute of Technology

Overview of our research on 'structure and reactivity' of gibbsite and boehmite under varied conditions of mechanical activation, e.g. mill type, milling energy and presence of a second phase is presented. Bulk and surface changes induced in the solids by milling are characterized in terms of morphology, particle size distribution, specific surface area and nature of porosity, crystallite size and zeta potential. Results on enhanced amorphisation of gibbsite in presence of a second phase (quartz, hematite etc), changes in zeta potential of gibbsite due to loss of texture during milling and anomalous decrease in surface area of boehmite during milling are reported. Reactivity of the activated solids in sodium hydroxide and variation in thermal transformation temperatures, is correlated with physicochemical characteristics of the samples and plausible explanation for the observed correlations presented. Significance of the results with specific reference to bauxite and alumina processing in Bayer process is highlighted.

3:00 PM
Research on Mechanically Activated Digestion Performance and Kinetics of Diasporic Bauxite: *Lv Guozhi*[1]; Zhang Ting'an[1]; Ke Xianyao[2]; Liu Yan[1]; Dou Zhihe[1]; Li Yan[1]; He Jicheng[1]; [1]Northeastern University; [2]Shenyang Alumium&Magnesium Engineering&Research Institute

This paper proposed a "mechanically activated-homogeneous digestion" technology as a strengthening method for diasporic bauxite digestion process of alumina production. Effects of digestion temperature, digestion time and rotary speed on digestion performance of diasporic bauxite were investigated by using "homogeneous digestion" equipment, and the digestion kinetics of diasporic bauxite were researched as well. The results indicate that mechanical activation can greatly improve the digestion performance of diasporic bauxite, and also broaden the size range of raw ore particles. The mechanically activated digestion temperature is 20°Clower than that of direct digestion. The relative digestion rate of alumina gets above 97% when the digestion conditions are temperature 245°C, mechanically activated ball speed 80rpm and holding time 60 minutes. The apparent activation energy of mechanically activated digestion is 57.30kJ/mol, which is 21.09kJ/mol lower than that of direct digestion, and the kinetic equation of mechanically activated digestion is $(1-\eta)-1/3-1=1.5532\times10^{-4}\exp(4.764\times105/T)t$.

3:20 PM
Mechanochemical Activation to Bauxite: *Fernanda Silva*[1]; Carla Barbato[2]; Rachel Santos[1]; Diego Seixas[3]; João Sampaio[4]; Marta Medeiros[1]; Francisco Garrido[1]; [1]IQ/UFRJ; [2]COPPETEC; [3]IQ/UFRJ-CETEM; [4]CETEM/MCT

The crystallized layer that compounds the bauxite's geological profile from NE Pará was ore dressed through the processes of crushing, screening, washing and grinding, in order to reach the same size distribution of that in the alumina production industry. After the preparation process, the sample (90%, < 0,21 mm) containing 5.3% reactive silica and 47.2% available alumina was submitted to mechanochemical activation with different kinds of reagents (CaO, Ca(OH)2, CaCO3, CaO+HCl, CaSO4), in different concentrations, which resulted in the formation of a calcium aluminium hydrosilicate (hydrogarnet). This phase was formed in the first 30 min of grinding with the use of CaO and Ca(OH)2. However, chemical and thermodynamic analysis showed that the principal phase obtained, katoite hydrogarnet, had the largest aluminum content in its chemical composition thus proving that it is not good for the Bayer process once it is not possible to reduce caustic loss.

3:40 PM
Effects of Roasting Pretreatment in Intense Magnetic Field on Digestion Performance of High Iron Bauxite: *Lv Guozhi*[1]; Zhang Ting'an[1]; Zhang Xuhua[1]; Liu Yan[1]; Dou Zhihe[1]; Li Yan[1]; He Jicheng[1]; [1]Northeastern University

This paper investigated the changes of phase and apparent morphology under the combined effects of intense magnetic field and temperature field and the effect law of different roasting conditions on the digestion performance of high-iron diaspore and settling performance of the digested slurry. The results indicate that roasting pretreatment under high magnetic field can change the microstructure and improve the digestion performance of bauxite. The reasonable roasting conditions with intense magnetic field for high-iron bauxite are as follows: roasting temperature 500°C, roasting time 60 minutes and magnetic field intensity 9T. The digestion rate of alumina of the roasted ore is 71.82%, about 20% higher than that of the raw ore and the molecular ratio of digestion liquor is 1.69 under the digestion conditions of temperature 210°C and time 60min. The settling performance of the digested slurry improved obviously after intense magnetic field treatment.

4:00 PM
Effect of Chamosite on Bayer Process of Diasporic Bauxite with High Silica: *Cao Wenzhong*[1]; Xun Zhang[2]; Weiwei Tian[2]; Hong Zhong[3]; [1]Environmental and chemical engineering institute, Nanchang university; [2]Environmental and Chemical Engineering Institute, Nanchang University; [3]Henan Company of Aluminium Corp. of China

Technological investigations were carried out based on the Bayer process. Predesilication characteristic of the bauxite, the effects of digestion temperature and retention time, concentration of Na2O amount of CaO addition on Al2O3 digestion efficiency in Bayer process and the settling characteristics of the red mud were determined. The bauxite in the northern region of China is diasporic type with high silica (in 6-15% SiO2). The main silica minerals in the bauxite are kaolinite and chamosite. The presence of high silica causes high bound-soda losses in the red mud in the Bayer process, but part of silica content in the bauxite was in the form of chamosite, the bound-soda losses could be greatly reduced with chamosite mineral by using Bayer process. Therefore, it is necessary to study digestion characteristics of the special diasporic bauxite and settling separation properties of the red mud by Bayer process.

4:20 PM
The Economical Flexibility for Processing Diasporic Bauxite: *Zhang Baiyong*[1]; Zhou Fenglu[1]; Guo Shen[1]; Liao Xinqin[1]; Ma Chaojian[1]; Dong Yafeng[1]; [1]Chalieco

Until now, the domestic diasporic bauxite resources is the primary supplied bauxite for alumina production, and Bayer, dressing Bayer, sintering, mixed combination and serial combination processes are parallel used to produce alumina product in China. At the same time Chinese diasporic bauxite resources was seriously depleted recently with the greatly increasing of capacity. In this paper, depending on current diasporic bauxite conditions, the raw material, energy consumption and raw materials & fuel cost are studied for different production processes to processing different grade diasporic bauxite, at same time the raw material, energy consumption and raw materials & fuel cost are discussed at same A/S for different processes, in order to provide references to economical usage of Chinese bauxite resources for Chinese alumina industry.

4:40 PM
Turkey Morcukur Bauxite Processing at ETI Aluminium: *Meral Baygul*[1]; Sedat Aslan[1]; Burak Ozen[1]; Serkan Ertugral[1]; Carlos Suarez[2]; [1]Eti Aluminium Co.; [2]Hatch Associates Consultant Inc

ETI Aluminium can process nearly 550.000 tons of bauxite and 230.000 Tons of alumina per year.The south region of Turkey produces boehmitic bauxite and various alumina/silica ratio. The reserve of Morcukur Bauxite in this region is about 6.000.000 tons of high reactive silica content. ETI started producing bauxite from the Morcukur deposits in 2007 because of easy handling and lower cost .60.000 tons of Morcukur bauxite have been produced from this mine but could not be used because of red mud settling problems . After XRF, XRD, Goethite/Hematite ratio and Organic content analysis ; and also autoclave efficiency (Parr Reactor) and settling performance tests , 10 % -40 % Morcukur bauxite has been processed in 2011 with a strict laboratory and process control. Results from grinding ,digestion and red mud settling performance in the process and laboratory are discussed in this paper.

Aluminium Processing: Rolling

2:05 PM
Implementation of a Combined Work-Hardening, Recovery and Recrystallization Model into a Through-Process-Model for Production of Aluminum Sheet: *Thiemo Brüggemann*[1]; Anna Rott[2]; Volker Mohles[2]; Günter Gottstein[2]; Kai Karhausen[3]; [1]Institute of Physical Metallurgy and Metal Physics; [2]Institute of Physical Metallurgy and Metal Physics, RWTH-Aachen University; [3]Hydro Aluminium Deutschland GmbH

Coupled optimization of alloys and process chains for aluminum sheet is a major goal of the aluminum industry. Since experimental methods are cost- and time-intensive, simulation tools are used to predict effects of material and process parameter changes on the product. Within this work, using rolling schedules from real production lines, the rolling process is simulated via a thermally coupled roll-gap model. This simulation tool is fully linked to a dislocation density based model, which, according to the calculated state variables, simulates work-hardening, recovery and recrystallization on a parallel timescale. The present model is capable of comprising influences of solute contents, particle radii, their volume fractions, and temperature. This framework is feasible to simulate a whole process chain within minutes and thus offers numerous process optimization trials in a reasonable amount of time. Simulation outcome will be compared to experimental findings and real process results of rolled AA8xxx Aluminum sheets.

2:25 PM
Comparative Microstructure and Texture Evolution in the AA1050 Aluminum Alloy Sheets Produced by DC and CC Methods: *Heber Otomar*[1]; Ronald Plaut[2]; [1]VM - CBA; [2]EPUSP

This study aims to compare, on an industrial scale, of the effect of the direct chill (DC) and continuous casting (CC) fabrication processes of AA1050 rolled and annealed sheets. Characterization of their microstructure and texture evolution from the as-cast condition up to the end condition of a deep-drawn cup was carried out. Stamping tests were performed to identify which process presents best performance. Different microstructures were obtained for the studies processes: the DC material was more homogeneous, both in terms of intermetallic distribution and grain size. The mechanical properties of the CC material were slightly higher than those for the DC material. Forming Limit Diagram (FLD) of the homogenized CC material presented the best results.

2:45 PM
Study on Mechanical Properties of 2024 Al Sheet Treated by SMAT and Hot/Cold Rolling: *Ka Po Cheung*[1]; San-Qiang Shi[1]; Jian Lu[2]; [1]The Hong Kong Polytechnic University; [2]City University of Hong Kong

The strengthening effects of hot/cold rolling and surface mechanical attrition treatment (SMAT) on aluminium alloy were investigated. Before performing the rolling processes, aluminium sheets were treated using SMAT on both sides for 40 min at room temperature. The parameters for the hot/cold rolling process include a range of operating temperature (-200 ^{o}C to 480 ^{o}C) and percentage of thickness reduction (up to 85%). Then the mechanical properties of rolled samples with different thicknesses were studied. Tensile test results show that the higher the percentage of reduction in thickness, the higher the strength of the rolled samples can obtain. Considering the yield and tensile strength, rolling at room temperature with the 80% thickness reduction is the optimum conditions for AA2024-T3 in this article, in which the yield and ultimate tensile strength have been increased by 54% and 79% respectively. It is also found that the ductility was also enhanced according to the operating temperature.

3:05 PM
Effects of Asymmetrical Roll Bonding on Microstructure, Chemical Phases and Property of Copper/Aluminum Clad Sheet: *Xiaobing Li*[1]; Guoyin Zu[2]; Ping Wang[3]; Rong Xu[4]; [1]School of Materials and Metallurgy, Northeastern University ; [2]School of Materials and Metallurgy, Northeastern University; [3]Key Laboratory of Electromagnetic Processing of Materials, Ministry of Education, Northeastern University; [4]The State Key Laboratory of Rolling and Automation, Northeastern University

The present paper investigated the morphology and chemical phases of interfacial layer of Copper/Aluminum clad sheet by scanning electrical microscope equipped with energy dispersive X-ray detector and X-ray diffraction, also measured the mechanical property through micro-hardness test. The results are that the interfacial bonding is enhanced and the thickness of interfacial layer increases with mismatch speed ratio rising. The improved interfacial bonding can be found from the tensile fracture. The formation of intermetallic compound (IMC) is promoted by the significant element diffusion at high speed ratio. For sample annealed at 400 \176C for 20 min, the formation of IMC is negligible, but the fracture lies between compounds. The micro-hardness on the interface decreases with speed ratio increasing. The study shows that the improvement of microstructure and mechanical property and formation control of IMC of Copper/Aluminum clad sheet can be achieved using asymmetrical roll bonding with high speed ratio.

Influence of Microstructure Representation on Flow Stress and Grain Size Prediction in A5XXX Alloys: *Johannes Lohmar*[1]; Markus Bambach[1]; Gerhard Hirt[1]; Kai Karhausen[2]; [1]RWTH Aachen University; [2]Hydro Aluminium Rolled Products GmbH

Integrated computational materials engineering is an up to date method for developing and optimizing complete process chains. In the simulation of a process chain, material models play a central role as they capture the response of the material to external process conditions. While much effort is put into their development and improvement, less attention is paid to their implementation, which is problematic because the representation of microstructure in the model has a decisive influence on modeling accuracy and calculation speed. The aim of this paper is to analyze the influence of different microstructure representation concepts on the prediction of flow stress and microstructure evolution when using the same material model. Scalar, tree-based and cluster-based concepts are compared for a multi-stage rolling process of an A5XXX alloy. It was found that implementation influences the predicted flow stress and grain size, in particular in the regime of coupled hardening and softening.

4:25 PM
Influence of Pre-Strain on Formability of AA3XXX Aluminum Alloy: *Yansheng Liu*[1]; Xiyu Wen[2]; Shridas Ningileri[1]; [1]SECAT Inc; [2]University of Kentucky

Changes in Strain path can impact material behavior. The influences of strain path change on tensile properties of materials have been thoroughly investigated in past decades. Formability is one of the important properties of sheet metals for automotive application. The current investigation focuses on the influence of strain path change on formability of the material. O-temper sheets were pre-strained 15% via different strain paths by rolling in rolling and transverse direction. Olsen and earing cup tests were conducted and compared with the original and two pre-strained samples. Strain distribution were measured by grid etching method and analyzed by ASAME software. The influences of pre-strain conditions, texture evaluation on formability and mechanical anisotropy were discussed. The result shows that pre-strain via different path has a significant impact on formability.

4:45 PM
From Molten Metal to 3.2 mm Wire for Mechanical Applications: *Giuseppe Marcantoni*[1]; [1]Properzi International, Inc.

Aluminium utilization is growing at a steady rate reaching 40 million tons per year considering remelt and semis. Among semis, aluminium rod accounts for approximately 10% of the worldwide consumption, mainly for power transmission. Numerous aluminium alloys have been developed and utilized for various mechanical applications and welding purposes. Many rod alloys are difficult to produce and require highly experienced operators and the most advanced machinery and technical know-how. In the form of wire, from molten metal to 3.2 mm wire, the situation becomes even more critical and only the latest Properzi C.C.W (Continuous Cast Wire) technology provides new possibilities within this industrial field. The Author explores state-of-the-art aluminium rod equipment and the range of application for the C.C.W. technology which allows the production of 1xxx – 2xxx – 3xxx – 4xxx – 5xxx – 6xxx – 7xxx – 8xxx series aluminium alloys for many industrial and specialty applications.

Effects of Cu, Mg, and Sr Additions on the Mechanical Properties and Machinability of Near-Eutectic Al-11%S Casting Alloys: Yasser Zedan[1]; Agnes Samuel[1]; *Fawzy Samuel*[1]; Saleh Alkahtani[2]; [1]UQAC; [2]AlKharj University

The effects of Cu (2.25, 3.5%), Mg (0, 0.3, 0.6%) additions, Sr modification, and T6-heat treatment on the mechanical properties and machinability of near eutectic Al-Si cast 396 alloy were studied, using a T6 treatment that provided hardness levels of 110±10 BHN required in commercial Al applications. Increase in Cu/Mg levels has a detrimental effect on drill life. The Mg-free alloy displays the lowest cutting force and moment, producing the highest number of holes drilled. Cooperative precipitation of Al2Cu, Mg2Si, Al2CuMg, and Al5Si6Cu2Mg8 hardening phases in Mg-containing alloys confer greater strength on the alloy than is the case with only Al2Cu precipitation in the Mg-free alloy. A comparison of the number of holes drilled in non-modified and Sr-modified alloys (with same Mg and Cu levels) reveals that the Si particle morphology has a noticeable effect in governing the tool life of such Al-Si alloys.

2:20 PM
Evolution of Iron Based Intermetallic Phases in Al-7wt%Si Hypoeutectic Alloy: *Anton Gorny*[1]; Sumanth Shankar[1]; [1]McMaster University

This study has methodically characterized the iron based intermetallic phases evolving during solidification of Al-Si binary alloys as a function of alloy melt superheat temperature, solidification cooling rate, purity of the initial pure Al and composition of Fe in the alloys. The initial superheat prior to solidification and the cooling rate during solidification played a significant role in the nature and type of these intermetallic phases evolving in the cast component. Contrary to the predictions of the evolution of only the ß (Al,Si,Fe) in these alloys by all commercial thermodynamic phase diagram simulation tools, the dominant phases were mostly metalstable intermetallics and significantly vary in nature and type with the process parameters. The results from this study will further enable better design of the Al-Si alloys with an in-depth understanding of the evolution of the intermetallic phases and methodologies to prevent or modify the same in the final cast components.

2:40 PM
A New Approach to Producing Large-Size AA 7055 Aluminum Alloy Ingots: Haitao Zhang[1]; *Jianzhong Cui*[1]; Hiromi Nagaumi[2]; [1]Northeastern University; [2]Suzhou Institute for Nonferrous Metals Research

In this paper, Low frequency electromagnetic field and air knife are applied simultaneously to produce large-size AA 7055 aluminum alloy ingots during DC casting. Moreover, the effects of low frequency electromagnetic field and air knife on the macro-physical fields during DC casting and the microstructure and crack in the ingots are studied and analyzed by the numerical and experimental methods. Comparison of the calculated results indicate that applying electromagnetic field can modify the direction and increase the velocity of melt flow and homogenize the distribution of temperature in the sump, and applying air knife can homogenize the distribution of temperature and decrease the stress and strain in the solidificated ingots. Further, the microstructure of the billet is refined remarkably and the crack is eliminated by applying electromagnetic field and air knife during DC casting because of modification of the macro-physical fields.

3:00 PM
Thermal Analysis and Microstructures of Modified Grain-Refined Al-7Si-Mg Cast Alloy: *Adel Mohamed*[1]; FH Samuel[1]; Saleh Al kahtanid[1]; [1]UQAC

This article aims to investigate the grain refining response of Sr-modified A356.2 alloy with various Al-Ti, Al-B and Al-Ti-B master alloys at different levels. Thermal analysis was used to evaluate the interactions between Sr and B, and between Sr and Ti. Microstructure was examined using optical microscopy and EPMA technique. Impact properties were evaluated for both as-cast and heat-treated conditions. The results reveal that adding B with levels higher than 0.1% leads to formation of particles containing predominantly B and Sr, such as SrB6. The Sr-B interaction may postpone grain refinement of the alloy containing 0.02-0.1%B. The addition of Ti and B greatly improves the alloy toughness but only in a fully modified state, and the right type of master alloy and addition levels are used. The toughness of all T6-tempered alloys is significantly higher than those obtained in the as-cast condition, regardless of the type of master alloy used.

3:20 PM
Effect of Solidification Velocity and Hydrogen Content on Porosity in Directionally Solidified A356 Castings: Hengcheng Liao[1]; *Qigui Wang*[2]; Wan Song[1]; Lei Zhao[1]; Ran Fan[1]; [1]Southeast University; [2]GM Global Powertrain Engineering

Micro-focus X-ray technology was utilized to evaluate the influence of solidification velocity and hydrogen content on the volume fraction, number density and sizes of pores in the directionally solidified A356 castings. The results indicate that hydrogen content has a significant influence on porosity formation. When hydrogen content is low, few small irregular-shape pores were observed indicating the dominate impact of solidification shrinkage. While in high hydrogen specimens, many large spherical pores were found. The pore size distribution also shows dual populations. The group of large pores is formed in the liquid far from the solidification front. The group of small pores is formed near the solidification front. When hydrogen content is high, increasing solidification velocity (from 0.1mm/s to 0.2mm/s) not only decreases volume fraction of porosity but also significantly reduces the maximum pore sizes of large pores.

3:40 PM
Grain Refiner for Aluminium-Silicon Sand Casting Alloys: *Magdalena Nowak*[1]; Hari Babu Nadendla[1]; [1]Brunel University

Al-Si alloys exhibit large grain structure when Al-Si alloy melt is solidified in sand moulds due to low cooling rate provided by the mould. Ti-based grain refiner is known to be less-effective to refine grain structure of Al-Si alloys due to formation of Ti-Si phase. Recently, we have developed an effective novel grain refiner (NGR) for aluminium-silicon sand casting alloys. Effectiveness of grain size under slow cooling conditions has been investigated. For comparative purposes, a range of sand casting alloys with NGR addition have been produced. The results show that the addition of novel grain refiner reduces the grain and eutectic size significantly for all these alloys at lower cooling rate <0.5 °C/s. As a result of fine primary Al grains, the porosity and elongation in the solidified alloys is notably improved.

Novel Casting Process of Developing a Carbon Modified Hyper-Eutectic Wear Resistant Aluminum-Silicon Alloy for the Forging Process: *Kuldeep Agarwal*[1]; Rajiv Shivpuri[1]; Matthew Blankenhorn[2]; [1]Ohio State University; [2]Aluminastic Corporation

Currently, most Al-Si alloy components are limited to cast structures where their strength and wear capabilities override the additional costs of testing for defects, rejections, and machining. This paper discusses the development of a 20-25% Si alloy based on the 4032 aluminum forging alloy composition that has low density and high wear resistance. To achieve these advantages in hyper-eutectic alloys, the carbon and copper contents are adjusted in the aluminum alloy during melt processing, electric field is used to disperse carbon, and equiaxed particles of primary silicon, carbides and graphite flakes are precipitated during solidification in the Al-Si eutectic. These micro- and nano-particles provide for higher wear resistance, higher modulus and toughness. Characterization is done to relate the different processing parameters and the microstructure formed and the properties obtained. Potential applications of this alloy are in automotive engines including pistons, cylinder heads and connecting rods where wear resistance is important.

4:35 PM
Solidification Analysis of the Hypereutectic Al-Si Alloys with Addition of Cu and Mg Using Neutron Diffraction: *Dimitry Sediako*[1]; Wojciech Kasprzak[2]; [1]National Research Council Canada ; [2]MTL-Canmet, NRCan

A good understanding of kinetics of solid phases' evolution during solidification of hypereutectic aluminum alloys is a key to controlling the as-cast microstructure and, in turn, enhancing service properties of industrial alloys. A study has been performed to evaluate the solidification kinetics for two hypereutectic Al-18wt%Si alloys with addition of 3wt%Cu and 3wt%Cu+1wt%Mg. This study included thermodynamic calculations of the solidification process using the FactSageTM 6.2 software package, as well as experimental thermal analysis, and neutron diffraction. The study revealed kinetics of solid Al, solid Si (both primary and eutectic), Al2Cu, and Mg2Si evolution, as well as an individual effect of Cu and Mg alloying additions on solidification path of the Al-Si system.

4:55 PM
Refinement of Primary and Eutectic Silicon Phases in the Shape Casting of Hyper-Eutectic Al-Si Alloys: *Mohammad Shamsuzzoha*[1]; [1]University of Alabama

The hyper-eutectic Al-Si alloys owing to being of low density materials and of excellent castibility are good candidates for aerospace and automobile applications. Our effort over the last few years have demonstrated that such hyper-eutectic Al-Si alloys containing no primary silicon phase, but of eutectic microstructure that assumes nano sized fibrous morphology for the eutectic silicon phase can be grown by directional solidifications. In a further pursuit on this effort, more hyper-eutectic Al-Si alloys containing ultra-refined primary and eutectic silicon phases have been grown by a different casting method, which is popularly known as shape casting. The process of fabrications and microstructure of the resulting alloys are presented.

5:15 PM
Analysis of Thermal and Structural Parameters and Microhardess Variations in Different Al-Cu Alloys Directionally Solidified: Carlos M. Rodriguez[1]; Adriana E. Candia[2]; *Carlos E. Schvezov*[1]; Mario R. Rosenberger[1]; Alicia Ares[1]; [1]CONICET/FCEQyN-UNaM; [2]FCEQyN-UNaM

The columnar - to - equiaxed transition (CET) was investigated in Al-Cu alloys (Al-1wt%Cu, Al-5wt%Cu, Al-15wt%Cu and Al-33.2wt%Cu) solidified directionally from a chill face in a vertical setup. The CET occurs when the temperature gradient in the melt ahead of the columnar dendrites and the liquid interphase velocity reach critical values. Also, we investigate correlations between microstructural parameters (grain size and dendrite arm spacings) with Vickers microhardness measurements in the directionally solidified samples. We observed that the Vickers microhardness is greater in the equiaxed zone than in the columnar or columnar to equiaxed transition (CET) zone, additionally, is greater on the edges of the samples than in the centre. The grain size and lamellae spacings increase from the columnar to the equiaxed structure. The established correlations were compared with the data in the available literature and the results are discussed.

Low Cost Video Emissions Monitoring Technique for Aluminum Smelting Applications: *Michael Gershenzon*[1]; Neal Dando[1]; Nathan Westendorf[1]; Steve Lindsay[1]; [1]Alcoa

Aluminum smelting plants emit gaseous and particulate fluoride, sulfur dioxide (SO2), carbon oxides (CO and CO2), perfluorocarbons CF4 and C2F6, and other by-products of aluminum electrolysis. The fugitive emission intensities for some of these compounds (most notably, fluorides) is strongly correlated with potroom work activities and work practices (e.g., anode change operations, metal tapping practices, pot hood placement, etc.). Therefore, work practice standardization and potroom personnel education regarding the impact of their day-to-day activities on smelter emissions are important components of a comprehensive emission reduction strategy. This work introduces a low-cost video emission monitoring technique utilized at Alcoa that allows overlaying real-time emissions measurements (e.g., HF, SO2, dust, etc.) on video recordings of specific work activities. The developed capability is used to more effectively and uniformly communicate the impact of work practices on plant environmental performance. Specific examples of high-impact work practices are presented and discussed.

4:00 PM
Electrolytic Cell Gas Cooling Upstream of Treatment Center: Bernard Cloutier[1]; Thierry Malard[2]; El Hani Bouhabila[2]; Fabienne Virieux[3]; *Philippe Martineau*; [1]Solios Environnement Inc; [2]Solios Environnement SA; [3]Fives Solios

The general use of high amperage cells in the last decade has created new challenges for Gas Treatment Centers (GTCs). Aluminum production capacity increases proportionally with the applied electric intensity. This leads to more waste heat by joule's effect which increases the cell outlet gas temperature. The cell gas temperature also depends on the ambient temperature. In hot climate, gas temperature at the cell outlet could exceed 190°C. For such application, it has become necessary to cool the gases before treatment by HF adsorption on alumina in order to protect the filtration media and to improve the overall scrubbing performance on fluorides. Several technologies have been developed and applied in recent years: dilution air cooling, water atomization in the upstream ducts, heat exchangers. The paper will present a technical and economical comparison of the various cooling technologies.

4:20 PM
Jet Induced Boosted Suction System for Roof-Vent Emission Control: New Developments and Perspectives: *Jean-Nicolas Maltais*[1]; Michel Meyer[1]; Mathieu Leduc[1]; Hyacinthe Rollant[1]; [1]Rio Tinto Alcan

Reducing fluoride emissions becomes necessary in production growth and/or tightening environmental regulation contexts. Over 40% of the roof vent emissions are generated by the pot during periods with opened pot hoods. These periods are therefore targeted for improvement, which is usually obtained by significantly increasing the pot exhaust flow while the hoods are opened. The Rio Tinto Alcan patented solution: Jet Induced Boosted Suction system, trialed and now rolled-out on AP22 potlines in Tomago, has been scaled up to fit the AP3X technology. This led to the implementation of an industrial demonstration on a 36-pot section in the Alma smelter, including automatic pot hood opening detection. The operational and environmental performance of the system has been evaluated during the trial. In parallel, the design and proof of concept of an AP60 version has taken place in LRF, preparing for future evaluation as part of the AP60 Jonquière project.

4:40 PM
HF Emission Reduction from Anode Butts Using Covered Trays: *Jean-Pierre Gagne*[1]; René Minville Minville[1]; Neal Dando[2]; Mike Gershenzon[2]; Steve Lindsay[3]; Harold Frenette[4]; Alain Moras[4]; Gilles Dufour[4]; [1]STAS; [2]Alcoa Technical Center; [3]Alcoa TN; [4]Alcoa Canada, Aluminerie Deschambault

During the production of aluminum from conventional prebake Hall-Héroult electrolysis, anodes have to be replaced on a regular basis. The anode butts are usually placed on uncovered trays for transportation, a practice that contributes to overall hydrogen fluoride (HF) emission. In 2000, anode tray covers developed by Alcoa Deschambault were implemented to significantly reduce fluoride emissions. In 2004, an Alcoa-STAS R&D team developed a second generation of anode tray covers for the new Alcoa Fjardaál plant. In 2009, the Alcoa STAS R&D team designed and fabricated an experimental test garage to allow the accurate full-scale in-plant measurement of temporal HF emissions from cooling anode butts trays. Over the last two years, comparative measurements were performed on covered and uncovered anode trays in a manner to allow estimation of the overall impact of covered trays back to zero time, or removal from the pot. This paper presents results of these studies.

Atomistic Effects in Migrating Interphase Interfaces - Recent Progress and Future Study: Interfacial Structure with Large Misfit and Deformation-induced Migration

Atomistic Structure and Energetics of the θ' (Al_2Cu) – Aluminium Interface: *Laure Bourgeois*[1]; Christian Dwyer[1]; Matthew Weyland[1]; Jian-Feng Nie[1]; Barrington Muddle[1]; [1]Monash University

The θ' phase is an effective strengthening precipitate in aluminium alloys and a well-known intermediate phase of the textbook decomposition sequence of an Al-Cu solid solution. Yet the atomistic mechanisms of its (notoriously difficult) nucleation and different growth modes remain poorly understood. In this contribution, aberration-corrected scanning transmission electron microscopy observations will be presented for the interfacial structure between aluminium and θ' precipitates in different Al-Cu-based alloys. In particular, we will show that the coherent interface of θ' with aluminium can adopt a structure that differs from that previously assumed based on the bulk crystal structures. These observations, combined with first-principles energetics calculations, demonstrate that this new interfacial structure constitutes an intermediate state in the atomistics of precipitate thickening.We will also present observations on the interaction between Sn and θ', and suggest potential factors for the beneficial role of Sn additions in promoting the nucleation of θ'.

2:30 PM
Crystallography and Interfacial Energy of Al6(Fe,Mn) Dispersoids Precipitated in AA5182 Alloy: *Yanjun Li*[1]; Jesper Friis[1]; Wenzheng Zhang[2]; Lars Arnberg[3]; [1]SINTEF Materials and Chemistry; [2]Department of Materials Science and Engineering, Tsinghua University; [3]Department of Materials Science and Engineering, NTNU

Al6(Fe,Mn) is an important type of dipspersoids in non-heat treatable aluminium alloys containing Mn and Fe. In this work, the morphology, habit plane and orientation of Al6(Fe,Mn) dispersoids precipitated during homogenization treatment of an AA5182 alloy have been characterized by using transmission electron microscopy. The orientation relationship between the dispersoids and Al matrix has been determined. The habit plane is found to be normal to a set of □g's. The interfacial structure at the habit plane of the dispersoids has been studied by atomic simulation and constrained coincidence site lattice (CCSL) analysis. The orientation of the habit plane and the preferential growth direction of the dispersoids can be explained in terms of a relatively high density of near-coincident site lattice points and a good atom-to-atom matching at the interface. Based on the orientation relationship found in the work, a preliminary first-principles calculation of the interfacial energy has been carried out.

2:50 PM
Interfacial Disconnections at Sb_2Te_3 Precipitates in PbTe: Mechanisms of Strain Accommodation and Phase Transformation at a Tetradymite/Rocksalt Telluride Interface: *Douglas Medlin*[1]; N. Heinz[2]; T. Ikeda[2]; G. Snyder[2]; [1]Sandia National Labs; [2]California Institute of Technology

Understanding the structure and formation mechanisms of interfaces between different telluride phases is important to the development of thermoelectric nanocomposites. Here, we investigate the interfacial structure of tetradymite precipitates in a rocksalt telluride matrix, focusing in particular on plate-like precipitates of Sb_2Te_3 in PbTe. Using high-resolution transmission electron microscopy (HRTEM), we investigate the structure and arrangement of interfacial disconnections—i.e. interfacial steps possessing dislocation character—observed in this system. Our analyses provide insight concerning the roles of these defects in accommodating the large interfacial misfit (6.7%) in this system and in mediating the transformation from the rocksalt to the tetradymite structure. Our observations also suggest how such interfacial disconnections could arise through the dissociation of crystal lattice dislocations that accommodate the misfit on initially flat segments of the interface.

Interface Facets in Systems with Large Lattice Misfit: *Wenzheng Zhang*[1]; Zhangzhi Shi[1]; Xiaopeng Yang[1]; [1]Tsinghua University

Well-defined facets of precipitates are often considered to have a coherent or semicoherent structure, but usually no coherent region(s) can be sustained if the precipitates have a significantly larger unit cell than that of the matrix. In this work, facets in systems with large lattice misfit are described with a CS-coherent structure (CS = coincidence site(s)). Two conditions are required to form such a structure in a facet: existence of dense CS at least locally and singularity in the secondary dislocation structure if secondary misfit exists. Satisfaction of both conditions in a rational crystal plane yields a rational facet and otherwise an irrational facet. Guidelines are provided to derive geometry of potential facets according to these conditions, with applications to different precipitation systems. The CS-structures are compared with semicoherent and incoherent structures in terms of ratio of near coincidence site in the structure. Migration of different facets is discussed.

4:00 PM
A Study of Plastic Strain Accommodation during Phase Transformation: *Michael Kuba*[1]; David Van Aken[1]; [1]Missouri University of Science and Technology

An often-overlooked consequence of phase transformations is the volume change. While elastic accommodation of the volume change has been analytically studied, very few studies have addressed the possibility of parent phase plasticity in accommodating the volume change. Acoustic emission is used here to study melting of embedded indium particles to show that dislocation multiplication occurs in the aluminum matrix to accommodate a 2.5% volume change. The geometrically necessary increase in dislocation density was calculated as $4.1 \times 10^{13}\ m^{-2}$ for a dispersion of sub-micron indium particles in an Al-17In alloy. Thermomechanical processing was also used to change the size and distribution of the indium particles to show a difference in acoustic emission signal strength of particles embedded at grain boundaries versus those embedded within the grains. Previous internal friction studies have shown that particles melting at grain boundaries have shorter relaxation times.

4:20 PM
Grain Rotation and Transformation of Austenite Grains upon Straining of a Si-Alloyed TRIP Assisted Steel: *Ganesh Kumar Tirumalasetty*[1]; Marijn A Van Huis[2]; Cees Kwakernaak[3]; Jilt Sietsma[3]; Wim G Sloof[3]; Henny W Zandbergen[4]; [1]Materials Innovation Institute (M2i)/ Kavli Institute of Nanoscience, Delft University of Technology; [2]Kavli Institute of Nanoscience, Delft University of Technology/EMAT, University of Antwerp; [3]Department of Materials Science and Engineering, Delft University of Technology; [4]Kavli Institute of Nanoscience, Delft University of Technology

Si-alloyed TRIP (transformation induced plasticity) steel was subjected to uni-axial straining experiments in order to assess the role of microstructure on the mechanical stability of austenite grains. Individual austenite grains were monitored before and after straining (up to 20 %) using electron back scattered diffraction (EBSD). Three different types of austenite grains were distinguished with different transformation behaviors. It was found that *twinned austenite grains* and *austenite grains present at grain boundaries* between larger ferrite grains typically transform first, in contrast to *embedded austenite grains* that are completely surrounded by a single ferrite grain. In the latter case, straining leads to rotations of austenite grains within the ferrite matrix before TRIP transformation into martensite occurred. The analysis suggests that in addition to the austenite-martensite transformation, austenite grain rotation is a significant factor contributing to the ductility of these steels.

4:40 PM
Strain Glass Caused by Nano-Scale Randomness -- Strain Glass Transition in Low-Temperature-Aged Ti48.7Ni51.3 Alloy: *Yuanchao Ji*[1]; Xiaobing Ren[1]; Xiangdong Ding[2]; [1]National Institute of Materials Science; [2]Los Alamos National Laboratory

Strain glass, a frozen short-range strain-ordered state, has been discovered in many defect-containing ferroelastic/martensitic alloys. Up to now all found strain glass systems have been shown to originate from atomic-scale randomness: randomly distributed point defects. In this study, we report an interesting finding that nano-scale randomness can also lead to the formation of strain glass. The sample under investigation was a Ti48.7Ni51.3 alloy, which undergoes a normal B2-B19' martensitic transition in a precipitation-free state. However, martensitic transformation is suppressed and the sample undergoes a strain glass transition when nano-sized, randomly distributed Ti3Ni4 precipitates (i.e., nano-scale randomness) were introduced into the alloy by a low-temperature aging treatment. The strain glass transition is characterized by a mechanical susceptibility anomaly with frequency-dependence, ergodicity-breaking, and invariance in average structure. The present finding suggests that nano-scale randomness, besides atomic-scale randomness, can create frustration to a ferroelastic system and lead to the formation of strain glass.

A Model for Diffuse Axonal Injury: *K Ramesh*[1]; [1]Johns Hopkins University

Computational models are often used as a tool to study impact biomechanics. The fidelity of such models relies heavily on an accurate description of the behavior of the materials involved, and the use of an appropriate measure of injury. Diffuse axonal injury (DAI) accounts for a large percentage of deaths due to brain trauma and is characterized by damage to neural axons. We have developed a measure of diffuse axonal injury based on an axonal strain injury criterion. We model the white matter as a nonlinear, anisotropic material, and use diffusion tensor imaging to incorporate the structural orientation of the neural axons into the computational model. We show that the degree of injury that is predicted in a computational model of DAI is highly dependent on the incorporation of the axonal orientation information and the inclusion of anisotropy into the constitutive model for white matter.

2:30 PM
Nanoscale Structural and Mechanical Characterization of Conch Shells: Haoze Li[1]; Zhi-Hui Xu[1]; *Xiaodong Li*[1]; [1]University of South Carolina

We used conch shells as an example to unveil that the third-order lamellae, which were thought to be signal crystals and the basic building blocks for conch shells, are composed of nanoparticles with diameters ranging from 20 to 45 nm. The nanocomposite third-order lamellae are not brittle, but somewhat ductile. The findings advance our understanding of the mystery of seashells' strengthening and toughening mechanisms, provide additional design guidelines for developing biomimetic materials, and lay a constitutive foundation for modeling of the deformation and fracture of biomaterials.

2:50 PM
Structure and Mechanical Behavior of the Dasypus Novemcinctus Shell: *Hongjoo Rhee*[1]; Mark Horstemeyer[1]; [1]Center for Advanced Vehicular Systems, Mississippi State University

Multiscale hierarchical structures, material properties, and mechanical behaviors of the nine-banded armadillo (Dasypus novemcinctus) shell were studied to provide fundamental knowledge for understanding biological composite systems. The armadillo's forward and rear shells comprise a sandwich composite structure of functionally gradient material, having relatively denser exterior bony layers and an interior bony network of foam. The band shell revealed a more complicated structure where adjacent bands are partially overlapped and connected with each other to provide flexibility in addition to protection. Compression test results showed a typical nonlinear deformation behavior similar to synthetic foams in which microbuckling is a key inelastic deformation mechanism. A comparison and contrasting study of the structure-property relations between the armadillo shell and other biological structural materials could provide fundamental understandings for deformation mechanisms which could lead to the development of novel bio-inspired safety system design methodologies.

3:10 PM
Self Healing Characteristics of Human Enamel: *Camilo Rivera*[1]; Dwayne Arola[1]; Alex Ossa[1]; [1]Eafit University

Tooth enamel is the hardest and most highly mineralized substance in the human body. There have been a number of studies dedicated to understand the crack growth resistance characteristics of this hard tissue using microindentation and fracture toughness experiments. These studies have provided an insight towards the main fracture mechanisms of this hard tissue and their correlation with its microstructure. However, there has been limited research aimed at understanding the self-healing characteristics of human enamel, a concept of substantial interest in the field of dentistry and regarding to the potential bioinspiration. This work presents a study of the self-healing ability of "young" human enamel from patients between 18-25 years of age. The apparent fracture toughness and brittleness of enamel were studied by means of microindentation. Microscopic observations revealed that cracks began the healing process immediately after initiation and finished after approximately 48 hours, reaching crack length reductions between 5-15%.

3:30 PM
Modeling Human Eye under Shock Loading: *Nicola Bonora*[1]; Luca Esposito[1]; Chiara Clemente[1]; Tommaso Rossi[2]; [1]University of Cassino; [2]Ospedale Oftalmico di Roma

The mechanical response of biological materials is complex and difficult to be determined experimentally. Anisotropy and visco-elasticplastic behavior make difficult the identification of the effective constitutive response under general stress state. When dealing with dynamic events, such as blunt impact or blast loading, the situation becomes even more complex due to strain rate and pressure dependent effects. Here a calibration procedure for identifying the more appropriate constitutive model to simulate the response of human eye tissues under dynamic loading conditions, is presented. A finite element model for the human eye was developed and constitutive model selection for tissues and the vitreous has been performed base on test data reported in the literature. Using the structural optimizer modFRONTIER, model parameters have been determined simulating the in-vitro instrumented impact experiment reported by Delori et al. (1969). The calibrated material models have been validated under different load rate and state of stress conditions.

4:00 PM Invited
Structure and Mechanical Behavior of Fish Scales: Wen Yang[1]; Yen-Shan Lin[2]; Jianan Li[3]; Po-Yu Chen[4]; Maria Lopez[1]; Vincent Sherman[1]; Eugene Olevsky[2]; *Marc Meyers*[1]; [1]Univerisity of California, San Diego; [2]San Diego State University; [3]Shanghai Jiao Tong University; [4]National Tsing Hua University

Scales provide protection and safeguard of fish from predators. Most scales have the similar constituents as other hard tissues such as bone and teeth, which mainly contain type-I collagen fibers and calcium phosphate-based minerals. The scales of two large fish, Arapaima gigas (a large Amazon basin fish) and Atractosteus spatula (the largest North American fresh water fish) are characterized mechanically and microstructurally. The Arapaimas scales have a laminate composite structure composed of an external mineralized layer and internal lamellae with thickness of 50-60 um each and composed of collagen fibers with ~ 1um diameter. The alignment of collagen fibers is consistent in each individual layer but varies from layer to layer, forming a non-orthogonal plywood structure, known as Bouligand stacking. The Atractosteus scales are highly mineralized and contain an external ganoin layer and an internal bony layer containing collagen fibers with a thickness of 100~200 nm. Micro and nanoindentation hardness tests were carried out, revealing the variation in values that provides optimum protection. Arapaima scales have a gradually decreasing hardness from external layer to the internal layer, while Atractosteus scales have a high hardness in their external layer (ganoin) and a discontinuous drop in internal layer. Tensile and bending testing of both scales carried out in the dry and wet conditions shows that the strength and stiffness are hydration dependent. The structure and mechanical properties are discussed in terms of the protection mechanisms for these fishes.

4:30 PM
Structural and Mechanical Design of Zebra Shark Teeth: Hao-Jen Fang[1]; Chang-Yu Sun[1]; Yao-Tien Ku[1]; *Po-Yu Chen*[1]; [1]National Tsing Hua University

The shape and morphology of sharks' teeth vary from species to species depending on their diet. Shark species that feed primarily on soft-bodied prey such as fishes and mammals have needle-like, sometimes serrated teeth for gripping and cutting while those that consume hard shelled mollusks and crustaceans have dense flattened teeth more appropriate for crushing and grinding. In this study, structure and mechanical properties of the teeth of zebra sharks (Stegostoma fasciatum) were investigated. Zebra shark have multiple rows and series of tricuspid shaped teeth, forming a crushing surface which are able to crush the sturdiest hard-shelled prey. The teeth consist of a hard external layer of enameloid and tough internal dentine. Nanoindentation and compression tests were performed on the teeth in dry and hydrated conditions. Results were compared with the soft prey-eating great white shark teeth and different functional adaptations and design strategies between the two species were discussed.

4:50 PM
Structure and Mechanical Properties of Alligator Osteoderms: *Irene Chen*[1]; Marc Meyers[1]; [1]University of California at San Diego

Alligator osteoderms are protective bony-plates embedded underneath the skin on the back of the animal. The osteoderm has a disc-like morphology with a tilted convex ridge at the middle of the plate with depressions on the surface and a porous region in the cross-section. Its main constituents are hydroxyapatite crystals. An abundance of granular mineralization is seen in untreated tissue. With the deproteination process, SEM images show a series of bundles of mineralized fibrilar structures oriented along the same direction, rather than in a random orientation. The demineralization process was completed by dissolving the minerals on the surface of the osteoderm. The SEM images reveal that the minerals being removed left hollow spaces with honeycomb-like structure and circular geometry of cells of 5um in diameter. Mechanical properties (i.e compression and impact) will be discussed. Nano and micro-indentation testings and CT scanning will be performed. Research support by NSF: DMR-1006931

5:10 PM
A Comparative Study of the Compressive Mechanical Properties of Young and Old Bovine Cortical Bone: *Ekaterina Novitskaya*[1]; Zherrina Manilay[1]; Steve Lee[1]; Joanna McKittrick[1]; [1]UCSD

The mechanical properties of untreated, demineralized, and deproteinized 18 month and 6 month old cortical bovine femur bones were investigated by compression testing in quasi-static regime in two anatomical directions (longitudinal and transverse). The compressive strength and elastic modulus were found to be smaller for the younger bone. Microstructural features, including the amount of osteonal bone, osteon morphology, and structure of Haversian systems of the samples from two different age groups were studied by optical and scanning electron microscopies. It was found that younger bone has a larger amount of drifting osteons and a higher level of porosity, both characteristics of a faster growing tissue. Energy-dispersive X-ray spectroscopy was applied to the samples from both age groups to measure the difference in mineralization between osteonal and interstitial (woven) bone parts. This research is funded by the National Science Foundation, Division of Materials Research, Ceramics Program (Grant 1006931).

Bulk Metallic Glasses IX: Alloy Development and Mechanical Properties

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee
Program Organizers: Peter Liaw, The University of Tennessee; Hahn Choo, The University of Tennessee; Yanfei Gao, The University of Tennessee; Gongyao Wang, University of Tennessee

Monday PM — Room: Swan 6
March 12, 2012 — Location: Swan Resort

Session Chairs: C. Liu, Hong Kong Polytechnic University; Y. Yokoyama, Institute for Materials Research

2:00 PM Keynote
Atomic Structures and Mechanical Properties of Bulk Metallic Glasses: *C. T. Liu*[1]; Yong Yang[2]; X. J. Liu[2]; [1]City University of Hong Kong; [2]Hong Kong Polytechnic University

Because of the lack of long-range periodic lattic structures, the mechanical behavior of bulk metallic glasses (BMGs)is fundamentally different from that of crystalline materials. Thus,the understanding of the mechanical behavior of BMGs with complex amorphous structures is the topic of active research at the present time. In this paper, we will provide a brief review of the recent research findings of unusual mechanical properties of BMGs, including size effect, anelastic deformation behavior, evolution of shear-band embryos, percolation for macroscopic yielding, stability of shear-band propagation, and universal strain for fracture. We intend to explain these unique properties with the atomistic models, involving both tightly-bonded atomic clusters and loosely-bonded free volumes, proposed recently.

2:30 PM
Production and Mechanical Properties of Roll Bonded Bulk Metallic Glass/Aluminium Laminates: *Daniel East*[1]; Mark Gibson[1]; Daniel Liang[1]; Jian-Feng Nie[2]; [1]CSIRO; [2]Monash University

Hybrid structures combining a high strength brittle material with a soft low strength material have been shown to be a successful method for the improving the toughness and flexural strength of the brittle material. In this study the production of bulk metallic glass and aluminium laminates by a combination of twin roll casting and roll bonding will be presented. The production variables must be such that the BMG retains its amorphous structure and also bonds adequately to the crystalline metal. The effect of rolling conditions on the bonding of BMG to crystalline metal will be presented. The effect of lamellae spacing and size on the impact toughness and flexural strength of the resultant hybrid material will also be presentedThe combination of two scalable technologies in twin roll casting and roll bonding may open markets for bulk metallic glass hybrid materials to the sheet materials market.

2:40 PM Invited
Micro-Scale Moldability and Mechanical Properties of Hypoeutectic Zr-Based Metallic Glasses: Sae Takashima[1]; T. Yamasaki[1]; K. Fujita[2]; A. R. Yavari[3]; A. Inoue[4]; *Y. Yokoyama*[5]; [1]University of Hyogo; [2]Ube National College of Technology; [3]SIMAP-CNRS; [4]Tohoku University; [5]University of Tennessee

Good micro-scale moldability is one of significant advantages of Zr-based bulk metallic glasses (BMGs), whereas the value of viscosity in supercooled liquid state is rather high to compare with Au-, Pd- and Pt-based BMGs. In this study, we tried to use the micro-patterned metallic mold for embossing process of hypoeutectic Zr-based BMG, therefore, we tried to reduce both Tg and viscosity in supercooled liquid state (SCL). As a conclude, we succeeded to found out hypoeutectic BMG with low viscosity of the order of 105 Pas in SCL, and enables to perform the embossing process for micro patterning by using the tough and long life Ni-W nanocrystalline metallic mold developed by Prof. T Yamasaki. We also examine the mechanical properties of hypoeutectic BMGs exhibiting a low Tg, low viscosity in SCL and wide temperature range of SCL under heating. Good plasticity is also obtained in there hypoeutectic BMGs under tensile loading.

3:00 PM Invited
Structural Order and Density in Bulk Metallic Glass Forming Liquids: *Ken Kelton*[1]; James Bendert[1]; Anup Gangopadhyay[1]; Nicholas Mauro[1]; [1]Washington University

Metallic liquids develop significant short- and medium-range topological and chemical order with supercooling; this is often dominated by icosahedral short-range order (ISRO). Experimental and theoretical studies indicate that this ISRO is intimately associated with the glass transition and raises the nucleation barrier for crystallization, which can favor glass formation. It is reasonable to expect a correlation between the liquid density and this structural ordering, with more ordered and stable liquids having a higher number density. Supporting this, a recent study showed that the density of Cu-Zr glasses showed local maxima at the best glass forming compositions. However, our recent studies show no corresponding maxima in the liquid densities at the liquidus temperatures. Instead, the best glass formers show the largest volume expansion coefficient. Possible reasons for this will be discussed. Supported by NASA (NNX07AK27G & NNX10AU19G) and the National Science Foundation (DMR-08-56199).

Amorphous Multilayers in the Al-Mn System: Wenjun Cai[1]; Shiyun Ruan[1]; *Christopher Schuh*[1]; [1]MIT

The lack of work-hardening and rapid strain localization of metallic glasses present a significant limitation upon their application potential. Amorphous/crystalline or amorphous/amorphous composites have the potential to enhance toughness of such amorphous materials without significantly compromising strength. In this work, Al–Mnx/Al–Mny multilayers were electrodeposited using a single bath process in room temperature ionic liquid. By varying the Mn composition between layers, the amorphous phase content in this single system can be systematically modulated, delivering microcomposites of amorphous and nanostructured phases. The microstructures of the multilayered Al–Mn are characterized and nanoindentation and nanoscratch tests are performed to demonstrate the property differential between layers. Control over both the layer structure and the structure within individual layers together offers unique opportunities to optimize multiple properties simultaneously.

The Role of Cu in an Iron-Based Bulk Metallic Glass: *Michael Miller*[1]; J. Gao[2]; Y Wu[2]; Z. Lu[2]; [1]Oak Ridge National Laboratory; [2]University of Science and Technology Beijing

Low cost, iron-based bulk metallic glasses are potential materials for use as transformer cores, as they can be processed to have superior soft magnetic properties to grain-oriented silicon steels and can be cast directly in the final form for the core elements. Doping a soft magnetic $Fe_{76-x}C_{7.0}Si_{3.3}B_{5.0}P_{8.7}Cu_x$ bulk metallic glass alloy with 0.3% Cu dramatically improves the glass forming ability. The roles of Cu (x=0, 0.3 and 0.7 at. % Cu) and the other solutes on the microstructure in the as-spun state and after an isothermal anneal of 0.5 h at 729 K has been investigated by atom probe tomography. The results indicate that the microstructure has phase separated into a fine scale distribution of Fe-rich and Cu-rich precipitates and carbides during annealing.Research supported by ORNL's Shared Research Equipment (SHaRE) User Facility, which is sponsored by the Office of Basic Energy Sciences, U.S. Department of Energy.

4:15 PM
Glass Formation and Properties of Fe- and Co-Based Ternary Bulk Metallic Glasses: Jianfeng Wang[1]; *Ran Li*[1]; Tao Zhang[1]; [1]Beihang University

Recently, we developed two families of simply ternary bulk metallic glasses (BMGs), i.e. Fe-P-C and Co-Ta-B alloys. For the Fe-P-C system, the glass-forming range and ability were pinpointed. As a typical sample for the Fe-based BMGs, Fe80P11C9 alloy show combinative advantages of advanced structural and functional materials with favorable soft-magnetic properties (magnetic polarization of 1.49 T, coercivity of 4 A /m and effective permeability of 11,000 at 1 kHz) and mechanical properties (compressive strength: 3.2 GPa and plasticity: ~1.4%). The ternary Co-Ta-B BMGs show ultrahigh compressive strength of 5.6–6.0 GPa, high specific strength of 639–654 Nm/g, Vickers hardness of 15–16 GPa, and distinct plastic strain of 0.5–1.5%. The strength and the specific strength of the Co-based BMGs are the highest values reported for bulk metallic materials known so far. The possible reasons of the superior mechanical properties related with atomic and electronic structures were clarified.

Metallic Glass Wireless Biosensors for Pathogen Detection: Suiqiong Li[1]; Shin Horikawa[1]; Yating Chai[1]; *Bryan Chin*[1]; [1]Auburn University

Metallic glass alloys of the Fe-B and Fe-Ni families display the unique property of magnetostriction. Compared with crystalline materials, these alloys exhibit some of the highest possible elastic-magnetic energy conversion efficiencies and hence make ideal sensors. Recently, free-standing, phage-based biosensors have been fabricated from these alloys. The biosensors are composed of a magnetostrictive resonator that is coated with a bio-molecular recognition element that binds specifically with a target pathogen. Once the biosensor comes into contact with the target pathogen, binding occurs. This causes an increase in the mass of the resonator resulting in a decrease of the biosensor's resonant frequency. These biosensor's can be manufactured using standard microelectronics fabrication procedures, resulting in a cost of less than 1/1000 of a cent per biosensor. The potential market for commercial applications of these metallic glass biosensors in food safety, medical and bioterrorism defense is estimated to exceed 50 Billion USD by 2015.

4:45 PM
Metallic Glasses for Electro-Catalytic Applications: *Sundeep Mukherjee*[1]; Marcelo Carmo[1]; Golden Kumar[1]; Andre Taylor[1]; Jan Schroers[1]; [1]Yale University

Materials for catalytic applications require large surface area and desirable chemistry to facilitate the reaction kinetics. Metallic glasses are multi-component alloys that exist in a wide range of chemical compositions and we have recently shown, have tunable nanostructure with large active surface area. Motivated by these characteristics, we have explored the use of a number of metallic glasses as electro-catalysts in direct alcohol fuel cells. We demonstrate that the activity and durability of the metallic-glass nanostructures are superior compared to benchmark catalysts. The activity of these catalysts is further enhanced by de-alloying mediated surface area enhancement. New strategies to develop large surface area nanostructures by accelerated de-alloying will be discussed.

4:55 PM Invited
Impact of Secondary Amorphous Phases on Properties of Metallic Glasses: *Eun Soo Park*[1]; [1]Seoul National University

The secondary amorphous phases (SAPs) in metallic glasses can be classified into two groups; those in phase separating metallic glasses (PSMGs) and multiple shear planes in pre-deformed metallic glasses. It is our understanding that SAPs in a metallic glass matrix can have a significant influence on the properties of metallic glasses like secondary phases in crystalline materials. However, there has been no systematic approach to understand the impact of SAPs on these metallic glasses. In this study, we examine the effect of SAPs on properties of various metallic glasses. First, we will provide a systematic discussion of the relationship between SAPs and properties of PSMGs. Second, we will discuss how multiple shear planes work as SAPs in metallic glass matrix based on variation of their properties in pre-deformed metallic glasses. Our results would contribute to a deeper understanding of various roles SAPs play in metallic glass matrix.

5:15 PM
Formation and Magnetic Properties of New CoTiZrCo Bulk Amorphous and Nanocrystalline Composites: *Yang Yuanzheng*[1]; Qiu Junhua[1]; Chen Xianchao[1]; Xie Zhiwei[1]; [1]Guangdong University of Technology

In this paper, the formation of new copper-based bulk metallic glasses containing some magnetic elements and their magnetic properties were studied. Fully amorphous alloys Cu50.4Ti27.1Zr16.2Co6.3 and Cu50.9Ti27.4Zr16.4Co5.3 with diameter of 3mm could be successfully prepared. The thermal stability, microstructure, magnetic properties and magnetoresistance effect were detected by DSC, XRD, SEM, VSM and PPMS, respectively. With the heat-treatment temperature increase, the saturated magnetization, Ms of Cu50.4Ti27.1Zr16.2Co6.3 alloy increases slightly; while Ms of Cu50.9Ti27.4Zr16.4Co5.3 alloy has little change. Besides, Ms of the alloy Cu50.9Ti25.4Zr16.4Co5.3Ni2 reaches to the maximum value about 17.0emu/g at 470□ for 30min. For the Cu50.9Ti27.4Zr16.4Co5.3 alloy hold under 480□ for 60min and Cu50.9Ti25.4Zr16.4Co5.3Ni2 alloy hold under 470□ for 30min, both of them have no MR effect at temperature 10K. But at 300K, MR effect of the former increases slowly to about 0.4%, while this effect of the latter increases to 1.2% at applied magnetic field about 30kOe.

5:25 PM
Fabrication of Mg-Based Amorphous Composites: *Junhua You*[1]; [1]Shenyang University of Technology

The microstructures, phase constituents, glass forming ability (GFA) and mechanical properties of Mg-based amorphous composites fabricated by copper casting were investigated by scanning electron microscopy, X-ray diffraction and universal mechanical tester. The results indicate that the second phases can be observed in the amorphous phase of alloy samples. With the adding of different metal elements, the kinds and contents of the second phases are different. The second phases of alloy samples are all the crystal phases, and the crystal phases increase the strength of alloys in different degrees. The compressive strength of (Mg58.5Cu30.5Y11)0.9(Zr35Ti30Be27.5Cu7.5)0.1 amorphous composites in diameter of 3mm is 953.8MPa.

CFD Modeling and Simulation in Materials Processing: CFD Modeling in Materials Processing II

Multi-Physics Modeling of Molten Salt Transport in Solid Oxide Membrane (SOM) Electrolysis and Recycling of Magnesium: *Adam Powell*[1]; Soobhankar Pati[1]; [1]Metal Oxygen Separation Technologies, Inc.

Solid Oxide Membrane (SOM) Electrolysis is a new energy-efficient zero-emissions process for producing high-purity magnesium and high-purity oxygen directly from industrial-grade MgO. SOM Recycling combines SOM electrolysis with electrorefining, continuously and efficiently producing high-purity magnesium from low-purity partially oxidized scrap. In both processes, electrolysis and/or electrorefining take place in the crucible, where raw material is continuously fed into the molten salt electrolyte, producing magnesium vapor at the cathode and oxygen at the inert anode inside the SOM. This paper describes a three-dimensional multi-physics finite-element model of ionic current, fluid flow driven by argon bubbling and thermal buoyancy, and heat and mass transport in the crucible. The model predicts the effects of stirring on the anode boundary layer and its time scale of formation, and the effect of natural convection at the outer wall. MOxST has developed this model as a tool for scale-up design of these closely-related processes.

2:25 PM Invited

Numeric Modeling for the Carbothermic Aluminum Process: *David Roha*[1]; [1]Alcoa

The high temperatures of the Carbothermic Aluminum Process make observations and measurements of an actual system very difficult. Therefore, from the onset Alcoa has used various numeric models to help us understand the physical phenomena occurring. Thermodynamic and Process codes have been used to predict its performance. Finite Element and CFD codes have been used to compute electric current and the resultant Joule heating. The flow of the molten slag and aluminum metal, which is mainly driven by bubbly flow is simulated using Eulerian/Eulerian multiphase treatment. Convective heat transfer, chemical reaction and sidewall freezing is part of the model. The gaseous headspace above the liquids is modeled separately as a single phase gaseous flow with Langrangian transport of feed particles. Heat transport is mainly due to radiation through a dusty medium. Back-reaction of Al and Al2O vapors with CO to form a fine condensate dust is calculated.

2:50 PM Invited

A Coupled CFD-PBE Approach Applied to the Simulation of the Inclusion Behavior in a Steel Ladle: *Jean-Pierre Bellot*[1]; Valerio De Felice[1]; Ismael L. A. Daoud[1]; Alain Jardy[1]; [1]Institut Jean Lamour

Gas-stirring ladle treatment of liquid metal has been pointed out for a long time as the processing stage mainly responsible for the inclusion population of specialty steels. A steel ladle is a complex three-phase reactor, where strongly dispersed inclusions are transported by the turbulent liquid metal / bubbles flow. We have coupled a population balance model with CFD in order to simulate the mechanisms of transport, aggregation, flotation and surface entrapment of inclusions. The simulation results, when applied to an industrial gas-stirring ladle operation, show the efficiency of this modelling approach and allow us to compare the respective roles of these mechanisms on the inclusion removal rate.

3:15 PM Invited

Multiphysics CFD Modeling of a Free Falling Jet during Melt-Blowing Slag Fiberization: *Dimitrios Gerogiorgis*[1]; Dimitrios Panias[1]; Ioannis Paspaliaris[1]; [1]National Technical University of Athens (N.T.U.A.)

Red mud fiberization is a process with remarkable potential, alleviating environmental pressure by transforming an aluminum by-product into marketable products. A promising mineral wool process is molten slag fiberization via an impinging air jet, which avoids mechanical wear and rotating parts. The molten slag which remains after pig iron casting flows out of a heated ladle orifice at high temperature (1600 °C) and adjustable flowrate, forming a free-falling vertical jet which visibly radiates its excessive heat: at a given distance, a high-velocity impinging air jet meets the vertical melt jet perpendicularly (or at an angle), inducing intensive droplet generation and subsequent fiber elongation. This paper focuses on high-fidelity CFD modeling of the molten jet flow under external cooling: the model encompasses all physicochemical phenomena (melt laminar flow, radiative cooling), considering temperature-dependent slag transport properties to understand how operational degrees of freedom (manipulated variables) can be used for process optimization.

3:40 PM Break

4:00 PM

Direct Numerical Simulation of Inclusion Turbulent Deposition at Liquid Metal/Slag Interface: *Arunvady Xayasenh*[1]; Laurent Joly[2]; Hervé Duval[1]; [1]Laboratoire de Génie des Procédés et Matériaux (LGPM) - Ecole Centrale Paris; [2]Département Aérodynamique, Energétique et Propulsion (DAEP) - Institut supérieur de l'aéronautique et de l'espace

Oxide inclusion transport and capture at liquid metal/slag interface is studied using direct numerical simulation of the liquid flow combined with Lagrangian particle tracking under conditions of one way coupling. The interface is modelled as a non deformable free slip surface. Turbulence is generated by a random forcing in a finite region parallel to the interface. The inclusions are randomly introduced in this region and tracked until their capture at the interface. The body force, the drag force and the forces due to fluid inertia and oxide inertia are taken into account in the inclusion dynamic equation. The effects of the turbulent Reynolds number and of the inclusion characteristics on the deposition velocity are examined. Moreover, the importance of the near surface turbulent events, sweeps and ejections, on the inclusion capture is highlighted.

4:20 PM

A Numerical Simulation of the Influence of Droplet Impact Dynamics on the Microstructure of Plasma Sprayed Coatings: *Jeffrey Yanke*[1]; Rodney Trice[1]; Matthew Krane[1]; [1]Purdue Center for Metal Casting Research, School of Materials Engineering, Purdue University

In plasma sprayed coatings, the impacting droplets' sizes, velocities, and angles of impact are dominant factors in determining the coating structure. To better understand the links between these deposition conditions and coating structure, a numerical model of the interaction of droplets as they are deposited on the substrate was developed. This model employs a volume of fluid method to track the droplet surfaces and the SIMPLER algorithm to solve the momentum equations on a staggered grid. These methods are combined with a novel technique for tracking multiple droplets and a simple solidification model that includes undercooling. This tool is used to investigate the role of deposition conditions on the evolution of the YSZ coating microstructure at the substrate as well as after the deposition of several layers of droplets. In addition, the model predicts the cooling rates of droplets as a function of thickness of the coating.

4:40 PM
CFD Calculation of Nitrogen Gas Quenching for Steel Ring Gears: *Junsheng Wang*[1]; Xuming Su[1]; Mei Li[1]; Ronald Lucas[1]; William Dowling[1]; [1]Ford Motor Company

Conjugated (solid/fluid) heat transfer by forced convection through recirculating gas has many practical applications. In this study, we present CFD calculations of gas quenching process during the production of steel ring gears. It is based on the heat conduction equation and k-γ equations for turbulence flow solved by a finite volume scheme implemented in Fluent. Comparing to precise measurements of thermal history inside the gears, we found that both convection and radiation must be considered. We devised an approach to incorporate transient heat flux, making this model applicable to process design. Temperature at different locations of the quenching load is not only controlled by quenching velocity and pressure but also determined by the geometry of cooling system. Successful application of CFD model helped optimizing geometry design and operating conditions. In addition, non-uniformity of temperature within a gear was also successfully predicted and coupled to finite element analysis for distortion prediction.

5:00 PM
Numerical Simulation of Erosion Using Computational Fluid Dynamics: *Harpreet Grewal*[1]; Harpreet Singh[1]; Anupam Agarwal[1]; [1]Indian Institute of Technology Ropar

Erosion related problems in industrial appliances causes huge loss of valuable resources especially due to the presence of solid particles in working medium. Number of erosion models available in the literature; have claimed to predict the erosion response better. In this work, some of these erosion models have been evaluated using finite volume frame work through computational fluid dynamics (CFD) methodology. Three most commonly used experimental test rigs (solid particle and unsubmerged slurry jet type and pot type) have been simulated and a comparison with the experimental results has been done. The study helps in understanding the effect of fluid medium and flow pattern on the erosion process. The knowledge acquired shows that phenomenological based erosion models give better results considering the wide range of operating parameters. The in-depth study of the flow field shows the possibility that erosion mechanism, being a parameter dependent, could change with location on the same specimen.

5:20 PM
A CFX-based Model of Ironmaking Blast Furnace Considering Layered Cohesive Zone: *Yansong Shen*[1]; Baoyu Guo[1]; Aibing Yu[1]; Sheng Chew[1]; Peter Austin[1]; [1]UNSW

A CFX-based mathematical model is developed to describe the flow-heat transfer-chemical reactions behaviours of gas-solid-liquid phases in an ironmaking blast furnace, where the layered cohesive zone is considered explicitly. The typical in-furnace phenomena of an operating blast furnace are simulated in terms of multiphase flow, temperatures, gas composition and reduction degree etc. The effect of different model geometry is investigated by means of comparing the predictions from slot model and sector model. The results indicate that the treatment of layered cohesive zone can naturally predict the in-furnace phenomena of a layered-burden blast furnace. The sector model gives significantly different predictions compared to the slot model. This model offers a cost-effective and easy-transferable tool to understand and optimize blast furnace operation.

5:40 PM
Modelling Pulverized Coal Injection in a Blast Furnace: *Yansong Shen*[1]; Aibing Yu[1]; Paul Zulli[1]; [1]UNSW

In order to understand the complicated phenomena of pulverized coal injection (PCI) in blast furnace (BF), several mathematical models have been developed, ranging from pulverized coal combustion in a pilot-scale test rig to coal/coke combustion in a real BF. This paper describes these PCI models in aspects of model developments and model applicability in practice. It is indicated that the three PCI models are all able to describe PCI operation qualitatively. The model of coal/coke combustion in a real BF is more reliable for simulating in-furnace phenomena of PCI operation qualitatively and quantitatively. Such model gives a more reliable burnout prediction over the raceway surface, which could better represent the amount of unburnt char entering the coke bed. These models are useful for understanding the flow-thermo-chemical behaviours and then optimising the PCI operation in practice.

Characterization of Minerals, Metals, and Materials: Characterization of Non-Ferrous Materials

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Materials Characterization Committee
Program Organizers: Jiann-Yang Hwang, Michigan Technological University; Sergio Montero, State University of North Rio De Janeiro; Chenguang Bai, Chongqing University; John Carpenter, US Department of Energy; Donato Firrao, Politecnico di Torino; Byoung-Gon Kim, Korea Institute of Geoscience & Mineral Resources; Mingdong Cai, Schlumberger

Monday PM — Room: Asia 2
March 12, 2012 — Location: Dolphin Resort

Session Chairs: Igor Bunin, Research Institute of Comprehensive Exploitation of Mineral Resources RAS; Byoung-Gon Kim, Korea Institute of Geoscience & Mineral Resources

2:00 PM
Characterization of New Phases in the Ti-Pt System: *Karem Tello*[1]; Anita Garg[2]; Ronald Noebe[2]; Michael Kaufman[1]; [1]Colorado School of Mines; [2]NASA Glenn Research Center

Platinum additions to Nitinol shape memory alloys, SMAs, increase their martensitic transformation temperatures and make them potentially attractive as high temperature SMAs. Unfortunately, the Ti-Pt phase diagram is poorly understood in the range 30-50 at.% Pt making the development of HTSMAs difficult. Alloys in this composition range have been characterized using DTA, SEM and TEM methods and found to frequently contain more than two phases after equilibration treatments; this suggests that interstitial contamination must be complicating the results and should be considered in any phase diagram analyses. Furthermore, two new phases were observed, namely Ti_5Pt_3 and Ti_4Pt_3 the former with a hexagonal structure $P6_3/mcm$, while the latter has not been fully characterized but has a complex and lower-symmetry structure that appears to be structurally related to Ti_5Pt_3. Attempts to determine the crystal structure of the Ti_4Pt_3 phase have been made using an *ab-initio* approach and the results will be presented.

2:15 PM
Characterization of Sn Whiskering by In Situ Nanoindentation in a Scanning Electron Microscope : *Nicholas Chapman*[1]; Jason Williams[1]; Nikhilesh Chawla[1]; [1]Arizona State University

The mechanisms for Sn whisker growth in Sn films are still not well known. The presence of a protective oxide has been postulated to control the formation of Sn whiskers from Sn thin films. In this investigation, the effects of oxygen on the degree of whisker formation were studied. We have used an in situ nanoindentation stage inside a scanning electron microscope to introduce local compressive stresses to drive whisker growth on the surface of the Sn thin film. The experiments were conducted under ultra-high vacuum, inert atmosphere, and air. The propensity, location of the whiskers relative to the indentation, and the morphology of the whiskers were controlled by environment and indentation stress. The relationship between stress, oxide on the surface, and whiskering mechanisms will be discussed.

2:30 PM
Columnar Microstructural Architecture in Electron and Laser Beam Melting of Metals and Alloys: *Edwin Martinez*[1]; Lawrence Murr[1]; Sara Gaytan[1]; Krista Amato[1]; Patrick Shindo[1]; Diana Ramirez[1]; Francisco Medina[1]; Jose Martinez[1]; Brenda Machado[1]; Ryan Wicker[1]; [1]University of Texas at El Paso

Unlike more conventional directional solidification, electron and laser-beam melting technologies involve building 3D components through layer-by-layer melt/solidification thermal cycling which creates novel, directional microstructural architectures. In this study we compared 3D optical metallographic image composite observations of columnar microstructural architectures in Cu, Co-29-Cr-6Mo-0.2C alloy and Ni-22Cr-9Mo-4Nb (alloy 625) fabricated by electron beam melting (EBM), and Ni-19Cr-19Fe-5Nb-1Al (alloy 718) by selective laser melting (SLM). Cu produced discontinuous columns of Cu2O precipitates while the Co-base alloy exhibited similar columns of cr23c6 precipitates. The ally 625 produced columns of Ni3Nb (γ”-bct) precipitates. All of the EBM-produced columnar microstructure arrays were spaced ~2 µm. In contrast, the SLM fabricated alloy 718 contained columnar microstructural arrays of NI3Nb (γ”) spaced ~ 0.8µm. Columnar grain structures with prominent [200] texture were also observed for these layer fabricated components by XRD analysis, and TEM analysis confirmed precipitate morphologies and crystallographic coincidences.

2:45 PM
Effects of Microstructural Changes on Shape Memory Properties of CuZnNi Shape Memory Alloys: *Sathish S*[1]; U S Mallik[2]; Raju T N[1]; [1]Dr. Ambedkar Institute of Technology; [2]Siddaganga Institute of Technology

Copper-based shape memory alloys are very sensitive to the thermal effects before and after the transformation, and these effects may cause important changes on crystallographic properties or the other transformation parameters of the alloys. In this study, CuZnNi shape memory alloys in the range of 38- 55 wt. % of Zinc and 0- 15 wt % of nickel, exhibiting ß- phase at high temperature and manifesting shape memory effect upon quenching to lower temperatures, were prepared through ingot metallurgy route. The alloys undergo a martensitic transformation upon quenching from ß- phase to lower temperatures. CuZnNi alloys were the influence of thermal treatments characterized for their microstructure using optical microscopy, the phases were determined by X-ray diffraction and martensitic transformation behavior by differential scanning calorimetry and shape memory effect. The alloys exhibit good ductility and shape memory effect.

3:00 PM
Effects of Texture and Extrusion Velocity on the High Strain Tensile Behavior of Zr: *Juan Escobedo*[1]; Ellen Cerreta[1]; Carl Trujillo[1]; Daniel Martinez[1]; Victoria Webster[1]; George Gray III[1]; [1]Los Alamos National Laboratory

Dynamic tensile extrusion experiments were conducted to investigate the response of Zr subjected to large plastic strains. The samples were prepared from clock-rolled and annealed, high-purity Zr and tested in two orientations, namely through-thickness (TT) and in-plane (IP). For the TT case the microstructure shows a strong basal (0001) texture. For the IP case, the samples had a nearly (10-10) fiber texture. The substructural and texture evolution were examined by means of electron back scatter diffraction to understand the response of Zr under this integrated loading condition. The results show that the IP samples showed a larger total elongation when compared to the TT cases. Extensive plastic deformation was observed in the IP samples, whereas twinning was the predominant mode of deformation in the TT samples. In both cases, all the specimens tested developed a (10-10) extrusion texture, independent of the initial texture.

3:15 PM Break

Improvement of Mechanical Properties in Severely Plastically Deformed Ni-Cr Alloy: Kuk Hyun Song[1]; *Han Sol Kim*[1]; Hyun Taek Son[1]; Won Yong Kim[1]; [1]Korea Institute of Industrial Technology

We carried out this work to evaluate the grain refining and mechanical properties in alloys that undergo severe plastic deformation (SPD). Conventional rolling (CR) and cross-roll rolling (CRR) were introduced as methods for SPD, and a Ni-20Cr alloy was selected as the experimental material. The materials were cold rolled to 90% thickness reduction and subsequently annealed at 700 °C for 30 min to obtain the fully recrystallized microstructure. The annealed materials after cold rolling were assessed through electron backscattered diffraction (EBSD) analysis to investigate the grain boundary characteristic distributions (GBCDs). The CRR process was more effective than the CR process in developing grain refinement; the grain size decreased from 70 µm in the initial material to 4.2 µm (CR) and 2.4 µm (CRR), respectively. The grain refinement affected mechanical properties such as microhardness, yield, and tensile strength, which were significantly increased relative to the initial material.

3:40 PM
Microstructure Development of Nickel Matrix/Carbide Composites: *Ayodeji Apata*[1]; [1]Wits

Vanadium carbide has outstanding tribological behaviour. Despite the attractive properties, industrial application of VC is still limited. Alloy compositions (of at least 99.65% purity) were selected based on the three component binaries. Six ~3g samples were made from the elemental components, and were arc-melted under an argon atmosphere, using Ti as an oxygen-getter. The as-cast and heat treated (at 1000oC for 1000 hours and quenched in water) samples were prepared metallographically. Images and composition analyses were obtained from a LEO1525 SEM with EDX, and X-ray diffraction (XRD) analyses were conducted using a Philips (PW-1810) X-ray diffractometer. SEM examination of the as-cast alloys has identified five phases to date: ~V8C7, (Ni), ~Ni2V, s and ~V6C5, which is in agreement with the component binaries. The heat treated samples showed very similar microstructures to the as-cast samples. The observed microstructures suggest the possibility of tailoring VC-Ni alloys for wear control.

3:55 PM
Microstructures and Mechanical Properties of Ni-Base Superalloys Fabricated by Laser and Electron Beam Melting: *K. Amato*[1]; S.M. Gaytan[1]; L.E. Murr[1]; P.W. Shindo[1]; J. Hernandez[1]; S. Collins[2]; F. Medina[2]; [1]The University of Texas at El Paso; [2]W.M. Keck Center for 3-D innovation

Ni-base superalloys are used in high-temperature applications due to their high corrosion and oxidation resistance. Directional solidification is a manufacturing method used to improve various properties of the alloys studied including elongation and hardness. Inconel 718 fabricated by electron beam melting is compared to Inconel 625 fabricated by electron beam melting as well and Inconel 718 fabricated by selective laser melting. Samples analyzed by optical metallography (OM), X-ray diffraction (XRD), scanning electron microscopy (SEM), and transmission electron microscopy (TEM) included as-fabricated, fabricated and HIP-ed, and fabricated and annealed cylinders. In all alloys, arrays of γ” (bct) Ni3Nb precipitates were observed in γ (fcc) NiCr grains, with columnar grains oriented in the [200] direction, parallel to the build direction. Tensile properties of both alloys are compared to wrought 625 and 718 alloys.

4:10 PM
Processing and Microstructural Control of Copper Foams for Thermal Wick Material Systems: *Keri Ledford*[1]; Stephanie Lin[2]; Jason Nadler[1]; [1]Georgia Tech Research Institute; [2]Georgia Institute of Technology School of Material Science

Novel processes are being developed to fabricate thin copper thermal wick samples of targeted porous microstructures. Structures of desired porosity, thickness and pore size and distribution are achieved by tailoring the incorporation of sacrificial polymer beads into slurry precursors. The thickness of the final structure is dictated by precisely controllable slurry application methods, such as spin coating. In a subsequent heat treatment, the polymer components thermally decompose, and the remaining copper particles sinter to form a reticulated foam. The resulting microstructures are characterized in terms of porosity, permeability and specific surface area.

4:25 PM
Microstructure and Mechanical Properties of Laser-Deposited Cu-30Ni Alloy: *Guru Dinda*[1]; Darryl Menifee[1]; Joseph Simpson[1]; Ashish Dasgupta[1]; Sudip Bhattacharya[2]; Jyoti Mazumder[2]; [1]Focus: HOPE; [2]University of Michigan

Cu–Ni alloys are extensively used for structures and components exposed to seawater and other marine environments due to their corrosion and biofouling resistance, machinability, and thermal and electrical conductivities. In the present investigation, Cu–30Ni alloy was deposited layer-by-layer on a rolled C71500 (Cu-30Ni) plate by a 5 kW CO2 laser using Cu–30Ni alloy powder. Mechanical properties of the deposit were evaluated using microhardness and tension tests. Scanning electron microscopy and electron backscatter diffraction techniques were employed to study the microstructural morphology and grain orientation. The lattice parameter and residual strain of the deposit were investigated using X-ray diffraction technique. Hardness and strength of the deposit were found to be lower than Cu-30Ni rolled substrate. Overall, the microstructure was columnar dendrite in nature due to the directional solidification of the melt pool. However, the size and orientation of the dendrites varied with the location of the deposit.

4:40 PM
Deformation Mechanisms at Varying Temperatures in Alloy 718: *Donald McAllister*[1]; Ning Zhou[1]; Ben Peterson[2]; Michael Mills[1]; [1]The Ohio State University; [2]Honeywell Aerospace

The primary deformation mechanisms in a γ'' strengthened, Ni-based superalloy, Alloy 718, were investigated at several temperatures. Tensile samples were extracted from the hoop direction of a forged disk and tensile tested to 0.5% plastic strain at strain rates between 0.00005 s-1 and 0.005 s-1. Samples were deformed at 75, 800, and 1200°F. The resulting dislocation and stacking fault structures were observed using transmission electron microscopy (TEM) to determine the dominance of either particle shearing or Orowan looping as the primary interaction between dislocations and the γ'' phase at each temperature. Observed deformation mechanisms were compared with computer modeling results based on field dislocation modeling coupled with general stacking fault energies obtained from experiments and ab-initio calculations. The results of this study provide insight into how temperature influences the deformation mechanisms in Alloy 718 and help identify key material parameters which control the critical shear stress of the alloy.

Computational Thermodynamics and Kinetics: In Honor of Dr. Long-Qing Chen, EMPMD Outstanding Scientist: Session II

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS Structural Materials Division, TMS: Alloy Phases Committee, TMS: Chemistry and Physics of Materials Committee, TMS/ASM: Computational Materials Science and Engineering Committee, TMS: Integrated Computational Materials Engineering Committee, TMS/ASM: Phase Transformations Committee, TMS: Process Technology and Modeling Committee
Program Organizers: Zi-Kui Liu, The Pennsylvania State University; Mark Asta, University of California, Berkeley; James Warren, The National Institute of Standards and Technology; Yunzhi Wang, Ohio State University; Raymundo Arroyave, Texas A & M University; Yu Wang, Michigan Tech

Monday PM — Room: Australia 3

Phase Field Modeling and Simulation of Critical Nuclei Morphology: *Qiang Du*[1]; [1]Penn State Univ

We present numerical simulations of the critical nuclei morphology in solid state transformations based on the phase field models. Contributions of anisotropic elastic energy are accounted for and we illustrate how they might significantly affect the nuclei morphology. A number of computational issues are also addressed, together with rigorous analysis of the underlying numerical algorithms. This is a joint work with Long-Qing Chen, Lei Zhang and Jingyan Zhang of Penn State.

2:25 PM Invited
Coarsening of Bicontinuous Two-Phase Mixtures: C. Park[1]; K. Thornton[1]; *Peter Voorhees*[2]; [1]University of Michigan; [2]Northwestern University

We examine the evolution of interfacial morphology produced following phase separation via phase ordering and spinodal decomposition in three-dimensions using phase field simulations. The phase separation process yields completely bincontinuous structures with spatially varying interfacial curvature. We quantify the morphology of these complex microstructures via the interfacial shape distribution, the probability of finding a patch of interface with a given pair of principal curvatures. The time evolution of this distribution is examined in terms of the flow in probability space. We also examine the relationship between the time rate of the change of the mean and Gaussian curvatures, the local normal velocity and its gradient along the interface. Even when the interfacial motion is local, set by the value of the mean curvature at a point, the tangential gradients in the velocity strongly affect the evolution of the curvatures and thus the interfacial morphology evolves in a nonlocal fashion.

2:50 PM Invited
Meso-Scale Phase-Field Simulation of Void Evolution and Swelling in Irradiated Materials: *Shenyang Hu*[1]; Yulan Li[1]; Charles Henager[1]; Richard Kurtz[1]; Xin Sun[1]; Moe Khaleel[1]; [1]PNNL

Prediction of microstructure evolution and thermomechanical property degradation in irradiated materials is critical to the scientific design of fuels and structural components in nuclear reactors. This work will discuss the applications of mesoscale phase-field method in modelling the microstructure and property evolution in irradiated materials. A generic phase-field model is proposed, which takes into account multiple material processes including the generation, diffusion and reaction of defects, nucleation of second phases, one dimensional motion of interstitials, and long-range elastic interaction. Volumetric swelling, which is one of the important phenomena observed in irradiated materials, is simulated to demonstrate the capability of the model. The temperature dependence of volume swelling is addressed through modelling the effects of defect mobility, defect recombination rate, sink strength on void nucleation and growth kinetics.

3:15 PM Invited
Modeling of Hydride Formation and Fracture in Zirconium: *San-Qiang Shi*[1]; [1]The Hong Kong Polytechnic University

Zirconium and its alloys are key structural materials used in the nuclear power industry. In service, these metals are susceptible to a corrosion process that leads to gradual pickup of hydrogen from the environment. At a certain hydrogen concentration level, complicated patterns of hydride precipitates can develop in the alloys, especially around stress concentrators. Hydride formation also involves a large volume expansion which causes plastic deformation around hydrides. Because of the brittleness of these hydrides, the original strength of the alloys can be reduced by orders of magnitude. Experimental results and modeling efforts are reviewed. In particular, phase field modeling of hydride formation and morphology evolution in zirconium will be presented. Major progresses and issues remaining will be summarized. The objective of this effort is to develop computational methodologies to predict realistic three-dimensional morphological evolution of hydride precipitates, and ultimately to predict fracture initiation at hydrides in zirconium alloys.

Diffuse Interface Field Approach to Modeling and Simulation of Colloid Systems: *Yu Wang*[1]; Tian-Le Cheng[1]; Paul Millett[2]; [1]Michigan Tech; [2]Idaho National Laboratory

Based on the conventional Phase Field Method, we present the development of a novel Diffuse Interface Field Approach to modeling and simulation of colloid systems. The model employs diffuse interface fields to describe multiple moving colloidal particles of arbitrary shapes, sizes and configurations, as well as the charge and electric/magnetic dipole properties of the particles. Particle interactions of long-range (electrostatic, magnetostatic) and short-range (mechanical contact, steric repulsion) as well as with fluid interface (capillary force) are taken into account. Evolving microstructures consisting of self-assembling colloid particles and multi-phase fluids with/without applied external field (used to tune long-range interaction forces and control particle microstructures) are simulated without explicitly tracking the arbitrary-shaped particle boundaries and multi-phase fluid interfaces. Simulations are presented to demonstrate the new model's capability and potential to explore processing routes to advanced materials with novel microstructures and improved properties.

4:35 PM Invited
Ostwald Goes to Hollywood: Time-Resolved 3D Study of Microstructural Coarsening by X-Ray Tomography: Thomas Werz[1]; *Carl Krill*[1]; [1]Ulm University

It's not only moviegoers whose imagination has been captured by the 3D revolution in imaging technology — even materials scientists have been swept up in the hype! Their excitement is understandable, given the new possibilities for materials characterization afforded by techniques such as serial sectioning and x-ray microtomography, which offer a 3D view of features heretofore seen only in 2D sections. Moreover, since tomographic imaging occurs nondestructively, time-resolved studies of microstructural evolution are now feasible. We have implemented this strategy in an investigation of Ostwald ripening in the model system Al-5 wt.% Cu. An image segmentation procedure was developed based on the watershed transformation, and correlation routines were written to facilitate the tracking of particle trajectories in time and space. With these "cutting-room" tools in place, the path has been cleared to shoot a movie of Ostwald ripening and have critics compare it to computer simulations. "X-rays, detector, coarsen!"

5:00 PM Invited
Computational Modeling of Oxidation and Corrosion of Alloys in Complex Environments: *Youhai Wen*[1]; Kaisheng Wu[2]; Long-Qing Chen[3]; Jeff Hawk[1]; [1]National Energy Technology Laboratory; [2]NETL/URS; [3]Penn State University

Advanced energy systems, such as oxyfuel and ultra-supercriticalsteam combustion boilers, oxyfuel and hydrogen turbines and advanced gasification systems, will operate at higher temperatures and in complex environments. Due to the complexity of a typical multi-oxidant environment, it is very challenging if not impossible to predict the corrosion product with confidence. The computational approach available is largely based on thermodynamic calculations without any consideration of kinetics effect. To address the kinetic effect, a multi-faceted modeling approach is being developed at NETL/DOE to study oxidation kinetics under different length scales. Some progresses are discussed in this presentation based on results from mean-field and phase-field methods. The computational tools can be used to simulate environmental effect on oxidation behavior.

Defects and Properties of Cast Metals: Porosity

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Solidification Committee
Program Organizers: Mark Jolly, University of Birmingham; Brian Thomas, University of Illinois at Urbana-Champaign; Carl Reilly, University of British Columbia

Monday PM — Room: Oceanic 4
March 12, 2012 — Location: Dolphin Resort

2:00 PM
Effect of Porosity on Deformation, Damage, and Fracture of Cast Steel: *Christoph Beckermann*[1]; Richard Hardin[1]; [1]University of Iowa

A combined experimental and computational study is performed to investigate the effect of internal shrinkage porosity on the mechanical behavior of cast steel under static loading. Steel plates containing various levels of porosity are cast in a sand mold, machined, and tensile tested until fracture. A significant loss of ductility is oberserved. Radiographic imaging is used to reconstruct the porosity field in the test specimens. The measured porosity field is then used in a finite-element stress analysis of the tensile tests. The local elastic properties are reduced according to the porosity fraction present and porous metal plasticity theory is used to model the damage due to porosity. Good agreement between measured and predicted stress-strain curves is obtained. The computational model proposed in this study allows for a detailed evaluation of the effect of porosity, including its size, shape and location, on the mechanical performance of a steel casting.

2:25 PM
Detection and Influence of Shrinkage Pores and Non-Metallic Inclusions on Fatigue Life of Cast Aluminum Alloys: *Yakub Tijani*[1]; Andre Heinrietz[1]; Wolfram Stets[2]; Patrick Voigt[2]; [1]Fraunhofer LBF; [2]Institut fuer Giessereitechnik

In this work, test bars of cast aluminum alloys EN AC-AlSi8Cu3 and EN AC-AlSi7Mg0.3 were produced with a defined amount of shrinkage pores and oxides. For this purpose a permanent mold with heating and cooling devices for the generation of pores was constructed. The oxides were produced by a contamination of the melt. The specimens and their corresponding defect distributions were examined and quantified by X-Ray computer tomography (CT) and quantitative metallography respectively. A special test algorithm for the simultaneous image analysis of pores and oxides was developed. The defective samples were examined by fatigue testing. The presence of shrinkage pores causes a lowering of the fatigue strength. The results show that pore volume is not sufficient to characterize the influence of shrinkage pores on fatigue life. A parametric model for the calculation of fatigue life based on the pore parameters obtained from CT scans was implemented. The model accounts for the combined impact of pore location, size and shape on fatigue life reduction.

2:50 PM

Quantifying Fe-Rich Intermetallic Formation and Subsequent Pore Interaction during Solidification of Al Alloys Using *in situ* Synchrotron-Based Tomographic Microscopy: *Chedtha Puncreobutr*[1]; André Phillion[2]; Julie L. Fife[3]; Peter D. Lee[4]; [1]Imperial College London; [2]University of British Columbia; [3]Paul Scherrer Institut; [4]The University of Manchester

The presence of intermetallics and pores in aluminium alloy cast components can often limit final fatigue life. In order to convert these large detrimental phases into a form that is acceptable for engineering applications, an improved understanding of their nucleation and growth mechanisms is required. In this study, ultra-fast synchrotron-based tomographic microscopy (one 3D data set (generated) per second with 3 µm voxels) was performed at the TOMCAT beamline of Swiss Light Source for a range of cooling rates and iron levels in an aluminum alloy (Al–7.5Si–3.5Cu–x-Fe(wt.%)). The nucleation temperatures and growth rates of both the intermetallics and pores were quantified. The interaction of the pores and intermetallics with the primary phase, and each other were also examined. The results illustrate that nucleation/growth of the β-intermetallics is a function of both Fe level and cooling rate. The results are compared to prior experimental results and numerical models.

3:15 PM

An Integrated Methodology for Optimizing Al-Si Diecastings in Automotive Applications Part 1 – Modeling the Influence of Casting Defects: Nicola Gramegna[1]; *Franco Bonollo*[2]; Giulio Timelli[2]; Stefano Ferraro[2]; Gianluca Quaglia[1]; [1]ENGINSOFT S.p.A.; [2]University Of Padova

International standards don't provide useful information about the mechanical properties of aluminum diecasting alloys, but only a value guide. In this part of the work a secondary aluminum alloy is diecast by using a multi-cavity die, to obtain flat specimens for static tensile testing, specimens for fatigue and impact testing, a plate and a specimen for stress corrosion testing. This specimens are used to know the "maximum" mechanical properties of a diecast aluminum alloy used. A microstructural analysis of the samples is made, in order to study the effect of casting defect on mechanical properties. The distribution of gas and shrinkage pores is related with numerical simulation of the multi-cavity die, in order to link the defect content with mechanical properties. A developed quality mapping approach shows how the final properties strongly depend on the position of the casting and the process parameters adopted.

3:40 PM Break

4:00 PM

The Influence of Bismuth on Microstructure and Porosity Formation in Hypoeutectic Aluminium-Silicon Alloys: *Jozef Kasala*[1]; Lubomir Caplovic[2]; Maria Lickova[1]; [1]Alexander Dubcek University of Trencin; [2]Slovak University of Technology in Bratislava

Multicomponent Al-Si based casting alloys are used for a variety of engineering applications. In order for such alloys to improve manufacturing characteristics, alloy element modifications are being made to further enhance the alloys machinability. In this paper, the effects of additions of bismuth on the microstructure and porosity of the strontium modified aluminium-silicon alloys containing 7 and 10 wt.% silicon were investigated. Microstructures and porosity were observed using optical microscopy, scanning electron microscopy and electron probe X-ray microanalysis techniques. The results show that a small amount of bismuth has no significant impact on the formation of complex intermetallic phases. The addition of bismuth can counteract the modifying effect of strontium leading to a noticeable coarsening of the eutectic Si particles. It was found that the modification effect of strontium decreases as the amount of bismuth increases. Bismuth additions alters the amount, characteristics, and distribution of porosity in Al-Si castings.

4:25 PM

Relationship between Pores Volume (by Density Measurements) and Pores Area (on Fracture Surfaces) of A356 Fatigue Specimens: *Alessandro Morri*[1]; Lorella Ceschini[1]; Ingvar Svensson[2]; Salem Seifeddine[2]; [1]University of Bologna; [2]Jönköping University

The mechanical properties of A356 alloy are largely influenced by the solidification microstructure and especially by defects, such as gas pores, shrinkage cavities and oxide films. For this reason casting simulation software to predict pores volume in complex castings were developed. Few data, however, are available about the relationship between the volume of pores and their distribution on zones of the components were the failure is localized. The aim of this paper was to find a relationship between the pores volume in fatigue specimens (evaluated by density measurement) and the pores area, measured on the fracture surfaces of the same specimens. The preliminary results show that the pores area percentage on the fatigue fracture surfaces can be greater than 10 times the mean volume percentage, so that in samples with 1% in volume of defects, the specimen showed a decrease of the cross section area of about the 10%.

4:50 PM

Non Homogenous Microstructure of Cast Iron Components – Challenge for Fatigue Evaluation of NDT Tested "Defect Free" Components: *Andre Heinrietz*[1]; Jens Eufinger[1]; Wolfram Stets[2]; Andreas Sobota[2]; Herbert Loeblich[2]; [1]Fraunhofer Institute of Structural Durability and System Reliability LBF; [2]Institut fuer Giessereitechnik gGmbH

In order to optimize spheroidal cast iron components for cyclically loaded applications, e.g. for wind mill power plants, the knowledge of the dependence of fatigue on the microstructure is essential to account for the non homogenous fatigue properties of cast components even if it's been tested as "defect free" with NDT methods. These qualities may differ by factor 5 in cycle life although ultimate strengths are equal. In the paper results of a recently finished research project are presented dealing with fatigue investigations of spheroidal cast iron with varying graphite structure, pearlite content and microporosity. Fatigue tests performed on specimens with varying content of microporosity as well as varying size and shape of spheroids are presented. The influence of microporosity in varying fields of spheroids is discussed as well as size effects on fatigue life.

5:15 PM

Fabrication of Ordered Porous Copper Alloy by Continuous Unidirectional Solidification: *Qinglin Jin*[1]; Yehua Jiang[1]; Rong Zhou[1]; [1]Kunming University of Science and Technology

Ordered porous metal (also known as Gasar or lotus-type material) is a new kind of porous material developed in recent years. The most important feature of the fabrication technique for ordered porous metal is unidirectional solidification of a gas saturated melt that causes simultaneous formation of solid metal and gas pores, resulting in long cylindrical pores filled with gas uniformly distributed in solid matrix. In this study, an ordered porous copper and its alloy were fabricated by a continuous unidirectional solidification method under a pressurized hydrogen atmosphere. A theoretical model was developed to relate the porosity, pore size and inter-pore spacing with the casting parameters. The effects of alloying elements (Zn and Ni) on the pore size and pore morphology were discussed by analyzing the solute redistribution at the solidification interface.

Strategies for Improving the Strength and Ductility of Nanostructured Light Metals: *Yuntian Zhu*[1]; Yonghao Zhao[2]; [1]North Carolina State University; [2]Nanjing University of Science and Technology

The strength and ductility of structural materials are frequently inversely related. In other words, high strength is often accompanied by low ductility, and vice versa. Inspection of the scientific literature reveals that this is also the case for nanostructured and ultrafine-grained materials, which are usually strong, but with accompanying low ductility levels. Conventional approaches to improve ductility often yield a loss of strength. This talk presents several approaches that can be effectively implemented to increase the ductility of nanostrutured/ultrafine-grained materials while simultaneously improving or at least maintaining their strength. The fundamental mechanisms that underlie the proposed approaches are discussed in this talk.

2:30 PM
Ultrafine Grained Aluminium Alloys: Processes and Superior Properties: Maxim Murashkin[1]; Georgiy Raab[1]; *Ruslan Valiev*[1]; [1]Ufa State Aviation Technical University

This presentation provides recent results on developments of the processing techniques based on severe plastic deformation (SPD) as applied to age-hardenable and non age-hardenable Al alloys. The unusual mechanical and functional properties of the Al alloys subjected to various SPD methods are presented in terms of the ultrafine-grained microstructure and segregation/precipitation formation in the alloys produced. The outlined 'portrait' of the Al alloys whose microstructure has been modified by SPD also includes such features as very high strength and ductility, fatigue resistance and electroconductivity. Finally, the potential of SPD processing techniques for developing marketable Al products with improved properties is discussed. This research was supported in part by United Company RUSAL.

2:50 PM
Effect of Microalloying with Aluminum or Yttrium on Grain Boundary Damping in Fine-Grained Magnesium: *Hiroyuki Watanabe*[1]; Akira Owashi[2]; Tokuteru Uesugi[2]; Yorinobu Takigawa[2]; Kenji Higashi[2]; [1]Osaka Municipal Technical Research Institute; [2]Osaka Prefecture University

The damping properties of fine-grained magnesium alloys were measured at elevated temperatures and at low frequencies in order to examine the effect of solid solution alloying on grain boundary relaxation through grain boundary sliding. We chose to examine aluminum and yttrium as alloying elements. The grain sizes of materials examined were ~2 μm irrespective of alloy composition. A sharp increase in damping capacity caused by grain boundary relaxation was observed at above a certain temperature for all materials examined. The temperature at which a sharp increase in damping capacity occurred increased with aluminum content in Mg–Al system. STEM–EDS analyses of the extruded Mg–Al alloys suggested no notable segregation of aluminum in grain boundaries. Therefore, aluminum is suggested to be effective in suppressing grain boundary relaxation in magnesium alloys. However, yttrium was more effective than aluminum in suppressing grain boundary relaxation.

3:10 PM
Characterization of Ductile Fracture in 5083 Aluminum using Micro Computed X-Ray Tomography: *Caroline Scheck*[1]; Marc Zupan[2]; [1]Naval Surface Warfare Center; [2]University of Maryland, Baltimore County

Micro-computed X-ray tomography (microCT) has emerged in recent years as a viable non-destructive three-dimensional imaging technique in material science. This technology is applied to characterize secondary Mg particles in plane strain 5083-H116 aluminum specimens whose geometries have been manipulated to create varying stress states (stress triaxiality). The movement of voids initiated during ductile fracture is linked to the measured Mg particle distribution. The tomography-measured Mg particles diameters and distributions are used as experimental inputs for a previously developed theoretical model to non-destructively measure strain to failure. The tomography measured strain to failures show excellent correlation to results obtained from experimental tensile testing and finite element analysis of the specimens.

Joint Ab-Initio and Experimental Study on the Effects of Rare Earth (RE) Elements on the Stacking Fault Energy and Plasticity of Magnesium Alloys: Stefanie Sandlöbes[1]; Martin Friak[1]; Alexej Dick[1]; Stefan Zaefferer[1]; Jörg Neugebauer[1]; *Dierk Raabe*[1]; [1]Max-Planck-Institut

Magnesium and most commercial wrought Magnesium alloys exhibit poor room temperature ductility and mechanical anisotropy caused by sharp basal-type recrystallization textures and limited availability of independent deformation mechanisms. The addition of rare earth (RE) elements in solid solution improves the room temperature ductility of Mg apparently through two mechanisms. First, RE alloying leads to weaker recrystallization textures. Second, such alloys show higher activity of non-basal deformation mechanisms that contribute a <c>-deformation component to the overall crystallographic velocity gradient. These deformation mechanisms are {10-11} <10-12> contraction, {10-11} {10-12} double twinning and pyramidal <c+a> dislocation slip. In particular, pyramidal dislocation slip is essential for the accommodation of strain along the <c>-axis. In this study the mechanisms responsible for the facilitated activation of these out-of-basal plane deformation modes are investigated by complementary transmission electron microscopy (TEM) and density functional theory (DFT) analysis of binary Mg-Y alloys.

4:10 PM
Abnormal Mechanical Properties of Strain Glass Alloys-A Simulation Study: *Dong Wang*[1]; Yunzhi Wang[2]; Xiaobing Ren[3]; [1]Xi'an Jiaotong University; [2]Ohio State University; [3]National Institute for Materials Science

A new glass state was discovered in Ni-Ti alloys [Phys. Rev. Lett 95, (2005) 205702], it was called strain glass because of the existence of randomly distributed strain. Based on our recent strain glass model [Phys. Rev. Lett. 105 (2010) 205702] which assumes that point defects alter the thermodynamic stability of martensite and create local lattice distortion, the transition behavior of a strain glass system under external stress was studied through phase field simulations. The stress-strain hysteresis loops of the strain glass at different temperatures show slim characteristics. Furthermore, the strain-temperature curves upon cooling and heating with different stress values show abnormal properties. At low stress, the systems show gradual and small strain change and can't form long range order martensite upon cooling, the gradual strain increase can compensate the contraction upon cooling—maybe the origin of invar effect of gum metal. These simulation predictions agree well with the experimental observations.

4:30 PM
Warm Forming Simulation of Magnesium Alloy AZ31B Sheets: *Ji Hoon Kim*[1]; Daeyong Kim[1]; Young-Seon Lee[1]; Myoung-Gyu Lee[2]; R. Wagoner[3]; [1]Korea Institute of Materials Science; [2]Pohang University of Science and Technology; [3]The Ohio State University

Magnesium alloy sheets show unique characteristics such as inflected strain hardening, asymmetric behavior in tension and compression, exhaustion of twinning at small strains, particularly at low temperatures, which cannot be described by the conventional constitutive models used for cubic metals. In this work, a practical constitutive model is developed for the magnesium alloy AZ31B sheets and is applied to the warm forming simulations. The unique temperature- and strain history dependent cyclic behavior is accounted for by the use of a novel asymmetrically evolving yield surface in addition to the conventional one, incorporating the coupling between slip and twinning. The developed constitutive model has been implemented into the commercial finite element program Abaqus/Explicit and is used for the warm forming process optimization.

4:50 PM
A Systematic Study of Solute Effects on Strength and Ductility of Mg from First Principles: *Joseph Yasi*[1]; Louis Hector[2]; Dallas Trinkle[1]; [1]University of Illinois at Urbana-Champaign; [2]General Motors R&D Center

New Mg alloys which can be formed at lower temperatures are of great interest to the transportation industry. Mg is the lightest structural metal at 2/3 the density of Al but has poor room temperature ductility. To have five active slip systems requires increasing non-basal dislocation mobility, and solutes play an important role. We investigate trends in substitutional solute interactions on basal and prismatic slip systems using density functional theory for alkali, alkaline earth, transition metals and rare earths in optimized screw dislocation cores. From this, we predict changes in prismatic cross-slip stress with temperature and solute concentration and observe how solute size and valency modify prismatic slip. We show Ca, K, Na, Sc, Y and Zr soften prismatic slip at low concentrations, allowing for a lower forming temperature.

5:10 PM
A Macroscopic Yield Function Coupled with Crystal Plasticity Theory for Modeling Forming of AZ31 Magnesium Alloy Sheets: *Nitin Chandola*[1]; Oana Cazacu[1]; Raja Mishra[2]; Kaan Inal[3]; [1]University of Florida; [2]General Motors; [3]University of Waterloo

We present a multi-scale computational tool to use an anisotropic yield function developed by Cazacu et al (2006) to generate yield surfaces for forming simulations of commercial grade AZ31 magnesium alloy sheets. This macro scale model uses input parameters generated using a microstructure based crystal plasticity model that incorporates slip and twinning mechanisms and the accompanying texture evolution. The crystal plasticity model is calibrated and validated at the microstructural level using experimental texture data as well as uniaxial tension and compression data. Both experimental data and crystal plasticity predictions are used to calibrate the macroscopic model. The coupled model is then validated by comparing its predictions of yield stress ratios and strain ratios for up to 10% effective plastic strain with experimental data. We compare the yield surfaces generated by the validated coupled model and the validated crystal plasticity model to assess the robustness and sensitivities of the calibration method.

Electrode Technology for Aluminium Production: Paste Plant Design and Improvement

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee
Program Organizer: Morten Sorlie, Alcoa Norway

Monday PM — Room: Americas Seminar
March 12, 2012 — Location: Dolphin Resort

Session Chair: Berthold Hohl, Eirich GmbH & Co KG

Adaptive Fuzzy Controller for Ball Mill in Anode Plant: *Edson Cruz*[1]; [1]Albras - Alumínio Brasileiro S.A.

An adaptive controller for keeping a ball mill working stably and efficiently is proposed in this paper. The controller is based on fuzzy logic control strategy by developing a method of adjusting the quantification and proportion factors. The selection of these factors makes a big influence on the static and dynamic performances of the controller. This new control strategy is implemented in Albras Anodo Plants. The controller program was developed with ladder language and runs on programmable logical controller (PLCs) from Allen Bradley. Anode plants are operating with the ball mills which are being controlled by fuzzy controllers, and the noise, that is the control variable is working around the established operation point. The results demonstrate the effectiveness and viability of the system that hereafter will be being implanted in other equipments of the anode plant.

2:35 PM
Use of under Calcined Coke to Produce Baked Anodes for Aluminium Reduction Lines: Rajesh Garg[1]; *Daniel Sulaiman*[1]; [1]Aluminium Bahrain

Anodes produced using under calcined coke (or Low Real Density Coke) reported to have less and homogenous reactivity of all anode components following baking, which results in lower carbon consumption and less carbon dust in pots. Increased butt thickness due to lower carbon consumption provides opportunity for amperage creep in Reduction lines. ALBA has unique arrangement of an in-house coke calcining operation with carbon plants for anode manufacturing. This gives ALBA an added advantage of lower fuel consumption in calciner on use of under calcined coke for anode production. ALBA used this opportunity and a trial batch of under calcined coke was produced at calciner with lower Real Density of 2.03 gm/cc. Anodes manufactured using this under calcined coke were tested in pots for 2-anode cycles. This paper describes about quality of anodes produced using under calcined coke and their performance in pot rooms.

3:00 PM
60 TPH Single Line Green Anode Plant Commissionned at Qatalum: *Christophe Bouche*[1]; Bertrand Somnard[1]; Sunil Bhajun[2]; Fabienne Virieux[3]; [1]Solios Carbone; [2]Qatalum; [3]Fives Solios

The first single line 60 t/h green anode plant ever was successfully commissioned at the Qatalum smelter. This green anode plant was designed to fulfil the anode requirements of the 585,000 TPY metal capacity smelter. The single process line is based on the Rhodax® technology for dry mix preparation and IMC® technology for the paste mixing/cooling already demonstrated at Sohar Aluminium at 36TPH capacity. For Qatalum, new equipment, including crusher, coke preheating screw, continuous paste mixer/cooler and vibrocompactor, had to be designed, optimized and fine tuned to suit the 60TPH production level without compromising the anode quality and the plant reliability. High capacity green anode plants contribute to lower the CAPEX of greenfield or brownfield smelter projects. This paper describes the technical challenges that were met to realize such high production capacity and summarizes the operation performance achieved during one year of industrial production

3:25 PM
Improvement of Anode Paste Quality and Performance of ALCOA Lista: Nils Saue[1]; Jon Ystgaard[1]; Jon Johannessen[1]; *Markus Meier*[2]; Raymond Perruchoud[2]; [1]Alcoa Lista; [2]R&D Carbon Ltd.

ALCOA Lista has experienced a severe crisis with up to 100 anode problems per week, mainly occurring as spikes, hanging anode ends, leak in stud holes, vertical cracks and dusting. The anode problems hindered a planned amperage increase. A systematic plant audit conducted by R&D Carbon revealed clear root causes that were responsible for the anode problems. The plant management and operation team swiftly implemented the recommendations of the plant audit and subsequent plant optimization. The major actions included a mixer revamp and adaptations of recipe formulation and mixing conditions. Today, the number of anode problems are down to 10 per week (2.4 in potline 3). The major actions are discussed in this document, which had a significant impact on the plant performance figures (current efficiency, carbon consumption, energy consumption and bubble noise) that eventually allowed a substantial increase of the line current from 120 to 130 kA.

4:10 PM
Baked Anode Quality Improvement through Optimization of Green Anode Plant Ultra Fine Content in Ball Mill Product and Process Parameters: Rajesh Garg[1]; *Daniel Sulaiman*[1]; Masood Toorani[1]; [1]Aluminium Bahrain

The two long term trends in the aluminum industry that will have the most effect on anode quality requirements are scarcity of good quality calcined coke for anode production and the current creep by pot lines. In ALBA Pot rooms gradually increased line current to increase Aluminium production. Therefore, there was need to improve anode quality and net carbon consumption so that the butts thickness at increased line current was maintained. In ALBA, for given set of raw materials, paste plant process parameters and dry aggregate composition, baked anode density was in the range of 1.580-1.585 g/cm3. With in-house research, baked anode density of 1.600-1.605 g/cm3 was achieved by optimization of ultra fine content in Ball Mill Product, and other process parameters of Green Anode Plant. The paper describes the work done on the optimization of the Paste Plant's dry aggregate recipe & process parameters and results achieved.

4:35 PM
Baked Anode Quality Improvement through Optimization of Green Anode Processing: Xu Haifei[1]; *Fan Lijun*[1]; Zhang Yang[2]; Sun Yi[1]; Cui Yinhe[1]; [1]SAMI; [2]Lanzhou Branch of Chalco

At Lanzhou smelter, there are more than 11 mainly delayed coke suppliers. The range of calcined coke real density was between 1.99 and 2.06kg/cm3, the resistivity was 480- 570µO.m, and the operating cost of rotary kiln was high due to the short life of tuyere nozzles and chamber lining. The apparent density of green anode was low and the deviation was ±0.05kg/cm3 because of variation in the recipe and process parameters. There was so much dust in the cells and the net carbon consumption was about 450kg/t.Al. By blending delayed coke, adjusting calcining process parameters and optimizing the recipe and process parameters of green anode manufacturing, the quality of calcined coke improved. The tuyere nozzles and chamber lining were not distinctly destroyed in the past 8 months, the quantity of dust in the cells has decreased, and the net carbon consumption has reduced to nearly 420 kg/t.Al.

Electrometallurgy 2012: Session I

Sponsored by: The Minerals, Metals and Materials Society, The Metallurgy and Materials Society of CIM, TMS Extraction and Processing Division, TMS: Hydrometallurgy and Electrometallurgy Committee

Program Organizers: Georges Houlachi, Hydro-Quebec; Antoine Allanore, Massachusetts Institute of Technology; Michael Free, University of Utah; Michael Moats, University of Utah; Edouard Asselin, UBC; Shijie Wang, Rio Tinto Kennecott Utah Copper; James Yurko, Materion Brush Beryllium and Composites

Monday PM — Room: Europe 5
March 12, 2012 — Location: Dolphin Resort

Session Chairs: Michael Free, University of Utah; Georges Houlachi, Hydro-Quebec

2:00 PM Introductory Comments

2:05 PM
Electrometallurgy – Now and in the Future: *Michael Free*[1]; Michael Moats[1]; Tim Robinson[2]; Georges Houlachi[3]; Neale Neelameggham[4]; David Creber[5]; George Holywell[6]; Marco Ginatta[7]; [1]University of Utah; [2]Republic Anode Fabricators; [3]Hydro-Quebec; [4]ind.LLC; [5]Rio Tinto Alcan; [6]Almagi, Inc.; [7]Ginatta Technologie

Electrolytic processing is used commercially to recover and/or refine metals such as aluminum, copper, magnesium, nickel, and zinc. There are also new and exciting opportunities to utilize electrometallurgy in the production of titanium, lead, and other metals. This paper will review some of the main technologies that are used to produce and refine metals as well as some of the recent advances and directions the electrometallurgy industry is moving to meet the challenges faced now as well as those that are likely to be faced in the future.

2:25 PM
Performance and Commercialization of the Smart Anode, MSA™, for Environmentally Friendly Electrometallurgical Process: *Masatsugu Morimitsu*[1]; [1]Doshisha University

This paper presents the development, performance, and commercialization of the smart anode, MSA™, for electrowinning of non-ferrous metals such as copper, zinc, nickel, and cobalt. The smart anode consists of amorphous oxide catalytic layers formed on a titanium substrate by thermal decomposition. The oxides contain nano-size IrO_2 or RuO_2 particles as the active component. Such oxides can reduce oxygen or chlorine evolution potential and suppress some unwanted side reactions on the anode such as MnOOH, CoOOH, or PbO_2 deposition. These features provide excellent improvement for electrowinning process; cell voltage reduction, no increase in cell voltage with time, no sludge, less maintenance, and others. The smart anode, MSA™, can make the electrometallurgical process more environmentally friendly.

2:45 PM
A Novel Oxygen Evolution Anode for Electrowinning of Non-ferrous Metals: *Tian Zhang*[1]; Masatsugu Morimitsu[1]; [1]Doshisha University

This paper presents a novel anode for oxygen evolution in acidic aqueous solutions to produce non-ferrous metals by electrowinning. The method to prepare the anode was thermal decomposition of a precursor solution, and the obtained anode consisted of oxide catalytic layers formed on a titanium substrate, in which the catalytic layer contains nano-oxide particles other than iridium oxide as the active component. The oxygen evolution potential was much lower than commercially available coated titanium anodes using iridium oxide so that the cell voltage with using the novel anode in the electrowinning cells was much reduced.

3:05 PM

Novel DSA® Anode for Electrowinning of Non Ferrous Metals: *Antonio Antozzi*[1]; [1]Industrie De Nora SpA

A new DSA® anode, patent pending, has been tailored for electrowinning of non-ferrous metals (Copper, Nickel, Cobalt, Zinc) by means of a new coating technology, already extensively referenced in the Chlor-alkali world. DSA® anodes are provided with noble-metal electrocatalytic coatings, mainly consisting of iridium-and-ruthenium oxides, obtained by thermal decomposition of their precursor's solutions on titanium substrates. Catalytic activity of a state-of-the-art DSA® anode has been increased by decreasing crystallite size of noble-metals without decreasing the decomposition temperature. It is known in fact below a certain value (400°C) the stability of these oxides, therefore their lifetime, is seriously compromised. Highly active DSA® anodes, having a quasi-amorphous phase, have been obtained at above 450 °C, therefore being not affected by lifetime issues. Advantages:* Improved Lead-free Cathode Product Quality Up to 0.550V, 27.5% power savings compared to industry standard, *Lead-tin-calcium Lead-free-green anodes, *Flexibility in production rate, *Ability to operate at increased Current Density

3:25 PM

Increasing Oxygen Charge Transfer Resistance on the Anode in Copper Electrowinning: *Reuben Mathew*[1]; [1]Laurentian University

Oxygen evolution is the main anode reaction in industrial copper electrowinning. The oxygen bubbles do not conduct electricity, thus increasing the electrolyte resistance. The oxygen bubbles formed at the anode rise to the surface, occupying a larger volume of the electrolyte at the top of the cell than at the bottom. This oxygen bubble concentration gradient contributes to a gradient in electrolyte resistance and consequently a tendency toward uneven current distribution. This phenomenon increases the chance for uneven growth on the cathode and short-circuits, particularly on the lower portions of the cathode. This issue may be ameliorated by increasing the charge transfer resistance for oxygen evolution down the height of the anode. This concept was studied by solving the current distribution for a 2-D model of a copper electrowinning cell using COMSOL.

3:45 PM Break

4:00 PM

Development of a Fully Dynamic Simulation of the Zinc Electrowinning Process: *Michael Mahon*[1]; Spencer Peng[1]; Larry Wasik[2]; Akram Alfantazi[1]; [1]University of British Columbia; [2]Aurel Systems

A dynamic simulation of a zinc tankhouse would be an effective tool to improve tankhouse production and cost efficiencies. A fully dynamic simulation has potential uses in the design of new tankhouses as well as in the optimization of existing facilities. Equations from previously validated models of a single cell have been adapted to the industrial dynamic process simulation software, CADSIM Plus. Based on the inlet concentration, current density, and electrode setup, the model can predict many parameters, including outlet concentrations, flow rates, current efficiency and energy consumption. Multiple cells are then simulated simultaneously, allowing for an entire tankhouse to be modeled. The finished simulation can be used to dynamically predict the conditions in a zinc tankhouse throughout a timescale. Further applications of this model include, tracking impurity buildup, modeling of recycle streams and the development of new flow regimes within the tankhouse.

4:20 PM

Aqueous Electrodeposition of Molybdenum: Thomas Morley[1]; Leah Penner[2]; Francois Benard[3]; Tom Ruth[1]; Paul Schaffer[1]; Stefan Zeisler[1]; *Edouard Asselin*[2]; [1]TRIUMF; [2]UBC; [3]BC Cancer Agency Research Centre

A novel method for molybdenum electrodeposition from aqueous electrolytes is presented. Metallic molybdenum is deposited from an acetate solution at near-neutral pH at temperatures not exceeding 50°C. This is the first report of aqueous electrodeposition of Mo to thicknesses well in excess of 1 micrometer. Deposit quality (adherence, morphology and mass) is characterized as a function of pH, electrolyte composition, current density and temperature. The thermodynamics of the process are discussed. Optimal conditions are identified and applications for this new technology are presented.

4:40 PM

Lead Anodes Performance in Nickel Electrowinning: *Farzad Mohammadi*[1]; Mathew Tunnicliffe[1]; Paul Nesbit[1]; Akram Alfantazi[1]; [1]University of British Columbia

Lead and its alloys have always been candidates for anodes in electrowinning plants since they are insoluble in the leach solutions. However, the annual cost of corrosion problems associated with these anodes is millions of dollars. In this study lead-silver and lead-calcium anodes were tested under typical electrowinning conditions and the effects of sulfuric acid and chloride concentrations on the overall corrosion performance of the anode materials were investigated. Corrosion rates of the electrodes were calculated using the discharge plateau (reduction of lead dioxide to lead sulfate) recorded during OCP measurements after galvanostatic experiments at 20 mA.cm-2, typical for electrowinning plants. SEM images performed after galvanostatic experiments revealed a good agreement between surface morphology of the electrodes and their corrosion rates. Oxygen evolution reaction (OER) rate and overpotential were determined for different electrode material/solution conditions.

5:00 PM

Effect of Different Electrolyte Additives in Zinc Electrowinning Process Using Taguchi Statistical Design Methodology: *Somayeh Dashti*[1]; Fereshteh Rashchi[1]; Ehsan Vahidi[1]; [1]University of Tehran

The main goals in zinc electrowinning process are decreasing of power consumption and increasing of current efficiency. In our previous researches, zinc electrowinning using Taguchi method was studied and the optimized conditions (anode composition: Pb-Ag0.5%-Sn2%-Sb1%, current density (A/m2): 500, acid concentration (g/L): 165, temperature: 60ºC and zinc ion concentration (g/L): 70) for the process was obtained. In this study, electrowinning of zinc in the presence of different additives in electrolyte was established and Arabic Gum, gelatin, sodium lauryl sulphate (SLS) and 1-hexyl-3-methylimidazolium hydrogen sulfate in five levels using Taguchi method was investigated. The optimum conditions and the most efficient electrolyte for zinc electrowinning were obtained using signal to noise analysis and analysis of variance (ANOVA). As a result, current efficiency and power consumption were shown to be linear function of these factors. Finally, surface morphology of cathodic deposit was studied by scanning electronic microscopy.

Atom Probe Tomography of Inorganic Materials and Their Devices Using Ultraviolet Laser Atom Probe: *Kazuhiro Hono*[1]; Tadakatsu Ohkubo[1]; [1]National Institute for Materials Science

Recent implementations of pulsed laser to assist field evaporation in atom probe tomography and the advances in the specimen preparation technique using the microsampling focused ion beam (FIB) method broadened the application areas of atom probe tomography to a wide variety of materials including metals, semiconductors, insulators and their devices. In this talk, we will update our recent atom probe studies on 3D nanotomography of various materials of industrial importance including sintered magnets, magnesium alloys, diluted magnetic oxides, lithium metal oxides, and metal/oxide interfaces. We will present features of atom probe tomography obtained using ultraviolet pulsed laser. The impact of the atom probe results to the materials science community will be briefly stated for each application example.

2:25 PM Invited

Microstructure of Cemented Carbides: *Hans-Olof Andrén*[1]; [1]Chalmers University of Technology

WC-Co based cemented carbides are primarily used for metal cutting and rock drilling. Seemingly simple – stoichiometric WC grains embedded in a cobalt binder phase - they have a surprisingly complex microstructure, and atom probe microanalysis has been used to investigate phase composition and interfacial chemistry. WC and any cubic carbide MC added (M = Ti, Nb, Ta or Zr) form a hard phase skeleton in which mainly cobalt segregates to WC/WC and WC/MC boundaries in sub-monolayer proportions. Cobalt dissolves W and C to an extent determined by the carbon potential during sintering, and in binder areas a diffusion profile of W (and any added M) is frozen in. Grain growth is determined by the interfacial reaction, and additions of Cr and V give rise to a thin cubic layer at the WC/binder interface, effectively restricting grain growth. Recently we found that WC has a low solubility for many elements.

2:50 PM

Possibility of Electron Beam Damage on the InGaN Well Layers of LED Evaluated by Atom Probe Tomography: *Woo Young Jung*[1]; Gil Ho Gu[1]; Chan Gyung Park[1]; [1]Pohang University of Science and Technology (POSTECH)

GaN-based LEDs usually reveal high internal quantum efficiency (IQE) despite their high threading dislocation density, typically 10^7-10^9/cm^2. The fluctuation of both indium (In) composition and thickness of InGaN multi-quantum-well (MQW) layers is believed to cause high IQE by suppressing non-radiative recombination of carriers through the threading dislocations. The fluctuation of In composition is usually analyzed by using either transmission electron microscope (TEM) or atom probe tomography (APT). The important issue on the possibility of electron-induced In fluctuation, however, still remains to be solved. Therefore, in the present study, any possibility of electron-induced In fluctuation in MQW layers has been evaluated by APT. Each APT sample, illuminated within a TEM under various exposure times of high energy electron beam (200keV), has been investigated by APT analysis. Both TEM and APT results will give a clue on the validity of fluctuation of In distribution in InGaN well layers of LED devices.

3:05 PM

From Two to Three Dimensions: the Mutual Benefits of Cross-Sectional Scanning Tunnelling Microscopy and Atom Probe Tomography: *Devin Giddings*[1]; Joris Keizer[1]; Rian Hamhuis[1]; Paul Koenraad[1]; [1]Eindhoven University of Technology

The microscopy techniques of cross-sectional scanning tunnelling microscopy (XSTM) and atom probe tomography (APT) both offer atomic-level characterization, yet have wildly different representations. Whilst XSTM is strictly a surface technique, where atoms are imaged directly, with great precision, APT is able to produce a 3D map of a specimen, determining atomic locations through reconstruction. APT has an extremely high mass sensitivity, allowing accurate determination of chemical species of an atom, but XSTM is measuring local electronic properties, able to probe the band structure. By analysing semiconductor nanostructures, such as quantum dots, we are able to juxtapose these two complimentary techniques. This allows us to both benchmark the capabilities of APT against the established XSTM technique and also verify structural composition inferred from planar XSTM images through comparison to the richer volumetric APT view. The unique capabilities of both can be harnessed to achieve a fuller understanding of nanostructural properties.

3:20 PM

Preliminary Investigation of the Microstructure-Property-Processing Relationships in a Series of Co-Cr-Cu-Fe-Ni-Al High Entropy Alloys: *Abraham Munitz*[1]; David Diercks[1]; Michael Kaufman[1]; [1]Colorado School of Mines

High entropy alloys have been developed recently where the entropy of mixing associated with combining multiple components purportedly favors the formation of simple structures (fcc and bcc). In this study, alloys containing equal parts of Co, Cr, Cu, Fe and Ni and varying amounts of Al from 0-30 at. pct. were prepared and examined in their as-cast condition and after various heat treatments using standard methods. The alloys become increasingly complex and harder as the Al content is increased, i.e., the structures solidify dendritically and then undergo one or more solid state reactions some of which appear to occur by spinodal decomposition consistent with previous reports on similar alloys in this six-component space. By combining DTA, heat treatments, microstructural analysis (SEM, TEM and 3DAP) and mechanical property measurements, an attempt will be made to explain the microstructural evolution in this new class of materials and their potential for structural applications.

Atom Probe Tomography Analysis of Solute Clustering in Al-Mg-Si Alloys: *Gang Sha*[1]; Gun Bulent[1]; Simon Ringer[1]; [1]The University of Sydney

Solute clusters are very important for the formation of precipitates microstructures in Al-Mg-Si alloys during ageing treatment. Most previous investigations employed 1DAP or conventional 3DAP to investigate the small solute clusters in the alloys. Those investigations collected only small data sets typically containing <1 millions ions, sometimes suffered with poor statistics. To date, there is a lack of systematic investigation to reveal the effect of alloy composition on the solute clustering at different temperatures. This contribution carefully investigated the solute clustering in the Al-Mg-Si alloys with Mg/Si ratios in the range of 2:1 to 1:2 aged at different temperatures over different time. A local electrode atom probe has been employed to collect large data sets (containing at least 20 M ions for each analysis) for better statistics in data analysis. The effects of alloy composition and ageing temperature on the clustering behaviours of these Al-Mg-Si alloys have been discussed.

4:25 PM Invited

Origins of Nanocluster Formation with Microalloying Elements Responsible for the Accelerated Precipitation of the Strengthening Phases in Age-Hardenable Aluminum Alloys: *Shoichi Hirosawa*[1]; Tomo Ogura[2]; Ai Serizawa[2]; Yoshiki Komiya[3]; Tatsuo Sato[4]; [1]Yokohama National University; [2]Osaka University; [3]Meisei University; [4]Tokyo Institute of Technology

In this paper, microstructural and microchemical analyses of age-hardenable aluminum alloys including Al-Cu-Mg, Al-Zn-Mg and Al-Mg-Si systems with a variety of microalloying elements have been performed by a three-dimensional atom probe (3DAP). It was found that the remarkable difference in mechanical strengths between the alloys with and without a particular microalloying element originates from different kinds of nanoclusters consisting of solute and/or microalloying elements, by which the subsequent strengthening phases are stimulated to precipitate. Such atomistic behavior of microalloying elements has been systematically predicted in terms of the two-body interaction energies based on a first-principles calculation under generalized gradient approximation (GGA) and full-potential Korringa-Kohn-Rostoker (FP-KKR) Green's function method. The established interaction energy map (IE map), in which the estimated interaction energies of microalloying elements are plotted against solute elements, is quite useful in designing high-strength aluminum alloys by means of microalloying additions.

4:50 PM

Chemical-Texture and Nanotopology in Hierarchy-Strengthened Al Alloys: *Peter Liddicoat*[1]; Maxim Murashkin[2]; Xiaozhou Liao[1]; Ruslan Valiev[2]; Simon Ringer[1]; [1]The University of Sydney; [2]Ufa State Aviation Technical University

Utilising solute structures at multiple length scales, hierarchy-strengthened Al alloys can exhibit yield strengths up to 1 GPa. Such internal alloy architectures are challenging to comprehensively characterise at the atom-scale – transmission-based microscopy (for e.g., TEM, XRD, or SAXS) may regularly encounter spectroscopic beam convolutions, from multiple nanocrystalline grains within a specimen, that can make information retrieval complex or impossible. Atom probe microscopy, a point-projection microscope, is not affected by grain size. Using novel techniques in atom probe to account for the complete activity of solute atoms, we will present the evolution of nanostructure at progressive strain increments imparted by high-pressure torsion in Al-Mg alloys. We will discuss defect-assisted solute clustering and the conceptual developments of chemical-texture and nanotopology to describe the intergranular relationships of misorientation and curvature to provide energetically favourable conditions for solute diffusion and partitioning.

5:05 PM Invited

Catalytic Reactions Investigated by Field Ion Microscopy and Atom-Probe Techniques: *Norbert Kruse*[1]; [1]University Libre de Bruxelles

Field ion microscopy (FIM) and atom probe (AP) techniques can be successfully employed to solve fundamental problems related to heterogeneous catalysis. For example, catalyst particles may undergo morphological shape transformation due to adsorption and reaction. In this contribution it will be shown by FIM that a hemispherical Rh nano-sized particle, conditioned as a tip, is transformed into a truncated half cube-octahedral particle through reaction with oxygen. AP-techniques reveal the outer Rh surface layers transform into RhO2. Video techniques can be applied to follow "live" the oscillatory reaction of oxygen with hydrogen on the surface of such a reconstructed Rh tip. The question for the identification of local adsorption sites of NO on Pt facets – recently demonstrated by the group of George Smith using the "catalytic AP" – will also be addressed. The reduction of NO with H2 likewise shows self-sustained oscillations with specific pattern formation on the nanoscale.

5:30 PM

Development and Recent Applications of FIM/APT for Heterogeneous Catalysis: *Paul Bagot*[1]; Tong Li[1]; Emmanuelle Marquis[2]; Edman Tsang[1]; George Smith[1]; [1]University of Oxford; [2]University of Michigan

In heterogeneous catalysis, the interaction of gaseous adsorbates with catalyst metal surface atoms is a fundamental area to understand for improving our knowledge and performance of these critically important materials. Over 80% of chemical reactions depend on catalysts, yet there is a great deal of basic science to be explored about the nature of the interactions. These in turn govern important processes including surface reconstruction and diffusion/surface segregation of metal species. FIM/APT studies offer a unique way of studying these processes. Alongside the atomic-scale resolution and chemical identities provided, the hemispherical end-form of the specimens provides a close model for real catalyst particles, exposing multiple crystallographic faces to the environment at the same instant. This presentation will cover experiments characterizing changes to materials following exposures, recent developments in instrumentation and sample preparation, and the latest work using APT to study core-shell particles as used in real catalytic systems.

5:45 PM

Buried Interface Analysis Using Atom Probe Tomography: *Suntharampillai Thevuthasan*[1]; Satyanarayana V. N. T. Kuchibhatla[1]; Arun Devaraj[1]; Fang Liu[2]; Shutthanandan Vaithiyalingam[1]; Manjula Nandasiri[1]; Bruce Arey[1]; Chongmin Wang[1]; Lisa Porter[2]; Robert Davis[2]; Ty Prosa[3]; [1]EMSL, Pacific Northwest National Lab; [2]Carnegie Mellon University; [3]Cameca Instruments Inc

This presentation examines the feasibility of using atom probe tomography for challenging materials systems that have not been thoroughly examined earlier. We report the first Local Electrode Atom Probe (LEAP®) analysis of bulk oxides which contain ion beam synthesized Au-nanoclusters. The influence of Au on the quality of the mass spectra obtained from the bulk oxides under the laser pulsing mode and the reconstruction results of the Au-clusters in the matrix will be discussed in detail. We will also discuss about the APT, STEM and high-resolution RBS analysis of GaN/InGaN multi-quantum well structures and doped ceria/zirconia multiplayer thin film systems. These results clearly demonstrate the power of APT in conjunction with other capabilities in the characterization of interfaces in layered structures. In all the system we draw the attention towards the significance of parametric space experiments in order to obtain best results from APT analysis.

Energy Nanomaterials: Li-ion Batteries and Beyond

2:00 PM

Self-Aligned Cu-Si Core-Shell Nanowire Array as a High-Performance Anode for Li-Ion Batteries: *Jun Qu*[1]; Huaqing Li[2]; John Henry[1]; Surendra Martha[1]; Miaofang Chi[1]; Hanbing Xu[1]; Nancy Dudney[1]; Michael Lance[1]; Shannon Mahurin[1]; Theodore Besmann[1]; Sheng Dai[1]; [1]Oak Ridge National Laboratory; [2]University of Tennessee

Silicon nanowires (NWs) have been reported as a high-capacity anode without pulverization during cycling. However, the high-aspect ratio NWs have high electrical resistance and thus inefficient electron transport. The NWs' nano-size interface with the substrate experiences high shear stress during lithiation, potentially causing the wire to separate from the current collector. This study developed a self-aligned Cu-Si core-shell NW array using a low-temperature, catalyst-free process. The amorphous silicon shell accommodates Li-ions without phase transformation, while the copper core functions as a built-in current collector to provide very short (nm) electron transport pathways as well as backbone to improve mechanical strength. Initial electrochemical evaluation has demonstrated good capacity retention and high Coulombic efficiency in a half-cell configuration. No wire fracture or core-shell separation was observed after cycling. However, electrolyte decomposition products largely covered the top surface of the NW array, restricting electrolyte access and causing capacity reduction at high charging rates.

2:20 PM

Investigation of Synthesis of Nano-$LiNi_{0.5}Mn_{1.5}O_4$ Cathode Material for Lithium-Ion Battery by In-Situ Neutron Diffraction: *Lu Cai*[1]; Zengcai Liu[2]; Chengdu Liang[3]; Ke An[1]; [1]Spallation Neutron Source,Oak Ridge National Laboratory; [2]Center for Nanophase Material Sciences ; [3]Center for Nanophase Material Sciences

Nano-$LiNi_{0.5}Mn_{1.5}O_4$is an attractive cathode material for lithium-ion batteries due to the high voltage plateaus, high discharge capacity, low cost, and non-toxicity. Different synthesis processes result in either disordered $LiNi_{0.5}Mn_{1.5}O_{4-\delta}$ (where Ni and Mn are randomly distributed at one crystallographic site) or ordered $LiNi_{0.5}Mn_{1.5}O_4$. Disordered $LiNi_{0.5}Mn_{1.5}O_{4-\delta}$ exhibit better rate capability and cycling stability than ordered $LiNi_{0.5}Mn_{1.5}O_4$. Therefore, the performance of the material is strongly dependent on the synthesis process. Neutron diffraction can easily distinguish these two phases because of the different neutron scattering factor of Ni and Mn, thus have the capability to provide direct monitoring of structural evolution during synthesis. In this study, in-situ neutron diffraction is used to study the phase formation and the order-disorder transition during heating and annealing. The correlation of structure to synthesis conditions will be discussed in details. We expect the results will provide guidance on the development of new cathode materials.

2:40 PM

Transmission Electron Microscopy Studies on Lithium Battery Materials II: Characterization of Mesoporous TiO2 Films: *Alpesh Shukla*[1]; Natacha Krins[1]; Guoying Chen[1]; Thomas Richardson[1]; [1]Lawrence Berkeley National Laboratory

Electrode porosity has significant impact on the performance of energy storage systems such as lithium batteries. However, owing to the complex porous network present in most composite electrodes, the role of pores and that of the active material is difficult to assess. A systematic study to understand the specific role of individual pore types and interconnections is therefore warranted in order to design highly efficient electrodes for lithium batteries. In this study model mesoporous TiO2 thin films with pore sizes varying from 3 to 40 nm were synthesized by dip-coating of tin-doped indium oxide (ITO) glass substrate using soft-templating methods. STEM tomography was used to characterize the three dimensional porous network and the orientation of pores with respect to the Li-insertion channels in TiO2. Also, the crystalline nano-domain structure and their orientation with respect to the thin film was studied using aberration-corrected transmission electron microscopy.

3:00 PM Invited

The Facts Influencing Rechargeability of Lithium/Air Batteries: *Ming Au*[1]; Elise Fox[1]; Hector Colon-Mercado[1]; Thad Adams[1]; [1]Savannah River National Laboratory

Li/air batteries attract great attention and interests for their high theoretic energy density and low cost. However, several challenges prevent Li/air batteries from practical application. The oxygen reduction and evolution both take place on the cathode and the effective and long-lasting bifunctional cathodes have not been developed yet. In order to reduce the products of the discharge, , effective catalysts have to be developed. To prevent volatile reaction of Li with water, the Li/air batteries have to use non-aqueous electrolyte or use dual electrolyte. The products of discharge, Li2O2 and Li2O are not soluble in the non-aqueous electrolyte currently used by researchers. Focusing on these issues, we have conducted our investigation on cathode architecture, catalyst, electrolyte and anode in regarding of the performance of the Li/air batteries. We will discuss our results and share our vision for the future of this technology.

Solution Precursor Plasma Synthesized Flexible Manganese Oxide Anodes for Li-Ion Batteries: *Ramesh Kumar Guduru*[1]; Raghavender Tummala[1]; Pravansu S. Mohanty[1]; [1]Univ of Michigan

The demand for high energy density Li-ion batteries for large scale applications is increasing. But, due to the limited specific capacity of carbon anodes, there has been extensive ongoing search for anode materials with more capacity. Manganese oxide is known for higher capacity than carbon with comparable potential. However, most of the efforts focused on preparation of Manganese oxide anodes employ time intensive techniques to obtain different kinds of nanostructured powders with a requirement of subsequent processing. We have developed a single step, inexpensive and scalable solution precursor plasma deposition route to develop nanostructured flexible manganese oxide electrodes. In this approach, a solution precursor comprising of manganese salts is fed axially into a high temperature plasma plume for accelerated thermo-chemical conversion prior to depositing a binder less coating onto a current collector. Thus developed electrode films confirmed the desired phase and their detailed microstructural and electrochemical analysis will be reported.

4:10 PM
Transmission Electron Microscopy Studies on Lithium Battery Materials I: Conversion Reactions in Nickel Oxide Nanoplates: *Alpesh Shukla*[1]; Jordi Cabana[1]; Peter Ercius[2]; Abhay Raj Singh Gautam[2]; Ulrich Dahmen[2]; [1]Lawrence Berkeley National Laboratory; [2]National Center of Electron Microscopy, Lawrence Berkeley National Laboratory

Transition metal oxides such as nickel oxide that work via a conversion reaction have emerged as attractive candidates for the negative electrode in lithium batteries because they can store as much as twice the amount of charge per unit of mass than intercalation-based carbon electrodes. In this study, nanoporous nickel oxide plates 100-150 nm in width and 10-15 nm in thickness were synthesized by thermal decomposition of hydrothermally-prepared nickel hydroxide crystals. The pore and domain structures were characterized using STEM tomography and aberration-corrected TEM, respectively. The process of nickel hydroxide decomposition was also observed directly by in-situ TEM experiments. The porosity calculated from the measured decrease in volume upon decomposition and the theoretical volume change obtained from the unit cell volumes of Ni(OH)2 and NiO were found to be in good agreement with the pore volume measured from the tomograms.

4:30 PM
New Method to Fabricate Nanoporous Silicon for Lithium Ion Batteries: *Xu Jiang*[1]; Thomas Balk[1]; [1]University of Kentucky

Silicon, because of its high capacity to store lithium, is increasingly becoming an attractive candidate as an anode material for lithium ion batteries(LIB). One significant problem with using Si for the anode is the large strain that accompanies charge-discharge cycling, due to swelling of the Si during Li insertion and deinsertion. Nanoporous Si(np-Si) offers a large amount of free volume for Li absorption, which allows the anode material to swell without cracking. In this paper we demonstrate a method to fabricate high-purity(100%Si content) np-Si thin films by dealloying precursor materials that had been deposited by magnetron co-sputtering. Microstructural characterization and chemical analysis of np-Si revealed a nanoporous structure with regularly distributed ligaments and pores, with a ligament size approximately 20nm. Coin-cell battery samples were prepared and subjected to charge-discharge cycling tests. These and other results will be discussed in relation to the suitability of np-Si as a LIB anode material.

4:45 PM
A Novel Type of Carbon Coated Sulfur Nanoparticles for Li/S Batteries: *Yan Yuan*[1]; Elton Cairns[1]; [1]LBNL

This kind of carbon coated sulfur nanoparticles have been synthesized via a novel liquid-synthesis technique, this reaction in the presence of a surfactant (polyethylene glycol-400) has been developed to get S-C nanoparticles by using sublimed sulfur powders, sodium sulfide, formic acid and carbon black (battery grade) under room temperature. It has been physically characterized by scanning electron microscopy, EDS, and thermo gravimetric analysis instrument. The SEM image shows that the size of carbon coated sulfur nanoparticles is around 30nm. The TGA result shows that the S-C sample is quite pure, and the ratio of sulfur and carbon is equal to what we set initially. Besides, it can be used as cathode in Li/S batteries, it improved the electrochemical performance of Li/S batteries.

Fatigue and Corrosion Damage in Metallic Materials: Fundamentals, Modeling and Prevention: Fatigue Property-microstructure Relationships and Crack Growth

2:00 PM Invited
Identification of Fatigue Crack Initiation from Surface Particles in High Strength Al Alloys: *Xinliang Zang*[1]; Wei Wen[2]; Zhiqiang Xu[1]; Alfonso Ngan[3]; Tongguang Zhai[2]; [1]Yanshan University; [2]University of Kentucky; [3]University of Hong Kong

A finite element analysis method was used to analyze the stress and strain fields around the particles in close proximity of the surface in high strength Al alloys, assuming the alloys were linear elastic-plastic continuum homogeneous. It was found that the thickness, position in depth, orientation and clustering of these particles had significant effects on the stress and strain concentration around the particles in the surface region. A focused ion beam was used to investigate the 3-dimensional geometry of the particles where micro-cracks were initiated. The results indicated that the thinner the particles in surface, the easier micro-cracks could be formed from the particles, though these micro-cracks might not necessarily propagate into the matrix of the alloys.

2:20 PM
Influence of the Inclusion Shape on the Rolling Contact Fatigue Life of Carburized Steels: *Yutaka Neishi*[1]; Taizo Makino[1]; Naoki Matsui[1]; Hitoshi Matsumoto[2]; Masashi Higashida[2]; Hideki Ambai[2]; [1]Sumitomo Metal Industries, Ltd.; [2]Sumitomo Metals(Kokura), Ltd.

It has been well known that the flaking failure in rolling contact fatigue (RCF) originates from nonmetallic inclusions in steels, and their apparent size is one of the important factors affecting RCF life. However, the influence of inclusion shape on the RCF life has not been fully clarified. In this study, attention was paid to the influence of the inclusion shape on the RCF life. This was evaluated by using carburized JIS-SCM420(SAE4320) steels which contained two different shapes of MnS-stringer type and spheroidized type-as inclusions. Sectional observations were made to investigate the relation between the occurrence of shear crack in the subsurface and the shape of MnS. It was found that the RCF life was well correlated with the projected length of MnS along the load axis, and the initiation of shear crack in subsurface was accelerated as the length of MnS increased.

2:40 PM
Effects of Size And Position of Al2O3 Inclusions On fatigue Crack Initiation in Low Carbon Bainitic Steel: *Tongguang Zhai*[1]; Xiucheng Li[2]; Wei Wen[1]; Chengjia Shang[3]; Linghui Du[4]; [1]University of Kentucky; [2]University of Science and Technology Beijing ; [3]University of Science and Technology Beijing; [4]CNMC Ningxia Orient Group Co. Ltd

Fatigue tests were conducted on a low carbon micro-alloyed steel produced by thermo-mechanical control processing, using four point bend at room temperature. The results showed that only single crack initiation occurred in each sample and that fatigue cracks were predominantly initiated from those Al2O3 particles. The position of these particles relative to sample surface was considered to be another factor effecting the fatigue crack initiation beside the particle size. A finite element analysis showed that the value of stress intensity factor was dominated by the depth of particle embedment and the real plastic strain at the edge of particle was influenced by the particle size. In addition, the 3-dimensional density of particles with different sizes was also recalculated basing on the 2-dimensional particle cross sectional area statistic result, which can be an explanation of fatigue cracks can initiate from smaller particles in the samples.

3:00 PM

Scale-Bridging Fatigue Monitoring in Magnesium Alloys: *Antonios Kontsos*[1]; Kavan Hazeli[1]; Prashanth Abraham[1]; Jefferson Cuadra[1]; Eric Schwartz[1]; Raghavendra Saralaya[1]; Tim Schmidt[2]; [1]Drexel University; [2]Trilion Quality Systems

The objective of this research is to in situ monitor and quantify critical relationships between reversible/irreversible microstructural changes and fatigue loading of Magnesium (Mg)-alloys using an innovative setup combining digital image correlation with acoustic emission monitoring and a conventional load frame. Research on the fatigue behavior of Mg-alloys has been significantly increased in view of the renewed interest on their applications. The limited crystallographic deformation mechanisms in hexagonal close-packed Mg-materials, including a-direction basal, prismatic and pyramidal slip, as well as c-direction pyramidal slip and deformation twinning/detwinning results to a distinct mechanical behavior upon cyclic loading, characterized by asymmetric tension/compression yielding, anisotropic hardening and hysteretic loops. Fatigue testing data of AZ31 specimen that comprise grain scale observations, full-field deformation/strain measurements and acoustic emission activity are presented. The measured strain heterogeneities are associated with pre- and post-damage conditions, while the recorded acoustic emission provides means for continuous fatigue monitoring.

3:20 PM

Effect of Orientation on Fretting Behavior of a Single-Crystal Ni-Base Superalloy: *Nabil Marouf*[1]; Siegfried Fouvry[1]; Philippe Belaygue[2]; [1]LTDS; [2]TURBOMECA

Single-crystal superalloy turbine blades are designed to improve creep resistance in a radial direction, requiring a radially crystal growth. As a result, cubic orientation in the attachment is constrained by wheel geometry, keeping in mind it is perhaps not the best to stand high multiaxial-cycling stresses and fretting stresses. Fretting experiments were conducted to investigate tribological behavior and cracking response of nickel single-crystal alloy, by means of a cylinder/plane contact (cylinder: Udimet720 plane: MC2). Three configurations were studied, choosing extreme planes orientations (001), (011) and (111). The first step was to determine sliding conditions and coefficients of friction. Then, crack nucleation threshold and growth kinetic were investigated. As expected, relative orientation between octahedral planes and fretting direction has an important effect on crack growth direction and kinetic On the other hand, nucleation threshold seems to be less influenced by crystal orientation, probably due to plastic strain introduced by shot peening.

3:40 PM Break

3:50 PM

Slip Transfer across Grain Boundaries and Its influence on the Development of Local Strain Heterogeneities in the Plastic Response: *Wael Abuzaid*[1]; Michael Sangid[2]; Jay Carroll[3]; Huseyin Sehitoglu[1]; John Lambros[1]; Ravinder Chona[4]; [1]University of Illinois at Urbana-Champaign; [2]Purdue University; [3]Sandia National Laboratories; [4]Air Force Research Lab

Heterogeneous plastic flow and strain accumulation at the microstructural level is a precursor for fatigue crack initiation. One of the contributing factors in the development of such strain heterogeneities is the interaction of slip with grain boundaries (GBs), which may block, or transmit slip across the interface. In this work, our aim is to develop a deeper understanding of strain accumulation in the vicinity of GBs and how it relates to the resistance exhibited by different GBs to slip transmission. Utilizing digital image correlation and electron backscatter diffraction, we establish the most likely dislocation reactions due to slip transmission and use that information to calculate the residual Burgers vector and strain magnitudes across each interface of a plastically deformed polycrystalline aggregate. From our analysis, we quantitatively show an influence of the magnitude of the residual Burgers vector on GB resistance to slip transmission and on plastic strains across GBs.

4:10 PM

Influence of Aluminide Coatings on Fatigue Behavior during Sustained-Peak Low-Cycle Fatigue in a Single-Crystal Ni-Base Superalloy: *Luke Rettberg*[1]; Tresa Pollock[1]; [1]University of California Santa Barbara

The influence of several different aluminide coatings on fatigue behavior has been examined for single-crystal Ni-base superalloy René N5 during sustained peak low-cycle fatigue (SPLCF). Fatigue specimens, aligned along the (001) direction, were tested in strain-control at 1093°C, with a total strain amplitude of 0.35% and A = -1 (R = -8). The testing cycle consisted of a 120s hold at -0.35% strain and a total unload/reload time of 3.0s. During the 120s hold, creep deformation reduces the compressive stress, causing the specimens to experience a tensile stress upon returning to zero strain. Samples from interrupted tests were examined to measure the depth of crack penetration in the coating, IDZ and substrate. Finite element modeling has been performed to assess the driving forces for extension of the oxide-filled cracks into the substrate. The characteristics of coatings that will extend the fatigue life will be discussed.

4:30 PM

Evolution of Microstructure and Mechanical Properties during Rolling Contact Fatigue in High Strength Case-Hardened and Through-Hardened Steels: *Ghatu Subhash*[1]; Nagaraj Arakere[1]; Bryan Allyson[1]; [1]University of Florida

Through-hardened M50 steel and case hardened M50 NiL and Pyrowear (P675) are commonly used materials in high performance aerospace roller bearing applications. Balls and Rods of above three materials were subjected to a range of rolling contact fatigue (RCF) cycles and the stress affected zones were probed using micro indentation. It was noted that while the increase in hardness of M50 was marginal, both the M50 NiL and P675 revealed an increase in hardness of around 1 GPa. RCF testing of M50 NiL balls (57 mm diameter) revealed a large elliptical shaped transformed region with 1 mm in minor axis and 4 mm size major axis. Stress-strain response of cylindrical specimens extracted from these regions revealed an increase in yield strength of approximately 400 MPa compared to virgin material. The presentation will discuss the associated microstructural modifications and relate them to property changes.

4:50 PM

In Situ Neutron Diffraction Measurements of Stress Fields Around a Fatigue-Crack Tip Under Loading: Soo Yeol Lee[1]; E-Wen Huang[2]; *Kuan-Wei Lee*[2]; Wanchuck Woo[3]; [1]Department of Materials Science and Engineering, Chungnam National University, Daejeon, 305-764, South Korea; [2]Department of Chemical & Materials Engineering and Center for Neutron Beam Applications; [3]Neutron Science Division, Korea Atomic Energy Research Institute

Fatigue crack growth mechanisms subjected to three different loading conditions (i.e. fatigued, tensile overloaded, and overloaded-underloaded) were investigated using neutron diffraction. First, the spatially-resolved neutron stress mapping was performed to directly measure the residual stress distribution around a crack tip immediately after applying the various loading conditions. Second, in-situ neutron diffraction was employed on the three compact-tension specimens exhibiting distinct crack-growth rates at the same applied ΔK within the retardation period. The internal strains/stresses evolutions in the vicinity of the crack tip were carefully examine in situ under loading in order to observe how the stresses near the crack tip are distributed under loading, as the closed crack gradually opens. Finally, the correlation between the measured internal stresses and the fracture mechanics parameters is investigated to account for the transient crack growth behavior, and the mechanisms concerning the overload/underload effects are suggested.

5:10 PM
Influence of Twin-Boundary on the Bauschinger's Effect in Cu Crystal- a Molecular Dynamics Simulation Study: *Di Zhu*[1]; Hao Zhang[1]; Dongyang Li[1]; [1]University of Alberta

Plastic pre-strain may decrease the yield strength of metallic materials when stressed in the opposite direction, known as Bauschinger's effect, which could considerably influence the performance of the materials during cyclic loading processes such as fatigue and fretting. In this study, effects of a twin boundary (TW) as an ordered obstacle on defects' generation, movement and annihilation during cyclic tension-compression loading processes were investigated, in comparison with those occurring in a single crystal (SC) system, using a MD simulation technique. It was observed that the Bauschinger's effect in the TW system was more asymmetrical with higher residual strain energy, compared to the SC system. It was demonstrated that the ductility of the SC system was elevated by the cycling loading but this was less obvious for the TW system. Efforts were made to elucidate mechanisms involved.

From Macro to Nano, Understanding Mechanical Behavior across Length Scales: A Structural Materials Division Symposium in Honor of Robert Ritchie: Fatigue

2:00 PM Introductory Comments

2:05 PM
Predicting the Behavior of Short Fatigue Cracks: *Jamie Kruzic*[1]; Sarah Gallops[1]; Rawley Greene[1]; [1]Oregon State University

While extrinsic toughening mechanisms (e.g., crack bridging, transformation toughening, etc.) are effective at providing crack propagation resistance in many materials and composites, these mechanisms result in a crack size dependence (i.e., "short crack effect") for the fatigue properties over crack sizes on the order of the extrinsic toughening zone size. Fatigue threshold R-curves are one route to understand and predict such crack size effects. Experimental results using compact tension and/or beam specimens for several crack bridging materials are presented. It is demonstrated that the fatigue behavior can be predicted by characterizing the bridging zone and quantifying the effects of crack bridging. It is shown how experimentally measured short crack data agrees well with predictions based on quantitative bridging zone characterization. It is expected that this methodology will be extendable to cover a wide range of materials toughened by crack bridging, including ceramics, intermetallics, composites, and biological materials.

2:20 PM
The Continuing Relevance of Small Fatigue Crack Growth Behavior in the Design and Life Management of Structural Aerospace Components: *Michael Caton*[1]; Sushant Jha[2]; M. Burba[3]; James Larsen[1]; Reji John[1]; Andrew Rosenberger[1]; [1]US Air Force Research Laboratory; [2]Universal Technology Corporation; [3]University of Dayton

The behavior of small fatigue cracks has represented an area of significant research interest over the past 30 years. Recent fatigue studies of numerous alloys employed in the aerospace industry have demonstrated that incorporation of the behavior of early crack growth remains an essential element to accurately predicting fatigue life limits. For several Ni-base superalloys, Ti alloys, and Al alloys, competing failure modes have been observed to drive the full lifetime distributions, whereby the life-limiting fatigue mechanisms are controlled by early or immediate crack initiation and small crack growth. Since design limits and inspection intervals of fracture-critical components are typically established based upon worst-case lifetimes, a thorough understanding of small crack behavior is required for accurate life predictions. A collection of small crack data will be shown for numerous alloys, examining the influence of loading condition and microstructure, and a framework for probabilistic prediction of life-limits will be presented.

2:35 PM
Relating Fatigue Crack Initiation and Small Crack Propagation to Microstructure in the Polycrystalline Nickel Base Superalloy, Rene 88DT: Jiashi Miao[1]; Tresa Pollock[2]; *J. Wayne Jones*[1]; [1]University of Michigan; [2]University of California Santa Barbara

In the very high cycle fatigue (VHCF) regime crack initiation is generally considered to dominate fatigue life. In this study, small crack propagation behavior and its dependence on the character of microstructural neighborhoods near crack initiation sites in Rene 88DT was examined in the VHCF regime using an ultrasonic fatigue apparatus operating at frequencies close to 20 kHz. Crack initiation resulted from cyclic strain localization on {1 1 1} slip planes near, but not on, S3 twin boundaries in large, favorably oriented grains. The likelihood that these nascent cracks would grow beyond the small crack regime to viable large cracks depended strongly on the local microstructural and particularly on the presence and extent of regions of similarly oriented grains surrounding the crack initiation sites. These findings are discussed in the context of the role of microstructural variability on fatigue life variability.

2:50 PM
Endurance Limits and Non-Propagating Cracks: *Herwig Mayer*[1]; Bernd Schönbauer[1]; Stefanie Stanzl-Tschegg[1]; [1]BOKU University Vienna

S-N curves of several materials show a pronounced change of slope in the high cycle fatigue regime, and failures are rare beyond certain lifetimes. Such behavior is found in mild steel and in several cast aluminium and magnesium alloys. Non-propagating fatigue cracks can be found in some cases analyzing the surface of specimens that did not fail within 109 cycles or more. Such cracks even were found in copper and high strength aluminium alloys at very high numbers of cycles, which are generally attributed to have no endurance limit. Examples of non-propagating cracks will be shown and analyzed with respect to possible minimum load amplitudes that can cause fatigue failure.

3:05 PM
Deformation Mechanisms of Small Crack Growth under Dwell-Fatigue in a Ni-Base Superalloy: *G. B. Viswanathan*[1]; Sushant Jha[1]; Sam Kuhr[2]; Jay Tiley[1]; Hamish Fraser[2]; Reji John[1]; C. Woodward[1]; [1]Air Force Research Laboratory; [2]The Ohio State University

The damage mechanisms that affect the small-crack growth behavior in Ni-base superalloys are strongly related to the fine scale microstructural features that surround the crack such as size and scale of second phase γ' precipitates, the grain boundary structures and neighboring grain orientations. A study is undertaken to probe these effects in LSHR, a Ni-base superalloy under high temperature low cycle fatigue (LCF) both under dwell and no-dwell conditions. The small crack growth studies were simulated by placing focused ion beam (FIB) notches on the surface of the samples before the tests. The tests were interrupted immediately after a measurable crack growth was observed. The region ahead of the crack was analyzed in detail by EBSD for grain orientations. Thin foils were extracted from grains immediately ahead of the crack for detailed investigation of the deformation substructures in the TEM. The results will be presented and discussed.

3:20 PM

Effects of Local Crystallography and Inclusion Geometry on Nucleation and Propagation of Short Fatigue Cracks in Al 2024-T351: Statistics and Mechanisms: Admir Makas[1]; Jaclyn Avallone[1]; Ross MacKinnon[1]; Ikshwaku Atodaria[1]; Dallas Kingsbury[1]; *Pedro Peralta*[1]; Aditi Chattopadhyay[1]; [1]Arizona State University

Nucleation and growth of short fatigue cracks can represent a significant fraction of the life of a structure. Quantification of these effects and their variability due to microstructural heterogeneity is key to predict residual life. Correlations between short fatigue crack nucleation and growth, crystallography of the local loading axis and inclusion geometry were studied via interrupted testing at stresses close to yielding in notched uniaxial and biaxial (cruciform) samples. Local crystallography was quantified using Electron Backscattering Diffraction. Nucleation sites were characterized using Optical and Electron Microscopy. The crystallographic orientation of grains with broken inclusions was quantified and correlated to the tendency for a matrix crack to propagate from them. Results indicate that local loading axes perpendicular to cracking facets produced by environmental effects favored short crack growth, particularly when combined with elongated Fe-rich inclusions. Damage mechanisms and modeling avenues are discussed. Funding by AFOSR Grant FA95550-06-1-0309, David Stargel program manager.

Understanding Fatigue Crack Growth by In Situ 3D X-ray Synchrotron Tomography: *Nikhilesh Chawla*[1]; [1]Arizona State University

Prof. Robert Ritchie's contributions in the area of fatigue of materials are seminal. In particular, his work has provided much insight into the fatigue crack growth mechanisms in metallic materials. X-ray synchrotron tomography provides a wonderful means of characterization damage in materials non-destructively. In this talk, I will describe in situ fatigue crack growth experiments in 7075-T6 aluminum alloy, using a three-dimensional (3D) x-ray synchrotron tomography. The approach involves capturing the microstructure during in situ fatigue testing in an x-ray synchrotron, followed by x-ray tomography and image analysis, and 3D reconstruction of the microstructure. Local variations in crack growth rate, investigations of fatigue crack closure, and correlation to local measurements of striation spacing were quantified and will be discussed.

4:05 PM

Leave-in-Place Laser Scanning for Fatigue Damage Monitoring and Prognosis: *James Earthman*[1]; Benjamin Buckner[2]; Kwai Chan[3]; Xiaoxi Liu[1]; Vladimir Markov[2]; [1]University of California, Irvine; [2]Metrolaser, Inc.; [3]Souwest Research Institute

A compact leave-in-place laser-scanning device for the detection and monitoring of fatigue damage precursors has been developed. The current device is shown to be capable of detecting fatigue-related changes in the surface bidirectional reflectance distribution (BRDF) of aluminum test samples, and detectable changes in BRDF are measured at a very early stage of fatigue development, when no cracks larger than about 50 μm in length have yet developed at the monitored location. The system power requirements are compatible with standard sensor mote architectures that are targeted for multiyear lifetimes without battery replacement. Results from our latest in situ fatigue tests will be discussed and compared with mechanistic model predictions of small crack initiation and growth.

4:20 PM

The Effect of Microstructure on Strain Field Inhomogeneities in Fatigue Crack Growth: *Jay Carroll*[1]; Wael Abuzaid[2]; Mallory Casperson[2]; John Lambros[2]; Huseyin Sehitoglu[2]; Ravinder Chona[2]; Brad Boyce[1]; [1]Sandia National Laboratories; [2]University of Illinois at Urbana-Champaign

Variability in fatigue lifetimes can largely be attributed to microstructure, but at this time, most microstructural effects are known only in a qualitative sense. A better quantitative understanding of the relationship between microstructure and inhomogeneous deformation behavior in fatigue could provide more accurate predictions of variability in fatigue crack growth rates and fatigue lifetimes. In this work, multiscale strain measurements from a high-resolution digital image correlation technique were used to study fatigue crack growth in a nickel based superalloy, Hastelloy X. Both sub-grain-level and macroscale strain fields were captured at intervals of fatigue crack growth. Lobes of elevated strain emanating asymmetrically from the crack were observed. The relationship between these inhomogeneities and microstructure was examined by comparing strain fields to full-field microstructural measurements obtained through electron backscatter diffraction. Additionally, the relationship between these strain fields and mode mixity was considered. This work was inspired by Robert Ritchie's compelling multiscale research on fatigue cracks.

4:35 PM

Reducing Uncertainty for Fatigue Life Limits at Notches in Two Structural Alloys: *Dennis Buchanan*[1]; James Larsen[2]; Andrew Rosenberger[2]; Reji John[2]; Sushant Jha[3]; Alisha Hutson[1]; W. John Porter[1]; [1]UDRI; [2]Air Force Research Laboratory; [3]Universal Technology Corporation

Fatigue life variability is modeled as a combination of a mean-lifetime and a dominant life-limiting crack growth mechanism in two materials: a powder metal nickel-base superalloy IN100 and a cold rolled plate of aluminum alloy 7075-T651. Specimens of both materials had a common double-edge notch geometry with a stress concentration factor of Kt = 1.89. Fatigue tests were conducted under constant amplitude loading at temperatures of 23°C and 650°C for the 7075-T651 and IN100, respectively. Fatigue failure initiated at sites located either along the notch surface or at the notch corner. Crack growth behavior was predicted for both of these initiation sites using a weight function solution and the cyclic and residual stress profiles from three-dimensional finite element analysis The predicted fatigue lives for a range of stress levels correlated well with the observed experimental data and the minimum (1 in 1000 probability of failure) lifetime limit for both materials.

4:50 PM

A Comparison of Cast Aluminum Bulkhead Fatigue Resistance: The Effect of Specimen Geometry: *Aindrea Campbell*[1]; John Allison[2]; [1]Ford Motor Company; [2]University of Michigan

Automotive cylinder block bulkheads were obtained from two aluminum casting suppliers for a study on the high-cycle fatigue resistance of these materials. The fatigue strengths were measured via a staircase protocol using cylindrical round bars. These values were ~20-30% lower than previously measured data where an hour-glass fatigue sample geometry was used. A model to predict the fatigue life and strength (at a given number of cycles) was developed and revealed that the hour-glass geometry had a predisposition to higher fatigue strengths due to the lower probability of sampling a casting pore local to the region with minimum radius and highest stress. It was concluded that previous fatigue data on the bulkhead materials were inflated due to the choice in fatigue specimen geometry. More conservative values, which better represent the expected material behavior and intrinsic fatigue resistance, were obtained using the cylindrical bar geometry.

5:05 PM
Predicting Fatigue Crack Growth Behavior at Different Crack Size Scales: *Anastasios Gavras*[1]; Diana Lados[1]; [1]Worcester Polytechnic Institute

Along with microstructure, the initial flaw size significantly affects the fatigue crack growth response of a material. In this work, focus was given to the initial flaw size. Long and small fatigue crack growth experiments were performed on various non-ferrous and ferrous structural materials with different microstructures. Long fatigue crack growth tests were conducted at three stress ratios (R=0.1, 0.5, and 0.7) and small fatigue crack growth tests were run at R=0.1. The differences in the response were evaluated, and the controlling crack growth mechanisms were related to microstructural characteristic dimensions specific to each material and microstructure. An original methodology that accounts for the differences between long, short, and microstructurally small crack growth data was also developed and will be presented and discussed from a design perspective.

Integrative Materials Design: Performance and Sustainability: Processing and Properties of Traditional and Novel Materials at Ambient and High Temperatures II and Condition Assessment and Monitoring

Sponsored by: The Minerals, Metals and Materials Society, TMS/ASM: Mechanical Behavior of Materials Committee
Program Organizer: Diana A. Lados, Worcester Polytechnic Institute

Monday PM — Room: Europe 2
March 12, 2012 — Location: Dolphin Resort

Session Chair: Diana Lados, Worcester Polytechnic Institute

2:00 PM Invited
AA362.0 Aluminum Alloy: Utilizing Improved Fatigue Properties of Sustainable Alloys in Design: *Kevin Anderson*[1]; Michael P. Mihelich[2]; William J. Towne[2]; Gregg D. Langenfeld[2]; Raymond J. Donahue[2]; [1]Mercury Fellow, Mercury Marine, Product Development & Engineering; [2]Mercury Marine, Product Development & Engineering

Traditional secondary (recycled) die-casting alloys have high iron content, lower damage tolerance properties, and a limited ability to be recycled into other alloys. First generation high damage - tolerant die-casting alloys replace iron with manganese, have good damage tolerance properties, and can be easily recycled into other alloys. Unfortunately, they are typically made from 100% virgin aluminum with high embodied energy. Second - generation AA362.0 alloy has good damage tolerance properties, is typically made from 100% recycled aluminum, and is easily recycled into other alloys. Alloy AA362.0 demonstrates that sustainable alloy design and good damage tolerance properties need not be mutually exclusive. The authors will present fatigue data for AA362.0 and show how material properties interact with the design of components to achieve design life goals. Several component examples will be discussed emphasizing where in the design process damage - tolerant material properties can improve performance and reduce development time.

2:25 PM Invited
Reduce Your Burden – Use Magnesium Alloys: *Norbert Hort*[1]; [1]Helmholtz-Zentrum Geesthacht

Global warming is an issue for industrialized countries all over the world. Especially in transportation solutions have to be found to reduce the CO2 emissions drastically. This can be done when the weight of airplanes, cars and trucks is reduced or the payload is increased. The extended use of magnesium alloys may be an appropriate solution to achieve this goal. The specific strength of common magnesium alloys is superior to widely used aluminium alloys and can even compete with steels. This presentation will give an overview on existing solutions and how an extended use of magnesium alloys can help to reach the climate goals of modern societies and to support a sustainable development.

2:50 PM Invited
Fatigue Crack Growth in Metallic Materials: Mechanisms and Design Methods: *Anastasios Gavras*[1]; Diana Lados[1]; [1]Worcester Polytechnic Institute

Fatigue crack growth experiments were performed on various metallic materials to understand the mechanisms of crack propagation and the responses at different crack size scales. The materials investigated include commonly used alloys, cast and wrought aluminum alloys (A535 and 6061), wrought titanium alloys (Ti-6Al-4V), and gray cast irons, as well as alloys manufactured by novel technologies. The microstructure was altered through chemistry, processing, and heat treatment to shed light on the effects of materials' characteristic features on fatigue crack growth. In addition, initial crack size effects were studied for each material by conducting long and small crack growth tests at various stress ratios (R=0.1, 0.5, and 0.7). The fatigue crack propagation mechanisms at the microstructure scale were identified and will be discussed. The differences in fatigue crack growth responses between long, short, and small cracks were evaluated, and a new design methodology that accounts for these differences will be presented.

3:15 PM Invited
Production-to-Retirement Condition Assessment and Monitoring for Aircraft CBM+: David Grundy[1]; David Jablonski[1]; Yanko Sheiretov[1]; *Vladimir Zilberstein*[1]; Neil Goldfine[1]; [1]JENTEK Sensors, Inc.

Modern design requirements, including the need to reduce the weight, can result in tighter safety margins in critical components. Effective condition assessment/monitoring is needed to ensure safety, lower life-cycle costs, and improve aircraft availability. Component life management can be improved by baselining component condition at production and mapping the product state and anomalies. This has become practical due to advanced digital nondestructive inspection tools. These tools offer sufficient sensitivity, resolution, and repeatability so that, when combined with digital mapping and tracking methods, they can detect early stages of damage and monitor evolution of the damage. This presentation focuses on the progress in MWM-Array Eddy Current Testing technology and its potential for integration into Condition Based Maintenance Plus Prognosis (CBM+) services. This includes a new failure risk assessment methodology incorporated into Component Adaptive Life Management (CALM™) framework with tools for inspection scheduling, failure risk assessment, and remaining life prediction for CBM+.

4:05 PM Invited
Materials for Aircraft Turbine Engines: *Vasisht Venkatesh*[1]; David Furrer[1]; [1]Pratt & Whitney

Abstract not available.

4:25 PM Invited
Effects of Hot Compressive Dwell Condition on the Fatigue Crack Growth Response of Cast Aluminum Alloys: *Xiang Chen*[1]; Diana Lados[1]; Richard Pettit[2]; [1]Worcester Polytechnic Institute; [2]FractureLab, LLC

Fatigue crack growth under Hot Compressive Dwell (HCD) conditions is an important failure mode for many high temperature applications, such as cylinder heads for internal combustion engines. Tensile residual stress build up at the crack root is considered a key factor contributing to crack growth under HCD conditions. To capture this effect, a new model was developed, in which residual stress contributions are added to the elastic response of the material to predict the behavior under HCD condition. Cyclic stress relaxation tests were conducted to model the process of tensile residual stress accumulation. A Blunt Compact Tension (BCT) specimen was designed and analyzed using Franc2D to determine the elastic behavior. Finally, crack growth tests on BCT specimens under HCD condition were performed to validate the model. These results will be presented and discussed for a cast 319 aluminum alloy with relevance to engine applications.

4:45 PM Invited
Modeling and Prediction of Elevated Temperature Crack Growth Rates: *Ryan Brodie*[1]; [1]Pratt & Whitney Rocketdyne

Crack rate testing was conducted on a Ni-based and an Fe-based superalloy to characterize the interaction between temperature, time and loading waveform, and to better understand the effect on overall crack growth rate. A model and methodology was developed to predict crack growth rate behavior for temperature-time-waveform combinations for which no test data exist.

5:10 PM
Towards an Understanding of the Oxidation Performance of Polycrystalline Nickel Superalloys: *David Crudden*[1]; Babak Raeisinia[1]; Roger Reed[1]; Mark Hardy[1]; [1]University of Birmingham

With the ever increasing air traffic, steeper ascents are demanded from aircrafts. This is achieved by operating engines at maximum thrust for longer durations, translating to prolonged exposure of the engine components to high temperatures. Nickel superalloys are the materials of choice for high temperature jet engine components. Operation at these temperatures accelerates material degradation. This problem is examined in the context of five polycrystalline nickel based superalloys that have been isothermally oxidised at 750 °C and 800 °C. The temperature capability of the alloys is characterised in terms of their oxidation behaviour and propensity to formation of undesirable TCP phases. In particular, the role of different alloying elements and grain boundary character is examined. Understanding the performance of these alloys is essential in defining optimum chemistries and microstructures for future alloys that will be engineered for improved oxidation resistance.

5:30 PM Invited
Advancements in Nuclear Materials Research at the Idaho National Laboratory: *John Jackson*[1]; Sebastien Teysseyre[1]; Richard Wright[1]; James Cole[1]; Douglas Porter[1]; [1]Idaho National Laboratory

Over the past decade, the Idaho National Laboratory (INL) has developed an impressive array of leading edge technology in support of Light Water Reactor Sustainability (LWRS) programs and development of Next Generation Nuclear Power (NGNP) plants. Capabilities in advanced micro-structural analysis of irradiated as well as un-irradiated reactor structural and pressure boundary materials supplement a full suite of mechanical characterization infrastructure. Recent advancements include acquisition of a Local Electrode Atom Probe (LEAP) and Transmission Electron Microscope (TEM) capable of handling irradiated materials as well as highly shielded mechanical test systems intended for characterization of such parameter as Irradiation Assisted Stress Corrosion Cracking (IASCC) resistance, and Fracture Toughness. The INL is currently involved in developing code cases for advanced, NGNP materials and will soon be involved in characterization of irradiated material properties for the LWR life extension effort. This paper covers current and upcoming nuclear materials research programs based at INL.

International Smelting Technology Symposium (Incorporating the 6th Advances in Sulfide Smelting Symposium): Smelter Design, Construction, Commissioning and Operation

Sponsored by: The Minerals, Metals and Materials Society, The Metallurgy and Materials Society of CIM, TMS Extraction and Processing Division, TMS: Pyrometallurgy Committee
Program Organizers: Jerome Downey, Montana Tech of the Univ of Montana; Thomas Battle, Midrex Technologies, Inc.; Jesse White, Elkem Solar Research

Monday PM — Room: Northern A3
March 12, 2012 — Location: Dolphin Resort

Session Chair: To Be Announced

2:00 PM
Boliden Rönnskär Smelter: Challenges and Opportunities for Modern Smelting
: Theo Lehner[1]; *Jan Stål*[1]; [1]Boliden Mineral AB

The Boliden Rönnskär Smelter operates in the European Context of tight environmental, health, and safety limits with ever-increasing regulations and tribulations. In the near future, further burdens may be imposed in the forms of carbon dioxide trading, suppliers' appetite for an increased share of the contained values, changing compositions, and competition for raw materials. In the face of these changes, European smelters, such as Rönnskär and Harjavalta, have demonstrated an astonishing power of survival. This presentation will begin with an up-date on today's operations, list and comment on current challenges, and present opportunities to increase survival power. An example of the latter is the ongoing investment into increased treatment capacity for e-scrap.

2:25 PM
Design and Commissioning of the Ausmelt TSL Lead Smelter at Yunnan Tin Company Limited: Helin Gu[1]; Xingcheng Song[1]; Xu Lan[1]; Ross Baldock[2]; Ross Andrews[2]; *Markus Reuter*[2]; [1]Yunnan Tin Company Ltd; [2]Outotec Pty Ltd

A commercial lead smelter using Outotec Ausmelt TSL Technology has been successfully commissioned and put into operation at Yunnan Tin Corporation Ltd operations near Gejiu City, in Yunnan Province, China. The plant was commissioned in July-August 2010 after 3 years of design and construction works. The process uses a 3 stage batch process to produce lead bullion, zinc fume and a discardable slag low in metal values. The paper provides details of this lead smelting project, including the theoretical evaluation of the multi-stage process chemistry, engineering design, plant commissioning and operation. Emphasis has been given in comparison between the design targets and actual performance of the plant highlighting the fast ramp-up to full production of the largest Ausmelt TSL lead furnace built to date.

2:50 PM
Granulation as it Pertains to Electric Furnace Matte, Converter Slag, and Converter Matte in a PGM Smelter: Greg Roset[1]; *Dayle Flynn*[1]; Jake Bummer[1]; [1]Stillwater Mining Company

Stillwater Mining Company operates a Platinum Group Metals smelter located at the base of the Beartooth Mountains in south-central Montana. Commissioned in 1990, the plant processes a copper-nickel sulfide concentrate from two mines, in addition to an intake of spent automobile and petroleum catalyst. Dry concentrates are processed at a rate of approximately 30,000 t/a through a 7.5 MW electric furnace. Stillwater's granulation system is a unique design that allows three different materials to be granulated in one granulator, i.e. Electric Furnace matte, Top Blown

Rotary Converter (TBRC) slag, and TBRC matte.This paper will also discuss process characteristics of Stillwater's granulation system and the improvements made to improve both equipment reliability and material recovery through the circuit

3:15 PM
Design, Development and Early operations of the Konkola Copper Mines Nchanga Smelter Direct Blister Flash Process, Chingola, Zambia: *Enock Mponda*[1]; Timothy Smith[2]; [1]KCM plc; [2]SNC Lavalin

Konkola Copper Mines plc owned and operated by the Vedanta group are expanding copper production in their Zambian Copperbelt operations, in particular in relation to the major development of the Konkola Deep Mining Project (KDMP) which will provide high grade long-life copper concentrate supplies. As part of their development plan a decision was made to build a major new greenfield copper smelter in Chingola along with associated acid production facilities. The KDMP mineralogy favoured installation of a direct to blister Flash Smelting furnace and the desire to recover important Cobalt values led to the inclusion of a novel integrated pyro-metallurgical slag treatment circuit with this project. The paper describes the project development, key design features and early operating experience since start-up.

3:40 PM Break

3:55 PM
Waste Heat Recovery from Industrial Smelting Exhaust Gas: *Geir Wedde*[1]; Anders Sorhuus[1]; [1]Alstom

Vast quantities of energy are released as heat to the environment from industrial operations. Many countries target waste heat recovery to mitigate CO2 emission. Exhaust gases from industries such as primary aluminium smelting, carry a substantial portion of the waste heat generated. For a cost efficient capture of more valuable heat (higher exergy), heat exchangers should operate on the exhaust gases upstream of the gas treatment plants. Heat exchange surface would be exposed to dust laden gases with risk of fouling. Heat exchangers of innovated design and operation have overcome the potential of excessive fouling rates. Heat exchangers of the "shell and tube" design have been demonstrated for exhaust gases from ferroalloy as well as primary aluminium smelters. In addition to the heat recovery, gas cooling results in smaller gas treatment plants with lower costs and reduced emission. The aluminium experience is exampled in the paper.

4:20 PM
High Performance Brands for the Nonferrous Metals Industry: *Dean Gregurek*[1]; Alfred Spanring[1]; Angelika Ressler[1]; Sonja Breyner[1]; [1]RHI AG

The complexity of metallurgical processes in the non-ferrous metals industry especially changes in the process conditions in combination with diversity of metal processing furnaces requires a precise knowledge of the system for the appropriate refractory product selection. Particular importance is still focused on the specific refractory consumption being as low as possible. The recycling routes in the base metals industry showed also a significant change of slag chemistries, process temperatures etc. which influences the performance of already approved linings. The raw material mix of primary smelters has also changed to a higher amount of secondary raw materials in the smelter feed. This acknowledgement of process-changes with decreased brick life-times was the signal for RHI AG to develop high performance refractory bricks especially for nonferrous metals applications. The internal lab tests with fayalithic slag showed very promising results compared to our approved MgCr – bricks for this highly important industry area.

4:45 PM
Sidewall Design to Improve Lining Life in a Platinum Smelting Furnace: *Isobel Mc Dougall*[1]; Jacques Eksteen[2]; [1]Tenova Pyromet; [2]Lonmin South Africa

The matte/slag tidal zone in a platinum smelting furnace is subject to severe process conditions which often lead to premature failure of the lining. The fayalite slag is aggressive to refractory bricks, whilst the Ni-Cu-Fe-S matte is aggressive to water-cooled copper cooling elements. A novel approach to the lining design was taken at Lonmin's new 10MW Furnace 2. An indirectly-cooled graphite ring was applied in this zone, with refractory bricks on the hot face. Thermal FEA modelling was conducted to determine the optimal design of the lining in this region of the furnace. The resistance to damage by slag and matte of two graphite grades was evaluated experimentally. The graphite is not wet by the matte, and is resistant to slag attack at operating temperatures

5:10 PM
SiC Formation in Submerged Arc Furnaces Producing Silicomanganese: *Per Anders Eidem*[1]; Jens Davidsen[1]; Merete Tangstad[2]; [1]Eramet Norway AS; [2]Norwegian University of Science and Technology

During excavations of submerged arc furnaces producing silicomanganese SiC formations have been found. Contributing to the size of the inactive area of the furnace, the active area of the furnace where reactions happen will decrease thus reducing the potential for pre-reduction in the furnace. This work studies the formation of SiC from the liquid-solid reaction between slag, metal and coke. Slags and metals with different levels of SiO2 and Si, respectively, has been studied. The slag and metal has been heated together with coke, and the samples investigated in XRD and microprobe. Wettability of slag and metal towards SiC was also done. The results show that SiC is formed on the coke particle through reactions with both slag and metal. For the metal, the carbon probably diffuses through the SiC to react with Si in the alloy. SiC formation with slag probably goes through the reduction of SiO_2</SUM> to Si.

IOMMMS Global Materials Forum: Materials in a Green Economy: An International Perspective: Session I

Sponsored by: The Minerals, Metals and Materials Society, TMS: Materials and Society Committee, TMS: Public and Governmental Affairs Committee

The Role of Materials Recycling in Economic Sustainability: *Brajendra Mishra*[1]; Warren Hunt[2]; [1]Colorado School of Mines; [2]Executive Director, The Minerals, Metals & Materials Society

As the enabler of technologies and industrial growth, materials play a pivotal role in global economic sustainability. The current global materials consumption by one estimate is over twelve billion metric tonnes and is expected to reach twenty billion by the middle of this century. This presentation will summarize the findings and recommendations pertaining to resource, recovery and recycling of materials and will focus on optimum engineering solutions to achieve economic, environmental and energy sustainability in manufacturing. These integrated manufacturing solutions to challenges for green economy encompass several interrelated areas, such as the transportation, energy, recycling, housing, food, water, and health sectors. Non-renewable materials recovery and recycling are the primary needs to sustain green economy. Specific information will be included on the nucleus of a consensus definition of sustainability as it applies to materials engineering to provide a common basis for deliberation.

2:30 PM Invited
Innovative Developments in Steel Industry to Address Global Environmental Trends: *Debashish Bhattacharjee*[1]; [1]Tata Steel Research Development & Technology

The global trends in environment are characterized by scarcity: Scarcity of water, energy and raw materials. As the world population is forecasted to increase enormously, the pressure is put on finding sustainable solutions for energy and clean water for the increasing population. Sustainable energy solutions include exploiting renewable energy sources that will not contribute to the climate change. It also means reducing energy consumption and eliminating wastes. This paper presents examples of innovative development work carried out in Tata Steel to address the global trends in environment.When it comes to renewable energy resources, solar energy is emerging as the most promising source. Work is carried out worldwide to find effective and affordable technologies for harvesting this uninterrupted energy source. Tata Steel is working on advanced technology for harvesting solar energy efficiently.

2:50 PM Invited
Recent Development of Materials for Green Energy in Korea: *Soon Young Hwang*[1]; Jin-Hong Kim[1]; [1]RIST

For the last few years, intensive materials developments for green energy have been made in Korea. In this presentation, recent progresses of developments will be presented including Si, SiC materials and sodium sulfur batteries, and Li-ion battery materials in Korea. For photovoltaics, poly-silicon is the major material, and several new plants have recently been constructed employing the Siemens process. However, a new economical silicone production is being developed such as a metallurgical method. For SiC materials, grand new projects have been initiated to develop semiconducting SiC materials with a number of institutions using various industrial methods. For a energy storage system (ESS), sodium sulfur battery, Li-ion battery, and redox flow battery developments have been also started to reach more than 1 MW generating capacity. Finally, government road maps of green energy materials developments will be shown as a summary.

3:10 PM Invited
Developing High Performance Steels in a Green Economy: *Chengjia Shang*[1]; Yuqing Weng[2]; [1]University of Sicence and Technology Beijing; [2]The Chinese Sciety for Metals

Reduce, reuse and recycle are the principles for eco-material which will be fundamental of green economy in future. Steel has many advantages, but the metallurgical processes generally relates with resource and energy consumption, CO2 emission, etc. Therefore, how to reduce the consumption of steel would be key issue for green economy, especially in the developing country. In China, with the developing of economy in the past 30 years, steel production is increasing more and more. However, comparing with the developed country, the annual consumption for population is still very low. Therefore, reducing steel requirement by increasing strength and other performance will be the only route for meeting the growing requirement of steel. With the R&D projects aiming to double strength, prolong the life serving time and upgrade safety/durability of steels which funded by goverment and industries, high performance steels have been developed for fast development of economy in China.

3:30 PM Invited
An Alternative Approach to Sustainable, Low-Carbon Energy: Inertial Fusion Energy and its Materials Challenges: *Tomás Díaz de la Rubia*[1]; [1]Lawrence Livermore National Laboratory

Increasing worldwide demand for energy is placing enormous pressure on natural resources, the global ecosystem, and international political stability. Alternative sources of energy are required in order to meet increased energy demand, stabilize the increase of atmospheric carbon dioxide, and mitigate the concomitant climate change. In response to this challenge, governments are urgently trying to develop new economical, sustainable, and environmentally friendly energy technologies. In fact, meeting CO2 targets and clean energy goals by 2050 requires accelerated development, prototyping, and deployment of new, competitive, low-carbon energy technologies. Business as usual will not do. In this contribution, I will describe how advances and progress at the National Ignition Facility help enable the development and commercial deployment of Inertial Fusion Energy. The NIF is expected to achieve thermonuclear ignition and burn of at DT fuel mixture before the end of 2012.

Metals, Materials and the Environment: *Bhaskar Roy*[1]; [1]M.N. Dastur & Company(P) Ltd

Metals and materials play a dominant role in the overall global socio-economic development. Increasingly exacting demands for newer, high quality materials with special properties and high degree of performance reliability have rapidly impacted the perspective pertaining to engineering and technology, and have, in turn, changed the concept and perception of metallurgy in recent times. Once largely confined to the development of ferrous and non-ferrous metals, stringent application requirement have today encompassed newer fields such as glass, ceramics, polymers and composites. Metal today are a part of the vast spectrum of engineering materials. This has widened the scope and opportunities for new generations of materials scientists and engineers. The role of materials scientists in improving the quality of life of our planet, without significantly impacting its environment, have assumed greater importance, and has become one of the most discussed issues.

4:25 PM Invited
A Strategy of Metal Supply for Sustainable Development and Supporting Technologies for It in Japan: *Takashi Nakamura*[1]; A. Inaba[2]; [1]Institute of Multidisciplinary Research for Advanced Materials; [2]Major of Applied Chemistry and Chemical Engineering

What are the most serious environmental issues in this century? There are, of course, several answers which depend on personality. “Global Warming, Climate Change” is expected as a most average answer. It is no doubt to be serious. Another answer is also to supply foods and water. These problems are also essential to keep lives. And I would like to add one more to them, which is a stable sustainable supply of mineral resources because most human beings live in the circumstances which are mainly consist of artificial products including many metallic products. So, we are living in natural environment with artificial circumstances. We can’t return to old historical lives. How we can success to do harmonious coexistence between keeping environment and economic growth, which is a trade off relation very often.

4:45 PM Invited
Multi-Eye Approach for Clarification of Surface/Interface Phenomena in Environment and Energy Materials: *Kotobu Nagai*[1]; [1]National Institute for Materials Science

Key issues of environment and energy materials are muliti-phase, noneqilibrium, non-steady processes at surface/interface of functional materials. NIMS-GREEN(Global Research Center for Environment and Energy based on Nanomaterials Science) is a national project of compact size with the mission to explore new methodology for solution of the key issues above-mentioned. The convergence of three research fields of materials process,characterization and computation is a basic structure and they are developing various " Environment Cells" to in-situ simulate the real action of surface/interface with various characterization equipments. The model computation will be applied to recognize the real phenomena using the experimental data.

5:05 PM Invited
Aluminium Production, Manufacturing and Recycling in Australia – Materials Innovation for a Clean Energy Future: *Malcolm Couper*[1]; [1]Monash University

According to the Australian Aluminium Council (AAC) Sustainability Report for 2010, bauxite production reached a record 71.5mill tonnes and additional value was added with the production of 20.3mill tonnes of alumina and close to 2mill tonnes of aluminium. CO2 emissions per ton of aluminium were down 10% from 2009. Around 80% of the alumina and aluminium production is exported and the industry provides direct and indirect employment for around 45,000 people in Australia. The potential rising cost of carbon and possible uncertainty in the allocation of permits and future carbon trading present risks to emission-intensive trade exposed (EITE) industries. Some of the innovative materials developments under way in support of the necessary changes to the aluminium industry in Australia and globally, will be described.

5:25 PM Invited
Natural Fiber Composites – Significant Contribution to a Green Economy: *Sergio Monteiro*[1]; Marc-Andre Meyers[2]; João Carlos Miguez Suarez[2]; [1]State University of the Northern Rio de Janeiro - UENF; [2]Military Institute of Engineering;Brazilian Association for Metallurgy, Materials and Mining

Technological expansion supported by advanced materials, mainly those synthetic and non-renewable, is contributing not only to the global industrial growth, but also to a continuous deterioration in our environmental conditions. All over the world, attention is being focused on the development and application of eco-friendly materials as steps taken toward a green economy. Natural fibers obtained from cellulose-based plants are typical examples of environmentally correct materials. Reinforcement of polymer composites with these lignocellulosic fibers is increasingly regarde as a viable alternative to synthetic fiber reinforcement. Biocomposites found in nature are also being investigated as model for new industrial materials with superior properties. This work presents an overview of the research efforts to develop stronger natural composites as well as their already existing successful industrial applications. In addition to technological advantages, the worldwide economical, social and environmental contribution of these natural composites to a "green" society is assessed.

2:00 PM
An Elasto-Plastic Micromechanical Method for Twin Driven Plasticity: *Laurent Capolungo*[1]; Pierre Alexandre Juan[1]; Stephane Berbenni[2]; Carlos Tome[3]; [1]Georgia Institute of Technology; [2]Universite Paul Verlaine; [3]Los Alamos National Laboratory

Recent measures of the evolution of internal strains within parent and twin domains in hexagonal close packed polycrystals revealed substantial differences in the deformation fields of each domain. It was suggested that these differences arise from back-stresses associated with elastic constant mismatch and plastic incompatibilities between parent and twin domains. A simple elastic study of the grain/twin inclusion problem based an the extension of the Tanaka Mori scheme already delineated the importance of elastic constants mismatches to the development of back-stresses in twin domains. Also, it was found that the effect of twin shape on the stress state within twin domains is particularly pronounced. The proposed work aims at developing a micromechanical based model capable of predicting these phenomena. The approach is to be based on an extension of the Tanaka Mori scheme applied in an Elasto-Plastic framework (EPSC). The model is applied to the case of polycrystalline Mg.

2:20 PM
Anomalous Twin Bands in AZ31 Mg Sheet Bending: James Crawford Baird[1]; *Bin Li*[1]; Sanaz Yazdan Parast[1]; Stephen Horstemeyer[1]; Haitham El Kadiri[1]; Paul Wang[1]; [1]Center for Advanced Vehicular Systems

Micro-texture examination for Mg alloys is usually performed after samples are unloaded. Unloading a deformed sample loses important microstructure and texture information due to detwinning. In fact, we recently reported that detwinning could affect not only stopped twins but residual twins as well. To circumvent this difficulty, a special fixture was designed such that continuous EBSD scan were enabled without unloading. We applied our design to the study of rolled AZ31 Mg sheet bending at room temperature. Through thickness EBSD scan during 3-point bending reveals anomalous {10-12}<10-1-1> twin patterns. In the compressed zone, the {10-12}<10-1-1> extension twins appear in an extremely localized fashion. Alternating twin bands were formed, each band comprising high density twins which allow identification of the originating stress state. In between the twin bands, twins were completely absent.

2:40 PM
Formation of Nano-Scale Twins and Low Angle Grain Boundaries during Fracture of Fine Grained Magnesium Alloys: *Alok Singh*[1]; Hidetoshi Somekawa[1]; Toshiji Mukai[2]; [1]National Institute for Materials Science; [2]Kobe University

Fine grained magnesium alloys show high fracture toughness, associated with void formation. Detailed microstructural evolution during a fracture toughness test of a fine grained Mg-Zn alloy has been studied here by transmission electron microscopy (TEM). Focused ion beam (FIB) technique was used for obtaining samples near crack. Initially, subgrain structures form ahead of the crack tip, after which {10-11} type twins of width of about 400nm form. They further twin by {10-12} twinning. Subsequent twinning occurs at a finer scale near the crack, forming configurations of {10-11}-{10-12} double twins and low angle boundaries. The scale of the twin domains became progressively finer to less than 50nm. It is suggested that in absence of enough dislocations to pile up causing fracture, deformation continues to occur by the twinning.

3:00 PM
Tensile and Creep Deformation Mechanisms in Rolled AZ31: Carl Boehlert[1]; Zhe Chen[1]; Ivan Gutiérrez-Urrutia[2]; Jan Bohlen[3]; Sangbong Yi[3]; Dietmar Letzig[3]; Javier Llorca[4]; *Maria Teresa Perez-Prado*[4]; [1]Michigan State University; [2]Max Planck Institute for Iron Research; [3]Magnesium Innovation Centre MagIC; [4]IMDEA-Materials

Basal slip and tensile twinning are the prevalent deformation mechanisms in randomly-oriented Mg alloys at low temperatures. At elevated temperatures, non-basal slip systems become active as their CRSS decrease rapidly. In strongly textured rolled or extruded alloys, the choice of slip and twinning systems is highly dependent on the Schmid factor. Here, an extruded Mg-1Mn-1Nd alloy was tensile tested in an SEM at temperatures of 50°C, 150°C, and 250°C in order to analyze the local deformation mechanisms through in-situ observations. EBSD was performed both before and after the deformation. The alloying elements inhibited the <10-10> fiber texture, typical of extruded Mg alloys, leading to the formation of a very weak extrusion texture. The tensile strength decreased with increasing temperature, and no change in the normal anisotropy was apparent. The proportion of the different slip systems activated will be presented and discussed with respect to the temperature, CRSS, and Schmid factor.

3:20 PM
Structural Origin of Reversible Twinning, Non-Schmid Effect, Incoherent Twin Boundaries and Texture of Hexagonal Close-Packed Metals: *Bin Li*[1]; Xiyan Zhang[2]; Haitham El Kadiri[1]; Suveen Mathaudhu[3]; Quancang Ma[1]; [1]Center for Advanced Vehicular Systems; [2]Chongqing University; [3]Army Research Laboratory

Profuse {10-12}<10-1-1> extension twinning occurs in Magnesium and other HCP metals during plastic deformation. This twinning mode presents abnormal properties such as reversibility, i.e., upon unloading or removal of external load, twins may shrink or disappear, giving rise to the pseudoelasticity. The {10-12}<10-1-1> twinning may also violate the Schmid Law which applies to all dislocation controlled deformations. The twin boundaries of the {10-12}<10-1-1> twinning may significantly deviate from the {10-12} twinning plane, at odds with twinning theory that requires twinning dislocations glide strictly on the twinning plane. HCP metals also present strong propensity of texture during thermomechanical processing such as extrusion, rolling or severe plastic deformation (SPD). We show that these properties of HCP metals can be well understood from the perspective of atomic shuffling that dominates the deformation twinning. EBSD, TEM and HRTEM observations will be presented to support our conclusions.

4:00 PM
Length Changes in Extruded Magnesium Alloy Bars Under Large Strain Free-End Torsion: Huamiao Wang[1]; *Peidong Wu*[1]; Ken Neale[2]; [1]McMaster University; [2]University of Sherbrooke

It is well-known that the axial stress development during fixed-end torsion and the axial strain during free-end torsion in polycrystalline metals are mainly due to initial texture and texture evolution. The predictions of these second-order axial effects depend strongly on the constitutive model – in particular on the description of anisotropic hardening. In the present study, large strain free-end torsion of extruded magnesium alloy bars is studied by using the recently developed Elastic Visco-Plastic Self-Consistent (EVPSC) model with various self-consistent schemes. In these models, both slip and twinning contribute to plastic deformations. It is shown that the predicted second-order length change is very sensitive to the initial texture, texture evolution and the constitutive models employed. Numerical results suggest that the free-end torsion test can provide an effective means for assessing the adequacy of polycrystal plasticity models for magnesium alloys.

4:40 PM
Non-Basal Textures in Magnesium Alloy Strips by Extrusion-Machining: *Dinakar Sagapuram*[1]; Mert Efe[1]; Wilfredo Moscoso[2]; Srinivasan Chandrasekar[1]; Kevin Trumble[1]; [1]Purdue University; [2]Pontificia Universidad Catolica Madre y Maestra

The positive effect of fine grain size and non-basal texture on formability of magnesium alloy sheets is well known. In the present work, Large-Strain Extrusion-Machining (LSEM), a low-cost, single-step deformation process was employed to produce commercial Mg-AZ31B alloy strips (0.2 μm thick and 6.4 mm wide). The deformation temperature was varied by preheating the workpiece to different temperatures (up to 375°C). At low deformation temperatures, fine grain structure (~2 μm) with basal poles tilted 30-40° away from the strip normal direction towards the chip-flow direction was observed. At higher deformation temperatures, basal poles were split about the normal direction by 10-20° in the transverse direction, while the grain size was in the 3-6 μm range. The activation of secondary slip systems with increasing deformation temperature is presumed to be the cause for these textural changes.

4:20 PM
Nano-Indentation Studies of Twinned Magnesium Single Crystals: Fumiaki Hiura[1]; Raja Mishra[2]; Michael Lukitsch[2]; *Marek Niewczas*[1]; [1]McMaster University; [2]General Motors Research & Development Center

Nano-indentation measurements have been performed on {10-12}<10-11> twin and adjacent matrix regions of deformed magnesium single crystals and the hardness values were analyzed by the Oliver-Pharr method. Although the hardness difference between the twin regions and the adjacent matrix was insignificantly small, the hardness values showed orientation dependence regardless of the twins' size and variants. This observation can be interrupted by texture-softening resulting from the lattice reorientation in the twin regions. In contrast, the experimental evidence for the Basinski hardening mechanism in {10-12}<10-11> twins, which is an increase in strength/hardness as a result of dislocation contributions within twin area, was not obtained from this experiment. This presentation provides framework for the discussion of the hardening/softening effect of {10-12}<10-11> twinning on the plastic flow in single crystalline magnesium and quantitative values for hardening parameters used in the crystal plasticity modeling.

5:00 PM
The Elastic-Plastic Transition in AZ31 Magnesium Alloy: *Kun Yang*[1]; Carlos Caceres[1]; [1]The University of Queensland

The Kocks-Mecking method of analysis is used to assess the fraction of the polycrystal that remains elastic while full plasticity develops in the aggregate. It is shown that what appears to be a very protracted elastic plastic transition is consistent with hardening by the athermal storage of dislocations around grains with a hard orientation for slip. The microplasticity involved in the process is discussed using data from the literature.

Magnesium Technology 2012: Primary Production

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Magnesium Committee
Program Organizers: Suveen Mathaudhu, U.S. Army Research Office; Wim Sillekens, TNO; Norbert Hort, Helmholtz-Zentrum Geesthacht; Neale Neelameggham, U.S. Magnesium

Monday PM — Room: Southern V

2:00 PM
Carbothermal Production of Magnesium: CSIRO's MagSonic™ Process: *Leon Prentice*[1]; Michael Nagle[1]; Timothy Barton[1]; Steven Tassios[1]; Benny Kuan[2]; Peter Witt[2]; Keri Constanti-Carey[1]; [1]CSIRO Process Science and Engineering; [2]CSIRO Mathematics Informatics and Statistics

Carbothermal production has been recognized as the simplest and cleanest route to magnesium metal, but has suffered from technical challenges of development and scale-up. Work by CSIRO has now successfully demonstrated the technology using supersonic quenching (the MagSonic™ Process). Key barriers to process development have been overcome: the experimental program has achieved sustained operation, no nozzle blockage, minimal reversion, and safe handling of pyrophoric powders. The laboratory equipment has been operated at industrially-relevant magnesium vapor concentrations (>25% Mg) for multiple runs with no blockage. Novel computational fluid dynamics (CFD) modelling of the shock quenching and metal vapor condensation has informed nozzle design and is supported by experimental data. Reversion below 10% has been demonstrated, and magnesium successfully purified (>99.9%) from the collected powder. Safe operating procedures have been developed and demonstrated, minimizing the risk of powder explosion. The MagSonic™ Process is now progressing to significantly larger scale and continuous operation.

2:20 PM
MagSonic™ Carbothermal Technology Compared with the Electrolytic and Pidgeon Processes: *Leon Prentice*[1]; Nawshad Haque[1]; [1]CSIRO Process Science and Engineering

A broad technology comparison of carbothermal magnesium production with present technologies has not been previously presented. In this paper a comparative analysis of CSIRO's MagSonic™ Process is made with the electrolytic and Pidgeon processes. The comparison covers energy intensity (GJ/tonne Mg), labor intensity (person-hours/tonne Mg), capital intensity (USD/tonne Mg per year installed capacity), and Global Warming Potential (GWP, tonnes CO_2-equivalent/tonne Mg). Carbothermal technology is advantageous on all measures except capital intensity (where it is roughly twice the capital cost of a similarly-sized Pidgeon plant). Carbothermal and electrolytic production can be environmentally similar, with typical emissions one-sixth those of the Pidgeon process. Despite recent progress, the Pidgeon process depends upon abundant energy and labor combined with few environmental constraints; pressure is expected to increase on each of those measures over the coming decade. Carbothermal reduction technology is likely to emerge as the optimum choice for future production.

2:40 PM
Scaling-Up Solid Oxide Membrane Electrolysis Technology for Magnesium Production: *Soobhankar Pati*[1]; Adam Powell[1]; Steve Tucker[1]; Steve Derezinski[1]; [1]MOxST Inc.

Metal Oxygen Separation Technologies, Inc. (MOxST) is actively developing Solid Oxide Membrane (SOM) electrolysis technology for production of magnesium directly from its oxide. The vital component of this technology is the oxygen ion-conducting solid zirconia electrolyte separating the molten flux (a mixture of salts and oxide) and the inert anode. The zirconia not only protects the anode from the flux but also prevents anode gas back-reaction, increasing the efficiency. This makes it possible to produce low-cost high-purity magnesium and high-purity oxygen as a by-product with no direct greenhouse gas emissions. In this paper we discuss the design modifications made to address the scaling-up challenges, particularly for producing magnesium in liquid form. The key accomplishment to date is the successful development of a prototype capable of producing few kilograms of magnesium per day. We will also describe the prerequisite properties of an inert anode and suitable materials for the same.

3:00 PM
Fluid Bed Dehydration of Magnesium Chloride: *Kamal Adham*[1]; [1]Hatch Ltd.

Molten salt electrolysis of MgCl2 is commonly used for the production of Magnesium metal. However, the electrolysis feed must be completely dry with minimum oxygen content. Therefore, complete dehydration of the MgCl2 brine or the hydrated salt is a required process, which is very challenging due to the ease of thermal degradation. Fluidized bed dryers are often used, under air and HCl environments. The key features of three different types of fluid bed technologies, which can be applied to MgCl2 dehydration plants, are described in this paper. In addition, a discussion of chemistry, unit operations and advantages associated with each option, is presented. The background information is provided based on open literature sources, including papers and patents. Most calculations are performed using commercially available metallurgical software, for the thermodynamics and mass/heat balances.

3:20 PM
Demonstration of Solar-Pumped Laser-Induced Magnesium Production from Magnesium Oxide: Yabe Takashi[1]; Ohkubo Tomomasa[1]; *Dinh Thanh Hung*[1]; Kuboyama Hiroki[1]; Nakano Junichi[1]; [1]Tokyo Institute of Technology

Studies of storing solar energy into chemical energy of magnesium (Mg) through reduction from magnesium oxide (MgO) by solar-pumped laser were conducted. We succeeded in solar-pumped laser-induced Mg production. Laser system consists of a 4 m2 Fresnel lens mounting on a sun tracker platform which focus solar radiation into laser head therefore over 100W (CW) output laser can be irradiated. A single laser beam is focused on a mixture of magnesium oxide and reducing agent silicon. High power density of focused laser leads to high temperature and the reduction reaction resulting in Mg production. The resultant vapor is collected on a copper plate and analyzed in terms of magnesium deposition efficiency. As a result, deposition efficiency of 2.3 mg/kJ was achieved.

3:40 PM Break

4:00 PM
Molten Salt Electrolysis of MgCl2 in a Cell with Rapid Chlorine Removal Feature: *Gökhan Demirci*[1]; Ishak Karakaya[2]; [1]Aselsan Inc.; [2]Middle East Technical University

An experimental electrolytic magnesium production cell was designed to remove chlorine gas from the electrolyte rapidly and demonstrate the beneficial effects of reduced chlorine dissolution into the molten salt electrolyte. The back reaction that is the main cause of current losses in electrolytic magnesium production was reduced as a result of effective separation of electrode products and decreased contact time of chlorine gas with the electrolyte. Moreover, smaller inter electrode distances employed and lower chlorine gas present on the anode surface made it possible to work at low cell voltages. Electrolytic cell was tested at different current densities and electrolyte compositions. Energy consumption of 7.0 kWh kg-1 Mg that is slightly above the theoretical minimum, 6.2 kWh kg-1 Mg, at 0.68 A cm-2 anodic current density was achieved for a MgCl2/NaCl/KCl electrolyte.

4:20 PM
Preparation of Aluminum-Magnesium Alloy from Magnesium Oxide in RECl3- LiF-MgF2 Electrolyte by Molten Salts Electrolysis Method: *Sh Yang*[1]; Fengli Yang[1]; Xianwei Hu[2]; Zhaowen Wang[2]; Zhongning Shi[2]; Bingliang Gao[2]; [1]Jiangxi University of Science and Technology; [2]Northeastern University

Aluminum-magnesium alloys were prepared from magnesium oxide by molten salt electrolysis method. 10w%RECl3-63.5w%KCl-23.5w%MgCl2-3w%MgO was taken as electrolyte. The results showed that RE could be attained in aluminum-magnesium alloy, and it was proved that the RE was reduced directly by aluminum. Magnesium in the alloy was produced by electrolysis on cathode. The content of RE in the alloy was about 0.8wt %-1.2wt%, and the content of Mg in the alloy was 1wt%~6wt% with electrolytic times. The highest current efficiency was 81.3% with 0.8A/cm2 current density. The process of electrolysis was controlled together by electrochemical polarization and concentration polarization.

4:40 PM
Experimental Study on Magnesium Extracted from Ascharite Mineral by Aluminium: *Peng Jianping*[1]; Wu Xiaolei[1]; Feng Naixiang[1]; Zhou Shigang[1]; Di Yuezhong[1]; [1]Northeastern University

In order to effectively utilize the ascharite mineral, in Liaoning province of China, the paper studied to extract magnesium from ascharite mineral with aluminium powder as reductant by vacuum thermal reduction method. And boron of the raw material was saved in residues that could be used to produce non-alkali glass fiber. So environment cannot be polluted during this process, as well as the process can create great economic value. Calcined material and the residues were taken XRD analysis respectively. Based on thermodynamic analysis, the Gibbs free energy and the critical temperature of reduction ascharite with calcium carbide were calculated. Based on some experiments the recovery rate was effected remarkably by the mass of reductant and the making briquettes pressure.

5:00 PM
Electrochemical Investigation on Chlorine and Electrolyte Intercalation into Graphite Anodes during Magnesium Electrolysis Process: *Bing Li*[1]; Jingwei Lou[1]; Mengfan Yan[1]; [1]East China University of Science and Technology

Cyclic voltammetry(CV) was used to investigate chlorine and electrolyte intercalation into three different graphite anodes from NaCl-KCl-MgCl2 melts at 700 °C. They were needle-coke (NC), the petroleum-coke (FPC) and common petroleum-coke (CPC), respectively with the same processing technology. Chlorine intercalation amount was characterized by the reduction current (reduction electricity quantity) on the reverse scan during the cyclic voltammograms. And the electrolyte intercalation was presented by the increase in oxidation charge between the forward .scan and the reverse scan during the CV measurements. The results show that among the three graphite anodes, NC shows the lowest reduction current and nearly no increase in the charge , while about 5-10 times increase in the charge for the PFC and CPC ,which implied that NC has a better resistance to electrolyte and chlorine intercalation.The results were further confirmed by the electrolysis experiments in NaCl-KCl-MgCl2 melts at 700 °°.

5:20 PM
Optimization of Preparation for MgO by Calcination from Basic Magnesium Carbonate Using Response Surface Methodology: *Bin Zhang*[1]; Jinhui Peng[1]; Libo Zhang[1]; shaohua Ju[1]; [1]Kunming University of Science and Technology

The conditions of technique to prepare MgO by calcination from Basic magnesium carbonate were optimized using a central composite design (CCD) of response surface methodology (RSM). A quadratic equation model for decomposition rate was built and effects of main factors and their corresponding relationships were obtained. The statistical analysis of the results showed that in the range studied the decomposition rate of Basic magnesium carbonate was significantly affected by the calcination temperature and calcination time. The optimized calcination conditions were as follows: the calcination temperature 435.5°C and the calcination time 121.6 min, respectively. Under these conditions the decomposition rate of cobalt oxalate was 99.17%. The validity of the model was confirmed experimentally and the results were satisfactory. In addition, the sample was characterized by X-ray Diffraction (XRD) and Scanning electron microscopy (SEM), respectively.

Materials and Fuels for the Current and Advanced Nuclear Reactors: Nuclear Fuels - Characterization

2:00 PM
Recent Developments in the Study of the Effects of Irradiation on the Microstructure of U-Mo Nuclear Fuels: *Dennis Keiser*[1]; Jan-Fong Jue[1]; Jian Gan[1]; Adam Robinson[1]; Pavel Medvedev[1]; [1]Idaho National Laboratory

The Reduced Enrichment for Research and Test Reactor (RERTR) program is developing low-enriched U-Mo fuels for use in research and test reactors that currently employ high-enriched uranium fuels. A large part of this development has been in-reactor testing of U-Mo fuels, and the subsequent characterization of the microstructures of the as-irradiated fuel plates. Optical metallography, scanning electron microscopy, and transmission electron microscopy have all been employed for characterizing irradiated fuel plates. This presentation will describe recent results from the different characterization activities and how they can be used to develop better understanding of how the fuel plate microstructures evolve as a function of the time in reactor. The effects of fission density, fission rate, and temperature on fuel plate performance will also be discussed.

2:20 PM
TEM Study on the Phase Development and Microstructure in a U-7 wt.% Mo vs. Al-7 wt.% Ge Diffusion Couple: *E. Perez*[1]; D.D. Keiser[1]; Y.H. Sohn[2]; [1]Idaho National Laboratory; [2]University of Central Florida

Fuel development for the Reduced Enrichment for Research and Test Reactors (RERTR) program has demonstrated that U-Mo alloys in contact with Al develop interaction regions with phases that have poor irradiation behavior. The addition of Si to the Al has been considered with positive results. Compositional modification to replace Si with Ge is now under evaluation to further improve irradiation behavior and recycling of spent fuel systems. In this study, the microstructural and phase development of a diffusion couple of U-7 wt.% Mo in contact with Al-7 wt.% Ge was examined by transmission electron microscopy, scanning electron microscopy and energy dispersive spectroscopy. The interdiffusion zone developed a three phase microstructure containing an amorphous phase, the orthorhombic-UGe_2 and the cubic-$(U,Mo)(Al,Ge)_3$ phase. Results from this study are compared to U-Mo vs. pure Al and U-Mo vs. Al-Si diffusion couples to discuss the differences in the microstructural evolution of the different interdiffusion zones.

2:40 PM

Observations and Analyses of Diffusion Couples, U-10 wt.% Mo vs. Zr: *Ke Huang*[1]; Youngjoo Park[1]; Dennis Keiser[2]; Yongho Sohn[1]; [1]University of Central Florida; [2]Idaho National Laboratory

U-Mo alloys as dispersed and monolithic fuel within Al-alloy matrix are being developed as a low enriched metallic fuel for the Reduced Enrichment for Research Test Reactor program. Interactions due to interdiffusion between the U-Mo fuel and the Al matrix have been observed during fuel processing and irradiation, and are of concern due to potential adverse effects. To explore diffusion barrier materials between U-Mo fuel and Al alloy cladding, U-10 wt.% Mo vs. Zr diffusion study were carried out in the temperature range from 973K to 1273K. The interdiffusion zone and concentration profiles were examined by scanning electron microscopy and electron probe microanalysis, respectively. Mo2Zr precipitates were observed along the diffusion bonded interface. Concentration-dependence average ternary interdiffusion coefficients on either side of Matano plane were calculated. These coefficients were also carefully examined to estimate respective tracer diffusion coefficients when the concentration of U, Mo or Zr becomes negligible.

3:00 PM

Mechanical Properties of U-Mo Fuels: *Ramprashad Prabhakaran*[1]; Douglas Burkes[2]; Jan-Fong Jue[1]; Amy DeMint[3]; Jack Gooch[3]; Dennis Keiser[1]; Daniel Wachs[1]; [1]Idaho National Laboratory; [2]Pacific Northwest National Laboratory; [3]Y-12 National Security Complex

The Reduced Enrichment for Research and Test Reactors (RERTR) program was initiated to develop new nuclear fuels to enable the research and test reactors to use low-enriched uranium fuels instead of high-enriched uranium fuels, without significant loss in performance. Hence, a new monolithic fuel type that possesses the greatest possible uranium density in the fuel region is being developed, where the fuel region consists of a single foil encased inside an aluminum alloy cladding. Currently, efforts are ongoing to evaluate the mechanical properties and microstructure of fresh U-Mo fuels, as a function of molybdenum content, carbon content and temperature. Small-scale specimen testing techniques, such as sub-size tensile testing, microindentation hardness testing and shear punch testing are being performed. Other materials characterization techniques, such as optical microscopy, XRD and SEM are being used in conjunction with the small-scale mechanical test methods.

3:20 PM

Metallurgical Characterization of the Delta Phase Formation in Uranium-Zirconium Alloy Fuels: *Sandeep Irukuvarghula*[1]; Sean McDeavitt[1]; Sangjoon Ahn[1]; [1]Texas A&M University

Uranium – 10 wt% zirconium (U-10Zr) alloy nuclear fuels have been used for many decades and new variations are under consideration ranging from U-5Zr to U-50Zr. As a precursor to studying fission gas behavior using ion implantation, a basic study of U-Zr metallurgy was completed. The initial focus was to clarify literature ambiguity regarding the formation of the UZr_2 delta phase. Sample alloys were created containing 0.1, 2, 5, 10, 20, 30, and 50 wt% zirconium. Initial structures were created via “furnace-cooled” and “gamma-quenched” temperature profiles. Samples of each composition and thermal profile were annealed under argon at 600°C for 24, 72, and 168 hours. Quantitative analyses were completed using an electron microprobe. The delta phase formed readily in annealed furnace-cooled samples whereas gamma-quenched samples exhibited sluggish transformations. The rate of cooling U-Zr alloys has a profound impact on the kinetics of delta phase formation.

3:40 PM Break

3:50 PM

Thermodynamic Assessment of the Uranium-Zirconium Alloy System for Nuclear Energy Applications: *Sangjoon Ahn*[1]; Sandeep Irukuvarghula[1]; Sean McDeavitt[1]; [1]Texas A&M University

Uranium – 10 wt% zirconium (U-10Zr) alloy nuclear fuels have been used for many decades and new variations are under consideration ranging from U-5Zr to U-50Zr. The thermophysical behavior of the uranium-zirconium system has been revisited using differential scanning calorimetry (DSC) and other methods. Alloys containing 0.1, 2, 5, 10, 20, 30, and 50 wt% zirconium were prepared by melt-casting ~40 g samples in yttrium oxide crucibles. The phase transitions observed using DSC analyses are in general agreement with the established phase diagram with a few notable exceptions that may, in part, be due to impurities. Most notably, the transition from the α(U)+γ phase field to the β(U)+γ phase field at ~662°C was never observed in these experiments. This observation is consistent with earlier experimental assessments of the U-Zr binary phase diagram as compared with the more recent computational assessments.

4:10 PM

Characterization of U-Zr-Ce and U-Mo-Ce Alloy Fuels Doped with In, Sb, and Pd: *Yeon Soo Kim*[1]; Gerard Hofman[1]; Tom Wiencek[1]; Ed O’Hare[1]; Jeff Fortner[1]; [1]Argonne National Laboratory

Fast reactor concepts achieving ultra-high burnup (~50%) without requiring refueling using metallic fuel have gained interest. Fission product lanthanide accumulation at high burnup and migration are potential life-limiting phenomena. As a means to prevent this problem, adding an element that forms stable compounds with lanthanides is proposed. The theoretical assessment shows that indium, thalium, and gallium are good candidates. Because these elements are low-melting metal elements, liquid metal embrittlement of cladding is a concern. Some other elements are also proposed that include Sb and Pd. Therefore, how these elements form compounds with the lanthanides is another measure of selection. As a screening test before in-pile tests, alloys of U-10X-2Ce-5Y, where X=Zr, Mo and Y=In, Sb, Pd, are fabricated and characterized by opical metallography and scanning electron micrography to select the best candidate. These metallography results and the theoretical method used to select the candidate elements will be presented.

4:30 PM

Interdiffusion between U - 10wt.% Zr and Fe Diffusion Couples Annealed at 903, 923, 953 and 973K: *Youngjoo Park*[1]; Ke Huang[1]; Bulent Sencer[2]; Rory Kennedy[2]; Yongho Sohn[1]; [1]University of Central Florida; [2]Idaho National Laboratory

Diffusional interaction between 10wt.%Zr metallic fuel and Fe was investigated using solid-to-solid diffusion couples that were annealed at 903K, 923K, 953K and 973K. Development of microstructure and phase constituents within the interaction layer was examined by scanning electron microscopy with X-ray energy dispersive spectroscopy. Multiple layered structures with complex microstructure consisting of various phases such as λ-, ε-, and χ-phases were observed. The thicknesses of multi-phase layers were measured at each temperature and employed to calculate the parabolic growth constant and activation energy. The average compositions through the interaction layer were systematically determined, and employed to construct semi-quantitative diffusion path on isothermal ternary diagrams. These diffusion paths are discussed to estimate the diffusional behavior of individual components and their interactions.

4:50 PM
Microanalysis of Irradiated Coated Particle Fuel from the AGR-1 Irradiation Experiment: *Paul Demkowicz*[1]; Isabella van Rooyen[1]; Scott Ploger[1]; Jessica Riesterer[1]; Brandon Miller[1]; [1]Idaho National Laboratory

The AGR-1 irradiation of TRISO-coated particle fuel specimens was recently completed and represents the most successful such irradiation in US history, reaching peak burnups of greater than 19% FIMA with zero failures out of 300,000 particles. Extensive post-irradiation examination of the fuel is currently in progress. A critical component of the fuel characterization is microanalysis of the irradiated fuel particles, including ceramography, scanning electron microscopy, wavelength dispersive spectroscopy, and transmission electron microscopy of coatings and fuel kernels. Among the primary objectives of this examination are to determine the effects of irradiation on coating integrity, correlate coating microstructures with the extent of fission product retention, and develop a better understanding of fission product diffusive release. Of particular interest is silver, which has long been known to exhibit relatively high release from coated particle fuel. This paper will highlight some of the microanalytical techniques being utilized and present preliminary results.

5:10 PM
Postirradiation Examination of High Burnup Metallic Fuels: *Heather Chichester*[1]; Douglas Porter[1]; Steven Hayes[1]; [1]Idaho National Laboratory

Within the Fuel Cycle Research & Development program, six metallic fuel alloy compositions were fabricated and irradiated in ATR. Irradiation to 653 effective full power days resulted in fuel burnups ranging from approximately 17-30 at.% HM. These alloys (e.g., U-29Pu-4Am-2Np-30Zr) are being studied in order to understand how fuel incorporating constituents from recycled light water reactor fuel would behave in fast reactors, with particular focus on transmuting actinides. Initial destructive postirradiation examinations of these alloys have been completed, including fission gas release, optical microscopy, and burnup analysis. Select results will be presented and compared to results from lower burnup companion experiments and the historical metallic fuel performance database.

Multiscale Modeling of Mechanical Performance from a Perspective of Materials Design: *Dennis Dimiduk*[1]; [1]Air Force Research Laboratory

Material and alloy design projects can now access growing set of new materials modeling and simulation tools to guide their efforts. The capabilities of such tools are expanding rapidly for representing mechanisms important to design at disparate length scales. The present talk focuses on the multiscale aspects of mechanical behavior simulation for the purposes of predicting materials performance. Selected tools and techniques are discussed from a viewpoint motivated by two questions: i) what multiscale tools and methods are able to provide predictive capabilities for materials design problems and, ii) how might the methods be incorporated into an integrated computational materials engineering framework to reduce the need for empirical data. The initial conclusion is that microstructure-level tools are significantly underdeveloped and are likely to remain so for some time; thus, a more structured approach to integrated computational and empirical methods is necessary.

2:30 PM Invited
MaterialsGenome®: Building Blocks of Materials: *Zi-Kui Liu*[1]; [1]The Pennsylvania State University

The building blocks of materials are individual phases. The ability of materials design resides on our capability to model the properties of individual phases and their interfaces as a function of materials variables such as temperature, pressure, compositions, and other field variables. In this presentation, we will discuss our activities in developing an infrastructure, named MaterialsGenome® (Trademark of MaterialsGenome, Inc.), for properties of individual phases. MaterialsGenome® is based on ESPEI [1]. ESPEI integrates databases (crystallographic, phase equilibrium, thermochemical, and modeled Gibbs energy data, etc) and database development (automation of thermodynamic modeling). The infrastructure of experimental data storage as well as the automation of database development is uniquely constructed in ESPEI. 1. S. Shang, Y. Wang and Z. K. Liu, "ESPEI: Extensible, Self-optimizing Phase Equilibrium Infrastructure for Magnesium Alloys," S. R. Agnew, N. R. Neelameggham, E. A. Nyberg, W. H. Sillekens, Eds., Magnesium Technology 2010, pp. 617-622.

Experimental Tools for the Materials Genome Initiative: *Ji-Cheng Zhao*[1]; [1]The Ohio State University

The Materials Innovation Infrastructure in the Materials Genome Initiative consists of three major components: computational tools, experimental tools and digital data. This talk will discuss experimental tools for high-throughput measurements of several materials properties such as elastic modulus, thermal conductivity, specific heat capacity, and thermal expansion. Application of these tools on composition-varying samples such as diffusion multiples can be used to quickly and efficiently obtain composition-phase-structure-property relationships for materials property database establishment. These tools not only have high spatial resolution, but also high accuracy, thus they can be used to obtain high-quality digital data for various materials properties for accelerated design of new materials. In addition, a diffusion-multiple approach can be used to effectively obtain phase diagram and diffusivity data for establishment of reliable thermodynamic and kinetic databases.

An Integrated CALPHAD Tool for Modeling Precipitation Kinetics and Accelerating Materials Design: *Qing Chen*[1]; Herng-Jeng Jou[2]; Gustaf Sterner[1]; Johan Bratberg[1]; Anders Engström[1]; Paul Mason[3]; [1]Thermo-Calc Software AB; [2]QuesTek Innovations LLC; [3]Thermo-Calc Software, Inc

CALPHAD tools, such as Thermo-Calc and DICTRA, together with related thermodynamic and kinetic databases have now been applied extensively in almost every aspect of materials design, from screening to processing, operating, and recycling. Their success relies on their capability to provide fundamental phase equilibrium and phase transformation information in materials of industrial relevance, which is possible due to the adopted methodology where free energy or atomic mobility of each phase in a multicomponent system is modeled hierarchically from lower-order systems, and model parameters are evaluated by considering both ab-initio and various experimental data. In this presentation, we introduce TC-PRISMA, a new user-friendly computational tool that extends the Thermo-Calc and DICTRA approach with additional interface property data in order to simulate the kinetics of precipitation process. Nucleation and growth models implemented in the software will be presented. Engineering applications of precipitation modeling and ongoing challenges will also be discussed as well.

4:20 PM Invited
Integrated Computational Materials Engineering for Precipitation Modeling of Multi-Component Alloys: *Fan Zhang*[1]; W. S. Cao[1]; S. L. Chen[1]; Chuan Zhang[1]; Y. A. Chang[1]; [1]CompuTherm, LLC

Precipitation hardening or age hardening provides one of the most widely used mechanism for strengthening many structural materials. Extensive amount of research has been devoted to simulate the microstructural evolution and the correlated hardening responses during the precipitation of different types of intermetallic phases. However, precipitation is a highly complex process and could involve simultaneous occurrence of nucleation, growth and coarsening. Accurate modeling of the precipitation process requires a synchronous consideration of all these contributions. Moreover, the necessary phase equilibrium information and mobility data must be constantly updated during the simulation. Therefore, such a simulation necessitates a smooth integration of thermodynamic calculation, kinetic simulation and property modeling of the material.In this presentation, we will present a framework for precipitation modeling of multi-component alloys by integrating thermodynamic calculation with multi-level kinetic models. Examples will be given for aluminum alloys and nickel alloys.

Direct 3-D Materials Characterization and Its Incorporation into Computational Models: John Sosa[1]; Daniel Huber[1]; Robert Williams[1]; Peter Collins[2]; *Hamish Fraser*[1]; [1]The Ohio State University; [2]University of North Texas

The successful development of accurate and validated computational tools most often requires an integration with materials characterization. Two functions are served, one being the provision of accurate physically-based descriptions of mechanistic details, and second being the validation of predictions yielded by the models. Hence, the most accurate means of materials characterization are required. In the present work, direct 3-D characterization methods have been developed, covering a wide range of length scales to permit descriptions of features from atomic dimensions to the macroscale. These techniques involve both serial sectioning and tomographical techniques. Considerable effort has been placed on the automation of these techniques, incorporating algorithms for image analysis. The results of these 3-D techniques will be compared with those obtained from stereological procedures using 2-D sections. The use of these new techniques to enable computational models will be described. This work has been supported in part by the ONR D3D program.

Use of Phase Field Method as a Tool for Alloy Design: Ning Zhou[1]; *Yunzhi Wang*[1]; [1]Ohio State University

In order to incorporate realistic multi-phase microstructures in property models for microstructure and micro-mechanism based alloy design, we discuss in this presentation the use of phase field method to carry out parametric study of effect of microstructure on deformation mechanisms in multi-phase alloys. Through individual examples we show how to use directly experimental images in phase field modeling at different length scales to explore mechanisms of dislocation-precipitate interactions and how to use computer generated microstructures to study effects of variation in microstructure (such as shape, orientation, and spatial distribution of precipitates) on deformation mechanisms. Such modeling has allowed for the development of (a) criteria and constitutive laws for crystal plasticity modeling and (b) fast-acting models for direct applications in alloy design.

Materials Processing Fundamentals: Physical Metallurgy of Steel

2:00 PM
Estimation of Yield Strength of Linepipe Steel Pipes by Stress-Strain Curves Obtained from Low-Cycle Fatigue Tests: *Seok Su Sohn*[1]; Seung Youb Han[1]; Sang Yong Shin[1]; Jin-ho Bae[2]; Nack J. Kim[1]; Hyoung Seop Kim[1]; Sunghak Lee[1]; [1]Pohang University of Science and Technology; [2]POSCO Corp.

Stress-strain curves obtained from low-cycle fatigue tests which could simulate the spiral piping and flattening processes of an API X80 linepipe steels were analyzed, and the estimation method of yield strength of the outer and inner walls of the pipe was suggested. The low-cycle fatigue test was conducted on the leveled steel sheet, and strain hardening and Bauschinger effects induced from differently subjected strain histories were evaluated and combined by the Swift's equation and Bauschinger stress parameter, respectively. By analyzing stress-strain curves, yield strengths of outer and inner walls were estimated to be 592 MPa and 492 MPa, respectively, which were lower by 20~80 MPa than those of the pipe. This difference was caused by the determining procedure of pre-strain and Bauschinger stress parameter for the simulation, the preposition of same strain hardening behavior depending on strain histories, and the difference between pre-strains depending on thickness location during the piping.

2:25 PM
Evaluation of Phase Transformations in Subcritical Temperature Austenitic Nitriding: *Yingying Wei*[1]; Zbigniew Zurecki[2]; Richard Sisson[1]; [1]Worcester Polytechnic Institute; [2]Air Products and Chemicals, Inc.

Conventional nitriding of alloy steels is a multi-hour surface hardening process carried out at ferritic temperatures and following a complete heat treatment cycle: austenitizing, transformation quenching and tempering at a temperature exceeding the nitriding temperature used. A novel, subcritical-temperature austenitic nitriding process was developed to accelerate the treatment and optimize the hardness and toughness of the core and nitrided layers while minimizing the distortion of steel parts treated. Due to a transient migration of impurities to the prior austenite grain boundaries, the mechanical properties of parts nitrided by either of these two processes are influenced by tempering conditions selected: time, temperature, and heating/ cooling rates. Aiming at elimination of temper-embrittlement effects, this paper will present results of research focused on the interplay between the tempering and nitriding conditions and phase transformations in both processes. Kinetics of interstitial diffusion and phase transformation-based dimensional control of nitrided parts will be also discussed.

2:50 PM
Influence of the Hot Rolling Process on the Mechanical Behaviour of Dual Phase Steel: *Mehdi Asadi*[1]; Heinz Palkowski[2]; [1]Benteler Automotive; [2]TU Clausthal

In recent years, the increased demand for advanced high-strength steels (AHSS) mainly had been driven by the need of the automotive industry to reduce weight and to improve safety. Beside good ductility and high strength, those steels have a high bake hardening (BH) effect, giving additional contribution to the strength of structural parts, subjected to the paint baking process. In this paper we concentrate results gained for hot rolled dual phase (DP) steels.For the simulation of changing process conditions within the final hot rolling the specimens were hot deformed using different schedules of temperatures and reductions, selected according to the non-recrystallization temperature (TnRX). It was possible to refine the DP steel structure by control-ling the deformation temperature and the amount of strain below TnRX during the thermo-mechanical controlled processing (TMCP). This structure refinement resulted in an improvement of the strength and BH behaviour. A wide spectrum of mechanical properties could be obtained depending on the different hot deformation schedules. The best strength and BH levels were recorded for the deforma-tion below TnRX at the highest amount of strain.

3:15 PM
Molybdenum Effects on the Recrystallization and Austenite Decomposition of a High-Niobium HSLA Steel: *Erik Pavlina*[1]; E. Damm[2]; John Speer[3]; Chester Van Tyne[3]; [1]Pohang University of Science and Technology; [2]The Timken Company; [3]Colorado School of Mines

The effects of molybdenum (0.15 weight percent addition) on the austenite recrystallization and decomposition of nominal Fe-0.05C-0.09Nb steels was investigated. The no-recrystallization temperature was determined from multiple-step hot torsion experiments. The no-recrystallization temperature was reduced by 10 K in the molybdenum-containing alloy compared to the base alloy. The austenite decomposition reaction was examined using no-force dilatometry and dilatometry after deformation ($\varepsilon = 1.0$) experiments. Molybdenum expanded the range of cooling rate over which acicular ferrite formed and promoted formation of granular bainite at the fastest cooling rates. Deformation below the no-recrystallization temperature increased the start temperature of austenite decomposition. In addition, deformation expanded the cooling rate regime over which granular bainite forms.

3:40 PM
The Steel Super Strengthening Phenomenon During Intensive Quenching: *Nikolai Kobasko*[1]; Michael Aronov[2]; Joseph Powell[2]; [1]IQ TEchnologies, Inc.; [2]IQ TEchnology, Inc.

It is stated that quenching with high cooling rates within the martensite range is equivalent to the low temperature thermo-mechanical treatment (LTMT) process. In this case, the superficial layer acts like a blacksmith: under conditions of high compressive residual stresses the plates of martensite arise explosively, deforming the austenite and creating extremely high dislocation densities, which are frozen during rapid cooling. This process is analogous to LTMT. For intensive quenching of steel parts, different IQ systems were used. They are installed at the Center for Intensive Quenching in Akron, Ohio, and at three commercial heat-treating shops. The paper summarizes the test data, connected with the mechanism of super strengthening phenomenon, obtained during the last several years and presented in numerous papers at different heat-treating conferences and forums.

4:20 PM
Three-Dimensional Characterization of Laser-Welds in 304-L Stainless Steel: *Jonathan Madison*[1]; Larry Aagesen[2]; [1]Sandia National Laboratories; [2]University of Michigan

A variety of edge joints utilizing a continuous wave Nd:YAG laser have been produced and examined in a 304-L stainless steel to advance fundamental understanding of the linkage between processing and resultant microstructure in high-rate solidification events. Acquisition of three-dimensional reconstructions via micro-computed tomography and serial-sectioning have allowed for qualitative and quantitative characterization among a matrix of weld joints in a material system of wide use and broad applicability. The presence, variability and distribution of micro-structural features such as porosity, phase microconstituents, and grain morphology have been examined for average values, spatial distributions and joint integrity. The variability of such measures have also been related to principle processing parameters such as weld speed, power and modulation.

4:45 PM
Continuous Casting Simulation of 2304 Duplex Stainless Steel Via Horizontal Directional Solidification Technique: *Qing Qing Sun*[1]; Hong Gang Zhong[1]; Xiang Ru Chen[1]; Qi Jie Zhai[1]; [1]Shanghai University

A horizontal directional solidification equipment, with an in-situ pouring system, was employed to physically simulate the solidification behavior of continuous casting. In this paper, the 2304 duplex stainless steel (DSS 2304) was investigated using this equipment due to its microstructure produced by continuous casting process was usually not satisfied. The grain size combined with the position of columnar to equiaxed transition (CET) of DSS 2304 were observed and the results showed these microstructure characteristics were very close to those of the continuous casting slabs. In addition, the influences of pouring temperatures and cooling conditions on the CET behavior were investigated. The results revealed that the length of the columnar grains decreased with decreasing the pouring temperatures and flow rates of the cooling water. Besides, the content of austenite decreases with increasing the distance from the chilled sidewall.

5:10 PM
Influence Of Cooling Rates On Nitrogen Precipitation Behaviors And The Ferrite Fraction In Cast 2507 Super Duplex Stainless Steel: *Dong Liang*[1]; Honggang Zhong[1]; Zhenxing Yin[1]; Qijie Zhai[1]; [1]Shanghai University

2507 super duplex stainless steel (SDSS) has been widely applied in a marine environment, attributing to its excellent pitting corrosion resistance and mechanical properties which are particularly determined by the nitrogen precipitation behaviors and volume fraction of ferrite. In this paper, various cooling rates were obtained by applying four different moulds with the common gating system. By which the influence of cooling rates on nitrogen precipitation behaviors and the ferrite fraction in cast 2507 SDSS was comparatively investigated. The results showed that nitrogen porosity could easily precipitate in cast 2507 SDSS under standard atmospheric pressure. The number of nitrogen holes increased with decreasing the cooling rates, and the holes mainly distributed in three zones, i.e. the interface between the horizontal and vertical columnar grains, top vertical columnar grains and the final solidification region. Additionally, higher ferrite fraction was obtained with lower cooling rates.

5:35 PM
Microstructure and Corrosion Behaviour of TiC Reinforced Duplex Stainless Steels Matrix Composites Synthesized by Laser Melt Injection: *Babatunde Obadele*[1]; Peter Olubambi[1]; Oluwagbenga Johnson[1]; [1]Tshwane University of Technology

The microstructure and corrosion behaviour of titanium carbide (TiC) reinforced duplex stainless steel matrix surface composites synthesized by laser melt injection technique was investigated. The surface melting operation was conducted using a 4.4 kW CW Nd:YAG laser with laser power of 1.5 kW, scanning speed of 0.4 to 1.0 m/min, beam size of 3 mm and argon shield gas flow rate of 4 L/min. The morphologies and microstructures of the coatings examined using SEM revealed homogeneous distribution of fine precipitates of TiC in the matrix, while XRD analysis confirm no phase changes. TiC addition significantly increased hardness values from 236 to 547 Hv0.1 but had decreased the corrosion resistance of the steels in 3.5% NaCl possibly due to the inter-granular carbide coating that prevented chromium from forming continuous passive oxide layers.

2:00 PM

Studies of Thermophysical Properties of Metals and Semiconductors by Containerless Processing under Microgravity: *Achim Seidel*[1]; Wolfgang Soellner[1]; Christian Stenzel[1]; [1]Astrium

Electromagnetic levitation under microgravity provides unique opportunities for the investigation of liquid metals, alloys and semiconductors, both above and below their melting temperatures, with minimized disturbances of the sample under investigation. The opportunity to perform such experiments will soon be available on the ISS with the EML payload which is currently being integrated. With its high-performance diagnostics systems EML allows to measure various physical properties such as heat capacity, enthalpy of fusion, viscosity, surface tension, thermal expansion coefficient, and electrical conductivity. In studies of nucleation and solidification phenomena the nucleation kinetics, phase selection, and solidification velocity can be determined. Advanced measurement capabilities currently being studied include the measurement and control of the residual oxygen content of the process atmosphere and a complementary inductive technique to measure thermophysical properties.

Advanced Measurement Devices for the Microgravity Electromagnetic Levitation Facility EML: *Juergen Brillo*[1]; Holger Fritze[2]; Georg Lohöfer[1]; Michal Schulz[2]; Christian Stenzel[3]; [1]DLR; [2]TU-Clausthal; [3]Astrium

For liquid metals and alloys, the most prominent and ubiquitous surface active element is oxygen. A few ppm can cause a dramatic decrease of the surface tension with a sign-reversal of its temperature coefficient. To obtain reliable surface tension data, measured in electromagnetic levitation on ground or under microgravity, monitoring and control of the oxygen partial pressure in the processing environment is indispensable. For this purpose, an oxygen sensing and control (OSC) system, based on a zirconia oxygen ion pump, has been developed by ESA (contract 19963/07/NL/PM). We report on field tests interfacing the OSC with an electromagnetic levitator. Results of surface tension measurements will be presented for pure liquid metals and alloys as function of temperature, oxygen partial pressure, and alloy composition. These data give insight into the oxygen interaction with liquid metal surfaces. Established thermodynamic models will be critically discussed.

3:00 PM

Electrostatic Levitation Furnace for the ISS: *Keiji Murakami*[1]; Naokiyo Koshikawa[1]; Kohichi Shibasaki[1]; Takehiko Ishikawa[1]; Junpei Okada[1]; Tetsuya Takada[2]; Tatsuya Arai[2]; Naoki Fujino[2]; Yukiko Yamaura[2]; [1]JAXA; [2]IHI Aerospace

JAXA (Japan Aerospace Exploration Agency) has just started the development of Electrostatic Levitation Furnce to be launched in 2014 for the ISS.This furnace can control the sample position with electrostatic force and heat it above 2000 degree Celsius using semiconductor laser from four different directions. The announcement of Opportunity will be issued soon for this furnce.In this presentation, we will show the specifications of this furnace and also the development schedule.

Thermophysical Property Measurements Under Reduced Gravity Conditions: Evolution and Status of theThermoLab Project

: *H-J Fecht*[1]; R.K. Wunderlich[1]; L. Battezzati[2]; E. Ricci[3]; J. Etay[4]; S. Seetharaman[5]; J. Brillo[6]; M. Watanabe[7]; K. Kelton[8]; D.M. Matson[9]; Robert Hyers[10]; [1]U. Ulm; [2]Universita di Torino; [3]CNR-IENI; [4]CNRS, SIMAP-EPM, PHELMA-Campus; [5]KTH Royal Institute of Technology, ; [6]Deutsches Zentrum für Luft- und Raumfahrt, ; [7]Gakushin University; [8]Washington University; [9]Tufts University; [10]University of Massachusetts

Thermophysical property values of industrial alloys in the liquid phase provide important input data for the modelling of casting and solidification in industrial metallurgical processes. Owing to the difficulty of handling metallic alloys in the liquid phase there is a considerable need of accurate thermophysical property values in the liquid phase which pertains in particular to high melting point reactive alloys such as Ti-alloys. The ThermoLab project was conceived to alleviate this need by using containerless processing techniques based on electromagnetic levitation in ground based laboratory and under reduced gravity conditions for thermophysical property measurement. In addition, a ground based measurement programme using, where possible, conventional thermoanalytic methods was performed. Properties of interest include calorimetric properties, density, surface tension and viscosity and the electrical conductivity. Alloys of interest are Ti-based alloys, Fe-alloys, Ni-based superalloys and Cu-alloys which are suggested by an industrial project user group. In the course of the project extensive use was made of parabolic flights for the measurement of the surface tension and the viscosity and of TEXUS sounding rocket flights. In addition to the experimental programme ThermoLab is concerned with the modeling of non-contact thermophysical property measurements in an electromagnetic levitation device including the development and verification of non-contact calorimetry and considerations of the influence of fluid flow on viscosity measurements by the oscillating drop method. Another aspect of modelling is concerned with the surface tension in particular the influence of surface active elements on the temperature dependence of the surface tension and with the calculation of phase diagrams. An overview will be given of the current status of the project, recent results and the progress towards implementation of this programme on the International Space Station.

Electrostatic Levitation: A Tool to Support Materials Research in Microgravity: *Jan Rogers*[1]; Michael SanSoucie[1]; [1]NASA/MSFC

Containerless processing represents an important topic for materials research in microgravity. Levitated specimens are free from contact with a container, which permits studies of deeply undercooled melts, and high-temperature, highly reactive materials. Containerless processing provides data for studies of thermophysical properties, phase equilibria, metastable state formation, microstructure formation, undercooling, and nucleation. The European Space Agency (ESA) and the German Aerospace Center (DLR) jointly developed an electromagnetic levitator facility (MSL-EML) for containerless materials processing in space. The electrostatic levitator (ESL) facility at the Marshall Space Flight Center provides support for the development of containerless processing studies for the ISS. Apparatus and techniques have been developed to use the ESL to provide data for phase diagram determination, creep resistance, emissivity, specific heat, density/thermal expansion, viscosity, surface tension and triggered nucleation of melts.The capabilities and results from selected ESL-based characterization studies performed at NASA's Marshall Space Flight Center will be presented.

4:55 PM Invited
Novel Needle-Network Multi-Scale Model for the Solidification of Highly Branched Dendritic Microstructures: Damien Tourret[1]; *Alain Karma*[1]; [1]Northeastern University

A novel multi-scale modeling approach is proposed to investigate quantitatively the solidification of large dendritic arrays on a scale much larger than the diffusion length. Dendritic branches are represented as a network of "needle crystals" on a scale larger than the tip radius. The tip radius and velocity of each needle is deduced from a standard microscopic solvability condition on the inner tip scale, and a "Flux Intensity Factor" (FIF), measuring the strength of the solutal diffusion gradient at the tip on the scale of the system. The FIF is mathematically isomorphic to the stress intensity factor for pure anti-plane shear and is evaluated using the fracture mechanics J-integral. The method is benchmarked against two-dimensional phase-field simulations on massively parallel Graphic Processing Units. Results demonstrate the power of this approach to simulate complex dendritic microstructures directionally solidified under microgravity conditions and to investigate the growth competition of misoriented columnar grains.

5:30 PM
Status of Viscosity Measurements by the Oscillating Drop Method in an Electromagnetic Levitation Device under Reduced Gravity Conditions: Jacqueline Etay[1]; Ivan Egry[2]; Koulis Pericleous[3]; *Rainer Wunderlich*[4]; [1]CNRS SIMAP-EPM; [2]DLR; [3]University of Greenwich; [4]Universitaet Ulm

The oscillating drop method in an electromagnetic levitation device under reduced gravity conditions has found wide applications for surface tension and viscosity measurements of high temperature reactive metallic alloys. Microgravity conditions are required because under 1-g conditions the strong levitation fields cause turbulent fluid flow which impedes the evaluation of the viscosity from the measured damping time constant of the surface oscillations. Magnetohyrodynamic modelling predicted a dependence of the damping time constant on the amplitude of the surface oscillations and on the residual positioning field. For a verification of these results a series of experiments on parabolic flights and on a TEXUS sounding were performed. The results indicate an effect of the initial surface oscillation amplitude and an effect of the positioning field on the damping time constant. From these findings limiting values of control parameters for the application of the oscillating drop method in an em-levitation can be set.

Mechanical Behavior at Nanoscale I: Atomistic Modeling on Deformation Mechanisms

Modeling Dislocation Nucleation and Strength in Nanowires and Nanopilllars: Andrew Jennings[1]; *Christopher Weinberger*[2]; Julia Greer[1]; [1]California Institute of Technology; [2]Sandia National Labs

Experiments have shown that plasticity in confined volume single crystals can be controlled either through single arm sources or dislocation nucleation; the transitions of which are size and microstructure dependent. Here, we develop a simple continuum model that captures the activation energy and activation volume of dislocation nucleation from free surfaces. The nucleation strength dependence on crystal orientation, surface facets and material properties are investigated and compared against traditional single arm source operation. This provides a map for transitions from conventional source limited plasticity controlled by single arm sources to surface nucleation.

2:30 PM Invited
Interface-Facilitated Twinning/De-Twinning: *Jian Wang*[1]; Nan Li[1]; Irene Beyerlein[1]; Nathan Mara[1]; Amit Misra[1]; [1]Los Alamos National Laboratory

We report recent work on twinning and detwinning in fcc and hcp metals and Cu/Nb multilsyers based on the in situ and ex situ TEM observations and molecular dynamics simulations. We found that interfaces (structures and slip systems across interface) play a crucial role in facilitating twinning and de-twinning. Four aspects are discussed. (1) Zeor-strain twinning/detwinning in single-phase fcc metals is achieved in association of incoherent twin boundary; (2) Cu-Ag coherent interface facilitates deformation twinning in Cu via slip transmissnion; (3) Cu-Nb incoherent {112} interface facilitates twinning in Cu due to the presence of the preferred slip systems across interface; and (4) deformation twinning in hcp metals nucleates at low misorientation angle grain boundaries. The main conclusion is that the atomic structures of interfaces (twin boundaries, two-phase interfaces, and grain boundaries) play a crucial role in nucleating and propagating deformation twins.

3:00 PM
Revealing the Failure Mechanisms in Nanomaterial Electrodes for Lithium Ion Batteries: *Ting Zhu*[1]; Shan Huang[1]; Xiaohua Liu[2]; Jianyu Huang[2]; [1]Georgia Institute of Technology; [2]Sandia National Laboratories

Lithium ion batteries (LIBs) are critically important for a wide range of applications, from portable electronics to electric vehicles. We made in situ observations of deformation and fracture in single nanowire/nanoparticle electrodes using a nanobattery cell inside a transmission electron microscope. Novel phenomena were discovered, including the size dependent fracture in silicon nanoparticles, anisotropic swelling and self-splitting in silicon nanowires, reversible nanoporosity formation in germanium nanowires during cycling, and cracking in the coatings of tin oxide nanowires. The multiscale chemomechanics models were developed to reveal the mechanistic origin of failures. The results provide insights into the electrochemically induced microstructural evolution in nanomaterial electrodes, and have implications for designing high capacity electrodes in LIBs.

3:20 PM
Effects of Size and Microstructure in Compression of Nanoscale Metallic Pillars by Molecular Dynamics Simulation: *Frederic Sansoz*[1]; [1]University of Vermont

This talk presents some recent advances using a new atomistic simulation technique to quantitatively examine how random dislocation networks evolve during deformation of nanoscale Cu pillars. In particular, this study aims to provide fundamental understanding of differences in finite-temperature plastic deformation between perfectly-crystalline nanocrystals and those containing preexisting dislocations. The technique used enables the simulation of key mechanisms of nanoscale plasticity observed in the past in nanopillars with different methods, such as in-situ nanocompression experiments or DDD simulations. Remarkably, atomistic simulations show that <111> Cu pillars less than 75 nm in diameter with a high initial dislocation density exhibit the same flow stress scaling in compression, as a function of pillar diameter, than that observed experimentally in Cu crystals with larger diameters and smaller densities. A deformation mechanism map is developed for Cu crystals with different diameters, and used to explain the origin of size-dependent plasticity in nanoscale fcc crystals.

3:40 PM
Emission of Dislocations from Random Grain Boundaries in Nanocrystalline FCC Materials: *Laura Patrick*[1]; Diana Farkas[1]; [1]Virginia Tech

We report a comparative study of dislocation emission from grain boundaries using model interatomic potentials representing various FCC metals. Molecular dynamics simulation techniques were used to apply virtual tensile tests to simulated samples with random tilt grain boundaries and a 40nm average grain size. The emission of dislocations resulting from tensile straining was analyzed in detail. Emission of leading, trailing and partial dislocations was observed at specific values of the strain that varied depending on the interatomic potential used. In addition to dislocation emission and motion, we analyzed the inhomogeneity of the strain in various regions of the samples. The qualitative pattern of dislocation emission and distribution of the overall strain was remarkably similar for all interatomic potentials analyzed. The results emphasize the critical role of sample geometry and microstructure in determining overall mechanical behavior.

Size-Affected Behavior in Pure Compression of Micron-Sized Metallic Crystals – a Theoretical Study: *Satish Rao*[1]; Dennis Dimiduk[2]; Michael Uchic[2]; Triplicane Parthasarathy[1]; Jaafar El-Awady[3]; Christopher Woodward[2]; [1]UES Inc.; [2]Air Force Research Laboratory; [3]Johns Hopkins University

Experimental studies show strong strengthening effects for micrometer-scale FCC as well as two-phase superalloy crystals, even at high initial dislocation densities. This talk shows results from large-scale 3-D discrete dislocation simulations (DDS) used to explicitly model the deformation behavior of FCC Ni as well as superalloy microcrystals under single-slip conditions. The study shows that two size-sensitive athermal hardening processes, beyond forest and precipitation hardening, are sufficient to develop the dimensional scaling of the flow stress, stochastic stress variation, flow intermittency and, high initial strain-hardening rates, similar to experimental observations for various materials. One mechanism, source-truncation hardening, is especially potent in micrometer-scale volumes. A second mechanism, termed exhaustion hardening, results from a break-down of the mean-field conditions for forest hardening in small volumes, thus biasing the statistics of ordinary dislocation processes. Effects of thermally activated cross-slip on the stress-strain behavior of microcrystals of Ni is also discussed.

4:40 PM
Nanoscale Investigation of Twinning and Detwinning during Strain-Path Changes in Magnesium: *Mehul Bhatia*[1]; Kiran Solanki[2]; Amitava Moitra[3]; [1]CAVS - Center for Advanced Vehicular System; [2]Arizona State University; [3]Pennsylvania State University

Plastic deformations in hexagonal materials are accommodated through the activation of diverse slip and twinning modes, which are controlled by critical resolve shear stresses and crystallographic orientations. In this work, we investigate the strain-path changes in single crystal and nano-crystalline magnesium to elucidate the load reversal effect on reported {10-12} <10-11> twinning and detwinning behavior using molecular dynamics. Simulation results indicate that twinning and detwinning alternates with the reverse loading along [0001] direction, i.e. most of the twins formed during tension, are removed when the load is reversed. The contributions of twinning with strain during deformation were evaluated based on the quantitative statistic of the twin area fraction. Yield asymmetry is more prominent in poly-crystal magnesium compared to single crystal magnesium. The significance of this research is that atomistic simulations of this ilk can help improve continuum strain hardening models for the HCP class of materials.

5:00 PM
Molecular Dynamics Study of Deformation Mechanism Map of Nanostructured Metal: Shigenobu Ogata[1]; *Yunjiang Wang*[1]; Guo-Jie Gao[1]; [1]Osaka University

Deformation mechanism map has been well established for conventional coarse-grained materials by H. J. Frost and M. F. Ashby[1], but there is little knowledge about the creep mechanism of nanocrystalline metals. Here we use classical molecular dynamic to draw a creep-mechanism map for nanoscale copper with grain size down to about 10 nm. We observe a transition from diffusive deformation at high temperature, low stress to displacive deformation at low temperature, high stress. The physical mechanism underlying the interesting mechanism transition will be explained by the competition among different stress-driven thermal activated processes.

5:20 PM
Defect-Free Core/Shell Nanowires Based on New Misfit Strain Relaxation Mechanisms: *Haijian Chu*[1]; Jian Wang[2]; Caizhi Zhou[2]; Irene Beyerlein[2]; [1]Yangzhou University; Los Alamos National Laboratory; [2]Los Alamos National Laboratory

Combining TEM observation and defect theory, we proposed and demonstrated a relaxation mechanism for misfit strain in core/shell nanowires, in which glide dislocations nucleate from surfaces. To predict the critical shell thickness corresponding to defect-free core/shell nanowires (NWs), we, for the first time, developed an accurate expression in describing the self-energy of a misfit elliptical dislocation loop in an anisotropic crystal that considers the influence of loop circumference, shape, and dislocation core radius on the self-energy. Using the energy formula, we systematically predict the critical shell thickness for defect-free Ge/Si core/shell NWs as a function of growth direction. Significantly the numerical results for the critical shell thickness are consistent with experimental results.

5:40 PM
Core Properties of Mixed Dislocations in BCC Iron: *Emmanuel Clouet*[1]; Mathilde Miguras[1]; Mathieu Albagnac[1]; [1]SRMP, CEA Saclay

We used atomic simulations with an empirical potential to study core properties of mixed dislocations in bcc iron. All studied dislocations have a 1/2[111] Burgers vector and are gliding on a {110} plane. The lowest core energy is obtained for the screw orientation. Variations of the core energy for a character lower than ~30° agree with a kinked dislocation description, whereas the core energy is quite constant beyond. The Peierls barriers, under zero stress, have also been calculated. The highest barrier is obtained for a mixed dislocation with a character ~70.5°. The estimation of the Peierls stress from these different barriers shows that the screw orientation is the hardest to make glide. The ~70.5° mixed orientation is also associated with a high Peierls stress.We then use ab initio calculations to look more precisely to the core properties of this ~70.5° mixed dislocation.

Mechanical Behavior Related to Interface Physics: Interface Evolution under Mechanical Loading: Experiment, Characterization, and Theoretical Modeling

2:00 PM Keynote

FCC/BCC Interface Evolution in Severe Plastic Deformation: *Irene Beyerlein*[1]; Jian Wang[1]; Nathan Mara[1]; Nathan Mara[1]; [1]Los Alamos National Laboratory

The goal of this work is to determine the class of bi-metal interfaces that will create composite materials with extraordinary failure resistance under extreme mechanical strains. The evolution of bi-metal interface properties were studied in Cu-Nb multi-layered composites synthesized using a severe plastic deformation (SPD) technique called accumulative roll bonding (ARB). EBSD and TEM analyses strongly suggest that most interfaces in nanolayered ARB material are {112}fcc//{112}bcc with a Kurdjumov-Sachs orientation relationship. Atomistic simulation, dislocation theory, and polycrystal plasticity modeling are employed to determine the structural aspects that make this interface stable under SPD and its role in governing slip and twinning activity.

2:30 PM Keynote

Thermo-Mechanical Solution of Film/Substrate Systems under Local Thermal Load and Its Applications: *Huiling Duan*[1]; [1]Peking University

Film/substrate structures are widely used in microelectronic and optoelectronic devices for decades and these structures usually undergo a local thermal load in applications. For example, the thermal atomic force microscopy (AFM) or scanning thermal microscopy (SThM) probe is used to heat poly ethylene terephthalate films to induce crystallization of the material, and the SThM is also used in nanoscale lithography on molecular resist films to fabricate various microstructures. A similar situation arises in the Laser Lift-Off technique (LLO) for separating GaN films from substrates. We present the solutions of temperature and stresses in a film/substrate structure under a local thermal load on the film surface. Then, this thermo-mechanical solution is applied to analysis of the temperature distribution, stresses, and damage of a GaN/sapphire system during the LLO process. It is shown that the laser with the Gaussian distribution of energy density can avoid less damage to the GaN films.

3:00 PM

Computational and Experimental Investigation of the Interfacial Dynamic Compressive Behavior of High Strength Aluminum Alloys: William Lee[1]; Pratheek Shanthraj[1]; Hanadi Salem[2]; *Mohammed Zikry*[1]; [1]North Carolina State University; [2]The American University in Cairo

The objective of this study is to identify the dominant microstructural and dislocation mechanisms related to the high strength and ductile behavior of high strength aluminum alloys, and how high strain-rate loading conditions would affect overall behavior on scales ranging from the nano to micro scales. Characterization techniques and specialized microstructurally-based finite-element (FE) analyses based on a dislocation-density based multiple-slip formulation that accounts for an explicit crystallographic and morphological interfacial representation of Ω and θ' precipitates and their rational orientation relations was conducted. As the microstructural FE predictions have indicated, and consistent with the experimental observations, the combined effects of θ' and Ω precipitates and dispersed Mn particles, acting on different crystallographic orientations, enhance the strength, the ductility, and reduce the susceptibility of high strength aluminum alloys to shear strain localization due to dynamic compressive loads.

3:15 PM

Deformation Mechanisms of Hall-Petch Strengthening in Bimodal Nanocrystalline Materials: *Chandra Pande*[1]; [1]Naval Research Laboratory

Recent experimental studies has demonstrated that polycrystals with a bimodal microstructure which consists of a mixture of nanoscale and microscale grains, has significantly higher tensile ductility with only slight reduction in tensile strength when compared to an all-nanocrystalline polycrystal. Bimodal microstructure is also expected to improve the fracture toughness and lower fatigue crack growth rates. We present a theoretical model predicting Hall Petch strengthening for such a system as a function of microstructure variables such as volume fraction of the larger grains and show that the predictions are consistent with experiments.

3:30 PM

Exploring and Exploiting Physical Properties of Molecular Crystals Subjected to Mechanical Milling: *M. Teresa Carvajal*[1]; Yuanyuan Jing[1]; Andrew Otte[1]; John Blendell[1]; [1]Purdue University

Mechanical stresses applied to molecule organic solids produce structural changes in the crystal lattice. This often affects key performance properties of pharmaceutical products and compromises their physical stability. There is little information on the structure-property-response of molecular organic crystals to stress. Particularly on microstructural defects such as dislocations and their influence on interfacial phenomena and surface interactions of crystalline particles. The goals of this study are to directly observe, via AFM nano-indentation, the microstructural response to applied mechanical loads and to elucidate their relationship with the bulk and surface properties via DSC and by IGC/XPS, respectively. Of specific interest are the differences in interfacial energies between the native crystals in contact with the defected crystals or the amorphous form. The results show that a systematic characterization of milled materials can be a highly informative tool for a fundamental insight of milling knowing consequences and potentially predict and control bulk behavior.

3:55 PM Keynote

Characterization and Modeling of Heterogeneous Deformation near Grain Boundaries in Titanium and Ti-5Al-2.5Sn: *Thomas Bieler*[1]; Darren Mason[2]; Claudio Zambaldi[3]; Philip Eisenlohr[3]; Chen Zhang[1]; Hongmei Li[1]; Leyun Wang[1]; Yiyi Yang[1]; Carl Boehlert[1]; Martin Crimp[1]; Rozaliya Barabash[4]; Wenjun Liu[5]; [1]Michigan State University; [2]Albion College; [3]Max-Planck-Institut für Eisenforschung; [4]Oak Ridge National Laboratory; [5]Argonne National Laboratory

The anisotropic deformation of commercially pure Ti and Ti-5Al-2.5Sn was investigated in tension and bending at 23C using interrupted quasi-static and in-situ creep tests. Initially polished and deformed microstructures were characterized using several electron microscopy, 3-D x-ray microdiffraction, and surface characterization methods. Patches of microstructure that exhibited heterogeneous slip and grain boundary ledge development were computationally deformed using crystal plasticity finite element code to simulate the physical experiments. Phenomenological hardening models were optimized using comparisons with conical indentation experiments. Ledge development was investigated using a new damage model that accounts for dislocation density mismatch at grain boundaries. By combining a tensorial measure of in-plane grain boundary deformation with localized mode-II shear stresses, a new metric was developed that distinguished between ledge-forming and topographically smooth grain boundaries. Comparisons between measured and simulated slip behavior reveal discrepancies between observed and simulated deformation behavior, and necessary improvements in model assumptions have been identified.

4:25 PM Keynote
Phase Field Modeling for the Effects of Coherency Stress and Vacancy Source/Sinks on the Interface Sharpening and Intermixing Rate in Coherent Nano-Multilayers: Haibo Wan[1]; *Yao Shen*[1]; Xuejun Jin[1]; [1]Shanghai Jiao Tong University

A phase-field model for vacancy-mediated interdiffusion in coherent multilayers is developed, focusing on the effects of coherency stress and vacancy source/sinks on the interface sharpening and intermixing rate. Two limiting cases are considered: vacancy source/sinks are uniformly and densely distributed, or not present at all. Remarkable interface sharpening is observed (1) at the presence of dense vacancy source/sinks when the two layers differ greatly in vacancy formation energy, or (2) at the absence of source/sinks when they differ greatly in vacancy migration energy. The coherency stress is found to promote the interface sharpening and intermixing rate if the faster component has the smaller lattice constant; otherwise, the stress has the opposite effect. When the difference in vacancy formation energy of the two components is much larger than in migration energies, the intermixing without vacancy source/sinks is faster than with dense source/sink; otherwise, it is slower than with dense source/sinks.

4:55 PM
Electron Backscatter Diffraction (EBSD) Measured Boundary Characteristics of Cu/Nb Nanolamellar Composites Fabricated by Accumulative Roll Bonding (ARB): *Rodney McCabe*[1]; John Carpenter[1]; Jonathan Ledonne[2]; Anthony Rollett[2]; Nathan Mara[1]; [1]Los Alamos National Laboratory; [2]Carnegie Mellon University

The interface characteristics of Cu/Nb nanolamellar composites fabricated via ARB are investigated as a function of layer thickness using EBSD. Starting with single, polycrystalline layers of Cu and Nb, repeated ARB steps are used to fabricate multilayers with nominal layer thicknesses (h) ranging from tens of microns to tens of nanometers. Neutron diffraction, performed previously, was used to investigate the evolving texture and found that an atypical rolling texture saturated at h = 128 nm becoming stable with further plastic strain. EBSD is used in this study to examine interface boundary misorientations and plane normal directions within a microstructural reference frame allowing for distinctions to be made between interfacial grains and those associated with the bulk. The EBSD data is used both to study the orientation relationships that occur across hetero-phase interfaces as well as to ascertain whether steady state and/or preferred boundaries are present at the various length scales.

5:10 PM
Chemical Changes Underlying Aging of Silica in Nano-mechanical Contacts: *Yun Liu*[1]; Izabela Szlufarska[1]; [1]University of Wisconsin - Madison

Friction and adhesion of silica are important both in naturally occurring phenomena, such as earthquakes, as well as in engineering applications, including wafer bonding. Molecular-level understanding of phenomena that take place in these frictional contacts is currently lacking. Here we focus specifically on aging of silica, a process by which static friction changes with time when two surfaces are held still. The origin of this behavior has been a subject of a decades-long debate. Here we will discuss chemical reactions that can lead to aging of a single-asperity silica contact in aqueous environments. Using calculations based on the Density Functional Theory and on the ReaxFF reactive force fields, we discovered that the formation of interfacial siloxane bridges can be responsible for the increase of interfacial strength. We demonstrate that the rate of this reaction slows down with time, which explains the experimentally observed logarithmic dependence of aging on hold time.

5:25 PM
Interfacial Response of Friction-Welded 304-Stainless Steel and 6061-Al in Tension: Cheng Liu[1]; Manuel Lovato[1]; *William Blumenthal*[1]; [1]Los Alamos National Laboratory

An experimental study of the interfacial response of friction-welded 304-stainless steel and 6061-aluminum under uniaxial tension loading was performed using 2-D video digital image correlation (DIC) to obtain full-field deformation mapping of dog-bone specimens perpendicular to the bonded interface. As expected, plastic deformation only occurred in the aluminum portion of the specimen. An unexpected observation was that the mechanical properties of the 6061-aluminum were no longer uniform or representative of the as-received material, but varied significantly within a small distance from the bonded interface due to the welding process. The high spatial resolution of the DIC strain technique (~0.25 mm for this application) allowed accurate evaluation of the mechanical behavior gradient in the aluminum near interface and demonstrated the usefulness of the DIC technique as a tool for improving bonding processes.

Mechanical Performance of Materials for Current and Advanced Nuclear Reactors: Mechanical and Small-Scale Testing of Reactor Materials

2:00 PM Invited
A Perspective on Current Challenges in Development and Application of Uniaxial Micro-scale Testing Techniques to Characterize the Mechanical Properties of Materials: *Paul Shade*[1]; Michael Uchic[1]; Dennis Dimiduk[1]; [1]Air Force Research Laboratory

Over the past decade, there has been considerable activity within the materials community to develop and apply mechanical testing methods that operate on micron- and sub-micron scale samples. Potential motivations for testing at small scales include the exploration of fundamental processes that govern plastic deformation and, the ability to probe for variations in properties that are sensitive to local changes in microstructure. Nonetheless, challenges remain in both conducting and interpreting experiments, which must be addressed before these techniques can be widely applied as engineering tools. Experimental challenges include slow and expensive sample fabrication techniques, limited temperature range of testing capabilities and a wide spectrum of device configurations and practices. Interpretation challenges include existence of sample-size effects, as well as a limited understanding of the mechanisms governing the transition from size-dependent to size-independent behavior. The present talk provides a selected perspective of these issues and, identifies areas for future research.

2:30 PM Invited
Benefits and Challenges of Small Scale Materials Testing for Nuclear Application: *Peter Hosemann*[1]; Daniel Kiener[2]; Stuart Maloy[3]; Jenny Martos[1]; [1]UC Berkeley; [2]Montanuniversiaet leoben; [3]LANL

Due to difficult handling of radioactive samples or the use of ion beam irradiated materials and the interest of a specific location on a given component, small scale testing is of great interest to scientists studying radiation damage in materials. While nanoindentation has been used for decades, micro compression and other more complex sample geometries have become available using Focused Ion Beam machining. We show the extent to which small scale mechanical testing on irradiated materials can be used today on structural materials but also on advanced fuel forms in order to gain a better understanding of the changes caused by radiation. However, small scale materials testing on ion beam irradiated materials are not without limitations and therefore it is important to evaluate the importance of size effects and other artifacts.

3:00 PM
Compatibility of MYRRHA Candidate Structural Materials with Lead-Bismuth Eutectic Environment: Effect of Strain Rate and Low Dissolved Oxygen Concentration: *Gunter Coen*[1]; Joris Van den Bosch[1]; Serguei Gavrilov[1]; [1]SCK-CEN

SCK•CEN has taken up the task of designing and building an accelerator driven system (ADS) cooled by lead-bismuth eutectic (LBE), called MYRRHA. To go from the basic design of the reactor towards detailed engineering, building and licensing, there is a need for conservative material data obtained in relevant conditions for the system under design. One of the material degradation effects, which is related to the interaction between the liquid LBE environment and the structural steel is liquid metal embrittlement (LME). It is a reduction of the ductility and fracture toughness of a metal when simultaneously subjected to stress and direct contact with a liquid metal. In order to obtain representative data from mechanical tests performed in LBE environment, one should investigate different factors affecting LME. In this paper, the influence of strain rate and low dissolved oxygen concentration in the LBE on the LME of T91 (modified 9Cr-1Mo) is described.

3:20 PM
Mechanical Testing of Nuclear Materials Using a MEMS Approach: *Nicholas Barbosa*[1]; David Read[1]; [1]National Institute of Standards & Tech

Miniaturization of specimens used for mechanical testing of nuclear materials is limited by the inability to adequately prepare small specimens; by the inability to test the specimens; and by uncertainty in the interpretation of results. In this presentation, a new approach to performing tests on tensile specimens with sub-millimeter gauge lengths will be discussed. Specimens were prepared through either EDM or chemical etching. A MEMS frame was used to grip the specimens and to link them to the displacement actuators and the load sensor. Displacements were measured through a digital image correlation technique applied to images captured via a microscope. The results of tests performed on 302 stainless steel in the annealed and full-hard conditions will be used to demonstrate the technique and to highlight the challenges and benefits associated with performing bulk measurements at this scale.

3:40 PM
Grain Size Effects in Micro-Scale Tensile Testing of 316L Stainless Steel: *Whitney Poling*[1]; Nicholas Barbosa[2]; Kip Findley[1]; David Read[2]; [1]Colorado School of Mines; [2]National Institute of Standards and Technology

A MEMS-based micro-tensile system was developed at NIST and is capable of testing rectangular tensile specimens with gage section dimensions on the order of tens to hundreds of microns. A potential application is in-situ tensile testing in harsh environments, such as a nuclear reactor pressure vessel. The test results can be influenced by microstructure size effects due to the size-scale of the specimens, so these size effects must be well understood to obtain reliable bulk mechanical property information from the test. Currently, grain size effects are being studied with cold-rolled 316L stainless steel sheet that is annealed to obtain target grain diameters of 5, 10 and 20 microns. With increasing grain size, fewer grains comprise the gage cross-section of the micro-tensile specimens. The effect of the number of grains in the micro-tensile specimen cross-section on measured mechanical properties and their agreement with results from conventional-sized tensile tests is being investigated.

4:20 PM
Small Specimen Testing for Evaluating Radiation-Induced Changes in Mechanical Properties of Structural Reactor Materials at High Irradiation Doses: *Ellen Rabenberg*[1]; Kyle Knori[1]; Brian Jaques[1]; Bulent Sencer[2]; Darryl Butt[1]; F.A. Garner[3]; [1]Boise State University; [2]Idaho National Laboratory; [3]Radiation Effects Consulting

During irradiation, the mechanical properties of reactor components progressively change, affecting its structural integrity; namely, ductility. It has previously been observed that hardening from radiation exposure reduces the ductility in metals. However, prior studies involving 12Cr18Ni10Ti austenitic steel report a regained ductility at doses higher than 55 dpa due to a gamma to alpha martensitic transformation, which occurs via the propagation of a deformation wave through the gage section of a tensile specimen. This “deformation wave” is being studied using miniature specimen testing. The shear punch and tensile tests are ideal as they allow post-irradiation examination in lightly shielded environments rather than in a hot cell. Correlations between these non-standard tests have been performed for 304-type stainless and MA957 ODS steels. Different factors affecting correlations between shear punch and tensile experiments and martensite formation, such as surface roughness and applied strain rate, are summarized for both un-irradiated and irradiated metals.

4:40 PM
Study of Size and Irradiation Effects on Mechanical Properties of Silicon Carbide Micropillars: *Chansun Shin*[1]; Hyung-Ha Jin[1]; Dong-Jin Kim[1]; Junhyun Kwon[1]; [1]Korea Atomic Energy Research Institute

Silicon carbide (SiC) and SiC/SiC composites have been proposed as a promising candidate material for structural components in fusion reactors due to its good thermal and mechanical properties under high temperature and irradiation. Characterization of the mechanical properties such as fracture strength is important to ensuring the reliability of ceramic structures. In this study, SiC micropillars of various sizes were fabricated by mask and inductively coupled plasma etching technique and compressed by using flat punch nanoindentation. Compressive fracture strength showed a clear specimen size effect. The strength increased from 6.5 GPa up to 18 GPa as the diameter decreased from 5.4 down to 0.7 microns. Brittle-to Ductile transition at room temperature was observed as the specimen size decreases. Ion irradiation was performed with Si ions. The effect of irradiation on the fracture strength of SiC micropillars was evaluated and the potential of this method will be discussed.

5:00 PM
Multi-Axial Mechanical Behavior of Zircaloy-4 and Effect on Initial Texture: Akawat Siriruk[1]; Matthew Kant[1]; *Dayakar Penumadu*[1]; Elena Garlea[2]; [1]University of Tennessee; [2]Y-12 National Security Complex

Zircaloy-4 (Zr-4) cylindrical tubes are commonly used in nuclear industry and for many applications requiring mechanical stability in extreme environments. Due to its crystal structure and processing techniques, significant texture and anisotropic mechanical properties are possible. In this study, combined axial-torsional testing is employed to probe macroscopic stress-strain behavior in three dimensions and corresponding yield surface in octahedral plane is obtained. Zr-4 rod samples are evaluated under pure tension and torsion, and Zr-4 tube samples are characterized under pure tension, torsion, and combined (tension and torsion) loading. 3-D digital image correlation using VIC-3D system was implemented to evaluate surface deformation patterns for evaluating strain localizations. Limited x-ray diffraction based texture analysis is performed to obtain an understanding of the effect of loading path on the material texture. Pole figures for Zr-4 rods and tubes are obtained both in axial and circumferential directions.

2:00 PM
Development of Al and Co Nanowires by the Method of Phase Separation: *Tanjore Jayaraman*[1]; Yuan Tian[1]; Jeremy Anderson[1]; Jeffrey Shield[1]; [1]University of Nebraska

Ability to manipulate nanoscale lengths is important for controlling physical properties in materials including mechanical, electronic, optical, and magnetic properties. Nanocomposites or array of nanowires have wide range of applications in viz. catalysis, solar cells, sensor technology (biological, chemical, photonic, magnetic, and gas). Nanowires with diameters less than 10 nm are known to exhibit many interesting and potentially useful properties. In this work we present the development of sub-10 nm array of nanowires in materials systems (Al-Si, Co-Si and Co-Al), that naturally separate into two distinct phases, and their characterization by x-ray diffraction, scanning electron microscopy, and transmission electron microscopy. By controlling various processing parameters, during physical vapor deposition (magnetron sputtering), including type of substrates, argon flow rate, RF power, substrate temperature, and substrate cooling rate during deposition - the desired two phase fibrous morphology of non-magnetic (Al) and magnetic (Co) nanocomposites were obtained.

2:20 PM
Thermal Modeling of Carbon Nanotube Growth Experiments: Kevin Maxwell[1]; Benji Maruyama[1]; *Jaimie Tiley*[1]; [1]US Air Force Research Laboratory

The use of carbon nanotubes in structural applications requires careful alignment of growth directions. To further refine the processing of these structures, researchers have designed specific heating systems to control growth kinetics and nanotube morphology. In this research, the finite element software Comsol was used to model the laser heating induced thermal behavior of carbon nanotube growth experiments. The analysis consisted of a coupled, multi-scale model governed by the 3D heat equation and a formulation for laser power and intensity. Data for the temperature of the silicon substrate used in the experiments was used to calibrate the model parameters, and the temperature of the nano-scale catalyst particles used to grow carbon nanotubes was predicted from the calibrated model. The results indicate that the temperature of the catalyst particles is similar to the temperature of the silicon substrate and depends on a particle's position with respect to the laser beam.

2:40 PM
Boron Nitride Nanotube Reinforced Aluminum Nanocomposites: *Debrupa Lahiri*[1]; Virendra Singh[2]; Mingdong Bao[1]; Luhua Li[3]; Sudipta Seal[2]; Ying Chen[3]; Arvind Agarwal[1]; [1]Florida International University; [2]University of Central Florida; [3]Deakin University

Boron nitride nanotubes (BNNT), with its excellent mechanical properties (E – 1200 GPa, tensile strength > 24 GPa) and low density (2.25 g.cm-3), is a potential reinforcement for lightweight metal-matrix composites for structural applications. This study reports synthesis and characterization of an aluminum matrix composite reinforced with BNNT. Al-BNNT composite, with 2 and 5 vol.% of reinforcement, is synthesized using two routes – (i) spark plasma sintering; and (ii) cold pressing and sintering in an inert atmosphere. A comparative analysis on densification, microstructural evolution and strengthening of the composite structures, synthesized using the different process routes, is presented.

3:00 PM
Fabrication of Aluminum Matrix Composite Reinforced by Intermetallic Compounds of Various Nano/Micro-Architectures: Can Zhu[1]; Yufeng Wu[1]; *Gap-Yong Kim*[1]; [1]Iowa State University

A novel fabrication technique using spray patterning and pressure-assisted reaction sintering that is capable of synthesizing hierarchically structured metal matrix composites is introduced. The approach uniquely integrates bottom-up and top-down fabrication methods to control nano/microstructures while effectively building large structural components. The spray patterning is utilized to transport Al and/or Ni nanoparticles dispersed in nickel nitrate hexahydrate solution to create nano/micro-architectures that form the reinforcing phase on an aluminum sheet. The patterned sheets are then densified and synthesized into a composite by forming intermetallic compounds of various configurations. Several configurations are fabricated, and bend test results are performed to understand the strengthening contributions from the hierarchical levels.

3:40 PM Invited
From Hard Coatings to Thermoelectrics: Effects of Nanostructure on Fundamental Physical Properties of $Hf_{1-x}Al_xN$ Alloys: *Brandon Howe*[1]; Andrey Voevodin[1]; Joseph Greene[2]; Ivan Petrov[2]; [1]Air Force Research Laboratory; [2]University of Illinois

We use the $Hf_{1-x}Al_xN$ alloy as a model system to study the effects of self-assembled and engineered nanostructures on the optical, electronic, thermal transport and elastic properties of $Hf_{1-x}Al_xN$ single crystal layers grown on MgO(001) by reactive unbalanced magnetron cosputter deposition using ellipsometry, temperature-dependent hall effect, picosecond probe thermoreflectance and acoustic transport measurements, respectively. I will continue by summarizing a systematic study into the effects of ion bombardment on single crystal reactively-sputtered $Hf_{0.7}Al_{0.3}N$/HfN superlattice layers and show that I can controllably manipulate the nanostructure in order to study its effects on the physical properties. In all, the physical properties are significantly altered by the nanostructure, leading to independent control of opto-electronic and thermal transport properties and show that by using this growth technique nanostructured transition-metal nitrides can produced which have great potential for high-temperature energy conversion applications.

4:20 PM
Formation of Nano Dispersed Ceramic-Metallic Composite Coatings: *Ratan Saha*[1]; M Farrokhzad[1]; T Khan[1]; [1]University of Calgary

The use of electrodeposited composite coatings with a nano dispersed ceramic particles have been widely considered for industrial applications in the recent years due to their enhanced hardness and wear resistance properties. In this study, nickel coating reinforced with a dispersion of nano sized Al2O3 particles was developed using electrodeposited technique and the coatings were investigated with respect to hardness and wear properties. The effects of post-deposition heat treatment on the morphology of the composite coatings were also studied. The microstructural features of the coatings were characterized by scanning electron microscopy and energy dispersive x-ray spectroscopy. Micro-indentation and wear tests were conducted to evaluate the hardness and wear resistance, respectively, of the deposited layer. The results showed that the hardness and the wear properties of the coatings increased with an increase of ceramic particles in the composite coating. The post-deposition heat treatment softens the coated layer.

4:40 PM
Microtruss Cellular Nanocomposites: *Khaled Abu Samk*[1]; Guojie Huang[2]; Milan Skocic[3]; Hatem Zurob[2]; David Embury[2]; Olivier Bouaziz[4]; Glenn Hibbard[1]; [1]University of Toronto; [2]McMaster University; [3]Grenoble Institut of Technology; [4]ArcelorMittal Research

New types of cellular nanocomposites can be created by carburizing the external surface of low carbon steel microtruss materials. Microtruss architectures are designed to resist externally applied loads through axial deformation and as such can exhibit significantly enhanced strength and stiffness when compared to conventional metal foams. They can also exhibit multifunctional characteristics such as energy absorption and thermal management. This study used the high formability of simple low carbon sheet steels to create an initial microtruss cellular architecture by plastic deformation. Mechanical strength was imparted via a graded composite structure wherein an external skin of ultrafine internal length scale martensite was created by carburizing. The microtruss nanocomposites exhibited up to a five-fold increase in compressive strength when compared to the conventional low carbon steel microtruss reference. The failure mechanisms were investigated in order to determine an optimal composite structure.

5:00 PM
Manufacturing and Characterization of an Auxetic Composite: *Fu-Pen Chiang*[1]; [1]Stony Brook University

An auxetic material has a negative Poison's ratio. As a result, it has some uncommon responses when loaded mechanically. For example, it resists indentation. Thus, the material could be used for platforms for which surface deflection due to load is not desirable. It has a very large shear modulus, thus it could be ideal as a core material for sandwich plates whose prevailing failure mode is core shear failure. Third, it also reduces noise propagation, thus it could be used as a noise insulation material. In this paper, we show how to transform an ordinary PVC foam composite into an auxetic composite by 3-D compression and heat treatment. Tests were performed to show the resulting material's resistance to indentation and low velocity impact. A sandwich plate using fiberglass face sheets was made and loaded in three-point bending. The failure mode was changed to interfacial disbond mode.

5:20 PM
Discarded Ultrafine Particulate Carbonaceous Materials Used as Reinforcers of Rubber Vulcanized Products: *Guillermo Martín-Cortés*[1]; Fabio Esper[1]; Luiz Sálvio Galvão Dantas[2]; Wildor Hennies[3]; Francisco Valenzuela-Díaz[3]; [1]Universidade Estácio de Sá; [2]Bentonisa-Bentonita do Nordeste S.A.; [3]Polytechnic School-University of São Paulo

Vulcanized rubber products as tires, auto parts, sport-shoes, and others are widely spread. Raw materials for vulcanized rubber products come from industrial process generating CO2 emissions. These products commonly use, at least 40phr of carbon-black filler obtained from petroleum in a contaminant process of incomplete burning of the fuel. NAOB® a rubber / organoclay nanocomposite material developed to make vulcanized rubber products without carbon-black is reinforced with only 10phr of organoclay. So to keep the material specific volume, maintaining or increasing its technological characteristics, additional reinforcing materials are used. Between the additional materials, are ultrafine particulate materials discarded from mining of some carbonaceous minerals that can be used directly from the mine or through an organic modification. This paper show some very good technological results obtained in rubber formulations after replacing the carbon-black by these set of materials.

5:40 PM
Properties of Additional Reinforcers Materials Used to Complement NAOB – A Rubber / Organoclay Nanocomposite Material: *Fabio Esper*[1]; Guillermo Martín-Cortés[1]; Luis Sálvio Dantas[2]; Adriana Cutrim[2]; Wildor Hennies[3]; Francisco Valenzuela-Díaz[3]; [1]Universidade Estácio de Sá; [2]Bentonisa - Bentonita do Nordeste S.A.; [3]Escola Politécnica da Universidade de São Paulo

Vulcanized rubber products are widely spread. Auto parts, tires, sport shoes and other products are examples of it. Most of the raw materials used in the formulations of vulcanized rubber products come from industrial process consuming time and energy but also generating CO2 emissions during the respective transforming processes. The traditional main reinforcing material used in rubber formulations is carbon-black which is a petroleum derivative obtained by the incomplete burning of the fossil fuel. The NAOB – a rubber / organoclay nanocomposite material was developed to make vulcanized rubber products without carbon-black. In NAOB the primary reinforcer is the organoclay, which participates in the formulation of the nanocomposite in much smaller quantities than the carbon-black. So to keep the material specific volume, maintaining or increasing its technological characteristics, additional reinforcing materials are used. This article presents some of the additional reinforcing materials for the NAOB and their technological characteristics.

2:05 PM Keynote
Microstructural Changes in Nanotwinned Cu Resulting from Unidirectional and Reversed High Pressure Torsion: C. Shute[1]; Y. Liao[1]; K. Tsuchiya[2]; Y. Zhu[3]; A. Hodge[4]; T. Barbee[5]; *Julia Weertman*[1]; [1]Northwestern University; [2]National Institute of Materials Science; [3]North Carolina State University; [4]University of Southern California; [5]Lawrence Livermore National Laboratory

The response of the microstructure of Cu samples containing aligned columns of nanotwins to extreme shear stress produced by high pressure torsion has been studied. The torsion was applied both in one direction only and reversed. It is found that under conditions of unidirectional torsion in which the overall shear strain is about 20, the shear deformation is largely confined to the near surface regions. The twins are destroyed to the depth at which the shear strain drops to about 1. Repeated reversal of the torsion up to the same overall shear strain destroys the twin structure altogether, leading to elongated grains of about 1 micrometer in length. Data will be presented of results of testing over a range of maximum torsions and numbers of reversals.

The Ultra-Small Angle X-Ray Scattering Instrument (USAXS) Instrument – Delivering Unique Science for More Than 25 Years: *Jan Ilavsky*[1]; Peter Jemian[1]; [1]APS, Argonne National Laboratory

A prototype USAXS was tested in 1985 at CHESS. In 1987, the instrument began serving users at NSLS X23A3. From 1998, the second-generation USAXS was installed at Advanced Photon Source, first at 33ID-D, then 32ID-B, and now 15ID-D. Since 1986, Gabrielle Long was the scientific lead navigating the instrument to serve a broad scientific community while continuing to develop. New geometries and uses were added: 2D collimated geometry, USAXS imaging, and lately combination with short pinhole SAXS and USAXS-XPCS. USAXS value goes beyond its user community, as it became the producer of standard samples for absolute intensity calibration. To satisfy requirement of future in-situ science investigations, upgrade plans include on-fly (continuous) scanning to reduce the measurement time of a single sample and an increase of operating energies up to 30keV. We will review the USAXS history, user science examples, and Gabrielle Long's influence on this unique and invaluable scientific resource.

Small-Angle Neutron Scattering Studies of Cement Hydration: *Andrew Allen*[1]; Jeffrey Thomas[2]; Hamlin Jennings[3]; [1]NIST; [2]Schlumberger-Doll Research ; [3]MIT

Despite much research, basic questions remain regarding the internal structure and role of water in ordinary Portland cement (OPC) concrete, the world's most widely used manufactured material. Most questions concern the primary hydration product and strength-building phase of OPC paste, the calcium silicate hydrate (C–S–H) gel, which precipitates as clusters of near-amorphous, nanoscale particles with an associated water-filled inter-particle pore system. In recent years, neutron scattering experiments, especially SANS, have made significant progress, and provided new insights into the fundamental physics and chemistry of cement hydration. For example, they reveal (for hydration under ambient conditions) that C–S–H has a higher atomic packing density than its mineral analogues, tobermorite and jennite. We can relate this to the chemical shrinkage of concrete during cement hydration, with implications for the design of new concretes incorporating pozzolanic cement additions intended to address environmental concerns and sustainability issues.

3:10 PM

Ultra-Small-Angle X-Ray Scattering—X-Ray Photon Correlation Spectroscopy Studies of Equilibrium and Nonequilibrium Dynamics: *Fan Zhang*[1]; Andrew Allen[1]; Lyle Levine[1]; Jan Ilavsky[2]; Gabrielle Long[2]; [1]National Institute of Standards and Technology; [2]Argonne National Laboratory

Ultra-small-angle X-ray scattering—X-ray photon correlation spectroscopy (USAXS-XPCS) is a new measurement technique for the study of equilibrium and slow nonequilibrium dynamics in disordered materials. Taking advantage of Bonse-Hart crystal optics, this technique fills a gap between the accessible scattering vector ranges of dynamic light scattering and conventional X-ray photon correlation spectroscopy. It also overcomes the limits of visible light scattering techniques imposed by multiple scattering and is suitable for the study of optically opaque materials containing near-micrometer sized structures. USAXS-XPCS has been applied to study the equilibrium dynamics of micrometer-sized colloidal dispersions and nonequilibrium dynamics of polymer composites and alloy steels. We anticipate that this technique will be important in the understanding of thermally-induced equilibrium dynamics of soft materials and nonequilibrium behavior of both soft and hard materials, and lead to technical payoffs in a wide range of areas such as the manufacture of self-repairing biologically critical materials.

3:25 PM Invited

Probing Materials' Reactivity Using X-Ray Pair Distribution Function Methods: *Karena Chapman*[1]; [1]Argonne National Laboratory

Understanding how advanced functional materials react and transform, at an atomic scale, is a characterization challenge with many diverse phenomena possible; components with varying particle size, morphology, and microstructure can evolve from multi-atom clusters to multi-million atom crystals. The pair distribution function (PDF) method shows great promise for providing quantitative insight such reactions. Recent advances in experimental methods, have improved the efficiency of X-ray PDF measurements, to allow time-resolved experiments with sufficient resolution to study reactions in solid materials. The PDF analysis probes the complete reaction from clusters to bulk, amorphous or crystalline, liquid or solid. This is in contrast to Bragg crystallographic analysis which is "blind" to the clusters which nucleate before growing into long-range ordered materials. The structural insights from the PDF data are obtained in parallel with phase concentration to allow different components to be distinguished and a robust quantitative analysis.

The Many Facets of Guinier-Preston Zones in Al-Rich Al-Ag: *Gernot Kostorz*[1]; [1]ETH Zurich

The solubility of silver in aluminum decreases rapidly with decreasing temperature from a maximum of about 25 at.% to less than 0.2 at.% below 200°C. Alloys containing <15 at.% Ag begin to decompose below about 420°C by forming coherent quasi-spherical Guinier-Preston zones followed by a metastable hexagonal phase and the stable Ag_2Al phase. The metastable miscibility gap has been studied by many researchers for over fifty years, but there is still no agreement on the assignment of metastable phases and temperature regimes. In particular, combined results of small-angle scattering and diffuse scattering have shed doubts on the existence of the presumed ε phase above about 170°C. These data and results of HAADF electron diffraction suggest that the zones may not always be homogeneous, but have a core-shell structure. The current state of knowledge will be assessed in the light of recent experiments and theoretical calculations published in the literature.

The Bonse-Hart Ultra-Small-Angle Scattering Camera Worldwide: Current Status: *Pete Jemian*[1]; [1]Argonne National Laboratory

The double-crystal camera design used to measure most ultra-small-angle scattering (USAS) measurements owes its name to two researchers, Ulrich Bonse and Michael Hart, who in 1965 defined the minimum geometry necessary to achieve practical measurements. Since its first incarnation in the 1949 thesis of Paul Kaesberg, the USAS instrument has undergone continual improvement in its design, leading to a wide range of scientific discovery in many fields including bone cement, energy materials, aerospace alloys, reactor steels, automotive tires, colloidal materials, flame pyrolysis, and many others. This talk will describe the development of the Bonse-Hart USAS instrument, noting those who advanced the art, and summarize the current status worldwide of instrumentation for USAS as it expands the base of scientific knowledge. This presentation is in honor of Dr. Gabrielle Long.

Waveguide-Enhanced Grazing-Incidence X-Ray Scattering: Probing Buried Nanostructures in Thin Films in Three Dimensions: *Jin Wang*[1]; Zhang Jiang[1]; [1]X-ray Science Division, Argonne National Laboratory

Grazing-incidence x-ray scattering (GIXS) can provide invaluable data to reveal structure of surfaces, interfaces and thin films. Because of their probing q-range (10-3-10 nm-1, translating to a real-space length scale ranging from 0.1 nm to 1 µm) and temporal resolution (10-3-1 s), grazing-incidence small-angle and wide-angle x-ray scattering (GI-SAXS and -WAXS) become increasingly important in characterizing nanocomposites and their formation at surfaces and interfaces in real time and real

MONDAY PM

conditions. In general, GIXS data yields only the in-plane structure and its correlation in planar samples. X-ray standing waves, generated by the interference of the scattered x rays from parallel surfaces of a thin film, can be used to enhance or reduce the scatterings from certain depths of the film. This work and the use of the Advanced Photon Source were supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02- 06CH11357

Interrelation between Grain-Size-Induced and Strain-Induced Broadenings of X-Ray Diffraction Profiles: What We Can Learn from It about Nano-Structured Materials?: *Emil Zolotoyabko*[1]; [1]Technion

One of the classical applications of X-ray diffraction to materials science is the measurement of grain size and average parameters of spatial strain distribution, thus characterizing the microstructure of polycrystalline materials. Two average strain parameters are of great importance: the mean strain value (i.e. the first moment of strain distribution), which leads to the shift of the diffraction peak position, and the mean square root value (i.e. the second moment or dispersion of strain distribution), which results in diffraction peak broadening. Usually, the two sources of peak broadening, i.e. due to finite grain size and dispersion of strain distribution, are considered independently. In this paper, we offer a phenomenological equation which relates the dispersion of strain distribution to grain size via the width of grain boundaries and the lattice disorder therein. Worked examples include crystallization processes from the amorphous phase and the order-disorder phase transitions in bio-composites during annealing.

5:05 PM Invited
Studies of the Early Stages of Temperature Induced Glass Devitrification: *Wim Bras*[1]; G Neville Greaves[2]; Simon Clark[3]; Martin Kunz[3]; Vladimir Martis[4]; Sabyasachi Sen[5]; [1]Netherlands Organization for Scientific Research; [2]University of Wales; [3]Lawrence Berkeley Laboratory; [4]University College London; [5]UC Davis

The formation of glass ceramics by heat treatments is a mature technological technique. However, the early stages of the process are difficult to study due to the nuclei and nanocrystal size. On-line X-ray scattering methods provide a wealth of information from the earliest stages of the process till larger crystallites have grown. We have studied the devitrification process of different glasses. The crystalline phases in the bulk compared to the surface and the growth kinetics and model of the bulk phase could be quantified. It was possible to determine the stress to which crystallites are subjected due to the mismatch between the specific volumes of the crystallites and the base glass. Surprising was that in some cases the exposure to X-rays induced crystallisation. This was not confined to the area that was directly exposed to the X-ray beam but also in a region of around 300 microns around this.

5:25 PM
Directly Imaging Microstructures Using Ultra-Small-Angle X-Ray Scattering: *Lyle Levine*[1]; Gabrielle Long[1]; Fan Zhang[1]; Jan Ilavsky[2]; [1]National Institute of Standards and Technology; [2]Advanced Photon Source

Ultra-Small-Angle X-ray Scattering (USAXS) imaging has been developed recently to probe directly the morphology and three-dimensional arrangements of small-angle scattering objects. USAXS imaging is an extremely high contrast full-field imaging technique that is size and shape sensitive, where images acquired at different reciprocal scattering vectors can reveal different microstructural features within the same sample volume. Examples will range from model tests on geometrically simple systems to self-assembly of amorphous carbon nanowires embedded in a polymer.

5:40 PM Invited
Measurement of S(q) as q → 0 in Amorphous Si: *Gabrielle Long*[1]; Ruobing Xie[1]; Steven Weigand[1]; Simon Moss[2]; Sjoerd Roorda[3]; Salvatore Torquato[4]; Paul Steinhardt[4]; [1]Argonne National Laboratory; [2]University of Houston; [3]Université de Montréal; [4]Princeton University

Amorphous silicon is a continuous random network (CRN) tetrahedrally coordinated glass. Florescu et al. [1] recently conjectured that a tetrahedrally coordinated CRN glass, which also is "hyperuniform" [2], has substantially larger photonic band gaps than CRN glasses that are not. A hyperuniform point pattern is one in which the variance of points scales with surface area rather than with volume, and $S(q \to 0)=0$ the same as in crystalline solids, which are the simplest form of hyperuniformity. It has been suggested that the band gap properties of real amorphous materials is related to their degree of hyperuniformity [1]. Our research looks into the nature of a-Si via a highly sensitive measurement of the long wavelength limit of the structure factor $S(q \to 0)$, which can indicate the presence of hyperuniform ordering. [1] M. Florescu, et al., Proc. Nat. Acad. Sci. USA (2010) 20658 [2] S. Torquato, F.H. Stillinger, Phys. Rev. E 68 (2003) 041113

Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Studies of Mechanical Properties and Effects of Current II

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Electronic Packaging and Interconnection Materials Committee

EBSD Investigation of the Relationship between Sn Orientation and IMC Evolution during Electromigration in Idealized SnAgCu Interconnects: *Christopher Kinney*[1]; Xioranny Linares[1]; Kyu-Oh Lee[2]; Fay Hua[2]; J.W. Morris[1]; [1]U.C. Berkeley; [2]Intel Corporation

In this study, idealized SnAgCu 305 samples, both polycrystalline and single crystalline of varying orientations, were examined initially in the EBSD. It is known that diffusion rates through tin can vary greatly depending on the orientation; and electromigration is also related to diffusion. Samples were subjected to 10,000 A/cm^2 at 100C for varying amounts of time, and re-examined in the EBSD. When the EBSD results are presented in the typical IPF map, correlations between various samples are not evident. However, when the EBSD results are viewed with respect to current flow, relationships between samples and relationships between the initial tin orientation and the orientation of the IMC Cu_6Sn_5 become clear. It was observed that certain orientations favor rapid IMC growth whereas others do not. Furthermore, some surprising results were found about the difference in IMC growth between single crystalline and polycrystalline samples.

Effects of Zn Addition on Electromigration Behavior of Sn-1Ag-0.5Cu Solder Interconnect: H. Liu[1]; Q. Zhu[1]; J. Guo[1]; *J. Shang*[2]; [1]Institute of Metal Research; [2]University of Illinois

Role of Zn addition on the electromigration behavior of SnAgCu alloy was investigated by examining the microstructure and mechanical properties of the Sn-1Ag-0.5Cu and Sn-1Ag-0.5Cu-1Zn solder interconnects. It was found that after electromigration, the polarity effect and strength loss occurred in the Sn-1Ag-0.5Cu solder interconnect but were suppressed in the Sn-1Ag-0.5Cu-1Zn solder interconnect. For the Sn-1Ag-0.5Cu-1Zn solder interconnect, the strong binding of Zn with Cu prevented the dissolution of the IMC at the cathode, and the reverse diffusion of the Zn elements counteracted the increasing vacancy concentration so that the strength loss due to electromigration was successfully inhibited.

2:50 PM

A New Physical Model for Rapid Life Prediction of Pb-Free Flip Chip Solder Joints in Electromigration Tests: *Tian Tian*[1]; Feng Xu[2]; Jung Kyu Han[1]; Daechul Choi[1]; Yin Cheng[2]; Lukas Helfen[2]; Marco Michiel[3]; Tilo Baumbach[2]; King-Ning Tu[1]; [1]UCLA; [2]Karlsruhe Institute of Technology; [3]ESRF

The early stage evolution of voids nucleation and growth induced by electromigration in Pb-free flip chip solder joints has been studied. We have quantitatively measured the growth rate of voids produced during electromigration by 1.0×10^4 A/cm^2 and 7.5×10^3 A/cm^2 respectively at 125 °C by synchrotron radiation high resolution x-ray laminography. Johnson-Mehl-Avrami phase transformation theory is proposed to provide a physical model to estimate failure time of the solder joints at early stages. The results were confirmed by statistical model of Weibull distribution function of lifetimes obtained under the same testing conditions.A intrinsic link between the Johnson-Mehl-Avrami model and Weibull distribution was discussed.

3:10 PM

Microstructural Evolution in Nearly Bi-Layered, Two-Phase Alloys from Current Stressing: *Andre Lee*[1]; K.N. Subramanian[1]; [1]Michigan State University

Imposition of high current densities causes material migration due to momentum transfer between electrons and atoms/ions. A clear quantitative understanding of the pathway of atoms/ions movement in multi-phase materials is far from complete. Recently, our group has developed a technique to fabricate solder joints with a nearly bi-layer microstructure. Using this type of joint, microstructural evolution in two-phase electronic solder joints were studied using Synchrotron X-rays, Optical, and Scanning Electron Microscopies. These studies have provided unique opportunities to address materials movement, microstructure evolution, as well as solid-state reactions, due solely to the influence of current stressing.

3:30 PM

No Current Crowding to Current Crowding Transition in Pb-free Solder Joint with Extremely Thick Cu: *Jung Kyu Han*[1]; Daechul Choi[1]; Masaru Fujiyoshi[2]; King-Ning Tu[1]; [1]UCLA; [2]Hitachi Metals, Ltd.

To reduce the current crowding effect, thick Cu Under-Bump-Metallization has been widely adopted in the electronic industry. As a future interconnects technology, Through-Si-Via 3D interconnects or micro-bump structures is believed to have even less current crowding. However, the statistical experiment and 3D finite element simulation indicate that there is a no current crowding to current crowding transition as the void grows. It makes a unique failure mechanism, different from the typical pancake void in flip-chip. Moreover, the study of marker displacement shows two different stages of the drift velocity, which demonstrates the back-stress effect. Since it takes time to build up the compressive stress at the anode, the drift velocity is faster in early stage and slower in later stage. Therefore, the electromigration flux can be likely to be overestimated when the constant velocity is assumed with one measurement or the observation is limited to the early stage only.

4:00 PM

Effect Of Alloying Elements On Electrification-Fusion Phenomenon Of Sn-based Eutectic Alloys: *Gong-An Lan*[1]; Truan-Sheng Lui[1]; Li-Hui Chen[1]; [1]Chung-Kung University, Tainan, Taiwan

Microstructural features of Sn-based eutectic alloys (Sn-9Zn and Sn-37Pb) on the electrification-fusion phenomenon are investigated in this study. Experimental results show that the critical fusion current densities (CFCD) of Sn-based alloys are closely related to resistivity of individual phase. The electrical current densities required for triggering microstructural evolution for Sn-9Zn alloy is larger than the CFCD of pure Sn (1399 Amp cm-2). Through the in-situ examination of microstructural evolution during electrification-fusion tests, the initial site of electrification-fusion-induced failure significantly emerges from individual Sn-based eutectic phase. The predominant liquidation phase of Sn-9Zn is Sn/Zn eutectic phase; that of Sn-37Pb comprises Sn/Pb eutectic phase, primary Sn phase and Pb-rich phase. According to the fusion distributed density in the liquidation zone, Sn-9Zn alloy has the great potential to replace Sn-37Pb alloy in the future electrification case.

4:20 PM

Irregular Cu Cathode Dissolution in Solder Joints under Electron Current Stressing: *Jia-Hong Ke*[1]; Ting-Jia Huang[1]; Ting-Li Yang[1]; C. Robert Kao[1]; [1]Department of Materials Science & Engineering, National Taiwan University

Metallization dissolution is one of the degradation processes in solder joints under current stressing. This process tends to occur on the cathode side, creating highly irregular interface. The mechanism responsible for such microstructure remains unidentified. In this study, a Cu/Sn/Cu line structure is used to reveal the microstructure evolution of cathode dissolution. We find a pronounced grain boundary grooving of intermetallic compound before the irregular cathode starts to develop. The grooving process is mainly driven by electromigration along grain boundaries or triple junctions. The interdiffusion and reaction in intermetallic phase are more significant at the valley of the grooves, leading to an irregular cathode interface. The result shows that electromigration along the grain boundaries of intermetallic phase has a large influence on the final cathode interface.

4:40 PM

Influence of Cu Column Under-Bump-Metallizations on Current Crowding and Joule Heating Effects of Electromigration in Flip-chip Solder Joints: *Yu-Chun Liang*[1]; W. A. Tsao[1]; Chih Chen[1]; Da-Jeng Yao[2]; Yi-Shao Lai[3]; [1]National Chiao Tung University; [2]National Tsing Hua University; [3]Central Laboratories, Advanced Semiconductor Engineering, Inc.

Electromigration behavior of SnAg solder bumps with and without Cu column under-bump-metallizations (UBMs) have been investigated under the current density of 2.16×104A/cm2 at 150°C. When SnAg solder bumps with Ni UBMs were current stressed, open failure occurred in the bump that has electron flow direction from the chip side to the substrate side. However, for the case with Cu column UBMs, cracks formed along the interface of Cu6Sn5 IMCs and the solder on the substrate side in the bump that has electron flow direction from the substrate side to the chip side. A three-dimensional simulation of current density distribution indicated that current crowding effect resulted in the void formation on both the chip and the substrate side for the two kinds of solder bumps. Another important finding is that the alleviation of current crowding by Cu column UBMs also helped decrease Joule heating effect in solder bumps during current stressing.

5:00 PM
Study of Joule Heating Effects in Eutectic SnPb and SnAg Solder Joints under High Current Density: *Xu Zhang*[1]; Sihan Liu[1]; Limin Ma[1]; Guangchen Xu[1]; Fu Guo[1]; [1]Beijing University of Technology

Basic understanding of heating conduction in electronic solder joints due to the Joule heating effect was carried out by using the infrared microscopy. In order to interpret the corresponding mechanism and provide a better understanding to Electromigration (EM) studies, a newly developed 1D solder joint with same cross-sectional area in solder alloy and Cu electrodes was employed in our thermal imaging analysis. Both eutectic SnPb and SnAg solder alloys were used to fabricate the joints due to their distinct electrical resistivity and thermal conductivity in nature. Joule heating effects under high current density were investigated in this study. Accordingly, the transient and steady-state heat conduction were identified and compared with different experimental conditions. Most important, effects of microstructure evolution of solder joints on temperature redistribution have been investigated as well. The results suggested that the phase segregation induced by EM can alter the temperature distribution of solder joints.

5:20 PM
Comparison of Electromigration Induced Failure between 3D IC and Flip Chip Solder Joints: *Hao Hsu*[1]; Fan-Yi Ouyang[1]; [1]Department of Engineering and System Science, National Tsing Hua University, Taiwan

The reliability issues of 3D IC on electromigration (EM) are being increasingly important since the raising demands on multiple functions and greater performance of consumer electronic products. However, due to the early development of 3D IC packaging technology, the details of reliability challenges in 3D IC packaging are still unclear. Different chips in the 3D IC technology are connected by micro bumps and through Si vias. With the reduction of bump sizes to 20μm, EM will be an important issue. In this paper, we have successfully studied the failure mechanism and microstructure change on EM in Pb-free micro-solder bumps. The experimental results of 3D IC were compared to that of flip chip solder joints, suggesting 3D IC exhibited better EM resistance possibly due to larger back stress. Furthermore, 3D simulation and in-situ infrared microscopy were also used to understand the temperature gradient and temperature distribution in the solder joints.

5:40 PM
Study of Electromigration Tests in Ultra-Low-Bump-Height Lead-Free Solder Joints with Nickel UBM Using Kelvin Bump Structure: *Ping Ju Ho*[1]; Yuan-Wei Chang[1]; Chih Chen[1]; [1]National Chiao Tung University

As electronic products become smaller, three-dimensional integrate circuit (3D-IC) has received more attention recently. In this study, the 5 μm high Sn2.5Ag solder joint were used to observe the failure mode in the ultra-low bump height case. To precisely monitor the different stages of failure during accelerated EM testing, a specific Kelvin bump structure is designed and fabricated in these samples. While a 8.5×10^3 A/cm^2 current density was applied at 200 °, the microstructures at different stages with the 5 %, 20 %, 100 %, 500 % resistance increase were obtained by scanning electron microscopy (SEM). The resistance curve showed three different stages, which increased rapidly in early stage, then maintained a certain linear slope at middle stage. Finally, the resistance rapidly increases again. With the proper designed Kelvin bump structure and well controlled test conditions, the different stages during EM test can be studied systematically.

Phase Stability, Phase Transformations, and Reactive Phase Formation in Electronic Materials XI: Phase Equilibria and Transformations of the Pb-free Solders and Thermoelectric Materials

Directional Solidification and Liquidus Projection of Sn-Co-Cu Alloys: Kai-Wen Pan[1]; *Sinn-Wen Chen*[1]; Chia-Ming Hsu[1]; Che-Wei Hsu[1]; [1]National Tsing Hua University

Ternary Sn-Co-Cu alloys are important to the electronic soldering. Liquidus projection is useful for the understanding of alloy solidification. Thirty seven ternary Sn-Co-Cu alloys were prepared from pure constituent elements. Their liquidus temperatures and phase transformation temperatures were determined by differential thermal analysis. The alloys were melted at temperatures higher than their liquidus temperatures and then quenched in air. The primary solidification phases were determined based on the microstructures and compositional analysis results of the as-solidified alloys. Directional solidification experiments of the Sn-5.0at%Co-15.0at%Cu and Sn-3.0at%Co-77.0at%Cu alloys were carried out to facilitate identification of primary solidification phases. The liquidus projection of the Sn-Co-Cu ternary system was constructed based on the experimental results. No ternary intermetallics as the primary solidification phases are found. All of the primary phases are terminal solid solutions and binary intermetallics, and are Sn, CoSn3, CoSn2, CoSn, Cu6Sn5, Cu3Sn, Co3Sn2, γ, ß, Cu and Co phase.

2:20 PM
Early Stages of Solidification in Sn-Cu and Sn-Cu-Ni Solders: *Christopher Gourlay*[1]; Sergey Belyakov[1]; Adrian Chiang[1]; [1]Imperial College London

Near-eutectic Sn-Cu and Sn-Cu-Ni alloys are widely used as Pb-free solders. For example, Sn-0.7Cu is often sold as a low-cost hobby solder and Sn-0.7Cu-0.05Ni is widely used in microelectronic assembly. This paper investigates the origin of microstructure during solidification of these alloys with a focus on nucleation and the early stages of growth. We examine how the nucleation difficulties of Sn influence the solidification sequence and the competition between coupled eutectic growth and growth of the primary phases in Sn-0.7Cu, Sn-0.9Cu and Sn-0.7Cu-0.05Ni. The paper then discusses the influence of Ni on the nucleation of Sn, the growth morphology of primary (Cu,Ni)6Sn5 and the onset of eutectic growth.

2:35 PM
Unidirectional Solidification of Eutectic Alloys in Thermoelectric Pb-Ag-Sb-Te: *Hsin-Jay Wu*[1]; Sinn-Wen Chen[1]; Teruyuki Ikeda[2]; G. Jeffery Snyder[2]; [1]National Tsing Hua university; [2]Materials Science, California Institute of Technology

Unidirectional solidification processing of two eutectic alloys with compositions of Ag-40.0at%Sb-36.0at%Te (alloy#1) and Pb-22.0at%Ag-40.0at%Sb-36.0at%Te (alloy #2) were performed using the Bridgman method. In both of the as-solidified alloys, formation of rod or lamellar Ag2Te phase in a matrix composed by the ternary AgSbTe2 and d-(Sb2Te) phases were investigated. These phases were resulted from a Class I reaction: L→Ag2Te+AgSbTe2+δ-(Sb2Te). Moreover, the volume fraction of Ag2Te phase in the alloy #2 changed along the temperature descending direction and caused a rod-eutectic to lamellar-eutectic transition. An electron backscattered diffraction technique (EBSD) was employed to examine the orientation relationship between the Ag2Te phase and the matrix phases. The Seebeck coefficients at room temperature were measured using a scanning Seebeck coefficient probe, and were ~80μV/K of the alloy #1 and ~125μV/K of the alloy #2, respectively.

2:50 PM
Phase Equilibria and Solidification of Ternary Sn-In-Cu Alloys: *Shih-Kang Lin*[1]; Sinn-Wen Chen[2]; [1]National Cheng Kung University; [2]National Tsing Hua University

Sn-In alloys are promising low-melting-point Pb-free solders. Knowledge of the Sn-In-Cu phase equilibria is important for Sn-In solder applications. The 250 °C isothermal section and liquidus projection of the Sn-In-Cu ternary system are established experimentally. At 250 °C, the η-Cu_6Sn_5 and η-Cu_2In phases form a continuous solid solution and the ternary Cu_2In_3Sn compound is observed. The δ_1-$Cu_{41}Sn_{11}$ phase is stabilized at 250 °C with the introduction of indium although it transforms into α-(Cu) and ε-Cu_3Sn phases via a eutectoid reaction around 350 °C in the binary Sn-Cu system. Except for the $Cu_{11}In_9$ and Cu_2In_3Sn phases, the other compounds all have significant indium-tin mutual solubilities. In the liquidus projection, a large compositional regime of η-(Cu_6Sn_5,Cu_2In) was found as the primary solidification phase and no ternary compound was found in the as-cast alloys. An interesting phenomenon is that the solidification paths of some Sn-In-Cu alloys surpass the liquidus trough after their intersections.

3:05 PM
Microstructure Formation and Phase Stability in Sn-Rich Sn-Ni Alloys: *Sergey Belyakov*[1]; Christopher Gourlay[1]; [1]Imperial College London

As a result of environmental issues and consequent legislation, lead-free electronics manufacturing has become a global trend. The importance of Ni in lead-free soldering is increasing as nickel is frequently used as a diffusion barrier and solders often contain Ni as an alloying element (e.g. Sn-0.7Cu-0.05Ni). This work investigates microstructure formation during solidification in Sn-Ni alloys containing 0-0.4wt%Ni. Unidirectional and multidirectional solidification experiments have been coupled with analytical electron microscopy to determine the phases that form, the solidification sequence, the crystallography of growth, and the orientation relationships between growing phases. The results are used to discuss the origins of metastability in Sn-rich Sn-Ni alloys.

3:20 PM
Transformation Kinetics and Dimensional Stability of Cu6Sn5: *Kazuhiro Nogita*[1]; Stuart McDonald[1]; Dekui Mu[1]; Christopher Gourlay[2]; Keith Sweatman[3]; Testuro Nishimura[3]; [1]The University of Queensland; [2]Imperial College London; [3]Nihon Superior Co. Ltd.

The use of tin-rich solders on copper substrates typically results in the formation of Cu6Sn5 at the soldered-interface. This intermetallic makes important contributions to the mechanical and electrical integrity of the soldered joint. Under equilibrium conditions, Cu6Sn5 exists as either a hexagonal or monoclinic allotrope at temperatures above and below approximately 186°C, respectively. In this study the hexagonal-monoclinic transformation is investigated in detail using synchrotron-based, variable temperature X-Ray diffraction. Metastable hexagonal Cu6Sn5 was obtained when the cooling rate from the high temperature phase field was sufficiently high. The temperature dependence of the rate of transformation of this metastable phase to the stable monoclinic allotrope was investigated. The significance of the results is discussed with reference to the dimensional stability of Cu6Sn5, which was directly measured in separate dilatometry experiments.

Materials for HT Lead Free Soldering and Development of the Thermodynamic Database for Relevant Materials: *Ales Kroupa*[1]; Alan Dinsdale[2]; Andrew Watson[3]; Jan Vrestal[4]; Adela Zemanova[1]; Pavel Broz[4]; [1]Institute of Physics of Materials, ASCR; [2]National Physical Laboratory,; [3]Institute for Materials Research, University of Leeds; [4]Department of Chemistry, Masaryk University

COST Action MP0602 (Advanced Solder Materials for High Temperature) ran between 2007-2011 and its main objective was to increase the basic knowledge of the crucial properties of alloys that can be used as to current high-temperature Pb-solders. The original aim was to study promising materials and describe their properties, which will allow them to be used successfully in a variety of industrial applications. One of the main outcomes of the Action is a thermodynamic database developed for high temperature lead-free solders (approx. 260-350°C). Currently the database contains 18 elements (Ag, Al, Au, Bi, Co, Cu, Ga, Ge, Mg, Ni, P, Pb, Pd, Sb, Si, Sn, Ti, Zn), but only crucial system assessments are included. The current situation especially in the field of lead free soldering at higher temperatures will be also described here. Examples of existing research projects, mainly oriented towards basic research in this field, will be presented.

4:10 PM
Time-Temperature-Transformation Diagrams of High Purity Powdered Tin: *Kazuhiro Nogita*[1]; Stuart McDonald[1]; Jonathan Read[1]; Shoichi Suenaga[2]; [1]The University of Queensland; [2]Nihon Superior Co. Ltd.

Tin is the main component of contemporary lead-free solders. Under equilibrium conditions, tin exists as either a tetragonal (beta-Sn) or cubic (alpha-Sn) allotrope at temperatures above and below approximately 13°C, respectively. The transformation from beta to alpha, often referred to as 'tin-pest' is poorly understood, despite the phenomena being documented over 100 years ago. With the transition to lead-free solder alloys and the availability of modern analytical techniques there is both an increased need and opportunity to better understand the transformation. This research was conducted to investigate the phase-transformation kinetics of the alpha to beta and beta to alpha transformations in high-purity powdered tin using variable temperature synchrotron XRD analysis. From the results, TTT (time-temperature-transformation) diagrams were developed, with the intention of being used as a baseline for examining the effects of composition in current generation lead-free materials.

4:25 PM
Thermoelectric Materials Design Based on Phase Separation between Half-Heusler MNiSn and Heusler M(Ni,Co)$_2$Sn (M = Hf, Zr): *Yoshisato Kimura*[1]; Naoko Katou[1]; Yaw-Wang Chai[1]; [1]Tokyo Institute of Technology

Half-Heusler (HH) compounds MNiSn (M = Hf, Zr, Ti) are well-known to show excellent thermoelectric properties at relatively high temperature. Authors found that the n-type properties can be converted to the p-type by the quaternary addition of Co while Co atoms occupy the vacancy site of HH. Further addition of Co results in the formation of a (Full-)Heusler (FH) compound Zr(Ni,Co)$_2$Sn which exhibits metallic behavior. To understand the phase separation between HH M(Ni,Co$_x$)Sn and FH M(Ni,Co)$_2$Sn (M = Hf, Zr), microstructure formation according to the phase separation was observed by high-resolution transmission electron microscopy and phase equilibria were investigated in detail. Needle like FH precipitates in the HH matrix at low Co content, and cuboidal HH precipitates in the FH matrix at high Co content. The nano-scaled interfaces formed due to the phase separation could be advantageous for reducing the lattice thermal conductivity through enhancing phonon scattering.

4:40 PM
Diffusion Mobilities in the Face Centered Phase in the Ag – Cu – In – Sn System: *Wojciech Gierlotka*[1]; Md. Azizul Haque[1]; [1]YuanZe University

The Ag – Cu – In – Sn system is one of the important lead – free solder alloy. The knowledge about interdiffusion between solder alloys and substrates or UBM layers may help to control the interfacial microstructure evolution and thus to design and optimize suitable soldering and aging process. The optimization of the diffusion parameters and simulation of the atomic mobilities in the face centered phase were done using the Dictra package. Good agreement between mathematical model and experimental data was obtained.

4:55 PM
Evaluation of Diffusion Barrier between SAC305 and Tellurium: *Chang-Yen Ko*[1]; Albert T. Wu[1]; Tai-Yin Lin[1]; [1]National Central University Dep. Chemical and Materials Engneering

Nickel was selected to be the diffusion barrier by electroless plating between Pb-free Sn3Ag0.5Cu (SAC305) solders and the Tellurium substrates. NiTe intermetallic compound formed at the interfaces between Ni-P and Te while (Cu,Ni)6Sn5 and (Ni,Cu)3Sn4 formed at the interfaces between solders/Ni-P. SAC305 was reflowed on the Ni-P plated Te substrates and sealed in vacuum. The samples were annealed at 120, 150 and 180°C for different duration of times. The growth kinetics of the IMC layers between SAC305/Ni-P and Ni-P/Te interfaces could be obtained. Nanoindentor was employed to evaluate the mechanical properties of the NiTe layer. EPMA was adopted to analyze the composition.

Processing to Control Morphology and Texture in Magnetic Materials: Processing to Enhance Performance in Rare Earth Permanent Magnets

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Magnetic Materials Committee

Program Organizers: Matthew Kramer, Iowa State University; Mike McHenry, Carnegie Mellon University; David Laughlin, Carnegie Mellon University; Jinfang Liu, Electron Energy Corporation; Bill Soffa, University of Virginia; Ivan Skorvanek, Institute of Experimental Physics

Monday PM Room: Europe 10
March 12, 2012 Location: Dolphin Resort

Advanced Processing and Microstructure of High Performance Permanent Magnets: *Oliver Gutfleisch*[1]; Thomas Woodcock[1]; Konrad Güth[1]; Juliane Thielsch[1]; Martina Moore[1]; Simon Sawatzki[1]; [1]IFW Dresden

In this talk various processing routes yielding highly textured permanents based on rare earth-intermetallics are reviewed1. This includes latest progress in sintering NdFeB, thermomechanical processing of melt-spun ribbons and hydrogen-assisted methods (HD and HDDR). Distinct differences in the texture inducement in these different types of magnets are elucidated by advanced microstructural characterization down to atomic scale resolution but also using EBSD and magnetic measurements to illustrate mesos- and macroscopic texture. Magnetic microstructure is largely effect by texture and this will be shown by in-situ MFM studies. Finally, options for magnetic field processing and bottom-up approaches using nanoparticles or nanoflakes are assessed; this in the context of moving towards textured AND exchanged-coupled systems - the next generation magnets. 1 Gutfleisch et al. *Adv. Mat.* 23 (2011) 821.

2:25 PM Invited
Restructuring of Grain Boundaries of Sintered NdFeB Magnets: *Mi Yan*[1]; [1]Zhejiang University

NdFeB sintered magnets are the widest applied RE magnets due to their excellent properties and the high performance/cost ratio. However, since the electrode potentials of the intergranular Nd-rich phases are far lower compared to matrix Nd2Fe14B, NdFeB magnets are very prone to corrosion. Moreover, the magnetic properties and ductility of NdFeB magnets are sensitive to the morphologies and structure of the grain boundaries. In this paper, through restructuring of grain boundaries, a new approach to substantially improve the corrosion resistance of NdFeB magnets is discussed, together with improvement of magnetic properties and ductility. Some experimental results are presented.

2:50 PM
Investigation of a Unique Texturing Mechanism in Ag-Containing $RE_2Fe_{14}B$ Alloys: Nathaniel Oster[1]; Daniel Cavanaugh[2]; Kevin Dennis[2]; R. McCallum[2]; Matthew Kramer[2]; *Iver Anderson*[2]; [1]Iowa State University; [2]Ames Laboratory

$RE_2Fe_{14}B$-type permanent magnet alloys display the highest known energy product. Properties can be further increased through the creation of an anisotropic exchange-spring composite. Texture and microstructure control are vital to the creation of an exchange-spring magnet showing desirable properties. One possible method to control these features is through the use of a minor additive. Silver recently has been identified as a promising additive, showing alteration of the solidification microstructure and a unique texture in low wheel speed melt-spun ribbons. In this study the mechanism behind the unique texture in these alloys is investigated through variation of composition and melt-spinning parameters (e.g. wheel speed). Characterization work to be presented includes scanning electron microscopy (SEM), x-ray diffraction (XRD), and orientation imaging microscopy (OIM). The texturing mechanism and its magnetic property implications will be discussed. This work was supported by DOE-EERE, VT Office, PEEM program, through Contract No. DE-AC02-07CH11358 at Ames Laboratory(USDOE).

3:05 PM
Thermodynamics Effect of Magnetic Field on the Solidification of Fe-Nd Eutectic: *Sophie Rivoirard*[1]; Eric Beaugnon[1]; Thomas[1]; [1]CNRS

Magnetic field processing is a new promising tool for the structural and functional control of materials. A high field modifies the Gibbs free energy. As a result, the phase with the highest magnetisation can be stabilised and hence transformation processes are modified. RE-Fe (RE=Pr, Nd) binary alloys have been extensively studied both for their high coercivity and for their important role in the magnetic properties of NdFeB permanent magnets. We used thermomagnetic measurements to evidence the effect of magnetic field on the liquid to solid transition in a Nd-Fe alloy using a Faraday balance. A shift of 1°C/T was observed in the solidification point toward higher temperatures when a magnetic field was applied. A discontinuous rod-like eutectic was observed as well as primary Nd dendrites and a feathered microstructure. A unidirectional solidification of the Nd dendrites parallel to the magnetic field was evidenced, especially for the higher field values.

3:20 PM
Studies of Anisotropic MRE-Fe-B Magnets Fabricated by Hot Deformation in a Vacuum Hot Press (MRE=Nd+Y+Dy): *Wei Tang*[1]; Kevin Dennis[1]; Nathaniel Oster[1]; Matt Kramer[1]; Iver Anderson[1]; Ralph McCallum[1]; [1]Iowa State University

Our mixed rare-earth MRE2(Fe, Co)14B melt spun ribbons or gas atomized powders in nano-crystalline isotropic microstructures exhibited improved temperature stability at or above 120°C but a relatively lower maximum energy product (BH)max (12 MGOe) compared to about 25 MGOe for (micron-sized) grain-aligned sintered MRE 2-14-1 magnets that were consolidated by traditional high temperature sintering. Unfortunately, these sintered MRE 2-14-1 magnets had a reduced temperature stability due to significant RE segregation within magnetic phase (2-14-1) grains.

In this study, anisotropic magnets induced by grain texture were fabricated by a hot deformation method from over-quenched (substantially amorphous) isotropic MRE 2-14-1 ribbons. The new magnets obtained an improved (BH)max and achieved improved temperature stability. The relationships of magnetic properties and microstructure to compositions and processing parameters of the new sintered magnets were analyzed and discussed. In addition, the effect of extrinsic sintering additives, such as Zn and Al, on magnetic properties was investigated.

Effect of Particle Size on the Coercivity of R-Fe-B (R=Nd, Pr) Powders Prepared by Surfactant-Assisted Ball Milling: Nilay Gunduz Akdogan[1]; Dan Neil[1]; Chris Brown[1]; Wanfeng Li[1]; Dimitris Niarchos[2]; *George Hadjipanayis*[1]; [1]University of Delaware; [2]NCSR ''Demokritos''

In this study a two-stage high-energy ball milling (HEBM) was performed to obtain R2Fe14B (R=Nd, Pr) nanoparticles and nanoflakes; first the coarse powders were made nanocrystalline by milling/melt-spinning, and then they were subjected to surfactant-assisted milling for different times. Different size nanoparticles have been obtained by varying the time of the first stage milling and the speed of the melt-spinning wheel. The coercivity of the nanoparticles was higher than the slurry (nanoflakes) and is increasing with increasing nanoparticle size. The 15 nm Nd2Fe14B nanoparticles had a coercivity of 9 kOe at 50K and 2.5 kOe at RT. Pr-Fe-B particles made from ribbons precursors had a coercivity above 30 kOe at 50 K. The larger value of coercivity observed in the Pr-Fe-B samples is attributed to the higher magnetocrystalline anisotropy of the Pr-Fe-B compound. Work supported by NSF DMR-1005871, DOE ARPA-E and a Marie Curie Fellowship

Fabrication of Anisotropic Nanostructured Rare-Earth Bonded Magnets: *J.P. Liu*[1]; [1]University of Texas-Arlington

We report fabrication of anisotropic bonded magnets fabricated using surfactant-assisted ball milling and magnetic-field processing. The fabrication involves preparation of nanocrystalline hard magnetic anisotropic Sm-Co and Nd-Fe-B nanoscale chips by surfactant-assisted ball milling in a magnetic field. The produced nanochips have high aspect ratio with their thickness of tens of nanometers and width and length of several hundred nanometers. It is found that application of magnetic fields during the ball milling strengthens the anisotropy of the nanoflakes and therefore improves the alignment. The aligned hard magnetic nanoflakes can then be processed into anisotropic bonded magnets with high energy product. X-ray diffraction patterns and magnetic characterization show c-axis alignment with strong magnetic anisotropy in the bulk magnets. The high energy product up to 19.1 MGOe has been obtained for anisotropic SmCo5 bonded magnets compared to 5.4 MGOe for the isotropic bonded magnets.

4:45 PM Invited
Textured Polycrystalline Permanent Magnet Nanoflakes: *Jinfang Liu*[1]; Baozhi Cui[1]; [1]Electron Energy Corporation

This paper will review the texture formation, magnetic properties, and microstructure of permanent magnet nanoflakes, which can be formed using ball milling technique for SmCo5, Sm(Co,Cu,Fe,Zr)z and Nd2Fe14B magnets. The magnetic properties of these flakes are very different for these materials. These nanoflakes could potentially be used for the fabrication of permanent magnets with high electrical resistivity, which will reduce eddy current losses and improve motor efficiency.

5:10 PM
Novel Sm-Fe-N Nanoflakes with High Coercivities: *Nilay Gunduz Akdogan*[1]; Wanfeng Li[1]; Alexander Gabay[1]; George Hadjipanayis[1]; [1]University of Delaware

In this work, magnetically hard Sm-Fe-N nanoflakes with coercivity values exceeding 10 kOe have been produced by surfactant-assisted ball milling using two different precursors: Sm_2Fe_{17} crushed ingot powders and melt-spun ribbons spun at different speeds. Different techniques were used to prepare the nanoflakes from the crushed powders; in one of the techniques the powders were first nitrogenated and then milled in oleic acid (OA) for different time. In another approach the powders were first milled in oleylamine (OY), and then nitrogenated at 400–450°C. The coercivity was much higher with the former technique, showing values beyond 10kOe. Very promising results were obtained when using melt-spun ribbons as precursors. Nitrogenization of the samples was performed at 400–450 °C and then the nitrogenated powder was milled with OA for 3 h and 4h. The flakes had a thickness below 200nm, an aspect ratio as high as 10^2-10^3 and Hc>7kOe. Optimization studies are under way and the results will be reported. Work supported by NSF DMR-1005871, DOE ARPA-E and a Marie Curie Fellowship

5:25 PM
Cluster Synthesis, Direct Ordering and Alignment of Rare-Earth Transition-Metal Nanomagnets: *Balamurugan Balasubramanian*[1]; Ralph Skomski[1]; Jeffrey Shield[1]; George Hadjipanayis[2]; David Sellmyer[1]; [1]University of Nebraska; [2]University of Delaware

Rare-earth transition-metal (R-TM) alloys show superior permanent magnetic properties in the bulk, but the synthesis and application of R-TM nanoparticles remains a challenge due to the requirement of high-temperature annealing above about 800 °C for alloy formation and subsequent crystalline ordering. Here we report a single-step method to produce highly ordered R-TM nanoparticles such as YCo_5 and $SmCo_5$, without high-temperature thermal annealing by employing a cluster-deposition system, and we investigate their structural and magnetic properties. Nanoparticles of size d = 10 nm are monodispersed (s/d ˜ 0.15) and have H_c values at T = 300 K of 8.0 and 2.0 kOe for YCo_5 and $SmCo_5$, respectively. Alignment of the easy axes is performed *via* a field applied to the clusters before deposition. These processing steps are highly desirable to create and assemble R-TM nanoparticle composites for future permanent-magnet and other significant applications.

Development of a Simple Empirical Model for Current Activated Pressure Assisted Densification: *J. Garay*[1]; A. Dupuy[1]; [1]UC Riverside

The Current Activated Pressure Assisted Densification (CAPAD) technique has been used to effectively densify a wide variety of materials. Various models have been proposed both from the system perspective and the densification perspective. The system models can calculate the important fields of the technique such as current, temperature and stress distribution, while the densification models are helpful in differentiating the effects of experimental parameters on the densification process. While these models are quite useful and are being continuously improved, they are often difficult to implement. Here we present an empirical model that can relate material density to some of the most important experimental parameters: temperature and pressure. The work is based on results from experimental measurement of densification rates on various classes of important materials. The model is intended to complement experiments and is particularly useful as a tool for choosing experimental parameters.

2:25 PM Invited
Issues in Transforming SPS (FAST) into a Viable Manufacturing Solution: *James Sears*[1]; [1]South Dakota School of Mines & Technology

Spark Plasma Sintering (SPS) also known as Field Assisted Sintering Technology (FAST) has the potential to revolutionize sintering and densification of various ceramic, metallic and composite materials. The main attributes that make this technology attractive include: short processing times, elimination of binders and sintering aids, minimal grain growth, wide range of materials, ability to handle fine (nano) materials, low cost tooling and near net shape processing. The current systems run in batch mode that limit through put. This paper examines several scenarios that may lead to improvements in productivity. This paper will also discuss some of the applications currently being commercialized.

2:50 PM
Advances in Current Activated Tip-Based Sintering (CATS): *Ahmed El Desouky*[1]; Kee Moon[1]; Sam Kassegne[1]; Joanna McKittrick[2]; Khaled Morsi[1]; [1]SDSU; [2]UCSD

Current activated tip-based sintering (CATS) is a new process that enables selective sintering of powders under high electric current densities using stationary or moving electrically conducting tips. This unique process has been recently used to produce macro as well as micro-scale sintered features for different systems such as metallic and intermetallic powder compacts. This presentation will discuss recent advancements in research on CATS.

3:05 PM
Low-Thermal Load Consolidation of Sm-Fe-N Flake Powder by Combination of Cyclic Compression and Current Sintering: *Kenta Takagi*[1]; Hiroyuki Nakayama[1]; Kimihiro Ozaki[1]; [1]National Institute of Advanced Industrial Science and Technology (AIST)

Sm-Fe-N compounds, which possess a high magnet performance, are difficult to sinter due to their thermal decomposability. We tried to fabricate the Sm_1Fe_7N sintered magnets from flake powders by cyclic high-pressure compaction and subsequent current sintering with low temperatures. Under the high pressure compression, the flake particles were densely packed while being broken up and orderly stacked. Thus, bimodal blend of different particle sizes brought disadvantages against densification and the coarser powder provided the denser compact. When the coarse powder of < 355µm was used, it was densified beyond 85% in relative density only by the cyclic compaction with the pressures above 1.2GPa. The compacts were rigidly consolidated by the current sintering in the temperature range of 350~400 °C without the decomposition. TEM observation verified interparticle sinter-bonding in the compacts. The developed process finally produced the sintered magnets with the high density up to 93%.

3:20 PM
Fabrication of TiN / Fe-Al Cermet from Mixture of TiN, Fe and Al Powders: *Hiroyuki Nakayama*[1]; Kimihiro Ozaki[1]; Keizo Kobayashi[1]; [1]National Institute of Advanced Industrial Science and Technology

TiN shows high hardness, good thermal stability. Hence, fabrication of TiN cermet considering an application for cutting tools is desired. Fe-Al intermetallic compounds are one of a candidate for binder of the cermet, because it shows good mechanical property and it is composed of common (low cost) elements. Therefore, in this study, fabrication of TiN / Fe-Al cermets were examined. TiN, Fe and Al powders were mechanically milled using a planetary ball mill under Ar atmosphere. The nominal composition of powder mixture was TiN - 10 mass% Fe3Al2. The milled powder was consolidated by current sintering. The sintered compact was composed of TiN and Fe-Al intermetallic compound. The intermetallic compound would be formed by the reaction of molten Al and solid Fe during the sintering process. The bending strength of the cermet showed 1.0 GPa. This value was higher than that of sintered TiN of 0.4 GPa.

3:35 PM Break

Liquid Phase Sintering of NiTi: *David Dunand*[1]; [1]Northwestern University

Near equiatomic NiTi powders sinter very slowly due to the ordered structure of the intermetallic, resulting in poorly bonded, weak structures even after long sintering times near the melting point. Here, recent research is reviewed on liquid phase bonding of NiTi with small amount of Nb, forming a liquid NiTi/Nb eutectic that wets the powders, and upon solidification, remains ductile and does not affect the shape-memory properties of NiTi. This method is used to create porous NiTi-Nb, where pores with controllable size, shape and volume fraction are created with a space-holder around which the NiTi/Nb powders are fully densified by liquid phase sintering.

4:15 PM
The Effect of Powder Morphology on the Sintering Behavior of Ti and Ti Alloy Powders: *Wei Chen*[1]; Yukinori Yamamoto[1]; William Peter[1]; Michael Clark[1]; Stephen Nunn[1]; Jim Kiggans[1]; Thomas Muth[1]; Ryan Dehoff[1]; Craig Blue[1]; Brian Fuller[2]; Kamal Akhtar[2]; [1]Oak Ridge National Laboratory; [2]Cristal US, Inc./ International Titanium Powder

Powder metallurgy offers near-net-shape cost-effective approaches to the fabrication of Ti components. This work compares the sintering behavior of CP-Ti and Ti-6Al-4V powders made by three different processes; gas atomization, the Armstrong Process® and the hydride-dehydride (HDH) process. CP-Ti and Ti-6Al-4V powders were uniaxially die-pressed at designated pressures up to 690 MPa to form cylindrical samples. The powders exhibited different compressibility due to their morphology differences and the morphology differences significantly affected their sinterability. Vacuum sintering below and above the beta-transus were both performed and the effect of sintering temperature was analyzed. Sintering shrinkage was evaluated and an ex-situ technique was used to record the powder morphology change before and after sintering. This research was sponsored by the U.S. DOE, Office of EERE Industrial Technologies Program, under contract DE-AC05-00OR22725 with UT-Battelle, LLC.

4:30 PM
Transparent Polycrystalline Alumina Obtained by SPS: Single and Double Doping Effect: *Burcu Apak*[1]; Halide Esra Kanbur[1]; Esra Ozkan Zayim[1]; Gultekin Goller[1]; Onuralp Yucel[1]; Filiz Cinar Sahin[1]; [1]Istanbul Technical University

Commercial nanocrystalline alpha alumina powders were used for fabrication of dense and transparent alumina by spark plasma sintering (SPS). High purity dopants such as MgO, Y2O3, TiO2 and CaO with 150 ppm amount were added to alumina and powder mixtures were densified by SPS between 1175 and 1300 °C using 80 MPa pressure for 5 to 20 min durations. The influences of MgO, Y2O3, TiO2 and CaO single and double doping on density, hardness, fracture toughness and microstructures of alumina samples are investigated. The highest hardness value was measured as 24.2 GPa in the sample doped with 150 ppm MgO and 150 ppm CaO sintered at 1175 °C under 80 MPa pressure for 20 min. The fracture toughness values were ranged between 3.3 and 4.9 MPa. m1/2. Alumina ceramic with 150 ppm MgO which was SPSed at 1175 °C for 20 min showed the highest RIT value as 55.5 %.

4:45 PM
Effect of TiC Addition on Sintering Behavior of ZrC: Burak Acicbe[1]; Ipek Akin[1]; Filiz Sahin[1]; Onuralp Yucel[1]; *Gultekin Goller*[1]; [1]Istanbul Technical University

Zirconium carbide (ZrC) has many exceptional properties such as high hardness, high melting temperature, chemical inertness, solid state stability, high thermal and electrical conductivity. These properties make it a promising material for ultrahigh temparature applications, wear resistant parts and cutting tools. However, the inherent brittleness, and low fracture toughness limit the applications of ZrC. In this study, ZrC ceramics were reinforced with TiC particles and composites with different compositions were prepared by using spark plasma sintering (SPS) technique. Samples containing 10 and 20 vol% TiC were sintered at 1900°C for 300 s under a pressure of 40 MPa. Shrinkage of the specimens during SPS process was continuously monitored. Densities of the composites were determined by the Archimedes' method. Fully dense ZrC-TiC composites containing 10 and 20 vol% TiC with a relative density of 99% were obtained. Mechanical properties and microstructural behavior of the composites will also be investigated.

5:00 PM
Sintering of Nanocrystalline Tungsten Powder: *William de Rosset*[1]; [1]Army Research Laboratory

Small metal samples have been made from nanocrystalline tungsten powder by sintering with the goal of producing high density parts. The parameters associated with sintering runs have been examined to see if there is an empirical relationship between them and the final part density. A function that depends on the time a sample spends above a critical temperature has been formulated that represents one specific batch of tungsten powder. The function has been applied to other batches of powder with some success.

5:15 PM
Mechanical Properties of Spark Plasma Sintered ZrC-SiC Composites: Sumbule Sagdic[1]; Ipek Akin[1]; Filiz Sahin[1]; Onuralp Yucel[1]; *Gultekin Goller*[1]; [1]Istanbul Technical University

Zirconium carbide (ZrC) is an important structural ceramic due to its high melting temperature, excellent chemical resistance, high electrical conductivity and good mechanical properties. This combination of properties makes it potentially useful in application of cutting tools, high temperature crucibles and thermal protection components. However, the nature of brittleness and lack of damage tolerance is one of the most crucial problems in their applications. In this study, ZrC-SiC composites with different compositions were prepared by using spark plasma sintering (SPS) technique. Samples containing 10 and 20 vol% SiC were sintered at 1900°C for 300 s under a pressure of 40 MPa. Densities of the composites were determined by the Archimedes' method. Fully dense ZrC-SiC composites with a relative density of 99% were obtained. Mechanical properties and microstructural behavior of the composites will also be investigated.

Science and Engineering of Light Metal Matrix Nanocomposites and Composites: Nanocomposites and Composites

Uniform Dispersion of Nanoparticles in Metal Matrix Nanocomposites: *Lianyi Chen*[1]; Hongseok Choi[1]; Axel Fehrenbacher[1]; Jiaquan Xu[1]; Chao Ma[1]; Xiaochun Li[1]; [1]University of Wisconsin Madison

The dispersion of nanoparticles in grains is crucial for the performance of the metal matrix nanocomposites. Uniformly dispersing nanoparticles into the metal matrix is still a great challenge. This paper demonstrates that a uniform dispersion of nanoparticles in metal matrix nanocomposites can be achieved by a combination of liquid state ultrasonic cavitation and solid state stirring. Two examples are presented in this report: (1) uniform dispersion of Al2O3 nanoparticles in A206 alloy and (2) uniform dispersion of graphene nanoplateletes in pure magnesium. The results obtained in this work provide a general methodology to uniformly disperse nanoparticles into metal matrix nanocomposites, paving the way for production of metal matrix nanocomposites with superior properties.

2:20 PM
Effect of Particle Size Distribution on the Response of Particle Reinforced Metal Matrix Composites: *Brandon McWilliams*[1]; KT Ramesh[2]; Chian Yen[1]; [1]US Army Research Laboratory; [2]Johns Hopkins University

An enhanced continuum model for the size dependent strengthening of ceramic particle reinforced metal matrix composites (MMCs) is used to explore the effect of particle size distribution on the deformation response of heterogeneous collections of particles. The model incorporates a "punched" zone around the particles that is the result of an increase in dislocation density due to geometrically necessary dislocations generated by the mismatch in coefficients of thermal expansion of the particle and matrix. Geometrically necessary dislocations result in localized hardening of the matrix around the particles, and the strengthening and size of this hardened zone are dependent upon the size of the reinforcing particles. In this work, these zones are explicitly accounted for in mesoscale finite element simulations of representative heterogeneous composite microstructures consisting of randomly distributed particles in a metal matrix. Effects of particle size distribution and strain rate on MMC deformation response is explored using this approach.

2:40 PM
Microstructure and Mechanical Properties of Gas Atomized CP Ti Containing Y2O3 and TiB: *Vincent Hammond*[1]; Sesh Tamirisakandala[2]; Brady Butler[1]; William Hanusiak[2]; [1]Army Research Laboratory; [2]FMW Composite Systems

Previous results obtained on lab-scale samples of CP Titanium reinforced with yttria (Y2O3) nanoparticles have indicated significant improvement in tensile properties. As a result, there is an interest in determining if similar property improvements would be observed in materials produced using large-scale processing methods. Hence, CP Ti powders containing yttria as well as TiB reinforcements were produced through gas atomization. Subsequently, the powders were consolidated into billets and extruded into 12.7 mm bars. The influence of the reinforcements on the performance of CP Ti was evaluated using both microhardness and room temperature tensile tests. Test results indicated that the strength improvements ranged from approximately 25% to more than 60%. The Y2O3/TiB reinforced samples showed the highest strengths; however, these samples showed an approximate 50% reduction in elongation whereas the Y2O3 only sample showed a negligible reduction. Electron microscopy was used to correlate microstructural features to mechanical properties.

3:00 PM
An Investigation on the Capability of Equal Channel Angular Pressing for Consolidation of Aluminum and Aluminum Composite Powder: *Reza Derakhshandeh Haghi*[1]; Ahmad Jenabali Jahromi[2]; [1]Fars Science and Research Branch, Islamic Azad University; [2]Shiraz University

In this study equal channel angular pressing (ECAP) was used as a technique for consolidation of attritioned aluminum powder (45µm) with varying concentration of nano alumina powders (35nm) in tube at 200 °C. The effect of ECAP on consolidation behavior of composite powder and mechanical properties of subsequent compacts are presented. It is found that ECAP has the capability of consolidating pure aluminum powder, Al-5vol% Al2O3 and Al-10vol% Al2O3 to near their theoretical density and also declustring of the agglomerated alumina particles after maximum four passes. However full consolidation of Al-15vol% Al2O3 before emanating the cracks on the tube material was not possible and about 7% porosity remains in the compacted composite which degrades the mechanical properties of this composite in comparison to the aluminum composites with 5vol% and 10vol% alumina.

3:20 PM
Effect of Core-shelled Nanoparticles of Carbon-Coated Nickel on Magnesium: *Yi Sun*[1]; Hongseok Choi[1]; Hiromi Konishi[1]; Vadim Pikhovich[2]; Robert Hathaway[2]; Xiaochun Li[1]; [1]University of Wisconsin Madison; [2]Oshkosh Corporation

Grain refinement is of significance for strengthening Mg alloys. This paper is to study grain refinement effect in cast Mg by carbon-coated Ni nanoparticles. With about 1.0 vol% of C-coated Ni nanoparticles by ultrasonically dispersion in pure Mg, the average grain size of cast magnesium was refined markedly from more than 1000um to 25μm. Mechanical property was enhanced significantly. The microstructure was examined by Polarized Light Microscopy, SEM, and TEM. TEM study indicates that a part of carbon-coated Ni nanoparticles remain intact and captured inside grains, while some other nanoparticles dissolved and formed Mg-Ni intermetallic phase near the grain boundary. Moreover, pure Ni was also added to pure magnesium to conduct comparison study. Mg with same amount of Ni can only produce a much larger average grain size, about 140um.

3:55 PM
Microstructural Control during In-Situ Synthesis of (AlN+Mg2Si)/ Mg Matrix Composites: *Xiao Ma*[1]; David Johnson[1]; Kevin Trumble[1]; [1]Purdue University

Fine particulate AlN/Mg composites have successfully been in-situ synthesized using pure bulk Mg and Al and Si3N4 powder as raw materials. Reaction under SF6/CO2 protective gas atmosphere at 770 to 850°C for an hour was used to produce composites containing 60, 40, 20 or 4.5 vol. % AlN (+residual Mg2Si) depending on the reaction temperature. The microstructures were characterized using X-ray diffraction, optical microscopy and scanning electron microscope. Fine AlN particles embedded within magnesium matrix in addition to larger size Mg2Si phase was observed after the in-situ reaction. The AlN particles were found to have formed from the prior Si3N4 agglomerates while the morphology of the Mg2Si phase was dependent upon the composition, temperature, and cooling rate. Thermodynamic calculations including the equilibrium and Scheil solidification paths of the resultant alloy after the in situ reaction were calculated and compared.

4:15 PM
In Situ Composite of (Mg2Si)/Al-Si-Cu Fabricated by Squeeze Casting: *Huseyin Lus*[1]; Gokhan Ozer[1]; Kerem Guler[1]; [1]Yildiz Technical University

An in situ formed Mg2Si/Al-Si-Cu reinforced metal matrix composite fabricated by squeeze casting are investigated. It is showed that primary Mg2Si crystals are formed by adding pure Mg into the hypoeutectic A380 aluminum-silicon-copper alloy. In order to increase castability and to obtain better properties squeeze casting technique is used. The results show that, the average size of primary Mg2Si particulates decreases from 87μm to 21 μm. Furthermore, the average porosity values of cast samples are decreased from %8.7 to %0.5 with the application of 30 MPa pressure during solidification.

4:35 PM
SiCp/Mg-Zn-Ca-Mn Mg Matrix Composites Fabricated by Stir Casting: *Xiaojun Wang*[1]; K.B. Nie[2]; K Wu[2]; X.S Hu[2]; M.Y Zheng[2]; [1]Harbin Institute of Technology ; [2]Harbin Institute of Technology

SiCp/Mg-Zn-Ca-Mn magnesium matrix composites were fabricated by stir casting and then extruded. Many particles at grain boundaries were coated by the large second phase, which weakened the bonding between matrix alloy and particles. As the volume fraction of particles increased, the content of the second phase decreased. Chemical reaction was not observed at interface. The Ca2Mg6Zn3 phase was observed at the interfaces. Hot extrusion improved the distribution of particles and refined the grain sizes of the matrix. As extrusion temperatures increased, the particles distribution was improved and the DRX grains grew up. The content of the second phase decreased with the increase of particle in the extruded composites. Hot extrusion significantly improved the mechanical properties of the composites. But the extrusion temperature differently influenced the mechanical properties in the composites with different volume fractions of particles.

4:55 PM
Ultrasonically Processed AS41 Magnesium Alloy Matrix Composites: Neeraj Srivastava[1]; *Gajanan Chaudhari*[1]; S.K. Nath[1]; [1]IIT Roorkee

TiC-AS41 magnesium alloy matrix composites were fabricated using ultrasound assisted solidification technique. It was observed that application of high intensity ultrasonic vibrations (~ 4.3 kW/cm2) to the melt resulted in uniform dispersion of TiC particles in the AS41 alloy matrix. The creep behavior of AS41 magnesium alloy and ultrasonically processed TiC/AS41 composites (2 % volume fraction of TiC particles) was investigated under conditions of constant compressive stress at temperatures up to 200°C. The results showed that the dispersed TiC particles significantly improved the high-temperature creep property of AS41 magnesium alloy.

5:15 PM
Optimization of Tensile Strength of Friction Stir Welded Al-(10 to14 wt.%) TiB2 Metal Matrix Composites: *Santhiyagu Joseph Vijay*[1]; Natarajan Murugan[2]; Siva Parameswaran[3]; [1]Karunya University; [2]Coimbatore Institute of Technology; [3]Texas Tech University

Metal Matrix Composites (MMCs) play a vital role in replacing many structural materials due to their superior mechanical and metallurgical properties. Processing those composites has always been a major factor influencing their application. Al-TiB2 MMCs are used as structural members in the marine industry. Friction Stir Welding (FSW) has revolutionized the process of joining those composites. In this paper, an attempt has been made to friction stir weld the Al-TiB2 MMCs and to develop a regression model for predicting the tensile strength of the weldment. The process parameters considered for FSW are tool rotation speed, tool traverse speed, axial load and weight percentage of TiB2 in Al matrix. The regression model is used to optimize the process parameter using Desirability Optimization Methodology to improve the tensile strength of the FS welded Al-TiB2 composites. The effects of process parameters on the tensile strength of the welded composites are analyzed and presented.

An Investigation into the Electrochemical Production of Si by the FFC Cambridge Process: Emre Ergül[1]; Ishak Karakaya[2]; Metehan Erdogan[2]; *Fuat Erden*[2]; [1]Aselsan Inc.; [2]Department of Metallurgical and Materials Engineering, Middle East Technical University

The FFC Cambridge process is a promising Si production technique for the expanding solar energy industry. In this study, SiO_2 was successfully reduced to Si in both $CaCl_2$ salt and $CaCl_2$-NaCl salt mixture at 2.8 V. In addition, reduction of porous SiO_2 pellets were compared with bulk

SiO_2 plates in terms of reduction rate. The overall reduction potential of SiO_2 pellets against the graphite anode at 750°C in molten $CaCl_2$-NaCl salt mixture was determined as 2.3 V by cyclic voltammetry which was supported by calculations. SEM examinations, ICP-MS, and XRD analysis were used for characterization. The produced Si powder was brown and found to be contaminated by the Ni and stainless steel plates used as the cathode contacting materials.

2:30 PM

Distribution of Boron and Phosphorus during Alloying and Slag Treatment of Metallurgical Grade Silicon: *Yulia Meteleva-Fischer*[1]; Yongxiang Yang[2]; Rob Boom[1]; Bert Kraaijveld[3]; Henk Kuntzel[3]; [1]Materials innovation institute/TU Delft; [2]Delft University of Technology; [3]Solwafer B.V.

Segregation of impurities during refining of metallurgical grade silicon (MG-Si) is an option to produce solar grade silicon (SG-Si). Directional solidification is a last step in production of SG-Si effective for removal of metallic impurities. The possibility is investigated to use metallic impurities originally present in MG-Si for removing boron and phosphorus. MG-Si has been treated using two methods: 1) alloying with calcium and 2) refining with Na2O-CaO-SiO2 slag, both by controlled cooling. The microstructure of silicon and the impurities distribution have been studied before and after the treatments. Using EPMA phosphorus and boron have been detected in 1-2 wt% concentration range in several intermetallic compounds in grain boundaries after both treatments. This observation points to a different possible mechanism of silicon refining from boron and phosphorus. Controlled cooling improves migration of phosphorus and boron to the silicide phases in grain boundaries, which can be removed by acid leaching treatment.

2:50 PM

Experimental and Molecular Simulation Studies of Silicon Production in an Microwave Furnace: *Jan-Philipp Mai*[1]; Gabriele Raabe[2]; Juergen Koehler[2]; [1]JPM Silicon GmbH; [2]University of Braunschweig - Institute of Technology

Here we present a new developed microwave furnace capable to produce small amounts of silicon metal. The energy efficient process is capable to produce high quality silicon metal, which can be purified with less complexity to silicon for solar cells. In a special designed microwave furnace a mixture of silicon oxide and carbon is heated up to a maximum temperature of 1,700 °C within a few minutes and silicon is produced. In order to optimize the silicon production it is essential to understand the reaction mechanism. Thus, molecular simulation techniques might provide insight into the complex processes. A new promising approach for MD studies of chemical reactions is the use of the reactive force field ReaxFF [1, 2].[1] A.C.T. van Duin et al., J. Phys. Chem. A 105, 9396-9409, 2001. Improved Material Efficiency in the Si Deposition from SiHCl3 under Mesoplasma Condition: *Makoto Kambara*[1]; Toyonobu Yoshida[1]; [1]The University of Tokyo

Equilibrium chemistries in the conventional Si deposition from SiHCl3 confirms that the relative amount of the stable Si solid is as highest ~ 25% at around 1400K because of the formation of more stable Si containing phases such as SiCl4 and SiCl2 over a wide temperature range. Under the mesoplasma condition, in contrast, such Si containing species are no longer stable and Si vapor becomes the most stable phase at >2500K in stead. One can thus foresee that the deposition efficiency is enhanced if Si vapor is to be rapidly condensed with increased degrees of non-equilibrium. Additionally, the mesoplasma process is characterized by its unique nano-cluster growth precursor which favors fast deposition and film structure modification. Based on this concept, we have demonstrated Si epitaxial films deposition at the deposition rate of >550 nm/s with the material yield of >50% at an increased RF input power of 24 kW.

3:50 PM

Impurities Distribution between SiO Gas and Reactant Materials in a Silicon Furnace: *Elena Dal Martello*[1]; Gabriella Tranell[2]; Oleg Ostrovski[3]; Guangqing Zhang[3]; Ola Raaness[4]; Kai Tang[4]; [1]NTNU ; [2]NTNU; [3]UNSW; [4]SINTEF

The control of the impurities inside the silicon furnace is a topic not widely investigated. Impurities in silicon can originate from quartz and carbon materials. In this work we correlate the impurity content in mixture of SiO2/SiC and SiO2/Si to the impurities carried out by SiO gas. The experiments represent the operative condition of the middle and bottom part of the furnace. Raw materials both in form of lumps and pellets are heated in graphite crucibles at 1700C and at 1900C. SiO gas is produced and collected as microsilica. Both microsilica and charge materials are analyzed chemically by ICP-MS. The experimental work is supported by thermodynamic simulations.The results give an understanding of the typology of the elements carried out of the furnace by SiO gas. In particular the abundance and typology of these impurities are correlated to the composition, the size and the physical state of the raw materials.

4:10 PM

The Kinetics of Boron Removal during Slag Refining in the Production of Solar-Grade Silicon: *Egil Krystad*[1]; Shuang Zhang[1]; Gabriella Tranell[1]; [1]NTNU

The kinetics of boron removal from liquid silicon during slag refining, as a process step in the production of solar grade silicon, has been investigated by means of small scale mass transfer experimental series at 1600°C, using a graphite crucible. The slags were SiO_2-CaO based, with or without addition of 19 wt% MgO. Experiments were carried out at slag-metal ratios of 1 or 2, where the silicon initially contained approx. 250 ppm boron. The mass transfer coefficients were found to be in the order of 1-3 × 10^{-6} m/s and were largely influenced by slag composition. The mass transfer rate was higher for the MgO-containing slag than the slags without MgO. The final equilibrium distribution of boron between metal and slag, L_B, was determined to be in the order of 2.3-3.3.

4:30 PM

Raman Spectroscopic Study of the Structural Modifications Associated with the Addition of Calcium Oxide and Boron Oxide to Silica: *Jeff Kline*[1]; Merete Tangstad[1]; Gabriella Tranell[1]; [1]NTNU

Raman spectroscopy as an instrumental technique for the determination of silicate structure is widely accepted. This method was utilized for analysis of structural modifications associated with the addition of network modifying oxides. Silicate slags are described by the extent of oxygen bridging. Therefore, understanding the structural modification of the silicate melt related to the addition of different oxides will provide important information regarding the removal of boron from silicon. Samples ranging from 45.5-64 wt% SiO_2 in the CaO-SiO_2 binary were evaluated. Boron oxide was added at 10, 5, 1 wt% to two CaO-SiO_2 base slags. Trends associated with the addition of the CaO to silica and structural variations accompanying the presence of boron oxide are presented.

4:50 PM

Structure Silicon Deposits Obtained by Electrolysis SiO2 in the Chloride-Fluoride Melts: *Oleg Chemezov*[1]; Aleksey Apisarov[1]; Andrey Isakov[1]; Yurii Zaikov[1]; [1]Institute of High-Temperature Electrochemistry Russian Academy of Science Ural Division

Silicon deposits containing 99,9 wt.% of main component were obtained by electrolysis SiO2 from chloride-fluoride melts. The operating temperature was varied from 500 up to 800° °C. The conditions for obtaining crystalline fibrous mickro or nanodeposits were determined. The deposits were investigated by ESM method.

Precipitates in Al-Cu Alloys Revisited: *Donald Siegel*[1]; Aniruddha Biswas[2]; Christopher Wolverton[3]; David Seidman[3]; [1]University of Michigan; [2]Bhabha Atomic Research Center; [3]Northwestern University

Atom-probe tomography, transmission electron microscopy, X-ray diffraction and first-principles calculations are combined to study composition evolution and solute segregation across a range of Al-Cu-based alloy systems, spanning from model alloys to multi-component commercial variants. For model alloys based on Al-Cu(-Si), most GPII zones and theta-prime precipitates are demonstrated to be Cu-deficient at lower aging temperatures. We also find evidence of Si partitioning to GPII zones and theta-prime precipitates, as well as significant Si segregation at the coherent alpha-Al/theta-prime interface. Our results suggest that Si catalyzes the early stages of precipitation in these alloys, consistent with the higher precipitate number densities observed in commercial Al–Cu–Si alloys. For the commercial alloy we report significant qualitative and quantitative differences in solute segregation at coherent and semi-coherent interfaces bounding a single theta-prime precipitate. The role of first-principles calculations will be highlighted as a means to provide "energetic explanations" for the experimental observations.

2:30 PM Invited

Evolution of Hetero-Interfaces in Alloys Forced by Severe Plastic Deformation: *Pascal Bellon*[1]; Robert Averback[1]; Nhon Vo[1]; Yinon Ashkenazy[1]; Daniel Schwen[1]; Elvan Ekiz[1]; Tim Lach[1]; Mohsen Pouryazdan[2]; Horst Hahn[2]; [1]University of Illinois; [2]Karlsruhe Institute of Technology

Plastic deformation can force the mixing of immiscible elements. In multiphase systems, this forced mixing depends significantly on the specifics of interfaces and on the strain path, since the mixing is superdiffusive when the mean free path of dislocations is large, and the mixing it is biased by thermodynamics for highly immiscible systems. Atomistic simulations on Cu-X alloy systems (X=Cu, Ag, Ni, Fe, V, Nb) reveal that the rate of forced dissolution of precipitates scales quadratically with precipitate radius for shearable precipitates, but only linearly for unshearable precipitates. In Cu-Nb bilayers, the rate of forced mixing during shearing is a strong function of orientation relationship and interface plane. Special orientations such as Nishiyama-Wassermann, for example, are remarkably stable against mixing. These results are compared to experimental observations on Cu-Ag, Cu-V, and Cu-Nb alloys deformed high-pressure torsion, and characterized by TEM and APT.

3:00 PM

Ab Initio Study of Competitive Coherent Hydride Formation in Zirconium Alloys: Ludovic Thuinet[1]; *Rémy Besson*[1]; [1]UMET

We present a detailed atomic-scale investigation of coherent hydrides in Zr alloys. While previous experimental and theoretical studies emphasized the gamma' (ZrH) and zêta(Zr2H) phases as potential precursors in the hydride precipitation sequence, they led to contradictory conclusions justifying further analysis of the nucleation of these two types of precipitates. To this aim, we take proper account of the three energy contributions (bulk chemical, interfacial and elastic) involved in Classical Nucleation Theory by incorporating original features such as (i) zêta bulk off-stoichiometry, (ii) anisotropic matrix/hydride interfacial energies and (iii) shape factors of platelike nuclei. These effects turn out to be essential to provide a realistic description of the conditions of temperature and H content leading to preferential gamma' or zêta formation. Our work provides a unifying picture of the previous, apparently diverging, works on coherent zirconium hydrides and emphasizes the importance of accurately calculating coherent interfacial energies in such systems.

3:20 PM

Compositional Evolution of Q-Phase Precipitates in an Al-Alloy via 3-D Atom-Probe Tomography: *Aniruddha Biswas*[1]; David Seidman[2]; [1]Bhabha Atomic Research Centre; [2]Northwestern University

The results of a 3-D local-electrode atom-probe (LEAP) tomographic study of the compositional evolution of Q-phase precipitates in a commercial age-hardenable aluminum alloy, W319, are presented. Three different aging conditions are investigated: 438 K for 8 h, 463 K for 8 h, and 533 K for 4 h. APT specimens are Ga+ milled using a dual-beam focused-ion beam (FIB) microscope and analyzed employing a 3-D LEAP tomograph. After aging at 438 K and 463 K, the Q-phase precipitates exhibit compositions rich in Cu but lean in Mg and Si. They evolve into a Mg-rich phase after aging at 533 K. This research provides the first experimental evidence for partitioning of Zn to the Q-phase precipitates. This effect is detected even though the bulk concentration of Zn is only 0.05 at. %. Furthermore, we observe co-precipitation of the theta-prime and Q-phase precipitates for all three aging conditions.

3:45 PM

Polyhedron Analysis for Structure Identification in Atomistic Simulations: Thomas Schablitzki[1]; *Jutta Rogal*[1]; Ralf Drautz[1]; [1]Ruhr University Bochum

Topologically close-packed (TCP) phases such as the \963-,\956- or Laves phases are of interest for a number of materials, including high-temperature superalloys or high-strength steels. The atomic structure of the different TCP phases is characterized by particular arrangements of Frank-Kasper coordination polyhedra. For the identification of the TCP phases in atomistic simulation data we fingerprint the surrounding of each atom. To this end we first extract the local coordination polyhedron for each atom from the atomistic data. In a second step correlations between the polyhedra are used to identify the structure and sublattices of the TCP phases. We demonstrate our method for a number of crystal structures and for adaptive kinetic Monte Carlo simulations of the interface between TCP phases and the alloy matrix phase.

4:05 PM

Investigation of Interfacial Precipitation and Segregation in Ultra High Strength Steel with TEM and 3D Atom Probe: *Matthew Hartshorne*[1]; Paul Novotny[2]; Michael Schmidt[2]; David Seidman[3]; Mitra Taheri[1]; [1]Drexel University; [2]Carpenter Technology Corporation; [3]Northwestern University

Ultra High Strength (UHS) steels used in high performance applications typically require large concentrations of alloying elements to achieve the required strength and toughness. The Carpenter Technology Corporation has developed a new family of UHS steels with comparable mechanical properties to current alloys, yet possessing markedly reduced levels of a wider variety of alloying elements. The strengthening mechanisms of this system are not well understood, necessitating a detailed investigation of its interfacial precipitation and solid solution hardening. Experiments will be presented detailing precipitate type and location within the microstructure by utilizing high resolution TEM and electron tomography. These experiments are coupled with 3D atom probe studies, which allows for the analysis of solute segregation at grain, lath and precipitate boundaries. The combination of these techniques provides a more comprehensive understanding of the role and interactions of each of the alloying elements in this new alloy.

4:25 PM
Fabrication and Characterization of Oriented Fe-$Y_2Ti_2O_7$ Interfaces: Implications to the Development and Optimization of Nanostructured Ferritic Alloys: *Tiberiu Stan*[1]; Yuan Wu[1]; G. Robert Odette[1]; Kurt Sickafus[2]; Hanna Dabkowska[3]; Bruce Gaulin[3]; [1]University of California Santa Barbara; [2]University of Tennessee; [3]McMaster University

Nano-structured ferritic alloys are dispersion strengthened by a high density of nanofeatures (NF) yielding remarkably high temperature creep strength and radiation damage resistance. The smallest 2-3 nm NF are complex $Y_2Ti_2O_7$ pyrochlore oxides. The Iron-NF interface is critically important, but is difficult to fully characterize. To complement characterization of the NF, a bulk interface was created by electron beam deposition of a thin Iron (Fe) layer onto a {111} $Y_2Ti_2O_7$ single crystal surface and characterized using SEM, AFM, XRD and TEM techniques. The polycrystalline Fe layer has two general oxide orientation relationships close to: a) $\{100\}_{Fe}//\{111\}_{ox}$ and $<100>_{Fe}//<110>_{ox}$; and, b) $\{110\}_{Fe}//\{111\}_{ox}$ and $<111>_{Fe}//<110>_{ox}$. HRTEM shows interfaces that are almost atomically sharp with various defects and more diffuse interface zones that, in some cases, include a thin FeO_x layer. This work will be refined and extended to other orientations and studies of the interface interactions with irradiation induced defects and helium.

4:45 PM
Atomistic Simulations of Cu Growth on ZnO Surfaces Using COMB Potentials: *Yu-Ting Cheng*[1]; Tao Liang[1]; Bryce Devine[1]; Beverly Hinojosa[1]; Aravind Asthagiri[2]; Simon Phillpot[1]; Susan Sinnott[1]; [1]University of Florida; [2]The Ohio State University

Cu/ZnO heterogeneous systems have been shown to catalyze the electrochemical reduction of carbon dioxide into hydrocarbons with high efficiency. Because the electrochemical efficiency and the selectivity of product is highly dependent on the nature of the electrode, the way in which ZnO surfaces support Cu clusters and stabilize their active sites is a key factor for maintaining catalyst activity. In this work, the adsorption of Cu clusters of various sizes on the ZnO surfaces are modeled using atomic-scale molecular dynamics simulations with charge-optimized many-body (COMB) potentials. Further, the adaptive kinetic Monte Carlo (aKMC) will be employed to explore the growth and coalescence of the clusters. The findings are validated against the results of density functional theory calculations and experiments.

5:05 PM
Microscopic Study of Cu-based Dilute Cu-Nb-W Ternary System: *Xuan Zhang*[1]; Pascal Bellon[1]; Robert Averback[1]; [1]UIUC

The dilute Cu-Nb-W thin films with a solid-solution as-grown state have shown some interesting microstructural properties under different treatments. (1)The samples annealed to as high as 830C have a bi-model precipitate size distribution. Smaller precipitates are richer in W. The bcc particle/fcc matrix interfaces are preferably to be K-S type. Particles larger than 5nm have a Nb-rich core and a W-rich shell, which is composed of small W-rich clusters. (2) The samples which are first ion irradiated at room temperature and second annealed at elevated temperatures have shown reversed core/shell structure. The irradiation gives rise to the formation of 1nm-sized W-rich clusters while most Nb atoms are still in solution. The following-up annealing makes the Nb precipitate to cover the W clusters. The variability in structures offers the flexibility in design interfaces optimized for applications, for instance for trapping point defects in irradiated alloys, thus enhancing their radiation resistance.

5:25 PM
Characterization of Reaction Layers in $Mn_{1.5}Co_{1.5}O_4$ Coated Fuel Cell Interconnects: *Neal Magdefrau*[1]; Lei Chen[1]; John Yamanis[1]; Ellen Sun[1]; Mark Aindow[2]; [1]United Technologies Research Center; [2]University of Connecticut

Ceramic coatings on metallic solid oxide fuel cell interconnects are a key component of the SOFC stack. These coatings prevent chromium poisoning of the cathode while also slowing the oxidation kinetics of the underlying alloy. Excessive oxidation of the interconnect alloy can lead to ohmic losses, which in turn limit the life of the stack. However, typical interconnect coating materials such as $Mn_{1.5}Co_{1.5}O_4$ (MCO) spinels can form complex reaction layers with the underlying alloy. Here we present electron microscopy data obtained from MCO coatings on Crofer 22 and Haynes 230 alloy substrates after static oxidation and area-specific resistance testing. It is shown that both the microstructure of the underlying alloy and the electric current have a profound influence on the morphology/evolution of the chromia subscale and the intermediate reaction layer(s). The significance of these observations for the lifetimes of such coated interconnects is discussed.

TEM Deformation Maps : Microstructure & Mechanical Behavior: *Muriel Veron*[1]; Edgar Rauch[1]; [1]SIMaP

An orientation and phase mapping technique (ASTAR) was recently developed for TEM with good reliability and reasonable acquisition time. Installed on a FEG TEM, orientation and phase maps are obtained with a spatial resolution of 1nm. This technique has many applications such as studying deformation mechanisms in structural materials e.g., steel or magnesium alloys, but also to address new challenges, for instance in-situ deformation of nano-crystalline palladium films. Combined with FIB technology to prepare TEM specimens, ASTAR provides new descriptions of deformation mechanisms in very specific locations. Two examples will be presented: firstly precise deformation mechanisms of Mg single crystals under a nano-indentor tip, followed by a more classical study of steels involving phase transformations.

2:30 PM Invited
Plastic Flow Heterogeneity and Yielding Instabilities: *Georges Saada*[1]; Tomas Kruml[2]; I. Kubena[3]; [1]LEM CNRS ONERA; [2] Institute of Physiscs of Materials Materials ; [3] Institute of Physiscs of Materials Materials

The occurrence of sharp yield points associated with band nucleation and propagation in aged and deformed steels (Lüders bands) or Al based alloys (Portevin-Le Châtelier oscillations) has been known for more than one century. The Lüders phenomenon has been shown to disappear by changing the sense of the applied stress. Systematic experiments on Al-Mg alloys, and low carbon steels reported in our communication show the same effect on the Portevin-Le Châtelier oscillations, and confirm the disappearance of the Lüders phenomenon in low carbon steels. Using careful measurement of the elastic-plastic transition during reverse straining, we show that this behaviour is a consequence of large scale microstructure heterogeneity, whose general features are analysed, and shown to describe satisfactorily the observed behavior.

2:55 PM Invited
A Dislocation-Based Model for Interpretation of Strain Path Changes in Steel and Magnesium: *Carlos Tome*[1]; Kohshiroh Kitayama[2]; Edgar Rauch[3]; Gabriela Vincze[2]; Jose Gracio[2]; Frederic Barlat[4]; [1]Los Alamos National Laboratory; [2]University of Aveiro; [3]Universite de Grenoble/ CNRS Grenoble; [4]Pohang University of Science and Technology

Polycrystal aggregates subjected to plastic forming exhibit large changes in the yield stress and extended transients in the flow stress following strain path changes. Since these effects are related to the rearrangement of the dislocation structure induced during previous loading, it is natural to employ a dislocation-based hardening model in order to comprehend such behavior. Here we present such model, implement it in the polycrystal code VPSC, and simulate strain path changes in low carbon steel and Mg AZ31. The path changes consist of tension followed by shear, and forward and reverse simple shear for carbon steel. In the case of Mg AZ31 we do tension followed by tension. In both cases the reloads were performed at different angles with respect to the preload tensile axis. The results are compared to experimental data and highlight the role that directional dislocation structures induced during preload, play during the reload stage.

Finite Element Implementation of a Self-Consistent Polycrystal Plasticity Model: Application to a-Uranium: *Marko Knezevic*[1]; Rodney McCabe[1]; Ricardo Lebensohn[1]; Carlos Tomé[1]; Bogdan Mihaila[1]; [1]Los Alamos National Laboratory

In this paper, we adapt a visco-plastic self-consistent polycrystalline model and integrate it in the implicit finite-element framework, to simulate crystallographic texture evolution and mechanical response of wrought a-uranium (orthorhombic structure). The constitutive equations include a multi-scale dislocation-based hardening law for multiple slip and twinning modes. The latter is necessary to model the highly anisotropic response of a-uranium. The predictive capabilities of the model are demonstrated by comparing numerical simulations against experimental measurements in simple compression, simple tension and four-point bending tests. The macroscopic strain hardening, texture evolution and dimensional changes are in good agreement with experiments performed on textured a-uranium.

4:00 PM Invited
Modeling Plasticity and Cracks at the Atomic Scales within a Continuum Framework: *Pierre-Antoine Geslin*[1]; Benoit Appolaire[2]; Alphonse Finel[2]; [1]LEM ONERA / CNRS ; [2]LEM ONERA / CNRS

We propose a model for plasticity at the atomic scale relying on continuum fields. It derives from a Lagrangian with a potential periodic in the relevant order parameter based on strain components. It naturally accounts for dislocation motion, but also for dislocation nucleation and annihilation, two features which are usually lacking (or introduced through local phenomenological rules) in other methods, such as discrete dislocation dynamics or continuous approaches based on dislocation densities. This model is thus able to bring qualitative insights on open questions occurring in multiphase materials involving dislocation motion as well as nucleation, such as (i) coherency loss at a precipitate interface and (ii) inheritance of plastic deformation by a growing precipitate. Extension of this model to incorporate damage and cracks will also be presented.

4:30 PM Invited
Spectral Elasto-Viscoplastic Formulation for the Prediction of Micromechanical Fields with Direct Input and Validation from Voxelized Data: *Ricardo Lebensohn*[1]; Jette Oddershede[2]; Grethe Winther[2]; [1]Los Alamos National Laboratory; [2]Risoe DTU

We present the extension to the most general case of elasto-viscoplastic (EVP) polycrystals of a formulation originally developed [1] as an efficient method to compute the micromechanical fields in deformed heterogeneous materials, directly from an image of their microstructure. Under this technique, the input microstructural image is treated using the Fast Fourier Transform (FFT) algorithm to solve the corresponding micromechanical problem. We show an application of the new EVP-FFT method to the prediction of grain-resolved internal stresses measured in-situ in a plastically-deformed copper polycrystal using three-dimensional synchrotron X-ray diffraction [2]. Binary and Ternary Interaction Coefficients in BCC Metals and Single Crystal Strain Hardening: *Ronan Madec*[1]; Ladislas Kubin[2]; [1]CEA, DAM, DIF; [2]LEM (CNRS/ONERA)

Dislocation dynamics simulations have now reached a stage where they are able to tackle such problems as the formation of dislocation microstructures and forest hardening in bulk single crystals. The connection between mesoscopic and continuum approaches of plasticity is based on the knowledge of the interaction matrix between slip systems and of the dislocation mean free paths, from which a hardening matrix can be derived. The objective of the present work is to establish this connection for BCC metals, using a dislocation dynamics simulation that is briefly described. Emphasis is on the determination of the interaction matrix in the high temperature regime, above the so-called “athermal temperature” at which lattice friction vanishes. Results on binary and ternary dislocation reactions will be discussed. Comparison between finite element crystal plasticity calculations using these coefficients and stress vs. strain curves are presented and the orientation dependence of strain hardening is discussed.

Titanium: Advances in Processing, Characterization and Properties: Processing and Process Modeling II

2:00 PM
Effect of Processing on Microstructure and Mechanical Properties of Ti-6Al-4V Fabricated Using Electron Beam Melting (EBM): *Nikolas Hrabe*[1]; Ryan Kircher[2]; Timothy Quinn[1]; [1]NIST; [2]Medical Modeling

Selective electron beam melting (EBM) is an additive manufacturing technique that shows great promise for fabrication of medical devices and aerospace components. Before its potential can be fully realized, however, a deeper understanding of processing-microstructure-properties relationships is necessary. Titanium alloy (Ti-6Al-4V) samples were built to allow investigation of the following processing parameters: distance from build platform and energy input. There was no discernible difference found in microstructure (prior-ß grain size and a needle thickness) or mechanical properties (UTS, YS, %EL, and Vickers microhardness) as a function of distance from build platform. This is thought to result from the ability of the control software to maintain relatively constant melt pool size. For a wide range of energy input (speed factor 30-40), small but discernible differences in microstructure (20% for a needle thickness) and mechanical properties (3% for UTS, YS, and microhardness) were measured.

2:20 PM
Surface Tension and Viscosity of Industrial Ti-alloys Measured by the Oscillating Drop Method under Reduced Gravity Conditions: *Rainer Wunderlich*[1]; Hans -Joerg FECHT[1]; [1]Universitaet Ulm

Thermophysical properties of Ti-alloys in the liquid phase are important parameters for modelling of casting and solidification used for improvements of process technology and product quality. Due to the high liquidus temperatures and the high chemical reactivity their measurement is, however, complicated and difficult with conventional techniques. Containerless processing based on electromagnetic levitation offers an alternative. An electromagnetic levitation device was constructed for operation on board parabolic flights and as payload on sounding rocket. Measurements of the surface tension and the viscosity were performed by the oscillating drop method. Microgravity conditions are afforded because under 1-g conditions the large levitation forces induce turbulent fluid flow which renders measurement of the viscosity impossible. An overview is given of the results of surface tension and the viscosity measurements of a variety of Ti-alloys including Ti64 with variants and different \149; -TiAl alloys such obtained.

2:40 PM
Fractographic Characterization of Electron Beam Freeform Fabrication [EBF3] Produced Ti-6Al-4V: *Cynthia Lach*[1]; Robert Hafley[1]; [1]NASA Langley Research Center

Electron Beam Freeform Fabrication (EBF3) is a layer-additive process that produces net-shaped structural components by feeding wire into a molten pool formed by an electron beam in a high vacuum. Selective aluminum vaporization has been documented due to vapor pressure differences of the alloy constituents. This can lead to variability in the alpha-beta microstructure, mechanical properties and fracture behavior. Ambient temperature tensile and fracture tests were conducted on EBF3-deposited Ti-6Al-4V. Comprehensive fractographic characterization was conducted in two crack growth orientations macroscopically to evaluate overall fracture morphology and microscopically to assess fracture modes. The LT specimens (crack propagating perpendicular to the deposition layers) exhibited slant fracture growth in contrast to the flat fracture observed for the TL specimens (crack propagating parallel to the deposition direction). These results are compared to conventional wrought product to understand the impact of EBF3 processing on the performance of Ti-6Al-4V.

3:00 PM
Microstructure and Mechanical Properties of Ti-6Al-4V Fabricated by SelectiveLaser Melting: *Marco Simonelli*[1]; Yau Yau Tse[1]; Chris Tuck[1]; [1]Loughborough University

Selective laser melting (SLM) has been used as an alternative manufacturing route to produce Ti-6Al-4V components. This study focuses on the influence of SLM parameters on the microstructure and mechanical properties of resultant Ti-6Al-4V components. Microstructure characterisation was carried out using various microscopy techniques including optical, scanning electron and transmission electron microscopy and electron backscattered diffraction. The SLM produced components shows an apparently lower ductility compared to those manufactured in a conventional ways such as forged or rolled. It is also found that martensitic phase shows different morphology in regions experienced different thermal history in the SLM. The microstructure details observed will be discussed in relation to the SLM parameters.

3:20 PM
Computational Modeling of Aluminum Evaporation and Flow in Electron Beam Button Melting of Ti-6Al-4V: *Zhongkui Zhang*[1]; Carl Reilly[1]; Daan Maijer[1]; Steve Cockcroft[1]; [1]The University of British Columbia

The Electron Beam Cold Hearth Remelting (EBCHR) process has emerged as a key process in the production of high quality Ti-6Al-4V ingot and electrode as it is able to effectively consolidate both sponge and scrap material. A comprehensive model of the melt pool produced during electron beam button melting has been developed to serve as an intermediate step in the development of a comprehensive tool for analysis and optimization of the industrial EBCHR process. The thermal-fluid model includes evaporation, compositional and thermally driven buoyancy, compositional and thermally driven Marangoni flow as well as flow attenuation in the mushy regime. Experimental investigations using Ti-6Al-4V and CP Titanium with two different electron beam patterns were conducted to elucidate the role of evaporation of aluminum in driving fluid flow. Surface velocity, temperature, Al concentration, mold heat flux and predicted melt pool profile have been quantified experimentally in order to verify the model.

3:40 PM
Computational Modeling of the Dissolution of Alloying Elements: *Jun Ou*[1]; Aniruddha Chatterjee[1]; Daan Maijer[1]; Steve Cockcroft[1]; Carl Reilly[1]; [1]The University of British Columbia

The dissolution of alloying elements within the bulk liquid is of utmost importance in alloy production to ensure homogeneity. A mathematical model based on a commercial Computational Fluid Dynamics software package has been developed to describe dissolution of an alloying element in bulk liquid. The model includes the effects of heat transfer, diffusion, buoyancy, Marangoni force and Darcy flow and has been used to assess the contributions of each factor on the dissolution kinetics of alloying elements. The results show that buoyancy and Marangoni forces are significant factors, which influence solute transport. The model has been successfully validated using experimental data from a water-ethanol analogue system, using the quantified temperature at discrete locations, surface velocities and solid/liquid interfacial profiles. The industrial relevance of the model has been demonstrated by modeling the addition of aluminum to titanium. These results show good agreement with experimental results obtained using an electron beam furnace.

Cost Effective and Eco-Friendly Process for Preparation of Wrought Pure Ti Material via Direct Consolidation of TiH_2 Powders: *Takanori Mimoto*[1]; Nozomi Nakanishi[1]; Thotsaphon Threrujirapapong[1]; Junko Umeda[1]; Katsuyoshi Kondoh[1]; [1]Osaka University

The direct consolidation of titanium hydride (TiH_2) raw powders in solid-state was employed to fabricate pure titanium (Ti) bulk materials by *in-situ* dehydrogenation of TiH_2 powders via powder metallurgy (P/M) route. In general, the production cost of Ti materials is expensive due to using commercially pure (CP) Ti powders after dehydrogenation. On the other hand, the novel process using TiH_2 powders as starting materials is a promising low cost approach for P/M Ti components. Furthermore, this new process is also attractive from a viewpoint of energy saving because the dehydrogenation is integrated into the sintering process. In the present study, TiH_2 raw powders were directly consolidated by conventional press at 600 MPa and the integrated sintering process including dehydrogenation to produce pure Ti billet. The hot-extruded pure Ti material showed excellent tensile strength and elongation, according to the requirement of ASTM Ti Grade 4 and 1, respectively.

4:30 PM

The Effect of Micro-Alloying on the Preform Fabrication of Titanium Alloys and the Forged Mechanical Properties: *Ma Qian*[1]; Y. F. Yang[1]; X. Wu[2]; S. D. Luo[2]; K. Xia[2]; C. J. Bettles[3]; G. B. Schaffer[2]; [1]The University of Queensland; [2]The University of Melbourne; [3]Monash University

Preform fabrication from powder has the advantages over ingot metallurgy of ensuring excellent chemical homogeneity, fine and uniform grain structures, and flexible compositional changes. The availability of the lower cost quality hydrogenated and dehydrogenated (HDH) titanium powder makes it a practically attractive route to titanium preform fabrication. Micro-alloying is an established simple and cost-effective means of improving the constitutional and microstructural characteristics and mechanical properties of metallic materials. This paper presents a detailed study of the effect of micro-alloying on the preform fabrication of lower cost Ti-Fe and Ti-Cu alloys and the subsequently forged mechanical properties. Micro-alloying with boron (B) and silicon (Si) resulted in noticeable microstructural refinement due to enhanced heterogeneous nucleation and dispersion strengthening in the as-sintered titanium alloy preforms, in addition to the improved densification. The subsequent isothermal forging further substantially modified the microstructure leading to very attractive mechanical properties.

4:50 PM

Linear Friction Welding of Titanium Alloys – Processing, Characterisation and Properties: *Hangyue Li*[1]; Simon Bray[2]; Yina Guo[1]; Jiayun Jiang[1]; Robin Wilson[1]; Paul Bowen[1]; [1]The University of Birmingham; [2]Rolls-Royce plc

The growing performance requirements for modern engines have motivated the use of integrated blisk constructions, in which separated machined blades and disk are joined to form a solid component, using a linear friction welding technology. The mechanical properties including fatigue, fatigue crack growth resistance, impact toughness and fracture toughness are reviewed for linear friction welded Ti-6Al-4V and Ti-6Al-2Sn-4Zr-6Mo, together with weld integrity assessments and detailed microstuctural analysis. An overmatch in hardness has been achieved as results of changes and refinement of microstructure in the welded zone. This gives rise to superior mechanical performance of the welded joints on the smooth and notched testpieces geometries, e.g. high cycle fatigue life and impact toughness, with failure location always identified outside the welded zone. By introducing a fatigue crack into the welded zone, damage tolerance related properties can be measured, which together with other assessments, contribute to the optimisation of welding process.

5:10 PM

Deformation Mechanisms in Near-α Titanium Friction Stir Welds: *Richard Fonda*[1]; Keith Knipling[1]; Adam Pilchak[2]; [1]Naval Research Laboratory; [2]Air Force Research Laboratory

We have investigated the mechanisms of microstructural evolution that occur during friction stir welding of a fully lamellar near-a titanium alloy. Friction stir welds of α and near-α titanium alloys have a narrow thermomechanically affected zone, often containing alternating bands of acicular α, similar to the base plate microstructure, and refined prior ß grains, similar to those observed in the weld nugget. We propose that these bands result from the development of periodic micro-shear bands and support this model through an analysis of 1) the observed microstructure and crystallographic texture and 2) automated reconstruction of the prior ß grain structure and orientations that were present during welding. This work represents the first complete analysis of the deformation mechanisms occurring in both the a and ß phases in the TMAZ of near-αtitanium friction stir welds.

5:30 PM

X-Ray Tomography of CP Titanium Friction Stir Welds Incorporating Fiducial Markers: *Jennifer Wolk*[1]; Richard Everett[2]; Stephen Szpara[1]; [1]Naval Surface Warfare Center; [2]Naval Research Laboratory

Friction stir welding (FSW) of titanium has the potential to reduce fabrication and life-cycle costs compared to conventional joining techniques. However, commercial-purity (CP) Ti has been found to be rather difficult to FS weld. Voids are frequently present, and control over weld consistency and quality is challenging. Markers have been placed in FS welds to aid flow visualization, process comprehension, and parameter optimization. In this paper, we discuss the initial use of nickel foil markers in 6 mm (0.25 inch) thick CP titanium FS welds. X-ray computed microtomography (XCMT), as well as standard microscopy techniques, has been utilized to study marker location, distribution, and material microstuctures in these welds. The presence of the markers affects welding loads, surface finish, and void formation compared to standard welding. The markers clearly show differences in material deposited in the advancing and retreating sides, and are capable of delineating different flows at different depths.

5:50 PM

Effect of Dual-Laser Beam Welding on Microstructure Properties of Thin-Walled \947-TiAl Based Alloy Ti-45Al-5Nb-0.2C-0.2B (TNB): *Jie Liu*[1]; Volker Ventzke[1]; Peter Staron[1]; Heinz-Günter Brokmeier[1]; Michael Oehring[1]; Nikolai Kashaev[1]; Norbert Huber[1]; [1]Institute of Materials Research, Helmholtz-Zentrum Geesthacht, Germany

The new generation of TiAl based alloys such as TNB could have a greater potential for industrial applications when suitable joining technologies will be available. Diffusion bonding and friction welding cannot be applied to join thin-walled TiAl structures. This work takes up the economic approach of laser beam welding techniques using two laser beams simultaneously. One laser beam having large spot size is used for pre-heating and the second for keyhole welding. The surrender of furnace equipment to achieve temperatures above brittle-ductile transition region can be realized by the application of this dual-beam process. The laser beam welded TNB is characterized using synchrotron X-ray diffraction, SEM, EDX, EBSD and microhardness testing to describe microstructure, residual stresses as well as microtexture in fusion zone, heat-affected zone and base material. The obtained results are showing that the dual-laser beam can be properly applied for defect-free joining of thin-walled TNB.

T.T. Chen Honorary Symposium on Hydrometallurgy, Electrometallurgy and Materials Characterization: Copper Electrorefining

METTOP-BRX-Technology – Industrial Application: *Christine Wenzl*[1]; Andreas Filzwieser[1]; Stefan Konetschnik[1]; [1]METTOP GmbH

The METTOP-BRX-Technology is a novel manifold electrolyte inlet, which allows improving productivity and production in new and existing tankhouses by achieving higher current efficiency and cathode quality, as well as using higher current densities higher than 400 A/m². Two installation examples are shown: Montanwerke Brixlegg AG, Brixlegg, Austria (upgrade existing tankhouse) and Xiangguang Copper, Yanggu, China (new tankhouse). Montanwerke Brixlegg AG has been using the METTOP-BRX-Technology since 2005, and converted half of the whole tankhouse to METTOP-BRX in 2011 in order to use a current density of more than 400 A/m².Xiangguang Copper started up their second tankhouse in May 2011. This tankhouse was constructed in the same way as the existing tankhouse, but was designed for 292,000 t/a cathode copper (existing tankhouse: 200,000 t/a) by using the METTOP-BRX-Technology. This production increase is caused by a much higher current density, namely 410 A/m², compared to 280 A/m² in the old tankhouse.

2:20 PM

Implementing Wireless Electrolytic Cell Monitoring System at Kennecott Utah Copper for Improved Operational Efficiency: *Ari Rantala*[1]; Daniel Kim[2]; [1]Outotec (Finland) Oy, Finland; [2]Rio Tinto Kennecott Utah Copper

On-line monitoring of electrolytic cell performance in copper electro-refining requires complex electrical measurement systems and efficient management of enormous volume of data. Based on Kennecott Utah Copper's innovation, Outotec has developed in partnership a novel electrolytic cell monitoring system, CellSenseTM System. As the system is based on self-powering from bus bars, wireless communication, on-line adaptive modeling and easy to access information and alarming, traditional obstacles of electrolytic cell monitoring are eliminated. With cell voltage and electrolyte temperature measurements, CellSenseTM System enables real-time cell performance discovery and early reaction to critical production or quality disturbances such as short-circuiting, flow blockages, cold cathodes or electrolyte temperature excursions. During past few years the system has been delivered to over 3500 commercial cells. In this paper the largest CellSenseTM System recently adapted by Kennecott Utah Copper with 1412 cells monitored on-line for high tankhouse performance, cathode quality and optimized operator work flow is presented.

2:40 PM

Autoclave Pressure Oxygen Leaching Of Anodic Copper Slimes: *Tracy Morris*[1]; Luis Navarro[1]; [1]ASARCO LLC

Anodic copper slimes produced during the electrolytic refining of copper are routinely batch leached to remove copper. At the Amarillo Copper Refinery an atmospheric leaching process was converted to an autoclave pressure vessel to improve the removal of copper, reduce the consumption of oxygen, improve leaching time and enhance tellurium recover.The benefits of pressurized versus atmospheric leaching of slimes were were soon realized by obtaining the desired level of decopperization with less time and with lesser quantities of reagents. The autoclave was designed and constructed with a unique oxygen injection system that enables good control of the leaching process and with no plug ups. Other features include a mass measuring system that balances the quantity of slimes to be leached to the desired final solution concentration based on initial feed concentrations. The end result was a more efficient and controllable leaching process for removing copper from slimes.

3:00 PM

Mechanism and Thermodynamics of Floating Slimes Formation: *Brent Hiskey*[1]; [1]University of Arizona

The global copper industry faces a technological challenge to develop processing schemes for more complex and impure ores and concentrates. Group 15 elements (As, Sb, and Bi) represent troublesome impurities both in terms of environmental impact and metallurgical processing. These so-call "dirty" copper concentrates are either unacceptable for smelting and refining or incur high penalties. The behavior of Group 15 elements is of critical importance in maintaining product quality and process performance. During copper electrorefining, these impurities are released to the electrolyte by electrochemical dissolution of the anode. Depending mainly on temperature, concentration, and oxidation state these elements can spontaneously co-precipitate from the electrolyte. These precipitates are referred to as floating slimes and their formation can have extremely detrimental effects on cathode purity. In this paper, the mechanism of floating slimes formation will be discussed and the fundamental thermochemistry will be reviewed and analyzed in relation to solubility properties.

3:20 PM Break

3:30 PM

Detellurization Process of Copper Anodic Slimes Leach Liquor by Cementation of Tellurium Using Elemental Copper: Tracy Morris[1]; *Luis Navarro*[1]; Weldon Read[1]; [1]ASARCO LLC

During the leaching of anodic slimes, tellurium dissolves into the leach liquor together with copper and must be removed before the solution is sent to liberator cells for copper recovery. Prior to the installation of autoclaves tellurium was precipitated using raw slimes that caused a run around of tellurium in the leaching circuit. After autoclaves were installed the old leach tanks were converted into tellurium reactors utilizing copper chips, steam and agitation to form a copper telluride precipitate. Tellurium levels of less than 10 mg/l are achieved in a timely manner.

3:50 PM

New Process of Precipitation of Sb and Bi from Copper Electrolytes with PbO_2: *Gerardo Cifuentes*[1]; Jaime Simpson[2]; Cristián Vargas[1]; [1]USACH; [2]ProPipe Ltda.

This paper presents a new process of precipitation of Sb and Bi present in copper refinery electrolytes in the presence of PbO_2 (Chilean Patent No. 45,037). To establish the conditions under which these compounds precipitating are forming, it was necessary to realise testing of PbO_2 consume, antimony extraction efficiency, stability tests, reaction kinetics, diffraction analysis and X-ray fluorescence, separation of size, plus observation of precipitates in the electron microscope. Preliminary tests was carried with synthetic electrolyte similar to copper refinery electrolytes, and then establish final testing with electrolytes from Chilean refineries.This process proves to be a real alternative for the treatment of copper refinery electrolytes for control of Sb and Bi in solution, presenting a very simple operation and low cost compared with competing processes. Keywords: Antimony, Bismuth, Precipitation, PbO2, Copper, Electrorefinning.

4:10 PM
Study of Electrolyte Impurity Precipitates at the Kennecott Refinery: *Justin McAllister*[1]; Daniel Kim[1]; Shijie Wang[1]; [1]Rio Tinto

At the Kennecott Utah Copper Refinery, impurities in the electrolyte are being precipitated in the circulation system and form a hard scale on the pipes. This scale must be removed periodically for proper electrolyte flow. Distinct layers of differing composition form as the operating conditions of the tank house changes. Scale samples from the inlet and outlet pipes were analyzed to discover the nature of the precipitate. Each sample was sectioned and examined under optical microscopy and SEM. The composition of the scale was analyzed using ICP, XRD, and SEM/EDX mapping. The rate of deposition was determined through measuring the amount deposited on new pipes after elapsed time intervals. In order to determine how to minimize the formation of the scale the mechanism was studied and the results are presented in this paper.

4:30 PM
Copper Refining Electrolyte Purification by the Use of Molecular Recognition Technology (MRT) for Bismuth Removal: *Luis Navarro*[1]; Weldon Read[1]; Tracy Morris[1]; [1]ASARCO LLC

Bismuth is a renowned contaminant in the electrolytic refining of copper that can render many a cathode to be outside ASTM standards and unsuitable for copper rod and other down stream products if not carefully controlled. This paper portrays the performance of Molecular Recognition Technology (MRT) for Bismuth removal at the Amarillo Copper Refinery and describes how the highly selectivity gel has been successfully used to achieve good bismuth removal and how many pit falls and draw backs have been overcome.

4:50 PM
Optimizing a Cascading Liberator: *Bradford Wesstrom*[1]; Omar Araujo[1]; [1]Freeport-McMoRan Copper & Gold

Impurities from electrolytic refinery are typically extracted from the electrolyte utilizing conventional electro winning cells. These cells are arrange in series with cascading solution flow and are commonly referred to as liberator cells. The Freeport McMoRan Copper & Gold El Paso Refinery has optimized the removal of arsenic in cascading liberator cells by utilizing two separate feed solutions. The primary feed solution is recycled liberator electrolyte and the secondary feed solution is “neat” tank-house electrolyte. The secondary feed solution is added based on the voltage response across the individual cells utilizing independent variable frequency drive (VFD) pumps. When the voltage across a cell changes, a signal is sent to the VFD pump to maintain a cell voltage of 1.98 volts. By maintaining this voltage the copper content in each cell exits at 2-4 grams per liter. This safely optimize the arsenic removal as copper arsenides on the liberator cathodes.

5:10 PM
Copper Electrorefining Impurity Evaluation: *Michael Free*[1]; Justin Mcallister[2]; Urian Marshall[1]; Megan Marshall[1]; Daniel Kim[2]; Shijie Wang[2]; [1]University of Utah; [2]Kennecott Utah Copper, LLC

Electrorefining copper cathode impurity levels were evaluated based on 1/10th scale laboratory electrorefining tests. Cathodes were evaluated near the top, mid-section, and bottom sections of cathodes on both set and mold sides and strip and scrap cycles. Slime weights were also measured, and slime and electrolyte samples were also evaluated for impurities. Results from these tests have been compiled and compared to evaluate the effects of changes in operating conditions and electrode location on cathode impurities.

Ultrafine Grained Materials VII: Deformation Mechanisms

Austenitic Steels Strengthened by Nano-Scale Twins: *K. Lu*[1]; Nairong Tao[1]; [1]Shenyang National Laboratory for Materials Science, Institute of Metal Research, Chinese Academy of Sciences

Recent studies showed that nano-scale twins are effective in strengthening metals with a superior strength-ductility synergy. By means of dynamic plastic deformation (DPD, i.e., deformation at high strain rates) and subsequent thermal annealing, a mixture structure of micro-sized recrystallized grains embedded with grains with nano-scale twins is formed in austenitic steels with low stacking fault energies. Tensile properties of the single-phased austenitic steels strengthened by nano-scale twins are systematically investigated. Strength and elastic modulus of the nano-twinned grains is determined by means of nano-indentation measurements and calculations in terms of rule-of-mixture, respectively. Strength-ductility combinations of the steel sample are analyzed with regard to the morphologies, volume fraction, and distributions of the nano-twinned grains and recrystallized micro-sized grains.

2:20 PM
Twinning Phenomena in Cryomilled Pure Mg and Mg-Al-Zn Alloy Nanocrystalline Powders: *Baolong Zheng*[1]; Ying Li[2]; Yizhang Zhou[1]; Suveen Mathaudhu[3]; Enrique Lavernia[1]; [1]University of California, Davis; [2]Los Alamos National Laboratory; [3]U.S. Army Research Office,

Twin boundaries in nanocrystalline (NC) metals are of interest due to their potential for strength enhancement with concurrent retention of ductility; their characteristics include: coherent nature, low interface energy, low dynamic recovery, and enabling of dislocation accumulation. Twin formation, however, is rarely observed in NC hexagonal close-packed (HCP) Mg metals when subjected to high levels of grain refinement to the nanoscale. In this study, powders of NC pure Mg and commercial Mg–Al-Zn alloy were synthesized via a cryomilling. The observation of twins with TEM and HRTEM is reported in both cryomilled NC pure Mg and Mg–Al-Zn alloy powders. The formation of twins might be attributed to the presence of a high strain and to the low (cryogenic) temperature during cryomilling. The formation of twins by cryomilling provides a promising approach to improve the mechanical properties of NC Mg and alloys.

2:35 PM

An Elasto-Plastic Dislocation and Disclination Model for Small Scale Plasticity: Application to Grain Boundaries and Triple Junctions: *Laurent Capolungo*[1]; Manas Upadhyay[1]; Vincent Taupin[2]; Claude Fressengeas[2]; [1]Georgia Institute of Technology; [2]Universite Paul Verlaine

In a large series of crystalline materials –such as nanostructured materials-, plasticity and thermally activated microstructure evolutions are dominated by the behavior of interfaces (e.g. grain boundaries) and by the interactions between grain boundaries and (1) dislocations and (2) other grain boundaries. In the present work, a general field defect dynamics method –able to model both dislocations and disclinations- is developed such as to address current limitations of constitutive models regarding interface driven plasticity . The work is first applied to a static case where the relationship between triple junction geometry and excess elastic energy is investigated. Second, the dynamics model is applied to the case of grain boundary deformation. In particular, the problems of grain boundary relaxation and of shear couple boundary migration are studied. It is found here that the Field Defect Mechanics model is capable of reproducing some of the key features of grain boundary deformation.

2:50 PM

Effect of Stacking Fault Energy on the Microstructural Evolution of Pure Cu and Cu-Al Alloys during Severe Plastic Deformation: *Xianghai An*[1]; Shiding Wu[1]; Zhefeng Zhang[1]; Roberto Figueiredo[2]; Nong Gao[3]; Terence Langdon[4]; [1]Shenyang National Laboratory for Materials Science,Institute of Metal Research,Chinese Academy of Sciences,; [2]Department of Metallurgical and Materials Engineering,; [3]Materials Research Group, School of Engineering Sciences,; [4]Departments of Aerospace & Mechanical Engineering and Materials Science, University of Southern California

Pure Cu and Cu-Al alloys with different stacking fault energies (SFEs) were processed by severe plastic deformation (SPD) methods to systematically explore the roles of the SFE in microstructure evolution. With a lowering of the SFE, the deformation mechanisms were gradually transformed from dislocation slip to deformation twins while shear bands were increasingly significant to carry the local plasticity. Concurrently, with decreasing SFE, the grain refinement processes were also transformed from dislocation subdivision to twin fragmentation, while the grain size was refined from the ultrafine region into nanoscale. Furthermore, the homogeneous microstructures are more readily achieved in materials with high or low SFE than in materials with medium SFE due to different mechanisms governing the microstructural evolution. Specifically, recovery processes are dominant in high or medium-SFE materials whereas twin fragmentation is dominant in low- SFE materials.

3:05 PM

Effect of Stacking Faults and Twin Boundaries on Grain Refinement Induced by High-Pressure Torsion: *Yanbo Wang*[1]; Xiaozhou Liao[1]; Yonghao Zhao[2]; Enrique J. Lavernia[2]; Simon P. Ringer[1]; Zenji Horita[3]; Terence G. Langdon[4]; Yuntian Zhu[5]; [1]The University of Sydney; [2]University of California; [3]Kyushu University; [4]University of Southern California; [5]North Carolina State University

A recent model developed to predict the smallest grain sizes obtainable by severe plastic deformation has worked well for materials with medium to high stacking fault energies (SFEs) but not for those with low SFEs. To probe this issue, we selected a Cu–30 wt.% Zn alloy with SFE ~ 7 mJ/m2 to investigate the grain refinement mechanism during high-pressure torsion processing. We found that stacking faults and twin boundaries have a significant effect on grain refinement. The density of stacking faults and deformation twins determines the smallest achievable grain size. Our results indicate that the grain refinement mechanisms in materials with low SFEs are fundamentally different from those of materials with medium to high SFEs.

3:20 PM Invited

Effects of Deformation Parameters and Stacking Fault Energy on Grain Refinement in Cu–Al Alloys Subjected to Plastic Deformation: *Nairong Tao*[1]; Y. Zhang[1]; K. Lu[1]; [1]Shenyang National Laboratoty for Materilas Science Institute of Metal Research, Chinese Academy of Sciences

Plastic deformation is effective in inducing grain refinement in polycrystalline materials, the kinetics of which is determined by deformation parameters and the nature of materials. In this work, effects of stacking fault energy (SFE) and deformation parameters on microstructure characteristics and tensile strength were investigated in Cu–Al alloys. It is showed that plastic deformation is dominated by twinning at the nano-scale in Cu-Al samples with <4.5% Al subjected to dynamic plastic deformation at liquid nitrogen temperature. Hence, the nano-scale grains are achieved via shear banding of nano-twins and interaction between dislocations and twin boundaries. For alloys with SFEs of >50 mJ m-2, dislocation slip dominates the plastic deformation when deformed by using quasi-static compression at room temperature. A map of deformation modes and corresponding strain-induced grain refinement is drawn in the space of SFE and processing parameters for the Cu–Al alloys.

3:40 PM

The Influence of Dislocation Density on Dislocation-Twin Boundary Interactions in Nanocrystalline Materials: *Song Ni*[1]; Yanbo Wang[1]; Xiaozhou Liao[1]; R.B. Figueiredo[2]; Hongqi Li[3]; S.P. Ringer[1]; T.G. Langdon[4]; Yuntian Zhu[5]; [1]The University of Sydney; [2]Federal University of Minas Gerais; [3]Los Alamos National Laboratory; [4]University of Southern California; [5]Department of Materials Science & Engineering, North Carolina State University

Dislocation–twin boundary (TB) interactions in nanocrystalline grains with different dislocation densities were investigated. We discovered that, in addition to intrinsic material properties and extrinsic factors reported in the literature including stacking fault energy, energy barriers for dislocation reactions at TBs, twin thickness, and applied stress, the dislocation density also plays a significant role in the dislocation–TB interactions. In a twinned grain with a low dislocation density, a dislocation can fully or partly penetrate or be absorbed by a TB via various dislocation reactions. While in a twinned grain with a high dislocation density, dislocations will be pinned and tangle each other at a TB, making it impossible for dislocations to slip across the TB via dislocation reactions. To release the strain energy caused by dislocation accumulation at the TB, partial dislocations will be emitted from the other side of the TB, resulting in the formation of secondary twins.

Deformation Mechanism of Columnar-Grained Cu with Preferentially Orientated NanoscaleTwins: *Lei Lu*[1]; [1]Institute of Metal Research, CAS

The strengthening mechanism of nanotwinned structure has attracted lots of attention, especially in the equiaxed-grained copper with random edge-on nanoscale twins where enhancements in strength and ductility are achieved simultaneously, and twin boundaries serves as effective barriers for dislocation slip transmission. In this talk, the plastic deformation of columnar grained Cu sample with nanoscale twins, which are preferentially oriented parallel to growth plane, were systematically investigated by tension test. It is interested to find that the effective TB confinement of threading dislocation slip inside the lamellar channels dominates the plastic deformation and strengthening behavior, which is different from the slip transfer process in the equiaxed-grained nt-Cu samples. Detailed microstructure investigation suggests that the columnar-grained Cu samples exhibit inhomogeneous deformation during plastic deformation.

4:30 PM
Deformation Twinning in Commercial Pure Titanium during Severe PlasticDeformation: *Yanjun Li*[1]; Yongjun Chen[2]; John Walmsley[1]; Hans Roven[2]; [1]SINTEF Materials and Chemistry; [2]Department of Materials Science and Engineering, NTNU

Twinning is an important deformation mechanism of hexagonal close packed (HCP) titanium during plastic deformation. However, the twinning behavior of titanium during severe plastic deformation can be much different from that occurred during conventional deformation. In the present work, the twinning behavior of commercial pure (CP)Ti subjected to severe plastic deformation, equal channel angular pressing (ECAP) and high pressure torsion (HPT), at different temperatures has been systematically studied by transmission electron microscopy (TEM) and electron backscattering diffraction (EBSD). The type, size, morphology and the twin boundary structure of different twins have been characterized. The influence of deformation twins on the formation of ultrafine grained microstructures of CP-Ti has been discussed.

4:45 PM
Mechanical Behavior of and Deformation Mechanisms in a Nanocrystalline Alloy: *Ruslan Valiev*[1]; Dmitry Gunderov[1]; Aleksander Lukyanov[1]; [1]Ufa State Aviation Technical University

To reveal the deformation mechanisms of fully dense metals with less than 30-50 nm grain sizes the tensile straining behavior of a nanocrystalline TiNi alloy has been thoroughly studied in the present work. Formation of the homogeneous ultrafine-grained structure with a grain size of about 30 nm was achieved through application of severe plastic deformation techniques. Microstructure evolution analysis comprised TEM/HREM, SEM, X-ray. Mechanical tests included measurements of strain rate sensitivity of flow stress, strain hardening, activation energy. There were received experimental evidence and provided a model description of dislocation activity, grain boundary sliding and grain rotation in the nanocrystalline material.

5:00 PM
Grain Refinement in Pure Titanium Processed by Severe Plastic Deformation: Y. Chen[1]; Y. Li[2]; X. Xu[3]; J. Hjelen[1]; *H. Roven*[1]; [1]NTNU; [2]SINTEF; [3]Jiangsu University

Grain refinement of commercial pure (CP) titanium during 1-8 passes of equal channel angular pressing (ECAP) and the effect of temperature on the deformation microstructures of CP Ti after one-pass ECAP are investigated by electron backscattering diffraction (EBSD). The results show that grain refinement mainly takes place in the first pass and the efficiency gradually decreases from 1 to 4 passes, reaching saturation with further increasing strain (6–8 passes). Differenct types of twins activated during one-pass ECAP at different temperature are analyzed systematically. Misorientation gradients and the driving force of dynamic recrystallization are discussed.

5:15 PM
Grain Boundary Sliding in Ultra-Fine Grained 5083 Al: *Ming-Je Sung*[1]; Jung Hun Han[1]; Farghalli Mohame[1]; [1]University of California, Irvine

Quantitative measurements and analysis of grain boundary sliding (GBS) in ultrafine-grained (UFG) 5083 Al by AFM was conducted at 573 K. The grain size of as-received cryomilled UFG 5083 Al was characterized by AFM, TEM and EBSD, and the average was found to be about 300 nm. Ion beam polishing/etching technique was used to reveal grain boundaries for AFM characterization. The vertical offset of GBS was measured by comparing predeformation and postdeformation AFM images. By analyzing these measurements, the contribution of GBS to the total strain was estimated as 22% and 36% at a strain rate of 10^-4/sec and 10^-1 /sec. It was demonstrated that the relatively low value of the contribution of GBS to the total strain is most likely the result of testing under experimental conditions that favor the dominance of region I (low-stress) of the sigmoidal behavior characterizing high strain rate superplasticity, which was previously reported.

5:30 PM
Structural and Mechanical Characterization of Nanostructured Al-1%Si Alloy Produced by Heavy Cold Rolling: *Tianlin Huang*[1]; Qingshan Dong[1]; Xu Gong[1]; Xiaoxu Huang[2]; Qing Liu[2]; [1]Chongqing University; [2]Risø National Laboratory for Sustainable Energy, Technical University of Denmark

Recently, recovery annealing induced decrease in tensile elongation has been reported in nanostructured Al samples, which has been attributed to a decrease in the density of mobile dislocations in the annealed samples. This study explores the possibility to prevent this undesired annealing effect by introducing incoherent particles in the microstructure. Nanostructured Al-1% Si alloy (ultra-high pure Al matrix: 99.9996%) samples have been produced by cold rolling to 98% thickness reduction, and then recovery annealed for 1h at temperatures up to 200°C. In all samples micrometer- and nanometer-sized Si particles were present in the microstructure. The cold-rolled sample exhibited a lamellar structure with boundary spacing of 230 nm, which increased to 800 nm after annealing at 200°C. Tensile results showed no decrease in the elongation in annealed samples. TEM observations suggested that an easy generation of dislocations at the particle interfaces may play a role in stabilizing the tensile deformation.

5:45 PM
Processing of Ultrafine-Grained Nickel by Dislocation Activities at Intermediate Dynamic Strain Rate: Microstructure Evolution and Mechanical Properties: *Lukasz Farbaniec*[1]; Guy Dirras[1]; Akrum Abdul-Latif[2]; [1]LSPM - UPR3407 CNRS; [2]Laboratoire d'Ingénierie des Systèmes Mécaniques et des Matériaux

Ultrafine-grained Ni microstructures were processed by means of Dynamic Plastic Deformation (DPD) at room temperature (RT) using a falling mass at a velocity of 10.38 m/s. The starting material was a commercially pure texture-free coarse-grained (~9 µm) Ni. The as-processed microstructure and its crystallographic texture were thoroughly investigated. In particular, electron backscattering diffraction and transmission electron microscopy experiments showed that the initial equiaxed grains evolved into a laminar structure of narrow domains of submicron sizes delineated by high angle grain boundaries. The mechanical behavior under quasi-satatic compression at RT at a strain rate of 2x10-3 s-1 was investigated in directions parallel and perpendicular to the DPD compression axis. Stress-strain responses showed an increase of the yield strength (620-750 MPa) compared to the initial state (80 MPa). In addition, the strain hardening behavior was also found to depend strongly on the orientation of the compression axis.

2012 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: 0-Dimensional Nanomaterials

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Nanomaterials Committee

Program Organizers: Jiyoung Kim, University of Texas; David Stollberg, Georgia Tech Research Institute; Seong Jin Koh, University of Texas at Arlington; Nitin Chopra, The University of Alabama; Terry Xu, UNC Charlotte

Tuesday AM — Room: Pelican 1
March 13, 2012 — Location: Swan Resort

Computational Study on Nanoparticles in Catalysis: Da Hye Kim[1]; Hyun You Kim[1]; Ji Hoon Ryu[1]; *Hyuck Mo Lee*[1]; [1]KAIST

Recent reports have attributed the remarkable catalytic activity of nanoparticles. We focus on catalysis by nanoparticles to design new catalysts. Computational methods can be used to describe details on surface chemical reactions and to understand and predict variations in catalytic reactivity of nanoparticles. We performed the density functional theory calculations to obtain adsorption properties, reaction pathways, and activation energies for CO oxidation on various nanoparticle systems. Based on calculation results and a modified kinetic model, examples that include how alloying, the structure, charge state of nanoparticles, reaction mechanism, and ligands surrounding nanoparticles affect the electronic configuration and catalytic properties of nanoparticles are reviewed.

9:10 AM
Characterization of Metallic Nano Particles Synthesized by Electrical Wire Explosion Technique for Catalytic Application: *Seung-Yub Lee*[1]; Gwang-Yeob Lee[2]; Hyo-Soo Lee[2]; Min-Ha Lee[2]; [1]Columbia University; [2]Korea Institute of Industrial Technology (KITECH)

Electrical wire explosion technique, one of the methods for producing metallic nano particles has gained recent interests due to its simple and fast process. In this study, Ni-Fe and Pt-Ni binary nano particles were synthesized from 0.1 mm diameter wires in de-ionized water. Microscopy analysis (TEM & EDX) shows core-shell structure with average particle size of 30 nm. Two metal elements tend to be separated by forming core shells, outer layers of which are oxygen rich compared to the core region. Synchrotron X-ray radiation was utilized to identify precise nano phases as well as their volume fraction. It is also found that the oxygen content in DI water is a critical parameter to control nano oxide layers. Based on these results, the appropriate experimental parameter search is in progress to obtain uniform particle size and desirable phase separation for catalytic application.

9:30 AM
Citrate Mediated Wet Chemical Synthesis of Fe Doped Nanoapatites: A Model for Singly Doped Multifunctional Nanostructures: *Rajendra Kasinath*[1]; Michael Klem[1]; Rorbert Usselman[2]; [1]Montana Tech of the University of Montana; [2]NIST-Boulder

The structurally forgiving nature of the apatite lattice can be employed to synthesize functional nano-hydroxyapatite (nHA) particles with calcium site substitution by metal atom doping. In this work we present an effective green synthetic methodology to synthesize equiaxed and highly dispersed Fe(III)-doped multifunctional nHA particles by controlled aging of a calcium phosphate precursor. It was seen that doping in the HA lattice, while employing this wet chemical technique, does not induce a structural change even with 60 atom% Fe-substitution. The Fe(III) doped nanoparticles exhibited both magnetic and luminescent properties. The magnetic properties were measured employing magnetometry and SQUID. Fe doped nHA particles exhibited green fluorescence under UV excitation as seen from florescence spectroscopy. While single property modulation in nHA has been previously shown by doping with metal atoms, herein we show that it is possible to design nHA particles, and perhaps others, with multifunctional properties with only one dopant.

9:50 AM
Selective Electrocatalytic Activity of Ligand Stabilized Copper Oxide Nanoparticles: *Christopher Matranga*[1]; Douglas Kauffman[1]; Paul Ohodnicki[1]; Brian Kail[1]; [1]US DOE- NETL

Organic ligands are commonly used as stabilizing agents during the synthesis of nanoparticles (NPs), but very little is known about their effect on NP reactivity. Metal oxide NPs are an interesting platform to study ligand influenced electrocatalysis because their surface composition and oxidation state can influence reactivity and product selectivity. The role of oleic acid ligands on the selective electrocatalytic activity of CuO and Cu_2O NPs has been evaluated and compared to bulk materials, as well as NPs with weakly interacting or no surface ligands present. Oleic acid capped NPs show a significantly enhanced catalytic selectivity and reactivity during methanol oxidation and CO_2 reduction reactions in comparison to the bulk and NP reference systems. In situ Raman, electrocatalytic studies, and ex-situ infrared spectroscopy meausurements indicate that the capping ligands sustain surface Cu-O species throughout these reactions which likely play a role in the observed catalytic activity.

10:25 AM
Preparation of Colloidal Quantum Dot Nanocrystals for Analysis by Atom Probe Tomography: *Sonal Padalkar*[1]; Bhola Nath Pal[2]; Jennifer Hollingsworth[2]; Lincoln Lauhon[1]; [1]Northwestern University; [2]Los Alamos National Laboratory

Colloidal quantum dots have outstanding luminescent properties, and non-blinking dots have recently been demonstrated through the synthesis of new core-shell structures. Here, giant quantum dots (GQD) consisting of a ~3 – 4 nm luminescent CdSe core and ~12 – 16 nm protective CdS shell were synthesized and prepared for 3D composition analysis by atom probe tomography (APT). Monolayer self-assembly, metal deposition, and lift-out with focused ion beam (FIB) milling were used to prepared GQD samples for atom probe analysis. A wedge shaped lift-out specimen was cut from a monolayer of GQDs sandwiched between two metal layers, and the rotated wedge was mounted on a micropost array to make a vertical specimen. The lift-out was sharpened precisely using annular patterns in the FIB to form a sharp tip with a diameter of ~100 nm. Preliminary APT analysis of the GQD will be presented, along with a discussion of sample preparation procedures.

10:45 AM
Supercapacitive Properties of Hydrothermally Synthesized Co3O4 Nanostructures: *David Mitlin*[1]; Huatao Wang[1]; Li Zhang[1]; [1]University of Alberta and NINT NRC

A hydrothermal process was employed to create a variety of Co3O4 nanostructures. We demonstrate that nominally minor differences in the synthesis temperature (50, 70 or 90°C) yielded profound variations in the oxide microstructure, with lathe-like, necklace-like and net-like morphologies of different scales resulting. This in turn resulted in significant variations in the supercapacitive performance that ranged from mediocre to superb. Specifically, the mesoporous net-like Co3O4 nanostructures that were synthesized at 50°C exhibited very favorable electrochemical properties: The net-like Co3O4 had a specific capacitance of 1090 F/g at a mass loading of 1.4 mg/cm2. At this high mass loading such performance has not been previously reported. SEM and TEM analysis of these samples revealed an interconnected array of sub-10 nm crystallites interspersed with a high volume fraction of pores that were on the same scale. The poorer performing microstructures were both coarser and much less porous.

11:05 AM
Synthesis and Silica Encapsulation of Magnetite Nanoparticles for Biomedical Applications: *Shampa Aich*[1]; Pravin Dixit[1]; [1]Indian Institute of Technology Kharagpur

Magnetite nanoparticles were prepared by co-precipitation of Fe_3O_4 from a mixture of $FeCl_2$ and $FeCl_3$ upon gradual addition of NH_4OH. Later, to prevent agglomeration and bio-degradation, those nanoparticles were coated with inorganic silica by modified Stöber process using tetra-ethoxy-ortho-silicate (TEOS) as the silica-shell building material. FE-SEM, DLS, and HR-TEM analyses revealed a successful synthesis of magnetite-core nanoparticles (50-125 nm) with varying shell-thickness. Silica-shell thickness and monodispersity of the core-shell nanoparticles were increased with TEOS addition and mechanical stirring. X-ray diffraction, FT-IR, and zeta (ξ) potential analyses confirm the synthesis of magnetite nanoparticles, silica gel and the silica coated magnetite nanoparticles. Magnetometer (VSM) measurements showed that the original magnetization of magnetite nanoparticle was merely affected by the coating procedure. The results obtained from In-vitro biocompatibility tests using incubated osteoblasts indicate that the silica-coated nanoparticles are promising candidates for further in vivo investigations of applications in medical diagnosis and drug delivering treatments.

2012 Symposium on Surfaces and Heterostructures at Nano- or Micro-Scale and Their Characterization, Properties, and Applications: Surfaces, Deposition, and Coatings

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS: Energy Conversion and Storage Committee, TMS: Nanomaterials Committee, TMS: Surface Engineering Committee, TMS: Young Leaders Committee, TMS: EMPMD Council
Program Organizers: Nitin Chopra, The University of Alabama; Ramana Reddy, The University of Alabama; Arvind Agarwal, Florida International University; Sandip Harimkar, Oklahoma State University; Jiyoung Kim, University of Texas at Dallas; Christopher Matranga, National Energy Technology Laboratory

Tuesday AM — Room: Pelican 2
March 13, 2012 — Location: Swan Resort

8:30 AM
Microstructures and Performance of Sputter Deposited NiAl-Cr-Hf and NiAl-Cr-Zr Coatings: *Joel Alfano*[1]; Mark Weaver[1]; [1]Univ of Alabama

Nickel-based superalloy components in the hot sections of commercial gas turbine engines are often protected by aluminide coatings due to their ability to function in oxidative and corrosive environments. However, the microstructures of these coated systems are metastable and change in service due to interactions with the environment and interdiffusion with the underlying substrate. The extent of these changes depends critically upon coating microstructure, chemistry, and the environment that the coated component operates in. This presentation highlights the influences of chemical composition, post-deposition annealing, and isothermal oxidation at 1050°C on the microstructures and properties of NiAl-Cr-Hf and NiAl-Cr-Zr overlay bond coatings. In particular, the results indicated that Hf additions inhibited the Al-deletion resulting in a slower formation of the thermally grown oxide as compared to the Zr containing samples. Hf containing samples also show more resistance to internal oxidation of the coatings. Results are discussed relative to conventional coating systems.

8:50 AM
New Trends in Superhydrophobic Coating Using PS/SiO2: *Ariosvaldo Sobrinho*[1]; Marcos Baracho[1]; Rômulo Navarro[1]; Felipe Mariz[1]; José Nascimento[1]; André Rodrigues[2]; [1]UAEMA / UFCG; [2]UFC/DEMA

Superhydrophobic coating materials used in high technology has been shown to be of high relevance in several technological applications such as polymers and composites, anti-corrosion metals, glass and ceramic water repellent, among others. Superhydrophobic surfaces, hydrophobic fabrics, water-repelent materials and superhydrophobicity are among the most widely used terms in the scientific literature. In this work were obtained superhydrophobic nanocomposites based on polystyrene core-shell particles (PS/SiO2). The angle of contact between the drop of water and surfaces of the materials (polymers, metals and ceramics), were measured by the inclination of the drop, giving an indication of the wettability of surfaces coated with the PS/SiO2 composites (polymers, metals and ceramics). The influence of the drying temperature and SiO2 percent on the wettability of nanocomposite coating were investigated. The behavior of the wet surface of the composite PS/SiO2 obtained depends crucially on the drying temperature and the proportion of SiO2 nano particles relative to polystyrene.

9:10 AM Invited
Production of SiC Using Thermal Plasma: M. Ramachandran[1]; *Ramana Reddy*[1]; [1]The University of Alabama

Thermal plasma processing is a high temperature process with high energy content that can tremendously increase the kinetics of a reaction by several orders of magnitude. The production of SiC was carried out using SiO2 as the feed material and methane as a reducing gas. The process was carried out at different molar ratios of SiO2:CH4 = 1:0.8, 1:1; and 1:1.5. The highest product yield of SiC was obtained at a molar ratio of 1:1 (SiO2:CH4) at a power of 21.6 kW. The product yield was reduced substantially when the plasma power was reduced to 18.9 kW and resulted in higher amounts of SiO2 in the product powders. Formation of elemental Si was also observed in some of the experiments. The product powders were characterized using X-Ray Diffraction (XRD), Scanning Electron Microscopy (SEM) and Transmission Electron Microscopy (TEM) to determine the phases formed and their morphology. The presence of nanowires was observed which were characterized using Selective Area Diffraction (SAD) in TEM.

9:45 AM
Surface Nanostructuring of Steel 35 by Electrospark Machining with Electrodes Based on Tungsten Carbide and Added Al2O3 Nanopowder: *Sergey Nikolenko*[1]; Nikolay Syuy[1]; [1]Institute of Materials Science, Khabarovsk Scientific Center, Far Eastern Branch, Russian Academy of Sciences

The study of the process of the AL manufacturing on steel 35 using mechanized ESA by the standard VK8 alloy and the VK8 alloy with an additive of 1–5% Al2O3 nanopowder made it possible to determine the reasonable parameters and modes for the model of the developed device. It was shown that the efficiency of the process of rough ESA increases upon an increase of the pulse duration up to the limit appropriate for a certain electrode material. The Al2O3 additive in the amount of 1 wt % into VK8 increases, compared to the standard VK8 alloy, the overall mass transfer and efficiency of the process of the AL formation by almost three times. The microhardness of the alloy layers exceeds by three–four times the microhardness of steel 35.

10:05 AM Break

10:10 AM
Synthesis and Characterization of Oxide-Based Core/Shell Nanowires: Lyndon Smith[1]; *Nitin Chopra*[1]; [1]The University of Alabama

Core/shell nanowire heterostructures are of great importance for energy applications and nanoelectronics. Towards this end, we report a unique hybrid approach to synthesize copper oxide/tantalum oxide core/shell nanowires by coupling bottom-up nucleation and growth processes.

In addition, structure and processing relationships were evaluated for these core/shell nanowires. The structures were characterized using X-ray diffraction (XRD), scanning electron microscopy (SEM), energy dispersive spectroscopy (EDS), transmission electron microscopy (TEM), Raman spectroscopy, X-ray photoelectron spectroscopy (XPS), and UV-vis spectroscopy.

10:25 AM

Triboemission Phenomena: Electronic and Photonic Outputs from Surface Modification, and Its Use as Novel Probes for the Dynamics of Surface Processes: *Gustavo Molina*[1]; Czeslaw Kajdas[2]; [1]Georgia Southern University; [2]Automotive Industry Institute PIMOT

The authors have obtained extensive data indicating that emission of low energy electrons, called electron triboemission, is produced from mechanical surface work, particularly from surface oxides and semiconductors under contact sliding. Emission of tribo-photons during friction has also been observed, the dynamics of their production being similar to that of electron triboemission. Electron triboemission is often seen as a case of electron exoemission , but such low-energy output may be just a fraction of the total electronic excitation on the surface, the majority of which being internal currents. All these electronic (and concomitant photonic) excitations during mechanical work are known to be important factors in some surface processes, in particular for initiation and control of mechano-chemical reactions and/or during surface interactions. This paper discusses the authors' work on triboemission, and the possible use of the developed measurement techniques as novel probes for the dynamics of surface processes.

How and Why Do Whiskers Grow from Sn Coatings?: *Eric Chason*[1]; Fei Pei[1]; Nitin Jadhav[1]; [1]Div of Engineering

Sn whiskers grow spontaneously out of coatings on Cu and have become a critical reliability problem, responsible for numerous system failures. We will describe studies to determine the mechanisms controlling their formation by measuring the relationship between Cu-Sn intermetallic (IMC) formation, stress and whisker density. This (and the work of others) has lead to a picture in which stress builds up due to IMC growth and causes whiskers to form at "weak grains", i.e., grains that have a stress relaxation mechanism that becomes active at a lower stress than its neighbors. Real-time SEM/FIB videos illustrate the growth process in detail. These show that whisker-like protrusions grow out of a single grain on the surface with little lateral growth. FEA (finite element analysis) calculations simulate the evolving stress and whisker growth for several different mechanisms that may lead to "weak" grains.

11:10 AM Invited

Flexible, Transparent, Conducting Films of Copper Nanowires: *Benjamin Wiley*[1]; [1]Duke University

Copper nanowires with diameters of 60 nm and lengths exceeding 20 µm have been synthesized in an aqueous solution of NaOH, ethylenediamine, Cu(NO3)2 and hydrazine. Meyer rod coating of these nanowires onto plastic substrates produced films with sheet resistances less that 30 ohm/sq, and transmittances greater than 85%. Unlike transparent, conductive oxides, films of copper nanowires remain conductive after severe flexing. The low cost, scalable processing, high electrical and optical performance, and unique mechanical properties of copper nanowire films make them a promising alternative to indium tin oxide for use in flexible displays, organic LEDs, and thin-film photovoltaics.

11:40 AM Invited

Synthesis of Multifunctional Surface Nanocomposites with Tunable Size, Composition, and Properties: Ritesh Sachan[1]; Sagar Yadavali[1]; Nozomi Shirato[1]; Gerd Duscher[1]; Hernando Garcia[2]; Stephen Pennycook[3]; Anup Gangopadhyay[4]; *Ramki Kalyanaraman*[1]; [1]University of Tennessee; [2]Southern Illinois University in Edwardsville; [3]Oak Ridge National Laboratory; [4]Washington University in St. Louis

Integrating different functionalities in small space is the driving force for present day technological advancement. Multi-functional nanoparticles is one way to achieve such systems. Here, we discuss a cost-effective synthesis using pulased laser self-organization of multilayer thin film heterostructures. As a protypical system, we have chosen immiscible Ag and Co metals and investigated the ensuing ferromagnetism and localized surface plasmon resonances. Such composites have applications in biological sensing and optical communication. We discuss electron microscopy studies of nanostructure of individual particles and correlate this with the observed optical and magnetic behavior. We also established the parameter space for independent control of particle size and composition that leads to predictive tunability in physical properties. These results establish that self-organization of multilayer metal films by nanosecond pulsed laser melting could be a cost-effective method to synthesize nanomaterials with multiple properties.

12:10 PM

Development of Nano-engineered Surfaces and Coating Technologies for Scale Mitigation: *Ghazal Azimi*[1]; Yuehua Cui[1]; J. David Smith[1]; Kripa Varanasi[1]; [1]MIT

Scale buildup is among major operational problems facing a wide variety of industrial applications. Despite the pervasiveness of the scaling problem, the fundamentals of scale formation have received relatively little attention, and it is not fully realized how to design scalephobic surfaces by tuning the surface energy attributes. Most state-of-the-art technologies in the field have either focused on developing more effective scale inhibitors, or on improving existing scale removal techniques. These technologies, although promising, are still plagued with environmental and high cost drawbacks. To address these challenges, herein, we adopted a transformational approach by fundamentally altering scale-surface interactions at the interface. Our approach consisted of manipulating both the surface chemistry and surface morphology. Results revealed a significant reduction in scale deposition with reducing the surface energy of the substrates. This work could be considered as an initiative in developing robust scalephobic surfaces by tuning the surface chemistry.

3rd International Symposium on High Temperature Metallurgical Processing: Basic Research of Metallurgical Process

8:30 AM

JIM INTERNATIONAL SCHOLAR: Effect of Shear Stress on Crystallization Behavior of Mold Flux for Continuous Casting: *Noritaka Saito*[1]; K. Kusada[1]; S. Sukenaga[1]; K. Nakashima[1]; [1]Kyushu University

Ionic liquids, like molten oxides, have a much higher electrical capacitance than solids, which is attributed to the difference in their polarization mechanisms. In the present study, we adopted the difference in the polarization mechanism, and extended it to the detection of crystallization in molten oxides under shear stress. We systematically investigated the effect of shear stress on the crystallization behavior of molten CaO–SiO2–R2O (R = Li, Na, or K) slags. As expected, at a particular temperature, the electrical capacitance of the molten silicates abruptly dropped by two or three orders of magnitude, thus clearly indicating crystallization. It was also found that for rotating-rod measurements, the temperatures at which the capacitance abruptly dropped were higher than those without the shear stress.

8:45 AM
Thermal Decomposition and Regeneration of Wüstite: *Zhiwei Peng*[1]; Jiann-Yang Hwang[1]; Zheng Zhang[1]; Matthew Andriese[1]; Xiaodi Huang[1]; [1]Michigan Technological University

The thermal decomposition and regeneration behaviors of wüstite were investigated by in situ high temperature X-ray diffraction (HT-XRD) under non-isothermal condition at heating rate of 4 K min^{-1} in vacuum ranging from 294 K to 973 K. Wüstite on heating decomposes to magnetite and iron up to 823 K, above which it exhibits marked tendency to regenerate. Investigation of thermal stability of the reaction system shows that the decomposition proceeds under kinetic reaction control while the regeneration is under thermodynamic control. Kinetics study based on the Coats-Redfern integral approximation method indicates that the decomposition reaction follows a Komatsu-Uemura model-based diffusion-controlled kinetics with activation energy of 32.860 kJ mol^{-1}. The thermodynamics analysis of regeneration reaction demonstrates that wüstite regenerates at lower temperature than stoichiometric ferrous oxide.

9:00 AM
Competitive Precipitation and Growth of Spinel Crystals in Vanadium Slag: *Xie Zhang*[1]; Bing Xie[1]; Jiang Diao[1]; Xiaojun Li[1]; [1]Chongqing University

Vanadium is widely utilized as an important element to improve the quality of alloyed steels in iron and steel industry. Moreover, the crystallization process of V-containing spinels plays a significant role due to the aim of achieving a fairly larger size of spinel crystals in vanadium extraction. Thus, a comprehensive exploration and discussion on the competitive precipitation and growth of vanadium, chromium and titanium spinel crystals in vanadium slag during a cooling process were carried out in the present study on the basis of a crystallization kinetic model. To be more specific, the abilities of forming crystal, precipitation order and suitable temperature range for crystallization of the three kinds of spinels were discussed with both theoretical and experimental methods.

9:15 AM
Expert System for Grate-Kiln Pellet Production Based on Mathematical Models of Temperature Field: *Xiaohui Fan*[1]; Yi Wang[1]; Xuling Chen[1]; [1]Central South University

The current control method of grate-kiln iron ore oxide pellet production is lack of accuracy and normalization due to the limited detection conditions. Therefore, mathematical model of grate-kiln temperature field is presented. With calculation of gas-particle heat transfer as well as enthalpy changes of moisture evaporation and magnetite oxidation, the thermal history of pellets throughout grate-kiln process can be acquired and used for estimate of production status. Taking the calculated results as well as detected data in production as inputs, process parameters such as running speed, fan opening and coal injection rate as adjusting objects, expert system for grate-kiln pellet production is outlined. Control rules are described in the form of a decision tree, and an efficient top-down-breadth-first OR tree search strategy is explained. Production application proves that control guidance of this expert system can solve production anomalies effectively and stabilize grate-kiln iron ore oxide pellet production.

9:30 AM
The Influence of Sodium Oxide on the Distribution Behavior of Some Elements at the S-Furnace of the Mitsubishi Process: *Yusuke Kimura*[1]; Ken-ichi Yamaguchi[1]; [1]Mitsubishi Materials Corp.

Secondary materials have long been processed at the S-furnace of the Mitsubishi continuous copper smelting and converting process at Naoshima Smelter and Refinery. Intensive recycling in the recent years has caused drastic changes in the chemical properties of the CL-slag, which is separated from matte in the smelting stage. Among various impurities included in secondary materials, the authors have studied the influences of sodium oxides in the CL-slag because the behavior of sodium oxide has scarcely been studied with respect to the copper smelting slag. The examinations have been applied experimentally on the distribution between slag and matte of minor element, especially arsenic whose acidic characteristics suggests strong affinity to sodium-oxide of basic characteristics in silicate melts. The results have been discussed by thermodynamic evaluations and the results of pyro-tests at the commercial furnace.

9:45 AM
Effect of Temperature on the Equilibrium Phase Relations and Liquidus of CaO-SiO2-FeOx-Al2O3 System: *Cuihuan Huang*[1]; [1]Northeastern University

CaO-SiO2-Al2O3-FeOx system is not only a primary sub-system of CaO-SiO2-Al2O3-MgO-FeOx-Na2O oxide system generated during the vitrification of municipal solid waste incineration ash, but also an important slag system for metallurgy process. Thus, its thermodynamic property of CaO-Al2O3-SiO2-FeOx is highly required to provide the essential thermodynamic datas for innocent treatment of the incineration ash and sustainable utilization of the vitrified bottom ash slag, as well as to the production of high quality metal. A comprehensive study involving the combination of high temperature equilibrium experiments with CALPHAD method was conducted to investigate the effect of temperature on the equilibrium phase relations and liquidus of CaO-Al2O3-SiO2-FeOx and its sub-systems. The calculated results with FactSage6.1 showed that the effect of temperature on the equilibrium phase relations and liquidus was appreciable. The liquid regions enlarged with increase of temperature from 1573K to 1873K, while the primary phase fields reduced distinctly. High temperature experimental results showed that the effects of temperature on the phase relations and liquidus location in FeOx-lower area of CaO-Al2O3-FeOx system and the mullite primary phase field of SiO2-Al2O3-FeOx system were notable. The liquid zone expanded obviously with the increase of temperature.

10:00 AM
Modelling of Slag Surface Tension from Thermodynamics: *Clemens Schmetterer*[1]; Patrick Masset[1]; [1]TU Bergakademie Freiberg

Within the efforts of replacing the full water quench in gasification reactors by slag cooling on ceramic particles surface tension of slag is being recognized as an important property. As experimental surface tension measurements under reactor conditions (high temperature and pressure) are a demanding task, surface tension modelling is desirable. The relation between thermodynamics and surface tension is given by Butler's equation. Models based on the activity and the ionic radii of the slag components are available for molten salts and were improved to be used for oxide based systems.Both models were emplyed to model the surface tension of simple slag systems (e.g. Al2O3 – SiO2). This work was accompanied by experimental determinations of the surface tensions of various mixtures and also of the pure components that are required as an input. In this contribution the modelling results, their background and the experimental results will be discussed and compared.

10:15 AM
Viscosity Determination of the Freeze Slag in Reaction Shaft of Flash Smelting Furnace: *Jinliang Wang*[1]; Yanxin Wu[1]; Liwei Liang[1]; Chuanfu Zhang[2]; [1]Jiangxi University of Science and Technology; [2]Central South University

According to the reaction shaft operation characteristics during the flash smelting process, 15 groups of slag samples containing high Fe_3O_4 were prepared by some chemical reagents, and then the slag viscosities were measured using a RTW-10 type synthetic test instrument for melt physical property by the rotating cylinder method. The effects of Fe/SiO_2,ω_{Fe3O4},ω_{Cu2O},ω_{MgO} and ω_{CaO} on the slag viscosity were also studied. Results show that slag viscosity is decreased with the increase

TUESDAY AM

of temperature, Fe/SiO_2, ω_{Cu2O}, ω_{MgO} and ω_{CaO}, and with the decrease of ω_{Fe3O4}, under the range of slag contents: Fe/SiO_2 1.36~1.78,ω_{Fe3O4} 17.83%~21.18%,ω_{Cu2O} 3.51%~8.34%,ω_{MgO} 2.21%~6.57%,ω_{CaO} 6.22%~9.87% and temperature range of 1250~1450°C. Only ω_{Fe3O4} and ω_{CaO} have great influence on the slag viscosity when temperatures as high as 1400°C or so. To form a freeze slag with higher viscosity inside the reaction shaft, ω_{Fe3O4} should be more than 20% and ω_{CaO} should be less than 6%.

10:40 AM
Effect of MgO Content on Melting Features of SiO2-CaO-MgO-Al2O3-FeO Slag in Nickel Laterite Metallurgy: *Xuewei Lv*[1]; Cheng Pan[1]; [1]Chongqing University,China

Physic-chemical properties of slag at high temperature play an important role in the pyro-metallurgical process of production of ferronickel alloy. It determines the operation efficiency, metal recovery ratio, energy consumption and the distribution of elements like S and P between the slag and metals. In the present work, the effect of MgO content on the melting features the slag was investigated. The MgO content in the SiO2-CaO-MgO-Al2O3-FeO in the quinary slag system varied from 14.5% to 22.5%. The results shown that all the slag samples begin to softening at the same temperature, the softening temperature, melting temperature, flowing temperature decrease with the increase of MgO content when the MgO content is in range of 14.5 and 20.5 pct mass, and when MgO content up to 22.5 percent, the temperatures increase sharply.

10:55 AM
High Temperature Deformation Behavior Of Nimonic C263 Superalloy: *Maribel De la Garza Garza*[1]; Martha Guerrero Mata[1]; Alejandro Lara Mendoza[1]; Victor Páramo López[2]; [1]FIME, UANL; [2]Frisa Forjados

High temperature operation of superalloys in aerospace and power generation components involve high creep and corrosion resistance. The present work focuses on studying the behavior of a C263 Superalloy, which is a precipitation hardenable nickel-chromium-cobalt alloy with an addition of molybdenum for solid-solution strengthening. Alloy C263 has high strength and corrosion resistance as well as having good formability and high temperature ductility in welded structures. Studying the hardening mechanisms allows the better understanding of its behavior. The hardening phenomenon in most Ni based superalloys is caused by precipitation of second phases, also the grain size evolution and distribution during the whole forging process should be controlled in order to improve mechanical properties. This development could define the parameters of the process route. For this work some samples were wrought varying the forging temperature to study the best flow deformation behavior, then grain size distribution and mechanical properties were analyzed.

11:10 AM
Influence of Silicon Content in Hot Metal on Mineralogical Characterization and Physico-chemical Properties of Vanadium Slag: Chongyang Zhao[1]; *Bing Xie*[1]; Xiaopeng Zhen[1]; Qingyun Huang[1]; Xie Zhang[1]; [1]Chongqing University

Extracting vanadium from vanadium containing hot metal into vanadium slag by BOF is the main vanadium production process in China. In this paper, the influence of Si content in hot metal on the quality of vanadium slag is analyzed. Synthetic vanadium slag with different SiO2 content were melted at 1673 K and then cooled to 303K at the cooling rate of 3□/min. Optical microscopy, SEM, EDS and XRD were used to analyze the mineralogical phases and crystallization behavior of vanadium slag. The results show that vanadium slag mainly contains spinel phase and silicate phase; V is enriched in the spinel phases while Si is concentrated in Fe2SiO4 CaFeSi2O6 and (Fe,Mn)2SiO4 as silicate phase. The melting point of slag increases gradually with the addition of SiO2; whereas viscosity decreases with an addition of 15~19% SiO2 and increases with an addition of 19~27% SiO2.

11:25 AM
A Model of Decarburization and Boil of Iron/Carbon Droplets: *Mark Schwarz*[1]; [1]CSIRO

A model has been developed for decarburization of iron/carbon droplets in an oxidizing atmosphere containing oxygen and/or carbon dioxide. Mass transfer across the gas-side and liquid-side boundary layers are taken into account as well as decarburization reactions at the interface. A spherically symmetric model was first developed and compared with data from experiments carried out in a tube furnace. This model has been extended to allow for non-uniform mass transfer effects resulting from flow of the oxidising gas over the droplet. Boil is assumed to occur when the supersaturation partial pressure of CO within the droplet exceeds a critical value for nucleation. Predictions of boil time agree well with the measurements for droplets contained in the tube furnace.

11:40 AM
Analysis of Influence Factors on the Melting Point of the Freeze Slag Inside Flash Smelting Furnace Brickless Reaction Shaft: *Jinliang Wang*[1]; Chuanfu Zhang[2]; [1]Jiangxi University of Science and Technology; [2]Central South University

Brickless reaction shaft is the latest progress for flash smelting furnace. However, there are many factors influence the melting point of the freeze slag inside brickless reaction shaft, and their variational regularities are not obvious, thus, it's difficult for conventional methods to analyze accurately the complex data. In this research, the experiment data of slag melting point were processed based on optimal discrimination plane. For this method, two orthogonal vectors were firstly built up based on the Fisher's criterion, and then the experiment data were projected onto the two vectors, thus, two-dimensional feature vectors were extracted as criteria to determine the factors effect degree on the slag melting point. Results show that the CaO content is the greatest factor to the melting point of the freeze slag inside brickless reaction shaft, the content of Fe_3O_4, SiO_2, Cu_2O and MgO is the second, and the FeO content is the last.

Advances in Surface Engineering: Alloyed and Composite Coatings: Session III

Chromium Nitride Coatings for Biological Applications: Aracely Rocha[1]; Liangxian Chen[2]; Chengming Li[2]; *Hong Liang*[1]; [1]Texas A&M University; [2]University of Science and Technology Beijing

Surface modification through coatings was made in order to improve adhesion between implanting materials and protein. The adhesion of albumen protein to CrN and CrAlN coatings on Ti alloy and Si wafer was studied using a method of rotational shear flow. CrN and CrAlN coatings provide improved wear resistance over pure Cr. These coatings offer a potential alternative to reduce wear in artificial joints. Experimentally, we developed a method to quantitatively evaluate the adhesive strength of proteins to the surface. Subsequently we study the interfacial mechanisms between coating surfaces and protein molecules. Results indicate that the protein adhesion depends on the substrate chemistry. The CrN and CrAlN coatings improve wear resistance with minimum to no influence with the substrate's interaction with the proteins.

Development and Characterization of Aluminum Matrix in-situ Aluminum Di-borides Composites Coatings for Tribological Applications: *Sudeep Ingole*[1]; Rajeshwari Paluri[1]; [1]Texas A&M University

Self-lubricating coatings with better mechanical properties for reduced friction and wear application have everlasting demand. Alumina is one such material which is a good choice for wear resistance applications like pump bearings, seal rings, piston components, etc. We attempt to develop a novel alumina based ceramic composite to further enhance its surface properties and develop composite coatings. This paper focuses on mechanical and surface characterization of borides formation under influence of varying percentages of boron in coating matrix. The results of XRD, FTIR, optical microscopy and E-SEM will be reported. Effect of sintering temperature and percentage of boron on mechanical properties will be discussed. Results showed that increasing percent of boron resulted in grain boundary diffusion and high sintering temperatures resulted in low porosity for lower wt % of boron. XRD results confirmed the formation of aluminum diboride (AlB2), boron oxide (B2O3) and aluminum borate (Al18B4O33).

9:25 AM
A Nanoindentation Study of Laser Deposited Nickel-Based Carbide Metal Matrix Composite Coating: *Samar Kalita*[1]; [1]Advanced Engineered Materials Center - University of North Dakota

The mechanical behavior of direct metal laser deposited (DMLD) carbide metal matrix composite coating is of relevant interest in a variety of applications. Since tensile testing is impractical for this purpose, depth-sensing indentation, which provides wealth of information seems promising. Here, DLMD was used to develop wear and corrosion resistant coating on AISI 1018 steel using a blend of Ni, Cr3C2 and WC12Co powders. The coating's integrity, microstructure and composition were analyzed by microscopic and spectroscopic techniques. The coated systems are evaluated in terms of mechanical properties (indentation modulus, M and hardness, H), wear ratio H/Er, and hardness parameters Km and P/S2, which can discriminate between homogeneous and non-homogeneous systems. The ratio between maximum penetration and contact-depth defined wear characteristics. Properties at different coating-depth were investigated. Hardness and Er at the top and interface-vicinity were 8.5 and 201.2 GPa, and 8.4 and 203.5 GPa, respectively; considerably higher than the substrate.

9:45 AM
In-Situ Synthesis of TiC/SiC/Ti3SiC2 Composite Coatings by Spark Plasma Sintering: *Ashish Singh*[1]; Sandip Harimkar[1]; Arvind Agarwal[2]; Srinivasa Bakshi[3]; David Virzi[2]; Anup Keshri[2]; [1]Oklahoma State University; [2]Florida International University; [3]IIT Madras

Composite coatings consisting of TiC/SiC/Ti3SiC2 phases have been synthesized on titanium substrate using spark plasma sintering (SPS). SPS technique allows processing of composite coatings in short sintering time and at low temperatures. The processing of composite coatings was achieved at 1300 ºC and 1400 ºC at 90 MPa. Identification and quantification of the phases have been performed using X-ray diffraction (XRD). Coatings microstructure was evaluated using SEM images. X-ray elemental maps obtained using EDS analysis has been used to study the distribution of different elements in the microstructure and study the phase evolution. A tentative mechanism for phase evolution has been proposed. Microhardness of the coating is found to be 3 times that of the Ti substrate which lead to a ~100 times lower wear weight loss in ball on disc wear tests.

10:05 AM Break

10:20 AM
Microstructure and Wear Properties of Laser In-situ Formation of TiB_x and TiC Titanium Composite Coatings: *J. Liang*[1]; C S Liu[2]; S Y Chen[2]; C X Ren[2]; [1]Northeastern University ; [2]Northeastern University

Ti-6Al-4V/B_4C mixed powder which are pre-pasted or synchronized fed on Ti-6Al-4V substrates separately were scanned by a 500W pulsed YAG laser to in situ format titanium composite coatings contained TiB_x and TiC ceramic reinforced phases. The influences of processing parameters and powder proportions on the microstructure and properties of the coatings were investigated. Three-layer composite graded coatings were formatted with prepasted B_4C increased 10 wt. % each layer. Microstructures and phases of coatings were analyzed by OM, SEM, TEM and XRD respectively. Results show that the microhardness and the amount of TiB_2 of the layer increased with the increase of B_4C addition. The average micro-hardness of a laser cladding composite graded surface layer is up to 1000HV, which is nearly 3 times of that of the substrate (367HV), and the wear weight loss decreased over 4 times.

10:40 AM
Surface Engineered CVD Diamond Coatings for Dry Machining Applications: *Humberto Gomez*[1]; Delcie Durham[2]; Kevin Chou[3]; Xingcheng Xiao[4]; Michael Lukitsch[4]; Ashok Kumar[2]; [1]Universdad del Norte; [2]University of South Florida; [3]The University of Alabama; [4]General Motors R&D Tech. Center

The insufficient adhesion of diamond coating on cutting tool has been the bottleneck in production lines, limiting its application in the dry machining of aluminum and magnesium alloys. In this study, diamond was deposited on WC-Co turning inserts pretreated using chemical etchings and CrN/Cr inter-diffusion barrier interlayer, to overcome the adhesion issues associated with the detrimental effect of cobalt. Rockwell indentations were performed on the diamond surfaces to qualitatively characterize the adhesion. Finally, dry machining processes using these diamond coated turning inserts were performed on a high silicon aluminum alloy. A systematically approach from the initial substrate surface characteristics in terms of the surface texture and surface/subsurface damage produced by the different pretreatments, in addition to the resulting diamond film quality and adhesion, are evaluated in terms of the machining tool life and its consequent wear and failure mechanisms.

11:00 AM
Creep Properties of Y-PSZ Coated 6063 Aluminum Alloy: Eray Erzi[1]; Cem Kahruman[1]; *Suat Yilmaz*[1]; [1]Istanbul University

Aluminum alloys have been used in industries for years because of light weight. But these materials have some disadvantages like low mechanical properties. For increasing of the mechanical properties of aluminum alloys can be coated with hard ceramics. In this study, T6 heat treated 6063 aluminum alloy were coated with %8 Y-PSZ powders by plasma spraying method. Subsequently, creep properties of the uncoated and coated samples were investigated. Temperature dependent creep tests were carried out at 100, 125, 150°C temperatures and at 170 MPa stress conditions. Stress dependent creep tests were carried out at 120, 145, 170 MPa stresses and at 100°C temperature conditions. The creep results of the uncoated and coated samples were discussed and compared.

11:20 AM
Effect of Pre-Oxidation Treatments on the Mechanical Properties of (Ni,Pt)Al Systems Measured by Nanoindentation: *Juan Alvarado-Orozco*[1]; Alma Mora-García[2]; Haide Ruiz-Luna; Haide Ruiz-Luna[2]; Luis Alberto Cáceres-Díaz[2]; John García-Herrera[2]; Juan Muñoz-Saldaña[2]; Jose Ortiz-Merino[2]; Gerardo Trapaga-Martinez[2]; Ricardo Morales-Estrella[2]; Doug Konitzer[2]; Enrique Samaniego-Benitez[2]; [1]Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional ; [2]Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional

The effect of isothermal oxidation treatments in the range of 900°C to 1200°C for 5h in oxygen controlled atmosphere on the mechanical

TUESDAY AM

properties of (Ni,Pt)Al (BC) +interdiffusion zone (IDZ) + Rene-N5 (SA) systems is presented. The mechanical properties were measured by cross-sectional nanoindentation analysis. The reduced elastic modulus (Er) and the indentation hardness (H) were estimated based on the Oliver and Pharr method. The results have shown that both, Er and H of the BC and SA are highly dependent of the oxidation heat treatments as a consequence of the aluminium depletion to form the thermally grown oxide (TGO), the growth of BC+IDZ as a result of a multi-element counter diffusion and the partial dissolution of γ/γ' SA. Trying to correlate the obtained mechanical properties with the structural and chemical properties, XRD and EDX analysis was conducted in the BC.

11:40 AM
Contribution of Ti Addition to the Electronic Structure and Adhesion at the Fe2Al5/Fe Interface in 55%Al-Zn Coating: *Guangxin Wu*[1]; Yuling Ren[1]; Jieyu Zhang[1]; Kuochih Chou[1]; [1]Shanghai University

We report a density functional theory investigation of the atomic structure, bonding, and ideal work of adhesion of the Ti addition to Fe2Al5/Fe interface, in order to explore the potential of Al-Zn-Si-Ti as a protective coating for steel. The results show that the clean interface has an ideal work of adhesion of 0.84 J/m2 while the presence of Ti dramatically increase adhesion via rearrangement of electron density and the character of the local density of states upon formation of the interface. Then, the stability and fracture toughness of Ti dopant Fe2Al5/Fe interface are discussed with a thermodynamic sense and Griffith fracture theory, respectively. Besides, the chemical bonding properties for the interfacial atoms are also discussed in this paper based on electronic structure and Milliken population. Our results provide theoretical evidence for the excellent adhesion behaviors of Fe2Al5/Fe interface.

Alumina and Bauxite: Red Mud Bauxite Residue

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee
Program Organizer: Benny Raahauge, FLSmidth

Tuesday AM — Room: Northern E3
March 13, 2012 — Location: Dolphin Resort

Session Chair: Tim Laros, FLSmidth Salt Lake City

8:30 AM
Bauxite Residue Management: *Ken Evans*[1]; Eirik Nordheim[2]; Katy Tsesmelis[3]; [1]Rio Tinto Alcan; [2]European Aluminium Association; [3]International Aluminium Institute

With some two to four tonnes of Bauxite Residue waste arising for every tonne of aluminium produced, the management of Bauxite Residue (or Red Mud) has always been a significant issue for the aluminium industry. However, the tragic fatal incident in Ajka, Hungary in October 2010 has reinforced the need for safe and effective management of storage areas globally.For the past five years the International Aluminium Institute has been involved in research into the management of bauxite residue and in 2011 created a set of voluntary objectives recommending that best practices are adopted to ensure that the Hungarian incident is never repeated elsewhere.This paper will review the current and best practices of bauxite residue management.

8:50 AM
Tests with New Flocculant for Red Mud Decanting in Alunorte: *Tatiani Santos*[1]; Juracy Filho[1]; Américo Borges[1]; Humberto Lima[1]; Juarez Borges[1]; Frederico Giust[2]; Alexandre Rabaça[2]; [1]Alunorte SA; [2]SNF do Brasil

To produce alumina with competitive costs and high efficiency on caustic recover with low flocculant consumption has been a challenge for the filtration area in Alunorte. This area has 7 production lines where together, handles about 4,4 Mtpy of red mud. Specifically at production lines 6 & 7, the washer chain has only high rate settlers and apart from that, they receive bauxite from Mineração Bauxita de Paragominas. The combination of these two aspects results on lower density in the settler underflows. One of the actions to increase underflow solids content was to replace the conventional polyacrylate flocculant by another one which could be capable to increase the density in the washer underflows. Among other trials were gotten good results from the use of FLOMIN OL 99 polymer in lab tests as well as in the plant. The discussion of these results is the main propose of this paper.

9:10 AM
Red Mud Filtration Test Results using AFP IV™ Automatic Filter Press: *Manfred Bach*[1]; [1]FLSmidth

Rsults of pressure filtration testing demonstrates that a standard design FLS AFP IV filter press can dewater red mud from initial feed concentrations of 30 – 44 wt% and produce final cakes containing 67-70 wt% solids. This paper outlines factors affecting the filtration rate and final cake solids concentration such as feed solids concentration, slurry temperature and feed pump delivery rate/pressure relationship as well as the configuration of the filter plates. The results are presented for different bauxite grades. Additional testing was performed to obtain filter cakes containing 75 wt% cake solids by evaluating high-pressure filtration at 30-60 bar using both recessed plate and membrane plate configurations. The tests demonstrate that high-pressure filtration above 30 bar can produce 75 wt% solids. Additional results from a second test series are presented on Chinese red mud resulting in filter cakes containing cake solids in the range of above 80%.

9:30 AM
Study on Dry –Method Volume Expansion Technology for Wet Red Mud Yard: *Li Mingyang*[1]; Xu Shutao[1]; Yi Xiaobing[2]; [1]CHALIECO; [2]CHALIECO

The wet red mud yard in Guizhou Branch of CHALCO is closed when it is used up to 1370m high, and it's difficult to construct the new red mud yard within a short term because of the difficulty in land requisition. In order to ensure the continuity of alumina production, it's required to expand the volume of the existing wet red mud yard by dry method. Based on many tests and studies on the basic performances of red mud filtration cake, the author in this article gives introductions of technologies on red mud dewatering, transportation, spreading out & stacking, reinforcing of weak red mud layer, recycle of waste water in red mud yard, and flood control & drainage etc. It's shown by study achievements that good economical and social & environmental benefits can be obtained by using dry-method volume expansion technology for wet red mud yard.

9:50 AM
ETI Aluminum Red Mud Characterization and Processing: Gokhan Demir[1]; *Sedat Arslan*[1]; Bekir Celikel[1]; Meral Baygul[1]; Carlos Enrique Suarez[2]; [1]ETI Aluminyum; [2]Hatch Associates Consultant Inc.

ETI Aluminum has capacity to process 541,000 tons of bauxite, produce 250,000 tons of alumina per year and generate approximately 260,000 tons of red mud. Red mud slurry is disposed at 30 % (w/w) solids and less than 3 g/L Na2O. ETI is focusing its efforts in maximizing extraction efficiency in digestion and improving decomposers yield. The red mud area is one of the most important topics that require serious study in terms of handling, recovery and environmental impact. A study has been initiated to determine red mud characterization, settling performance and separation strategies. XRF, XRD, TG/DTA, IR, SEM/EDX, BET and PSD analysis have been conducted to define red mud physical and chemical characteristics. Many settling tests have been performed to select the most suitable and economic flocculant that provides the best compaction, overflow clarity with an acceptable settling rate and enhanced rheology. Also ETI might face red mud disposal area problems in the following years. ETI has initiated a fast track program towards the improvement of the dewatering of red mud and increase disposal area life time.

10:10 AM
Studies on Metal Flow from Khondalite to Bauxite to Alumina and Rejects from an Alumina Refinery, India: *Birendra Mohapatra*[1]; Barada Mishra[1]; Chittaranjan Mishra[2]; [1]Institute of Minerals & Materials Technology(IMMT); [2]Other

Alumina is produced from khondalite hosted bauxite of Indian origin in the Alumina refinery employing the time tested Bayer's Process. In the process, about 40% of unwanted elements are rejected as undigested sand and red mud. During the whole cycle; major, minor, trace and RE elements in these litho-units get redistributed, either depleted or enriched. Khondalite, the source rock of bauxite, is rich in silica, moderate in alumina and iron with minor titanium. Bauxite becomes rich in alumina and iron with subordinate titanium and negligible silica. After alumina recovery from bauxite, most of the valuable metals including REE get accumulated in the refinery rejects. The studies, while establishing the extent of various metals dispersed in khondalite, bauxite, undigested sand, red mud and alumina also reveals the state of enrichment of valuable metals in undigested sand and suggests possible means to recover some of them.

10:30 AM
Directions for Large Scale Utilization of Bauxite Residue: *Andrey Panov*[1]; Gennady Klimentenok[2]; Gennadiy Podgorodetskiy[3]; Vladislav Gorbunov[3]; [1]RUSAL Vami; [2]RUSAL Engineering & Technology Centre; [3]National University of Science and Technology "MISIS"

Solving the problem of large-scale utilization of Bayer process bauxite residue (red mud) becomes more and more vital for the increasing number of alumina refineries around the globe. Till now, in spite of the fact that many technically sound process routes have been developed, only a few of them have been implemented, once local economic and market conditions were favorable. Being a complex and poor ore for extraction of iron, alumina and titanium, treated red mud has to compete with other low cost materials; this is often economically unfavourable. In this paper the most promising utilization directions are discussed and focus areas for research by the world scientific community are outlined.

10:50 AM
Production of Pig Iron from NALCO Redmud by Application of Plasma Smelting Technology: *Partha Mukerjee*[1]; Bhagyadhar Bhoi[1]; Chittaranjan Mishra[2]; Ramani Dash[3]; Bijay Satapathy[2]; Kalidas Jayasankar[1]; [1]Institute of Minerals & Materials Technology(IMMT); [2]National Aluminium Company Limited; [3]Gandhi Institute of Engineering & Technology(GIET)

Red Mud , a by-product generated from the caustic leaching of bauxite to produce alumina in the Bayer Process, causes serious environmental problems & is considered as a hazardous industrial waste. A Novel Process has been developed for production of Pig Iron from NALCO Red Mud by employing Plasma Smelting Technology. Red Mud containing 15-40% Fe2O3 was subjected to Thermal Plasma Smelting by use of Extended Arc Plasma Reactor at a temperature of 1600o C for a period of 30 minutes & high quality pig iron was produced . Effect of various process parameters like basicity, amount of reductant, plasmagen gas, input electric power and reduction time for recovery of Pig Iron has been studied and optimised. Basicity of 0.3 , reduction time of 25 minutes at 12.5 KW power was found to be optimum for maximum recovery of Pig Iron (70%) from Red Mud in 1 kg scale.

Finite Element Simulation Analysis of the Ultrasonic Vibration Forging of an Aluminum Cylinder Workpiece: *Yanxiong Liu*[1]; Qingyou Han[1]; [1]Purdue University

The propagation of ultrasonic wave in the solids can greatly affect the material properties. In this paper, the deformation characteristics of the ultrasonic vibration forging for aluminum alloy are investigated. For the ultrasonic vibration forging, during the forging process, the ultrasonic wave propagates in the specimen at the same time. A detailed analysis and understanding of the mechanism of improvement is not possible on the basis of conventional experimental observations because ultrasonic vibration processing phenomenon occurs at a high speed. Hence, in order to study the mechanism of ultrasonic vibration forging, the finite element modeling was performed by using Abaqus/explicit. The metal flow of the ultrasonic vibration forging is totally different form the conventional one, there will have no "drum" effect in the forming process, which is the main characteristic in the conventional forging. Moreover, the stress and equivalent plastic strain distributions after the ultrasonic vibration forging process were explored.

8:55 AM
Refinement of Fe-Intermetallic Compounds by Caliber Rolling Process of Al-Mg-Si-Fe Alloys: *Chakkrist Phongphisutthinan*[1]; Hiroyasu Tezuka[1]; Tatsuo Sato[1]; Susumu Takamori[2]; Yoshiaki Ohsawa[2]; [1]Tokyo Institute of Technology; [2]National Institute for Materials Science

Fe-intermetallic compounds are well known as harmful to mechanical properties and formability, especially the plate-like β-AlFeSi. Recycling process of aluminum scraps commonly contains high amount of Fe content which results in degraded properties compared with primary aluminum production. In this study, thermo-mechanical process of Al-0.9mass%Mg-(2.0-2.3)mass%Si-(1.0, 1.5 and 2.0)mass%Fe alloys by caliber rolling was performed to investigate the refinement of Fe-intermetallic compounds and mechanical properties. Homogenized ingots were sequentially caliber rolled at 300°C and 450°C to 95% area reduction. The caliber rolling process can effectively refine the harmful Al-Fe-Si compounds into more favorable size and good distribution in the Al matrix. Fine fragmented Fe-intermetallic particles with the size of 200nm were achieved. The caliber rolling can effectively improve mechanical properties with good ultimate strength of 345-360MPa and high elongation of 15-25%.

9:15 AM
Analytical and FEM Modeling of Aluminum Billet Induction Heating with Experimental Verification: *Mark Kennedy*[1]; Shahid Akhtar[2]; Jon Arne Bakken[2]; Ragnhild Aune[2]; [1]Norwegian University of Science and Technology; [2]Norwegian University of Science and Technology

Induction heating is commonly used in the re-heating of aluminum billets before forging or extrusion. Powerful finite element modeling (FEM) tools are available to assist in the design of such processes; however, such models should be validated by comparison with analytical solutions or experimental results to ensure accuracy. Induction heating experiments have been performed using a number of different coil designs and work piece dimensions at 50 Hz. Aluminum alloys with different electrical conductivities have been used, i.e. 6060 and A356. Process parameters such as: current, power, magnetic field, electrical conductivity, etc. have been measured with high precision instrumentation. Experimental data are presented and compared with equivalent 1D analytical and 2D axial symmetric FEM modeling results. The effect of frequency on the induction heating process is reviewed using the validated analytical and FEM models. Some recommendations are given with respect to appropriate modeling techniques, boundary conditions and numerical mesh sizes.

The Evolution of Mechanical Properties and Microstructure in Early Stages of Natural Ageing on 2024 Plates: Gheorghe Dobra[1]; *Ioan Sava*[1]; Cristian Stanescu[1]; Marin Petre[1]; [1]ALRO

The evolution of plasticity of heat treatable alloys in W temper is important for an efficient stress releasing by stretching or compression (Tx51 and Tx52 tempers) but also for some special hardening operations that combine cold working and ageing practices. For the alloys that have a significant natural ageing, the environment temperature has an important influence. In order to evaluate the influence of this temperature, the mechanical properties and the microstructure were investigated at various temperatures between -10 and + 80 °C and ageing time between 0 and 80 h on plates in alloy EN AW 2024, using standard tensile tests, electronic microscopy and X Ray diffraction.The results demonstrate that from many standpoints (mechanical properties, plasticity, electrical conductivity, microstructure etc.) the ageing transformations end before the limit of 96 hours that is considered as standard.

10:35 AM
Formation of Intermetallic Compound on the Interface of Copper/Aluminum Clad Sheet Produced by Asymmetrical Roll Bonding and Annealing: *Xiaobing Li*[1]; Guoyin Zu[2]; Ping Wang[3]; Rong Xu[4]; [1]School of Materials and Metallurgy, Northeastern University ; [2]School of Materials and Metallurgy, Northeastern University; [3]Key Laboratory of Electromagnetic Processing of Materials, Ministry of Education, Northeastern University; [4]The State Key Laboratory of Rolling and Automation, Northeastern University

Copper/aluminum clad sheet produced by asymmetrical roll bonding and annealing possesses good interfacial bonding, but can be damaged by the intermetallic compound (IMC) formed on the interface. The present paper has studied the formation of IMC on the interface of Cu/Al clad sheet with different mismatch speed ratio by scanning electronic microscope equipped with energy dispersive X-ray detector and X-ray diffraction. It is found that the thickness of interfacial layer increases due to the considerable diffusion caused by the shear deformation energy during roll bonding process. The formation of IMC is promoted by the significant element diffusion at high speed ratio. For sample annealed at 400°C for 20 min, the formation of IMC is negligible, but the fracture lies between compounds. The results show that the IMC forms on the interface with annealing, especially for clad sheet roll-bonded with high speed ratio, and the formation destroys the interfacial bonding.

10:40 AM Question and Answer Period

Aluminum Alloys: Fabrication, Characterization and Applications: Thermal Mechanical Processing

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Processing Committee
Program Organizers: Subodh Das, Phinix LLC; Tongguang Zhai, University of Kentucky; Zhengdong Long, Kaiser Aluminum

Tuesday AM — Room: Northern E1
March 13, 2012 — Location: Dolphin Resort

Session Chair: Xiyu Wen, University of Kentucky

8:30 AM
Modeling of As-Cast A356 for Coupled Explicit Finite Element Analysis: *Matthew Roy*[1]; Daan Maijer[1]; [1]The University of British Columbia

Design tools to simulate the manufacturing processes applied to aluminum components require computationally efficient finite element methods. While static processes such as casting employ implicit techniques, dynamic processes such as forging may only be modeled with explicitly. A commonplace practice to expedite explicit simulations is to employ time or mass scaling, which can lead to unexpected thermal-mechanical behaviour in coupled analyses. In both cases, the development of fully coupled thermo-mechanical simulations necessitates the use of a constitutive model that is capable of defining the flow stress as a function of temperature, strain, and strain rate. In this work, a material model for as-cast A356 is presented and applied in a range of fully coupled deformation models. Implicit and unscaled explicit models will be compared to explicit models with large amounts of scaling. Strategies for applying a material model to minimize error and maximize computational effort are discussed.

8:50 AM
Textures, Particle Structures and Mn Solution in Al Matrix of a Continuous Cast AA3004 Aluminum Alloy after Cold Rolling and Annealing: *Xiyu Wen*[1]; Yansheng Liu[2]; Jingwu Zhang[3]; Shridas Ningileri[2]; Tongguang Zhai[1]; [1]University of KY; [2]Secat Inc.; [3]State Key Laboratory of Metastable Materials Science and Technology

Measurements of textures of an AA3004 aluminum alloy sheets made from twin belt casting after cold rolling and annealing are carried out by use of the orientation distribution function (ODF) method. The particle structures of the sheet samples are observed and analyzed by use of scanning electronic microscopy (SEM) and Transmission electron microscopy (TEM) as well as X-ray diffractionmeter (XRD). In addition, Mn solution in grains with different orientations of Al matrix was evaluated by using Kikuchi pattern from TEM technique. The textures, particle structures and Mn solution in grains with different orientations of Al matrix resulting from the thermo-mechanical processing are studied and presented.

9:10 AM
Observation of Structure Evolution during Annealing of 7xxx Series Al Deformed at High Temperature: Cory Parker[1]; *David Field*[1]; [1]Washington State University

Deformation of polycrystalline materials results in a heterogeneous distribution of dislocation structures that are dependent upon the local character of the microstructure. 7xxx series aluminum alloys are particularly complex because of the wide range of particles and solute atoms that are in the material. High temperature deformation results in a microstructure that may be essentially free from dislocation structures at one position but have relatively high dislocation content at another position. Electron backscatter diffraction was used to quantify and map the dislocation density tensor at various positions through the metal.

Subsequent annealing resulted in the development of recrystallization nuclei that were also observed by EBSD and related to the measured dislocation structure.

9:30 AM
Study of Homogenization Treatments of DC Cast 5xxx Series Al-Mg –Mn Alloy Modified with Zn: Akram Halep[1]; *Tamara Radetic*[1]; Miljana Popovic[1]; Endre Romhanji[1]; [1]Department of Metallurgical Engineering, Faculty of Technology & Metallurgy, University of Belgrade, Belgrade, Serbia

Microstructural changes of DC-cast 5xxx series Al-Mg-Mn alloy modified with Zn addition during a range of homogenization treatments were studied through the thickness of a rolling ingot. The homogenization treatments included: (i) low temperature annealing at 430°C, (ii) high temperature homogenization at 530-550°C and (iii) low-temperature annealing in the 420-480°C. Microstructure evolution was followed by electrical resistivity measurements, optical microscopy, SEM and TEM characterization and microanalysis. During the homogenization, decomposition of the supersaturated solid solution, present in the as-cast state, occurred. Distribution of the precipitates was dictated by segregations and could be related to the partition coficients of alloying elements. It was found that during the high temperature homogenization not only dissolution processes occurred, but also precipitation of new phases. This resesrch was supported by the Ministry of Education and Science, Republic of Serbia, and Impol-Seval Aluminum Mill, Sevojno, under contract number TR 34018 and E!4569.

9:50 AM
Microstructure Evolution of 7003 Aluminum Alloy by Equal Channel Angular Extrusion Process: Qingnan Shi[1]; *Gang Yang*[1]; Liangwei Chen[1]; Xiaoqi Wang[1]; Zaohua Liu[1]; [1]Kunming University of Science and Technology, School of Materials Science and Engineering

The 7003 Al alloy was prepared by equal channel angular extrusion process (ECAP), which microstructures were characterized by transmission electron microscope (TEM). Results showed that dislocation density increases obviously and the average grain size decreases with increasing passes of ECAP. However, after the fourth pass of ECAP, average grain size fails to decrease remarkably and the microstructure is still inhomogeneous. Some parallel micro-bands and the second phase MgZn2 are present in the alloy during annealing.

10:10 AM
Steel-Aluminium Composite Castings for High-Performance Die Cooling Applications: *Heiner Michels*[1]; Andreas Bührig-Polaczek[1]; David Becker[2]; [1]RWTH Aachen, Foundry Institute; [2]Fraunhofer Institut für Lasertechnik

When processing plastic or metal on die casting machines, controlling the die temperature is a crucial process factor. Optimised cooling can provide short cycle-times and increased productivity, but is hard to realize by common means. Die inserts produced by Selective Laser Melting (SLM) allow a to-the-point layout of shape and cooling conduits. Yet, producing solid SLM volume is time and cost consuming. The relatively low heat conductivity of steel limits the positive effects furthermore. The current study shows results of research directed towards an innovative cost-efficient production of high performance cooling solutions, improving the inserts overall heat conduction, wear and high temperature resistance. An aluminium alloy, procuring high heat conductivity, is poured into a steel SLM shell structure. The formed interbond-phases are analysed, the effect of surface structures to reduce air gap formation and enhance the material interbond is tested as is the deformation and dissolution behaviour of cooling conduits.

10:30 AM Break

10:45 AM
High Strength Al-Mg-Mn Alloy Sheets Fabricated by Twin Roll Casting: *Hyoung-Wook Kim*[1]; Suk-Bong Kang[1]; Jae-Hyung Cho[1]; [1]Korea Institute of Materials Science

Al-Mg-Mn alloy sheets with different Mg and Mn contents were fabricated by twin roll casting and rolling process and the microstructure of the sheets was investigated. The twin roll cast Al-Mg-Mn alloy sheets had a fine dendrite size and very fine precipitates due to high cooling rate during the casting process. The density of fine Al6Mn precipitates of the annealed sheets increased with increasing Mn and Mg content, so that large number of fine Al6Mn precipitates inhibited recrystallization and grain growth in Al-Mg-Mn. The strength of Al-Mg-Mn alloy sheets increased with increasing annealing temperature due to additional precipitation of fine Al6Mn precipitates at elevated temperature. The maximum tensile strength and yield strength of the samples in this study were 428MPa and 236MPa of the Al-5wt%Mg-1.5wt% alloy sheets annealed at 450°C for 1hour, respectively. The nano-size precipitates and fine grain size improved tensile and yield strength of the Al-Mg-Mn sheets. Al-Mg-Mn sheets fabricated by twin roll casting and rolling have a superior strength to conventional Al-Mg-Mn alloy sheets due to fine Al6Mn precipitate in Al matrix.

11:05 AM
Increasing Mechanical Properties of AA 6082 by Optimizing Chemical Compositions and processing Parameters during Extrusion: Milan Tercelj[1]; *Matevz Fazarinc*[1]; Goran Kugler[1]; Iztok Perus[1]; [1]University of Ljubljana

AA 6082 aluminum alloy is used as constructional material for highly loaded automotive parts thus increasing of yield stress and ductility is of a great importance. Database of mechanical properties of processing parameters and chemical compositions for hot extruded profiles of the alloy was obtained. CAE neural networks individual and spatial analyses was performed to determine the influences of processing parameters and alloying elements, e.g. Mg, Si, Mn, Fe, and Cu, on mechanical properties. The results of the analyses revealed a new understanding of their influences, and the possibility of increasing the mechanical properties if processing parameters and correlations between chemical elements were closer to the optimum values. Optimization was carried out in order to increase yield stress and elongation simultaneously. In practice, the obtained values for mechanical properties have confirmed the optimized values of influential parameters as correct.

11:25 AM
Investigation of the Porosity Evolution during Hot-Compression Tests on an Aluminum Alloy: *Agouti Siham*[1]; Bouchard Pierre-Olivier[2]; Piellard Mickael[3]; Le Brun Pierre[4]; Bozzolo Nathalie[2]; [1]Centre of materials forming; [2]Centre of Materials Forming; [3]Aubert & Duval; [4]Constellium CRV

After casting, alloys ingots generally exhibit central voids that must be reduced during the forming process. In this study, a special Aluminum 7050 alloy with a high Hydrogen content is used as a model material. A laboratory hot compression test is used to investigate the voids evolution during hot-deformation. During compression tests, voids may be either completely closed and healed, or closed but un-healed, or un-closed. In order to identify which of these mechanisms do occur, complementary techniques were used: non-destructive ultrasonic control and SEM observations to detect un-closed voids; fracture surface SEM observation to detect closed but un-healed voids. The influence of thermally induced stresses is also assessed by performing heat-treatment and quenching after hot-compression. Comparisons of the ultrasonic control results before and after hot-compression showed that the voids were closed after hot-compression. However, the fracture surface SEM observations on the compressed specimens revealed the existence of un-healed voids.

11:45 AM
Effect of Strain Rate on the Microstructural Development in DC Cast Al-15Si Alloy: *Chunxia Wang*[1]; Fuxiao Yu[1]; Dazhi Zhao[1]; Xiang Zhao[1]; Liang Zuo[1]; [1]Northeastern University, China

Hot compression at 573K under different strain rates was conducted on DC cast Al-15%Si alloy. The effect of strain rate on the microstructure development was investigated. Microstructural characteristics and deformation behavior of Al-15% Si alloy were discussed by analyzing of flow curves, optical microscope and EBSD. The results show that the peak and steady-state stresses are influenced by increasing of strain rate. The alpha-Al dendrites are almost disappeared and the morphology and size of Si particles is nearly the same as prior to deformation with less of them cracked after hot deformation under every strain rate. The size of continuous dynamic recrystallized grains (CDRXed) decreases and the volume fraction of these grains increases with the strain rate increases. The fraction of HABs is increased gradually and that of LABs is decreased considerably as strain rate increases. It is realized that deformation under high strain rate help for CDRX to occur.

12:05 PM
Influence of High-Pressure Torsion on Mechanical Properties and Microstructural Evolution in 2197 Al-Li Alloy: *Yuan Yuan*[1]; Huimin Lu[1]; Xuguang Li[1]; [1]Beihang University

In present work, 2197 Al-Li alloy has been processed by high-pressure torsion (HPT) at applied pressure of 1GPa and different shear strain γ in the range of 77.7 and 259.0. Optical microscope (OM) and transmission electron microscope (TEM) provide the detail information of grain sizes and microstructure of the deforming alloys. Vickers indentation analysis is used to evaluate the microhardness of the deformed samples. Tension test is employed to obtain the tensile strength σb and elongation δ at room temperature. The results show that nice microstructure and properties are achieved when the pressure is 1GPa and the shear strain γ is 259.0, for the grain sizes in the range of 0.1~0.4μm, microhardness up to 163HV0.2, and σb at 500.8 MPa and elongation d of 10.57%, higher than the peak aging treatment (T8) state of 474.7MPa, with the elongation d of 9.25%.

Aluminum Reduction Technology: Energy Saving

Research and Application of Energy Saving Technology for Aluminum Reduction in China: *Feng Naixiang*[1]; Peng Jianping[1]; Wang Yaowu[1]; Di Yuezhong[1]; [1]Northeastern University

Aluminum electrolysis is known as more energy consumption and more pollution. The DC power of aluminum electrolysis before the technology of aluminum reduction cells with a new-type of cathodes design being applied in China was about 13000 kWh/t. After 2010, nearly all the aluminum smelters have used the technology of new type of cathode design and 800~1000 kWh/t of aluminum reduction can be achieved easily. The DC power of aluminum electrolysis is nowadays 12100~12300 kWh/t. 18000 kWh DC energy power of an aluminum reduction cell in Chuangyuan Smelter is achieved. In present paper, three different type cathodes design are given and the surface oscillation of liquid metal in the cells are studied by means of hydraulic model and numerical simulation. By using the technology of small size of anode and narrow central channel between the anodes under busbar, the energy power of less 11500 kWh/t of aluminum reduction is expected.

8:50 AM
Low Energy Cell Development on AP Technology™: *Olivier Martin*[1]; Bertrand Allano[1]; Etienne Barrioz[1]; Aurore Escande[1]; Yves Caratini[1]; Nolwenn Favel[1]; [1]Rio Tinto Alcan

During this decade the energy market is changing rapidly and new smelter projects may face large ranges of energy block size, significantly different energy prices and environmental regulations. To provide more choice in this complex and changing situation, Rio Tinto Alcan announced two years ago a new strategy of developing flexible solutions. On the same platform have been developed cells at very high productivity and cells with low energy consumption. This strategy has been delivered with the APXe and AP60 cells, able to operate with the same framework in the range 500-600 kA with energy efficiency between 12.0 and 13.2 kWh/kg. This new development incorporates an environmental dimension,aiming to reduce dramatically the air emissions of future smelters. The prototype results have confirmed the feasibility of such ambitious targets and shown that innovation is a key factor to develop the cell of 2020's, at low energy consumption and reduced environmental footprint.

9:10 AM
Review on the Energy Saving Technologies Applied in Chinese Aluminum Reduction Industry: *Fengqin Liu*[1]; Songqing Gu[1]; [1]Chalco

The energy saving technologies applied in Chinese aluminum reduction are reviewed in this paper. The energy saving technology development in China in the aluminum reduction field could be divided into three stages. The first stage was retrofit of sodburge cells to prebaked anode cells and technology development of large amperage prebaked anode cells, which happened mainly in 1990's. The second stage was wide applications of the large amperage prebaked cell technology and the improvement of such relevant technologies as physical fields simulation, cell control systems and high quality anode and cathode manufacturing etc., which covered the first 6-7 years of this century. The third stage has lasted up to now, which mainly focused on the energy saving in the present prebaked cells by cell cathode and lining structure modifications and high performance operation and control system applications.

9:30 AM
Numerical Simulation on Coupled Multi-field of the Perforated Anode in Aluminium Reduction Cells under Low Carbon Operation: *Hesong Li*[1]; Xi Cao[1]; Yingfu Tian[2]; [1]Central South University, China; [2]Chongqing Tiantai Aluminum Industry Co.Ltd

Perforation on the anode block is a new way of thinking. The bubble under the anode block can be eliminated from the holes, and the energy consumption is reduced. The physical and mathematical models of perforated anode and bubble layer were established. The simulation results show that the thickness of the bubble layer is 1.28cm of the perforated anode, reduced by 0.72cm compared to a normal anode, of which corresponding voltage is less than 240mV; the minimum temperature of anode block is 704.3°C,and the temperature distribution in a horizontal plane presents a wave shape due to the holes; the voltage drop of the perforated anode is 379mV and the current density distribution of the perforated anode and ordinary anode are consistent; the maximum of thermal stress is 17.4MPa in the perforated anode, which is far less than the allowable stress. The perforated anode industrial was conducted on three cells. The average cell voltage of perforated anodes decreases 229mV than the traditional reduction cell after long-term operation, which is agreed with the theoretical calculation.

9:50 AM
Improved Energy Management during Anode Setting Activity: *Ali Jassim*[1]; Gregory Meintjes[1]; Arvind Kumar[1]; Jose Blasques[1]; Mohammed Sadiq[1]; Maryam Al-Jallaf[1]; Ali Al Zarouni[1]; [1]Dubal

In prebake aluminium reduction cells, the continuous electrochemical and chemical oxidation of the anodes requires their regular replacement in a predetermined sequence. It's important to maintain cell stability and thermal balance during the anode exchange. The higher amperage operation at Dubal pushed the 'anode current density' towards the anode effect threshold limit. Moreover during anode removal, this threshold limit is challenged causing a higher likelihood of AE. Therefore, the anode setting logic was revamped in order to improve the energy balance whilst operating at an anode current density greater than 1A/cm2. An optimum utilization of resistance set point combined with an automated down movement of anodes prior to anode removal was introduced. Thereby it improved the thermal balance resulting in a reduction in anode effect frequency by 29% and cell voltage by 9mV. This paper summarises the methodology of optimising energy balance during anode setting at Dubal.

10:20 AM
The Transition Strategy at Alouette towards Higher Productivity with a Lower Energy Consumption: *Pascal Coursol*[1]; Jules Coté[1]; Francois Laflamme[1]; Pascal Thibault[2]; Alexandre Blais[2]; Dany Lavoie[1]; Serge Gosselin[1]; [1]Aluminerie Alouette; [2]Rio Tinto Alcan

The Alouette aluminium smelter at Sept-Iles, Quebec was commissioned in 1992 with a nominal capacity of 215,000 tonnes/year based on AP30 cells operating 264 pots at 300 k Amp. Since that time, the plant has expanded and in 2005 one potline of 312 pots was added plus a test Section of 18 pots. The cells currently operate at nearly 370 k Amp for a capacity of 575,000 tonnes/year. In quest of higher productivity and profitability, Alouette is planning a transition to 400 k Amp based on the new High Performance (HP) AP30 cells, referred to as "400HP". In designing this new cell, lining, rodding procedures and materials of construction were modified. The main performance objectives and the development steps towards putting the 400HP pots online and bringing the production lines to 400kA are described in this paper.

10:40 AM
Experimental Studies of the Impact of Anode Pre-Heating: Otavio Fortini[1]; *Srinivas Garimella*[1]; Edwin Kunn[1]; Yimin Ruan[1]; Benyam Yacob[1]; Jack Sorensen[1]; [1]Alcoa

The adverse impact of anode setting on the current efficiency (CE) is well known in the aluminum industry, although few published studies exist. When a cold anode is lowered into the bath, it immediately quenches a layer of frozen bath, on the bottom surface, that may extend to the metal pad. It takes time, energy, and bath motion to melt this layer. Until then, the anode current distribution is uneven and the bath motion is disrupted around the newly set anodes. These effects are hypothesized to lead to higher noise and lower CE. The paper summarizes experiments, conducted at Alcoa Warrick, during which anodes pre-heated to 480-510 deg C (bottom surface) were set in a few pots over 60 days. The studies suggest potential to double the rate of load up, reduce energy consumption by 40 kWh/mt, and increase CE by 0.5-1%. Approaches to supply hot anodes are discussed.

11:00 AM
Depth Analysis and Potentiality Exploitation on Energy-Saving and Consumption-Reduction of Aluminum Reduction Pot: Jianfei Zhou[1]; *Marc Dupuis*[2]; Jun Huang[1]; Xiaobing Yi[1]; Feiya Yan[1]; [1]Guiyang Aluminum Magnesium Design & Research Institute; [2]GéniSim Inc

In view of the existing status with aluminum overcapacity and lower aluminum price in China, many companies adopted various measures to reduce the production cost and the energy consumption, but there has been no normalization theory and method as yet. Aimed at the existing status and the market demand, this paper puts forward the evident effects of energy-saving and consumption-reduction in aluminum reduction pot using new thermal insulation pot lining design, application of optimal cathode structure, reduction of horizontal current device, proper application of new lining materials and proper combination of relevant process parameters based on the finite element software ANSYS and using the thermal field simulation software of international simulation Prof. Mr. Dupuis as calculation method, combining the actual production data. Practice proves that the above-mentioned method combining design, simulation and experiment can become the effective and feasible way to achieve low energy consumption, low cost and high profit.

11:20 AM
Development and Application of SAMI's Low Voltage Energy-Saving Technology: *Dongfang Zhou*[1]; Xiaodong Yang[1]; Wei Liu[1]; [1]Shenyang Aluminium & Magnesium Engineering & Research Institute Co. Ltd

In this paper one low voltage energy-saving technology for aluminum reduction cell is developed by SAMI, this technology can largely reduce horizontal current in the metal pad and improve the MHD stability of the cell. Some industrial testing results of this technology by SAMI and its application on different type cells in Chinese smelter are finally presented to illustrate how their contributions is to make D.C. power consumption close to 12000 kWh/t-Al without current efficiency loss compare to the prior technology.

11:40 AM
Twin Air Compressor for Energy Saving and Backup Capability: Anne-Gaëlle Hequet[1]; *Serge Despinasse*[1]; [1]ECL

Since the first Pot Tending Machine commissioned by ECL™ 50 years ago, all the new options, tools and technical solutions have been conceived and designed only to meet with smelters' challenges: reduce energy consumption and consequently allow significant cost savings and ensure safe and secure operations.In close collaboration with a world-class air compressor designer and manufacturer, ECL™ has then developed and equipped its Pot Tending Machine with a new standard of air compressor: the twin air compressor. Instead of just one big energy-intensive compressor, two smaller and lighter compressors are in most cases used separately (anode changes), except for tapping operation. By running them alternately at only 90% of their full capacity, there are definite energy savings with the additional benefit of a longer operational life for the compressor. Furthermore, the size and weigh of this new standard greatly ease maintenance operations.

Atomistic Effects in Migrating Interphase Interfaces - Recent Progress and Future Study: Kinetics of Phase Transformations in Ferrous Alloys

The Role of Interfaces in the Development of Microstructure in Bainitic Steels: *Gary Purdy*[1]; R. Hadian[1]; G. Botton[1]; [1]McMaster University

The addition of silicon to alloy steels can act to suppress or delay the formation of carbides. In the present work, the formation of ferrite from alloyed austenite with and without Si additions has been used to further elucidate the nature of the bainite transformation. Isothermal transformation products in a Fe-0.5%C-5%Ni (mass %)steel have been compared with a similar alloy with 1.5% Si added and with those in a Fe-0.4%C-3%Mn-1.8%Si alloy. In the Si-containing alloys, ferrite forms initially as groups of Widmanstaetten plates, which thicken with reaction time and adopt increasingly complex morphologies. The orientation relationships, habit planes and defect structures of the resulting ferrite/ austenite interfaces are reported. The Si-free steel, isothermally transformed below Ms, yields a mixture of autotempered martensite and bainitic ferrite. The OR's and habits of the cementite precipitates in the two phases are compared, and consequences for the nature of the bainite reaction are considered.

9:00 AM Invited

A Study on the Kinetics of Bainite in Steel: *Annika Borgenstam*[1]; [1]KTH

There have been two conflicting hypotheses about bainite in steel for a long time: the diffusional and the diffusionless hypothesis. The diffusionless hypothesis claims that the growth of bainitic ferrite is rapid and occurs without diffusion of carbon. The diffusional hypothesis on the other hand claims that the growth of bainitic ferrite is controlled by carbon diffusion. It was recently shown that several microstructural observations can be explained by the diffusional hypothesis and it is here shown that several kinetic observations also favor the diffusional hypothesis. The effect of alloying elements on the growth of bainite will also be discussed.

9:30 AM Invited

The Effect of Alloy Composition on the Stagnant Phase during the Austenite-Ferrite Transformation: *Sybrand Van Der Zwaag*[1]; Hao Chen[1]; [1]Technical University Delft

Recently the concept of cyclic partial transformations has been proposed in order to study the austenite-ferrite interfacial kinetics in the absence of simultaneous nucleation effects. Unlike the case of regular austenite ferrite phase transformations, cyclic partial phase transformations show clear effects of the local interface compositional profile. These effects are most noticeable in the so-called stagnant phase, during which the interface barely moves, even in the presence of a significant driving force. In this paper we will present the result of our simulations on the length of the stagnant phase as a function of the alloy composition.

10:00 AM

A Model for Calculating C-curves for Widmanstätten and Bainitic Ferrite: *Peter Kolmskog*[1]; Annika Borgenstam[1]; [1]Royal Institute of Technology, KTH

A model for calculating C-curves for the transformation of austenite to Widmanstätten and bainitic ferrite is presented. The model is based on the diffusional hypothesis which claims that there is no difference between these two transformation products and that the growth of the two is controlled by carbon diffusion. In this model the start temperature for Widmanstätten and bainitic ferrite, WB_s, is included and needs to be calculated. For calculating the WB_s temperature a model, previously presented by Hillert et al. is improved to get a better predictive capability for Mn, Ni, Cr, Mo, V, Ti and B alloyed steels. The improvement is based on experimental data obtained from both literature and new experiments. Comparisons with other models for calculating C-curves as well as WB_s or B_s are also presented.

10:20 AM Break

10:35 AM

Alloying Element Partitioning and Phase Transformations during Rapid Heating and Cooling: Tapasvi Lolla[1]; Brian Hanhold[1]; Gary Cola[2]; *Sudarsanam Babu*[1]; [1]Ohio State University; [2]Sirius Protection, LLC

An advanced high strength steel (tensile strength > 2000 MPa and elongation > 10%), containing mixed bainite and martensitic microstructure, has been developed through rapid heating (> 400K/s) to austenite phase field and rapid cooling (>500K/s) to room temperature. The mechanism for such microstructure evolution is rationalized based on incomplete dissolution of alloy carbides, originally present the initial microstructure, into the austenite phase. In addition, arguments were made on incomplete carbon homogenization within the austenite phase field. The validity of the above mechanisms was evaluated using computational thermodynamics and kinetic models. Calculations show sensitivity of the dissolution kinetics to composition of alloy carbides (e.g. Chromium concentrations). Some of the challenges of extending local-equilibrium assumption at the carbide/austenite interface (e.g. intermittent formation of Cr enriched ferrite) will be discussed. Impact of these results towards developing a welding process that minimizes the softening at the heat-affected-zone will be discussed.

10:55 AM Invited

Austenite Stabilization through the Quench and Partition Process: *Amy Clarke*[1]; John Speer[2]; Robert Hackenberg[1]; Emmanuel De Moor[2]; [1]Los Alamos National Laboratory; [2]Colorado School of Mines

The quench and partition (Q&P) process has been developed to employ carbon transport from martensite to austenite during a partitioning treatment after initial quenching between Ms and Mf. Quenching within this temperature range produces specific fractions of martensite, while the partitioning treatment promotes stabilization of the remaining austenite through carbon enrichment. The aim of Q&P is to produce substantial amounts of carbon-enriched retained austenite, whereas carbide formation is a more typical means of reducing carbon supersaturation during conventional tempering. In this work, a 0.19C-1.59Mn-1.63Si (wt.%) steel was partitioned at temperatures ranging from 350 to 450°C for times up to 1000s. The kinetics of carbon partitioning and the amount of retained austenite after Q&P processing were examined. The local austenite stability, or the austenite carbon concentration with respect to distance from the austenite/martensite interface, was considered. Bainite formation as a possible mechanism to enrich austenite during partitioning is also addressed.

11:25 AM

Partitioning of Carbon into Austenite Matrix during Bainite Transformation: *Naoki Takayama*[1]; Goro Miyamoto[1]; Tadashi Furuhara[1]; [1]Tohoku University

The carbon enrichment to austenite (γ) during bainite transformation is investigated by means of FE-EPMA in an Fe-0.15C-1.5Mn-0.05Si-0.03Nb (mass%) alloy transformed at 873K where bainite transformation stasis was appeared. In the early stage of transformation, carbon is enriched into a large γ region up to the T_0 composition at γ / bainitic ferrite (BF) interface although average carbon concentration in γ is much lower than the T_0 composition. Meanwhile, the carbon concentration within thin γ between parallel BFs is almost uniform and clearly exceeds the T_0 composition. During the stasis, pre-existing inhomogeneous distribution of carbon in γ is diminished by diffusion in BF and γ. And, the average concentration of γ becomes close to the T_0' composition. Such carbon enrichment can be understood by the rejection of carbon from BF either a diffusional or diffusionless growth.

Biological Materials Science Symposium: Biological and Bio-Inspired Materials I: Hard Biomaterials

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division, TMS: Biomaterials Committee

Program Organizers: Nima Rahbar, University of Massachusetts Dartmouth; Candan Tamerler, University of Washington; Po-Yu Chen, University of California, San Diego; Molly Gentleman , Texas A&M University

Tuesday AM	Room: Swan 7
March 13, 2012	Location: Swan Resort

Session Chairs: Ryan Roeder, University of Notre Dame; Candan Tamerler, University of Washington

8:30 AM Keynote

Peptide-Tailored Solid Interfaces: From Biocompatibility to Self-assembly and Biomaterialization: *Mehmet Sarikaya*[1]; [1]University of Washington

Proteins enable biology to be viable through molecular interactions with <nM specificity to targets. Using biology as a guide at the molecular dimensions, we biocombinatorially select, bioinformatically

enhance and genetically tailor solid binding peptides and utilize them as molecular building blocks in carrying out molecular and nanomaterials science and engineering. Genetically engineered peptides for inorganic materials (GEPI) are used as bionanosynthesizers in biomaterialization, heterofunctional linkers to create thermodynamically stable interfaces between dissimilar materials, and as molecular assemblers for the targeted and directed assembly of nanobiomaterials towards addressable ordered architectures with genetically designed functions. Here, we will give an update of the utility of a variety of GEPIs in nanoinorganic formation for hybrid probe design and bionanosensors; biofunctionalization of implants, biomineral formation for tissue regeneration and restoration, and in peptide-enabled nanobioelectronics and -nanobiophotonics to demonstrate the expanding paradigm in nano/bio-technology and nanomedicine. Primary funding is by NSF-MRSEC and BioMat Programs.

9:10 AM
Design of Bone-Mimetic Scaffolds: *Ryan Roeder*[1]; Timothy Conrad[1]; Robert Kane[1]; [1]University of Notre Dame

Metallic scaffolds exhibit excellent mechanical properties but are bioinert and radiopaque, inhibiting radiographic assessment of bone ingrowth. Ceramic and polymer scaffolds are radiolucent and may be bioactive, but are limited to non-load bearing applications due to their brittleness and compliance, respectively. Polyetheretherketone is a high-performance thermoplastic ideal for load-bearing applications, but bioinert. Collagen is a constituent of the extracellular matrix of bone, ideal for synthetic bone graft substitutes, but collagen scaffolds are alone too weak for immediate load-bearing post-implantation. PEEK and collagen scaffolds were reinforced by bioactive calcium-deficient hydroxyapatite whiskers, which are exposed on the surface and embedded within scaffold struts. Hydroxyapatite whisker reinforced PEEK scaffolds were able to mimic the mechanical properties of vertebral trabecular bone. Hydroxyapatite whisker reinforced collagen scaffolds were prepared using novel processing methods and achieved properties up to twenty times greater than any previous collagen scaffold. Scaffold permeability and bioactivity was also investigated in vitro.

9:30 AM
Mechanical Behavior of a Cellulose-Based Scaffold in Vascular Tissue Engineering: *Parisa Pooyan*[1]; Rina Tannenbaum[1]; Hamid Garmestani[1]; [1]Georgia Institute of Technology

As an essential structural component, scaffold plays a significant role in the design of a vascular substitute for small grafts. Stable mechanical properties and appropriate chemical functionalities are the critical parameters in such a design. Cellulose nanowhisker (CNW) with its unique advantages could potentially constitute an acceptable candidate in scaffolding of a tissue-engineered vessel. Inspired by this possibility, we have designed a fully bio-based scaffold reinforced by CNW fibers. Comparable to carbon nanotubes or kevlar, CNWs impart significant strength and directional rigidity at only 0.2 wt%. To verify our experimental results, theoretical mechanical models were also investigated in this study. Based on these comparisons, the formation of a three-dimensional rigid percolating network imparts an excellent mechanical stability at such low fiber concentration. We believe our fibrous porous microstructure with the improved mechanical properties could expand the biomedical applications of cellulose-based materials while provide a potential scaffold in vascular tissue engineering.

9:45 AM
Sheep Hydroxyapatite (SHA)- Commercial Inert Glass (CIG) Composites: *Nermin Demirkol*[1]; Faik Oktar[2]; Eyup Kayali[3]; [1]Kocaeli University; [2]Marmara University; [3]Istanbul Technical University

In this study, microstructures and mechanical properties of sheep hydroxyapatite (SHA) - commercial inert glass (CIG) composites were investigated. The production of hydroxyapatite (HA) from natural sources is preferred due to economical and time saving reasons. The goal of development of SHA-CIG composites is to improve mechanical properties of HA. SHA composites were prepared with the addition of different amounts of CIG and sintered at the temperature range of 1000-1300 °C. The physical and mechanical properties were determined by measuring density, compression strength and Vickers microhardness (HV). Structural characterization was carried out with X-ray diffraction (XRD) and scanning electron microscopy (SEM) studies. The experimental results were discussed to determine optimum amount of CIG addition as a reinforcement material and the effect of sintering temperature on the microstructure and the mechanical properties of SHA composites.

Mineralization of Dense Collagen Scaffolds Using a Polymer-Induced Liquid-Precursor (PILP) Process: Yuping Li[1]; Taili Thula[2]; *Laurie Gower*[2]; [1]University of Minnesota; [2]University of Florida

Bone is a hierarchically-structured composite which imparts it with unique mechanical properties and bioresorptive potential. In our prior studies, we have shown that when using a polymer-induced liquid-precursor (PILP) mineralization process, we can effectively achieve intrafibrillar mineralization of collagen fibrils. While this leads to a nanostructure that emulates that of bone, isolated rigid mineralized fibrils in a porous scaffold will simply crush under an applied load. Therefore, our current efforts are devoted to mineralization of densely packed collagen matrices, which can then provide a means for emulating the microstructure, and therefore mechanical properties, of bone. Here we show that a densified collagen matrix which resembles the extracellular matrix of primary bone can be created with a plastic compression technique. Upon mineralization, these composites can attain a modulus (as determined by nanomechanical analysis) comparable to primary fetal bone.

10:40 AM
Assessing Biocompatibility and Mechanical Properties of Degradable Metallic Biomaterials: *Puneet Gill*[1]; Norman Munroe[1]; Amit Datye[2]; Rupak Dua[1]; Sharan Ramaswamy[1]; [1]Florida International University; [2]University of Tennessee Knoxville

Metallic materials continue to play an essential role as biomaterials to assist with the repair or replacement of various diseased or damaged parts of the anatomy. This investigation focuses on the manufacturing of biodegradable metallic stent materials, which degrade at desired rates under body simulated conditions. The alloys are tested for their mechanical integrity, surface energy and biocompatibility. Improved mechanical properties are achieved with the addition of alloying elements. The metallographic characteristics associated with those properties are studied by scanning electron microscopy (SEM), X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS) and transmission electron microscopy (TEM).

11:00 AM
Anisotropical Behavior and Phase Transformation in Bone: *Ahmet Ucisik*[1]; Mehmet Aksoy[2]; Isil Kutbay[3]; Metin Usta[3]; Cuma Bindal[4]; [1]Bogazici University; [2]Ministry of Health Istanbul Division; [3]Gebze Institute of Technology; [4]Sakarya University

Human bones present extraordinary, exceptional nature as of birth. All of them are always dynamic even while there is no movement. Osteoblast-osteoclast activities, piezoelectricity, flow through Haversian channels, mass transport etc. make bone dynamic. In this study, micro-structural differences and variations on the mechanical behavior of bone and phase transformations due to injections of anticoagulants during healing of fractured animal bones are investigated. Several different types of mechanical test, micro-structural analysis, XRD and FTIR studies revealed structural changes caused by injection of anti-coagulants; it is found that same bone may alter its crystallographic nature. Mechanical tests performed on human bones, “femur, tibia, fibula” of the same patient and spongeous bone on the hip joint” show differences in “stress-strain” behavior of three bones of the same person that imply each bone has different mechanical behavior and anisotropy in single section of bone respectively.

11:20 AM
Fatigue Behavior of Ti-6Al-4V for Medical Applications after Surface Modification by Anodization: Fernanda Potomati[1]; Laís Possato[1]; Enrico Giordano[1]; *Claudemiro Bolfarini*[1]; [1]Universidade Federal de São Carlos

The new developments and studies of surface modifications are generally driven and focused on biological studies. Engineering studies on mechanical properties of the implants with surface modified do not follow the dynamic of the biological studies. As the fatigue life is a determining property in the use of an implant, this work aimed at to study the fatigue behavior of alloy Ti-6Al-4V subjected to a surface modification through a anodization technique. For this, SxN (stress x number of cycles) curves were obtained through methods specified by standards and literature. Scanning electron microscopy and roughness measurements were used for surface characterization. Contrary to previous results obtained by using a surface modified by laser remelting that led to a 30% loss in the fatigue life when compared to Ti-6Al-4V alloy without surface modification, the anodized surface led to a small increase in the fatigue life.

11:40 AM
Morphological Evaluation of Osteoblast-TiO2 Nanotube Interfaces: *Tolou Shokuhfar*[1]; Chang Choi[1]; Craig Friedrich[1]; [1]Michigan Technological University

The rate and degree of bio-assimilation for an implant is principally governed by the initial cascade of cellular events at the interface. The primary physiological reactions that dictates osteoblast adhesion, and subsequent extracellular bone matrix deposition are now recognized to respond most directly to nanometric topography. Osteoblast interaction and attachment with TiO2 nanotubes was investigated using focused ion beam milling. The SEM images of the FIB milled cells revealed high attachment and growth of the cell inside the hollow section of the nanotubes. EDS analysis suggested that the bond between the TiO2 nanotube substrate and the adjacent osteoblast cell layer was composed of Ca and P elements mimicking the bond in the bone tissue itself. These observations revealed a truly direct contact between the osteoblasts and the titania nanotubes followed by calcium and phosphorous deposition on the nanotubes as an indication that TiO2 nanotubes have regulated osteoblast functionality and differentiation.

Bulk Metallic Glasses IX: Structures and Mechanical Properties I

Atomic Level Flow Dynamics in Metallic Glasses: *Takeshi Egami*[1]; Takuya Iwashita[1]; [1]University of Tennessee

Traditionally the flow of a liquid is described by continuum fluid dynamics. Atomic dynamics is considered to be irrelevant, because the Brownian motion of an atom is so random. However, such an assumption may not be justified for supercooled liquids, or dynamic flow in glasses, such as those in the shear band. Indeed the molecular dynamics (MD) simulation of steady state flow in metallic glasses shows that the atomic dynamics of flow is highly heterogeneous both in time and space. The MD results were analyzed in terms of the anisotropic pair-density function (PDF). The length-scale of spatial heterogeneity is of the order of 1 nm, and depends weakly on the strain rate. The atomic level strain in the strained zone is so high that it causes a cascade of atomic level mechanical failure, resulting in dynamic heterogeneity. Work supported by the US Department of Energy, Office of Basic Energy Sciences.

9:00 AM
Nucleation Reactions during Deformation and Crystallization of Metallic Glass: *Seth Imhoff*[1]; John Perepezko[1]; Mingwei Chen[2]; Sergio Gonzalez[3]; Akihisa Inoue[2]; [1]University of Wisconsin-Madison; [2]Tohoku University; [3]Universitat Autònoma de Barcelona

Nucleation reactions play a central role in both bulk metallic glasses (BMG) and nanostructured materials. For BMG crystal nucleation must be suppressed. For nanostructured materials it is necessary to promote a high nucleation density. Beyond crystallization reactions nucleation is critical for promoting shear band formation to achieve a homogeneous deformation and useful ductility. The study and analysis of nucleation reactions for these different situations requires a consideration of the stochastic nature of nucleation, the influence of heterogeneous sites, and the controlling transport properties. For shear band nucleation, the stochastic nature can be effectively probed by employing instrumented nanoindentation tests and analyzing a statistically significant number of measurements of the first pop-in shear band nucleation events. In nanostructured composites, the early growth characteristics are linked to the maximum particle density that can be achieved and the coarsening kinetics determine how the population will change during operation at higher temperatures.

High Energy X-Ray Scattering Studies of Plastic Process Zones around Fatigue Crack Tips in Metallic Glasses: *Todd Hufnagel*[1]; Uday Vempati[1]; Jon Almer[2]; [1]Johns Hopkins University; [2]Argonne National Laboratory

Metallic glasses can achieve remarkably high fracture toughnesses, given their lack to work hardening or microstructural features usually associated with toughening mechanisms in crystalline materials. To study the fracture process, we have used high-energy x-ray scattering to study the plastic process zone around fatigue crack tips in a metallic glass. Far away from the crack tip, we map the elastic strain as a function of position. Closer to the crack tip, the strain diverges from the expected behavior (from an analytical calculation of the strain around a crack tip), allowing us to determine the extent of the plastic zone. The size of the plastic zone decreases with temperature, correlating with a decrease in the critical stress intensity. Within the process zone, the strain measurement becomes unreliable, because the x-ray scattering pattern is affected by plastic deformation processes.

9:30 AM Invited
Irreversible Lattice Deformation and Enhanced Fragility Under Fatigue in Amorphous Solids: *Despina Louca*[1]; Peng Tong[1]; Gongyao Wang[2]; Peter Liaw[2]; Yoshihiko Yokoyama[3]; Anna Llobet[4]; Yiming Qiu[5]; Yunfeng Shi[6]; [1]University of Virginia; [2]University of Tennessee; [3]Tohoku University; [4]Los Alamos National Laboratory; [5]NIST Center for Neutron Research; [6]Rensselaer Polytechnic Institute

Amorphous metals exhibit unique properties that could have a widespread industrial impact. How they mechanically respond and deform under applied stress, which is vital to their functionality, is not yet well understood. Here we show that fragile behavior is enhanced in glasses under fatigue in part due to shrinkage of loosely bonded regions. By combining neutron diffraction, inelastic scattering and specific heat measurements, we observe a drastic local atomic rearrangement that is hysteretic in temperature and scales with the compression frequency. Associated with this is a softening in the dynamics envisaged in the so-called Boson peak where not one but two collective excitations are observed corresponding to two kinds of localized oscillators that may be a signature of strong glass formers. The suppression of the two excitations under fatigue indicates a decrease in the number of soft-like regions of loosely bound atoms that renders the glass more fragile.

Structure and Dynamics of a Metallic Glass during Mechanical Deformation: *Wojciech Dmowski*[1]; Takuya Iwashita[1]; Konstantin Lokshin[1]; Yoshiko Yokoyama[1]; Chin-Pi Chuang[1]; Matthew Stone[1]; Takeshi Egami[1]; [1]University of Tennessee

Metallic glasses are inherently disordered, having a distribution of atomic sites, yet it is assumed that deformation is microscopically elastic. We studied changes in the atomic structure and dynamics of metallic glasses in situ during deformation below the elastic limit. We used high energy x-ray diffraction and the anisotropic pair distribution function analysis (PDF). Analysis showed that the anisotropic PDF could be divided into elastic (affine) and anelastic components, and for any applied stress level about 24% of the apparent strain was anelastic. Therefore microscopic deformation is never truly “elastic”. The inelastic neutron scattering was performed during compression up to 1.5 GPa. Neutron scattering was analyzed as a function of energy and momentum transfer. The elastic scattering component showed anisotropy typical for compression. However, the inelastic component at Qp indicated softening under compressive loading. This work was supported by the U.S. DOE under DE-AC05-00OR-22725 and NSF-DMR-0906744.

Investigation of Microstructure and Property Variations in Metallic Glass Matrix Composites: Nicholas Hutchinson[1]; Anupriya Agrawal[1]; Wolfgang Windl[1]; *Katharine Flores*[1]; [1]The Ohio State University

Recent work has demonstrated the effectiveness of adding crystalline phases to a metallic glass matrix in order to improve mechanical performance, such as tensile ductility. This presentation will discuss efforts to quantitatively describe the micro- and atomic-level structure of the glass-crystalline interface, and its effect on damage evolution in the composite. Detailed analysis of three-dimensional microstructure reconstructions of Zr- and Ti-based glasses reinforced by ductile crystalline dendrites reveal changes in the interface curvature with thermal processing which may be linked to shear band multiplication and thus the ductility and toughness of the composite. The influences of the curvature and other microstructural length scales, as well as the properties of the individual phases, on strain distribution are examined via finite element analysis. Molecular dynamics simulations are underway to describe dislocation-shear band interactions at interfaces in simple glass-crystalline composites. Implications for metallic glass matrix composite composition and microstructural design will be discussed.

10:45 AM Invited
Origins of Tensile Ductility and Work-Hardening in TRIP CuZr-Based Bulk Metallic Glass Composites: Y. Wu[1]; D. Ma[2]; A. D. Stoica[2]; Z. Y. Zhang[1]; W. L. Song[1]; G. Y. Wang[3]; G. M. Stoica[2]; X. L. Wang[2]; K. An[2]; *Z. P. Lu*[1]; [1]University of Science and Technology Beijing; [2]Oak Ridge National Laboratory; [3]University of Tennessee

Guided by the concept of “transformation-induced-plasticity” (TRIP) concept, we obtained tensile ductility and work-hardening capability in ZrCu-based bulk metallic glass (BMG) composites which undergo martensitic transformation during tensile deformation. In this talk, we will focus on origins of the observed tensile ductility and work-hardening behavior, including the following aspects:1).How the composites accommodate the macroscopic plastic deformation,2).What contributions of the austenitic B2 CuZr phase and the martensitic transformation are, and 3). Why the mciroalloying elements (such as Co) benefit the mechanical properties of the glassy composites.

11:05 AM
Short and Medium Range Order in Ca-Mg-Cu Amorphous Alloys: *Oleg Senkov*[1]; Yongqiang Cheng[2]; Daniel Miracle[1]; Evan Ma[2]; Emma Barney[3]; Alex Hannon[3]; [1]Air Force Research Laboratory; [2]John Hopkins University; [3]ISIS Facility, Rutherford Appleton Laboratory

The atomic structures of $Ca_XMg_{25}Cu_Y$ amorphous alloys were studied as a function of Cu content using the GEM diffractometer at the ISIS high-intensity pulsed neutron source. An increase in the Cu content broadened the first sharp diffraction peak (FSDP) of the structure factor S(Q) and shifted it to higher Q. The shift and broadening of FSDP were interpreted as arising from the shortening of the average interatomic distance and narrowing of the distribution of interatomic distances, respectively. The S(Q) curves contained a medium range order pre-peak at $Q \sim 1$ A^{-1}. An analysis of the amorphous atomic structures obtained using a combination of quantum molecular dynamics and Reverse Monte Carlo methods allowed identification of specific short range and medium range order features in these Ca-Mg-Cu alloys. In particular, these amorphous structures were interpreted as consisting of closely packed Cu-centered clusters, which resulted in the Cu-Cu medium range order correlation.

11:15 AM Invited
Neutron and X-Ray Diffraction Studies of Crystallization in Bulk Amorphous Alloys: *Dong Ma*[1]; Alexandru Stoica[1]; X.-L. Wang[1]; [1]ORNL

An amorphous alloy has short-to-medium range order and is thermodynamically metastable. Upon heating to near or above its glass transition temperature, crystallization that promotes long range order will take place. In this regard, neutron and x-ray total scattering techniques are useful tools in providing structure/phase information at multiple length scales upon crystallization. Here we report the crystallization behaviors of bulk amorphous alloys investigated using both neutron and x-ray diffraction. The knowledge gained from these measurements, in conjunction with microscopic studies, provides useful insights into the phase transformation kinetics that have important implications on glass-forming abilities.

11:35 AM
Structural Anisotropy of BMGs after Mechanical Deformation: *Yang Tong*[1]; Zbigniew Witczak[2]; Chin-Pin Chuang[1]; Takeshi Egami[3]; Wojciech Dmowski[1]; [1]University of Tennessee; [2]Inst. High Pressure Phys.; [3]ORNL

We performed equal channel angular processing (ECAP) of bulk metallic glasses in Zr and La based systems. The deformation was carried in medium with external hydrostatic pressure of 1.2 GPa. The applied nominal stress during ECAP was about 10% below the elastic limit. The resulting shear strain was 0.2 for Zr and 0.4 for La-based glasses. The as prepared and deformed samples were cut to 0.5 mm thick slices with different orientations with respect to the ECAP channel axis. Structural studies were performed using high energy x-ray diffraction. The data were analyzed to obtain structure and the pair distribution functions. We observed anisotropy in the diffraction pattern implying macroscopic uniform strain. Same diffraction experiment was performed after thermo-mechanical creep. We will discuss origin of the apparent strain without external stress in the ECAP and creep samples. This work was supported by the NSF-DMR-0906744 and U.S. DOE under DE-AC05-00OR-22725.

11:45 AM Invited
In Situ High Temperature X-Ray Diffraction Studies on Bulk Metallic Glasses: *Norbert Mattern*[1]; [1]IFW Dresden

The thermal behavior of bulk metallic glasses has been investigated by in situ high energy synchrotron X-ray diffraction. Repeated heating and cooling procedures were performed between glassy and super-cooled liquid state. The observed changes of the structure factor during heating and cooling through the glass transition give evidence for the transition into the super-cooled liquid state at the caloric glass transition temperature. The changes in positions of the first and second diffraction maximum indicate reversible structural changes with temperature differently in the glassy and in the supercooled liquid state. For the glassy phase the shift in position of the first maximum scales approximately with the thermal linear expansion however not for the super-cooled liquid state. Structural relaxation has only a minor effect on the position of the first maximum. The influence of quenching rate, pre-annealing, and mechanical deformation on the temperature dependence of structural parameters is discussed.

12:05 PM
Mechanical Behavior of Zr/Hf Based Bulk Metallic Glasses under Uniaxial Quasi-Static and Dynamic Compression: *Weihua Yin*[1]; Laszlo Kecskes[2]; Qiuming Wei[1]; [1]UNC Charlotte; [2]WMRD,US ARL

In this work, we have examined the quasi-static (strain rate \8773 10^{-3} s^{-1}) and dynamic (strain rate \8773 10^3 s^{-1}) responses of Zr/Hf based bulk metallic glasses (BMGs) from different casting processes. We find the failure stress of both BMGs increases with decreasing strain rate and weight percentage of Zr. For most of the quasi-static specimens, an amount of 2% plastic strain is observed. However, for dynamic testing, no plastic deformation is detected, and dynamic failure occurred almost immediately after the elastic deformation. Shear-band formation remains the dominant deformation mechanism with light emission during both loading processes. Using SEM to examine the post-loading specimens, a nearly flat fracture surface and a uniform distribution of the vein-like patterns are found in the quasi-static specimens. However, an uneven fracture surface and scattered distribution of vein-like patterns are observed in the dynamic specimens. Multiple shear bands are only found in the quasi-static specimens.

Cast Shop for Aluminum Production: Grain Refinement and Castings

8:30 AM
Effect of Grain Refiner Amount on the Hot Tearing of 6xxx Alloys During DC Casting: *Muhammad Umar Chandia*[1]; Arild Håkonsen[2]; John Hafsås[1]; [1]Hydro Aluminium; [2]Hycast AS

The purpose of the grain refiner addition during the Direct Chill (DC) casting of billets is to obtain fine homogeneous grain size and to avoid the hot cracking for a given set of DC casting parameter. However the relation of grain refiner amount to different casting parameters like casting speed and water amount are not very clear. This work was conducted to study the effect of grain refiner amount on the critical casting speed at which hot cracking occurs during DC casting of extrusion billets. Full scale DC casting trials of 6xxx alloy were performed. Four addition rates of grain refiner were used. For each amount of grain refiner the speed of casting was increased step by step after each half meter of casting until hot tears formed in all the billets. In this paper the results of the casting trials will be presented and discussed.

8:50 AM
Grain Refining of Pure Aluminum: *Lucy Han*[1]; Corey Vian[2]; Jie Song[2]; Zhiwei Liu[2]; Qingyou Han[2]; Clause Xu[3]; Lu Shao[3]; [1]West Lafayette Jr./Sr. High School; [2]Purdue University; [3]Hans Tech

Grain refiners are currently used in casting aluminum alloys to reduce the grain size and to produce equiaxed grains during solidification of the alloys. Using inoculants to refine grains makes alloys castable but produces several disadvantages, including particle agglomerates, local defects, and impurities. In contrast, ultrasonic vibrations can be used in the place of grain refiners to refine grains without the disadvantages of using inoculants. In this study, high intensity ultrasonic vibrations were applied during solidification of pure aluminum. The grains of pure aluminum treated using ultrasonic vibrations were compared to the grains obtained using the TiB2 grain refiner. It was found that the grain size in the ingots subjected to ultrasonic vibrations was much smaller than those with the addition of grain refiners.

9:10 AM
Study on the Microstructure Changes of Hypereutectic Aluminum Casting Alloy Using Ultrasonic Vibration Process: *Jie Song*[1]; Qingyou Han[1]; [1]Purdue University

The microstructure changes using the ultrasonic vibration process method and Al-P modifier on permanent mold castings of hypereutectic aluminum alloy (Al-20Si) were studied by using optical and scanning electron microscopy. The Al-P modifier could modify the pro-eutectic silicon phase from a large polyhedral shape to a smaller polyhedral shape but had no effects on the morphology of the eutectic silicon phase. In samples subjected to ultrasonic vibration during its solidification process, however, both hypereutectic and eutectic silicon phases were significantly modified. Furthermore, the aluminum phase was also significantly changed. Small polyhedral silicon particles and globular aluminum grains were formed in the region near the probe (zone one). In the region far away from the probe (zone two), the hypereutectic silicon refined as in zone one, as the partly eutectic phase changed to globular alpha aluminum phase and polyhedral silicon phase.

9:30 AM
A Mathematical Model and Computer Simulations for Predicting the Response of Aluminum Casting Alloys to Heat Treatment: *Chang-Kai Wu*[1]; Makhlouf Makhlouf[1]; [1]Worcester Polytechnic Institute

In this publication we report on our efforts to develop a mathematical model and the necessary material database that allow predicting physical and material property changes that occur in aluminum casting alloys in response to precipitation-hardening heat treatment. We use the commercially available finite element software ABAQUS and an extensive database that was developed specifically for the aluminum alloy under consideration – namely, A356.2 alloy. The model produces multiple outputs at each node including the thermal history of the component, the final geometric distortion, the magnitude and type of residual stresses that develop in the component and mechanical properties.

9:50 AM Break

10:10 AM
Understanding and Improving Chemical Capability in the Casthouse: Kolbjørn Halse[1]; Amanda Bowles[1]; *Inge Johansen*[1]; [1]Hydro Aluminium

An aluminium casthouse casts aluminium in charges (or drops). These charges are made to particular customers' ordered chemistry specification. The ability for a casthouse to accurately and consistently produce charges inside the customers' specification is crucial for productivity. In addition, it is important that a casthouse can accurately and consistently measure the real composition of each charge. In this paper the sources of uncertainty in the chemistry are classified and discussed. The use of a model to study sensitivities on the predicted process capability (Cpk) from changes in charging accuracy, conditions during analysis, sampling and adjustment is demonstrated. The model can be used as tool to indentify improvement potentials.

10:30 AM
Effects of Water Content of Frozen Mold on Fluidity of Aluminum Alloy: *Naoki OMURA*[1]; Shuji Tada[1]; [1]National Institute of Advanced Industrial Science and Technology(AIST)

A frozen mold which is produced by freezing the mixture of sand and water is expected to improve the poor working environments such as noise, vibration and dust. Actually, the frozen mold is now applied to iron and bronze casting. The fluidity, however, might be the key to spread this technique to light metals because the frozen mold has the possibility to accelerate those solidifications due to its large cooling capacity. In this study, the fluidity of aluminum alloy (AC4CH) cast to the frozen mold was investigated. The flow length of AC4CH aluminum alloy cast into the frozen mold increased with decreasing water content of mold and was much improved by arranging gas vent port to the cavity. It was confirmed that AC4CH aluminum alloy has better fluidity against the frozen mold rather than the conventional green sand mold.

10:50 AM
Simulation Tools to Complement Cast House Design and Daily Operation: *Laszlo Tikasz*[1]; Robert McCulloch[1]; Scheale Duvah Pentiah[1]; Robert Baxter[1]; [1]Bechtel Canada Co.

In this paper, cast house operation is considered as a true example of a Flexible Manufacturing System (FMS), whereby a target product mix is reached by adapting both process parameters and production plans, respectively. The examples presented here were initiated by challenging cast house operation situations. The results derived from the simulation scenarios were used to propose mitigating measures and to corroborate suggested solutions. From the components of the simulation tool-set, further models are built. As is often required, models can be configured and applied to, among others, cast house design, production planning, operations decision support and to operator training: In-depth knowledge of cast house operations and dynamic process modeling has been turned to a practical engineering tool. It is regularly used by Bechtel's Mining & Metals "Aluminum Center of Excellence" (ACE) group to deliver recommendations and results to clients in global aluminum smelter projects.

11:10 AM
Formation of Microstructure in Al-Si Alloys under Ultrasonic Melt Treatment: *Liang Zhang*[1]; Dmitry Eskin[2]; Alexis Miroux[3]; Laurens Katgerman[1]; [1]Delft University of Technology; [2]Brunel University; [3]Materials Innovation Institute

It is well known that ultrasonic melt treatment (UST) provides many benefits to casting processing, especially for the refinement or modification of as-cast structure. There is a lack for systematic studies on Al-Si alloys, although a number of reports are available on hypo-eutectic A356-type and hyper-eutectic (18-24% Si) alloys, showing primary Al or Si refinement. In this paper, the effect of UST on the formation of microstructure was systematically analyzed in hypo-eutectic (6%), eutectic (12.5%) and hyper-eutectic (18%) Al-Si alloys, including commercial piston alloys. The results show that ultrasonic treatment of Al-Si alloys can refine grain structures in all types of Al-Si alloys. Significant refinement of primary Si phase in hyper-eutectic Al-Si alloy can be observed as well. In near-eutectic or eutectic Al-Si alloys, UST, along with its effect on grain refinement, shows some potential in refining primary Si particles in a wide range of melt temperatures.

8:30 AM Keynote
A Multiscale Transient Modeling Approach for Predicting the Solidification Structure in VAR Processed Alloy 718 Ingots: *Laurentiu Nastac*[1]; [1]The University of Alabama

This paper describes the development and validation of a comprehensive multiscale modeling approach capable of predicting at the mesoscopic scale level the ingot solidification structure and solidification-related defects commonly occurring during the vacuum arc remelting (VAR) process. The approach consists of a coupling between a fully transient macroscopic code and a mesoscopic solidification structure code. The predictions from the multiscale model including grain morphology and size, primary and secondary dendrite arm spacings, Laves and NbC phases, tendency for freckling and columnar-to-equiaxed transition were validated against experimental measurements for a 20-inch diameter VAR alloy 718 ingots. The validated model was then used to investigate the effects of melting rate and ingot diameter on the solidification structure of VAR processed 718 ingots.

9:00 AM Invited
A Multiscale Model for the Simulation of V.A.R. Ingot Solidification: Mathieu Revil-Baudard[1]; *Alain Jardy*[2]; Faustine Leclerc[3]; Miha Zaloznik[2]; Véronique Rebeyrolle[3]; Hervé Combeau[2]; [1]Institut Jean Lamour / Areva NP Cezus; [2]Institut Jean Lamour; [3]Areva NP Cezus

Since the quality of Vacuum Arc Remelted ingots is linked to their chemical homogeneity and metallurgical structure, a modeling study of the solidification during VAR has been undertaken. It is based on the solution of the coupled transient heat, momentum and solute transport equations during the remelting of a cylindrical ingot. Solidification mechanisms implemented in the model include a full coupling between energy and solute transport in the mushy zone, and accounting for nucleation and finite diffusion of solutes at the microscopic scale, in both solid and liquid phases. This modeling can be applied to actual multi-component alloys. In this paper, the macrosegregation in Zircaloy 4 ingots is investigated. To validate the model, one single melt of a homogeneous electrode has been specifically performed. The comparison between the predicted macrosegregation and the experimental results shows the importance of accounting for solutal convection to forecast properly the macrosegregation in remelted ingots.

9:30 AM Invited
The Effect of Slag CapThickness on the Pool Depth in Electroslag Remelting: *Jeffrey Yanke*[1]; Rodney Trice[1]; Matthew Krane[1]; [1]Purdue Center for Metal Casting Research, School of Materials Engineering, Purdue University

In the electroslag remelting process, the slag cap serves as the source of heat to melt the consumable electrode. The slag cap thickness and properties control the solidification time and sump shape of the ingot. Throughout the process, slag freezes to the mold wall forming an electrically and thermally insulating slag skin. This paper uses numerical simulations to investigate the role that slag cap thickness plays on the depth of the liquid metal pool during the ESR process and on the melt rate of the electrode at constant current. To counter the effect of freezing slag, fresh slag is often added during the electroslag remelting process. The effects of the frequency of this addition on the sump shape and melt rate are also studied.

10:00 AM Invited
Mathematical Modeling of Fluid Dynamics and Vessel Vibration in the AOD Process: *Christian Wuppermann*[1]; Antje Rückert[1]; Herbert Pfeifer[1]; Hans-Juergen Odenthal[2]; Erich Hovestädt[2]; [1]RWTH Aachen University; [2]SMS Siemag AG

During the argon oxygen decarburization (AOD) process high-chromium steel melts are de-carburized by oxygen and inert gas injection through sidewall nozzles and a top-lance. Due to the large amount of the injected processing gas, low frequency oscillations of the vessel can be observed. It is suspected that these oscillations can detrimentally influence the converter's structure. The exchange of forces between fluid and the surrounding vessel is the focus of this study. An oscillation model was developed and tested, one objective being to limit the computational effort which is necessary for fully coupled and time resolved CFD and FEM simulations. Experimental results obtained from water-model studies as well as from on-sight measurements are available and were used in order to validate the numerical results.The authors' intention is a contribution towards a more in depth understanding of the factors influencing vessel vibration during the AOD process.

10:30 AM Break

10:50 AM
Solute Redistribution, Liquid/Solid Interface Instability, and Initial Transient Regions during the Unidirectional Solidification of Ti-6-4 and Ti-17 Alloys: *Laurentiu Nastac*[1]; [1]The University of Alabama

The importance of investigating solute redistribution during the unidirectional solidification of multi-component alloys is broadly discussed in the literature. Relevant industrial directional solidification processes for alloy processing include continuous casting, remelting processes (Plasma Arc Melting (PAM), Eletroslag Arc Remelting (ESR) and Vacuum Arc Remelting (VAR) processes), Czochralski crystal growth technique, and floating zone techniques. A transient analytical model is used in this article to study the solute redistribution, the liquid/solid interface stability, and the size of the initial transient region during the unidirectional solidification with an axially moving boundary of Ti-6-4 and Ti-17 alloys. The liquid/solid interface stability is based on an extended transient constitutional undercooling criterion. The effective partition coefficients of the alloying elements in these Ti-based alloys were determined based on specially designed experimental measurements. It is shown that both the value of the partition coefficients and the withdrawal velocity magnitude have a significant impact on the directional solidification processing of Ti alloys.

11:10 AM
CFD Modeling of Splash in Molten Materials Processing Operations: *Mark Schwarz*[1]; [1]CSIRO

Splash must often be avoided or minimised in many materials processing operations, but in some cases the process can be designed to control splash for heat and or mass transfer. In all cases careful design is required and CFD modelling can play a critical role in this. Unfortunately, splash is a complex process for which CFD modelling has not been widely applied in the design arena. The phenomenon involves multi-scale issues, with surface properties playing an important role. The paper describes the physics of splash mechanisms, particularly as caused by bubbling through molten metals, and summarises some of the CFD techniques that have been used to simulate such splash. Examples of CFD models developed for modelling splash in ferrous and non-ferrous smelting processes are described.

11:30 AM
Numerical Analysis of Electromagnetic Field in an Electroslag Remelting Process with Three –Phases Electrodes: *Baokuan Li*[1]; Fang Wang[1]; Meilong Shan[1]; Fumitaka Tsukihashi[1]; [1]Northeastern University

As the advantage of uniform bus loading, the electroslag remelting (ESR) furnaces with three –phase installation by delta or star connection are mainly used to produce the large or super large ingot. The electrical efficiency is significantly improved as the short circuiting through the molten slag. However, little is found about fundamental research on the electromagnetic field of the ESR system with three –phase installation. A three-dimensional (3D) finite element model was developed to simulate the current density, magnetic field, electromagnetic force and Joule heating for a system of electrode, slag and ingot in the ESR system with three –phase installation. Effect of Some parametric such as the applied current, position of electrodes and slag thickness have also been examined.

11:50 AM
Influence of the Electric Current Frequency on the Electroslag Remelting Process: *Abdellah Kharicha*[1]; [1]University of Leoben

In the present paper, the droplet formation during melting of a 420 mm diameter flat electrode is simulated with an advanced three dimensional multiphase-Magneto-hydrodynamic numerical model. The momentum, energy and electromagnetic fields are fully coupled. The computational domain includes a layer of slag and a layer of liquid steel. A VOF approach is used for the interface tracking and a potential formulation is used for the electric and the magnetic field. In the present work we present the results for electric current frequency from 1 to 50 Hz. We show that at frequencies lower than 10Hz, the system behaves almost as what was predicted with a DC current. For frequencies higher than 20 Hz, the fluctuations of eddy current start to interact with the liquid dripping frequency. The movement of the slag/metal interface is also affected by the electric skin effect occurring at frequency higher than 30 Hz.

Characterization of Minerals, Metals, and Materials: Characterization of Minerals and Ceramics

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Materials Characterization Committee
Program Organizers: Jiann-Yang Hwang, Michigan Technological University; Sergio Montero, State University of North Rio De Janeiro; Chenguang Bai, Chongqing University; John Carpenter, US Department of Energy; Donato Firrao, Politecnico di Torino; Byoung-Gon Kim, Korea Institute of Geoscience & Mineral Resources; Mingdong Cai, Schlumberger

Tuesday AM — Room: Asia 2
March 13, 2012 — Location: Dolphin Resort

Session Chairs: Doyle Fiona, University of California, Berkeley ; Chen-Guang Bai, Chongqing University

8:30 AM
A Novel Low-Energy Route for the Extraction of Copper And Cobalt Metals/Alloys from the Zambian Sulphide Concentrates: *Yotamu Hara*[1]; Animesh Jha[1]; [1]Leeds University

Conventional smelting of copper – cobalt – iron sulphide concentrates result in the oxidation of cobalt and iron, which are subsequently lost into the slag. The emission of SO2 bearing gas from smelting causes serious health and environmental problems. In this research, three different types of copper –cobalt–iron sulphide concentrates, derived from froth flotation were investigated. The concentrates, each containing more than 40 wt % percent gangue material, have been directly reduced in the presence of lime and carbon in the temperature range of 800 °C–1300 °C, for the production of copper, cobalt and iron. We demonstrate the basic principles of process physical chemistry for the recovery of alloy by carrying out a detailed process analysis utilising the predictions from thermodynamic equilibrium and the results from kinetics of reduction reaction. The effects of temperature on the reduction kinetics and alloys formation, have been determined and analysed in detail.

8:45 AM
Structural and Chemical Modification of Sulfide Mineral Surfaces by High-Power Nanosecond Pulses: *Igor Bunin*[1]; Valentine Chanturiya[1]; Alexey Kovalev[1]; Irina Khabarova[1]; Elizaveta Koporulina[1]; [1]Research Institute of Comprehensive Exploitation of Mineral Resources RAS

This paper presents new theoretical and experimental data on possible mechanisms for the formation of micro- and nanophases on the surfaces of sulfide minerals under the effect of high-power nanosecond electromagnetic pulses (HPEMP). The gas outflow from nanosecond breakdown channels of sulfide minerals under HPEMP is considered, with allowance for the condensation of iron vapors. The condensation of matter in an outflowing jet is shown to be an effective mechanism for structural and chemical transformations of sulfides. It is established, that electrode potential of pyrrhotite is moved together in the negative party owing to formation of iron oxides (hydroxides) and iron sulfates by HPEMP (10(3) pulses), that provides decrease of xanthate sorption and reduction flotation extraction of pyrrhotite, whereas electrode potential of pentlandite gets more positive values at the expense of additional formation of element sulfur, that causes increase of xanthate sorption and, as a consequence, increase of nickel sulfide extraction.

9:00 AM
Characterization of Magnetic and Non-Magnetic Iron Oxide Nanoparticles Synthesized by Different Routes: Alyssa Maich[1]; E. Yegan Erdem[1]; *Fiona Doyle*[1]; [1]University of California, Berkeley

There is an expanding interest in synthesizing high quality magnetic nanoparticles, notably for biomedical applications. Different routes have been reported for synthesizing magnetite and maghemite. However, some ambiguity remains on their precise chemistry, intermediates, and final products, due to the structural similarity of maghemite and magnetite, and the relative ease of redox transitions during synthesis. Here we present TEM, x-ray and electron diffraction, and supplemental studies aimed at characterizing the products from two different reaction systems, thereby clarifying the reaction chemistry. The first hydrolyzed aqueous FeCl2 and FeCl3 chlorides with ammonia in a microfluidic reactor; although the product had an even size distribution, it included non-magnetic goethite. The second system thermally decomposed iron(III) acetylacetonate in ether. Although in the second system oleylamine has been reported to serve as both a reducing agent and capping ligand to control particle characteristics, our studies revealed little reduction, with maghemite dominating as a product.

9:15 AM
Characterization of Concentrate, Pellet and DRI Samples for Trace Elements: *Mingming Zhang*[1]; [1]ArcelorMittal Global R&D

Three samples received from the EAF shop have been characterized by chemical, X-ray diffraction (XRD), optical microscopy (OM) and scanning electron microscopy (SEM) methods. The objective of this characterization work is to investigate the occurrence of nickel, copper, zinc, sulfur and phosphorus in these samples and identify their origin and associations with iron minerals in the concentrate samples. The samples were identified as Mineral, Pellet, and HRD. The latter is the DRI product. All three samples were received as fine powders. The results indicate that, in the mineral sample, magnetite is the major iron oxide mineral with hematite as a second phase based on the OM and XRD studies. Pyrite [FeS2], chalcopyrite [CuFeS2] and bravoite [(Fe,Ni)S2] are major sulfide minerals. Trace amounts of apatite [Ca5(PO4)3(F,Cl,OH)], wardite [Na4CaAl12(PO4)8(OH)8 6H2O], giniite [Fe5(PO4)4(OH)3 2H2O] and vivianite [Fe3(PO4)2 8H2O] were identified by SEM and XRD. Microscopic studies also indicated that most of the sulfide grains in the mineral sample are present either as liberated fine particles (about 10 microns) or as inclusions within the magnetite and hematite grains. XRD studies revealed magnetite as the major mineral with subordinate amounts of hematite and pyrite confirming the microscopic findings. Copper, nickel, and zinc are mainly present as chalcopyrite, bravoite, and franklinite [(Zn,Mn,Fe)(Fe,Mn)2O4] in trace amount in the mineral samples, respectively. Impurities carry over to the Pellet and HRD samples. Chemical analyses of the three iron-bearing samples indicate that sulfur and phosphorus in the Pellet sample exceeded the specification. Since liberated pyrite and chalcopyrite particles were observed both in mineral and pellet samples, magnetic and flotation processing routes for this ore should be effective for sulfide removal but at the cost of iron losses. The high phosphorus content of all three samples indicates that there are phosphates which are difficult to remove by the current concentrating process (magnetic separation and flotation).

9:30 AM
Dielectric and Temperature-Rising Characteristics of Ore Fines Materials in Microwave Field: *Hongbo Zhu*[1]; Linqing Dai[1]; Jinhui Peng[1]; Wei Liang[1]; Zheng Wei[1]; Zhenliang Weng[1]; Qianxu Ye[1]; Jian Chen[1]; [1]Kunming University of Science and Technology

The dielectric constant and dielectric loss factor of Dahongshan concentrate, millscale, anthracite and light-burned dolomite were tested in different frequency and temperature. In addition, the temperature-rising characteristics of the materials in the microwave field of 2.45GHz in frequency were studied. The results showed that the Dahongshan concentrate reached 1250°C in 330s, whereas the millscale needed 855s, the anthracite needed 820s, and the microwave absorbing property that sudden changed at about 400°C became stronger with the temperature rising on the condition of the microwave power of 2KW and the mass of 30g. The research provided the foundation of further study on making direct reduced iron by microwave heating.

9:45 AM
Characterization on the Roughness of the Iron Ore Particles: *Xuewei Lv*[1]; Xiaobo Huang[1]; [1]Chongqing University,China

The characterization of the surface roughness of the mineral particles is of vital importance for the studies of the mineral processing. In this study, an evaluation of the roughness of the iron ore particles, with the measurements of size distribution and the measurements of specific surface area with the liquid nitrogen absorption, was developed. The main theory of this method is the fact that the roughness of the particle influences the specific surface area apparently. The specific surface area of the particles can be measured with the laser diffraction method and the liquid nitrogen absorption method. The influence of the surface roughness of the particle can be measured with the nitrogen absorption and cannot be measured with the laser diffraction. Therefore, the roughness can be got by comparing the specific surface area with two measurement methods.

10:00 AM
Synthesis and Characterization of Al, Ag, Ti, Cu, and B Substituted Hydroxylapatite: *Celaletdin Ergun*[1]; Thomas Webster[2]; Gurbuz Gunes[1]; Abdurrahman Bahadir[3]; Huinan Liu[4]; Ibrahim Erden[5]; [1]Istanbul Technical University; [2]Brown University; [3]MSTU; [4]University of California, Riverside; [5]Yildiz Technical University

Hydroxylapatite, have been used in numerous orthopedic applications. Recently, nano-crystalline HA is used as an adsorbent for removing pathogenic proteins from blood for purification since HA has good blood compatibility as well as a ability for selective protein adsorption. Besides, it has numerous non-medical applications including packing media for column chromatography, gas sensors, catalysis and host materials for lasers and luminescent materials. Its crystal structure permits a wide range of iconic substitutions, which is an effective method to modify its properties. For instance; the substitution of rare-earth ions can lead changes in refractive index and lattice parameters. Ag doping may provide antibacterial resistance, while Ti, Zn, Sr may increase its biological performance. Sb and Mn doping can provide fluorescent performance which is used in fluorescent lamps. The purpose of the current paper is to synthesis B, Ti, Ag, Al, Cu substituted HA and characterize for materials properties and biological performance.

10:15 AM
Electric Resistivity of Fine Chromite Ore: Cheng Pan[1]; Xuewei Lv[1]; Chenguang Bai[1]; Xuyang Liu[1]; Donghai Li[1]; [1]Chongqing University

Fine chromite ore is the common raw material to produce ferrochrome alloy through the submerged electric furnace process. The electric resistivity of fine chromite plays an important role in the operation efficiency because it effects the current distribution greatly. The effect of particle size and the contact area between two particles on electric resistivity were investigated at room temperature for various of chromite, and the relationship between the electric resistivity of mixed particles and the volume ratio of lump ore to fine ore was also studied. The results shown that the electric resistivity increases with the increase of particle size, and the electric resistivity of mixture decreases with the increase of volume ratio of fine ore.

10:30 AM
Reduction of Agglomerated Manganese Ores in Ferromanganese Production: *Thomas Brynjulfsen*[1]; Merete Tangstad[1]; [1]Norwegian University of Science and Technology

Manganese ore fines, generated during mining and transportation, can not be added to the submerged arc furnace directly as they will prevent even gas flow through the burden. Low gas permeability in the burden will lower the degree of pre-reduction of ore subsequently increase the carbon and energy consumption of the process. In order to utilize manganese ore fines in the furnace they are agglomerated into sinter, pellet or briquettes. The agglomeration process will however change the reduction properties of the ore.In this work the melting and reduction properties of different agglomerates has been investigated. Agglomerates from different commercial ores have been produced and the melting temperature and melting mechanisms has been studied. The mineralogy of the raw ores and agglomerated has been found using XRD, and the composition established using EPMA(WDS). The effect of adding fluxes such as dolomite and quartz has also been investigated.

10:45 AM
Making Direct Reduced Iron from Millscale Containing Coal by Microwave Heating: *Linqing Dai*[1]; Hongbo Zhu[1]; Jinhui Peng[1]; Jian Chen[1]; Qianxu Ye[1]; [1]Kunming University of Science and Technology

Recycling of ferro-waste through coal-based direct reduction process not only can eliminate industrial waste pollution, reach clean production, but also improve comprehensive abilities and economic benefits of steel plants. Millscale fines have good microwave heating characteristics, better than anthracite below 720°C. The results showed that on the condition of 60 min at 1100°C, the ratio of coal to material is 22%, the metallization rate increased with the ratio of millscalle, and it is up to 98.23%.

11:00 AM
Ceramic Pigments with Spinel Structure Obtained by Low Temperature Methods: *Oscar Restrepo*[1]; Edgar Chavarriaga[1]; Leidy Jaramillo[1]; [1]National University of Colombia

This paper presents the results of the manufacturing ceramic pigments with spinel structure, using methods of synthesis of low temperature. In this work we obtained spinel structures type by the methods of Self-combustion, Coprecipitation, Microemulsion, Gel citrate and Pechini. These methods become an attractive alternative to traditional method (ceramic method), since we can work at a lower temperature, reducing manufacturing costs, lower fuel consumption, less wear on equipment and other environmental and economic implications. Also it is possible to have control over features such as stoichiometry, morphology of the products, reaction times and structures. The products obtained by these routes will be used in the manufacture of ceramic pigments and characterized using different techniques such as X-ray diffraction (XRD), scanning electron microscopy (SEM) and UV-VIS spectrophotometry.

11:15 AM
Synthesis and Characterization of Jarosite-Type Compounds with Arsenic: Francisco Patiño[1]; Iván Reyes[1]; Mizraim Flores[1]; *Miguel Pérez*[1]; Martín Reyes[1]; Julio Juárez[1]; [1]Universidad Autónoma del Estado de Hidalgo

Jarosites structure type compounds allow the incorporation of several elements of environmental importance such as arsenic during their precipitation. Arsenic integrated into the structure of jarosite can be stabilized in a wide range of environmental conditions (pH, temperature, etc.) that are tolerated by the pure jarosite. Sodium and potassium jarosites with arsenic incorporated were synthesized using the precipitation method in sulfate media and several methods of characterization were used. XRD results showed the products obtained are pure phases. Morphology of both compounds showed spherical particles with majority sizes between 37-54 microns with rhombohedral crystals strongly welded joined together, being more evident in the arsenojarosite. The stoichiometry according to chemical analysis are as follows: for arsenojarosite [K0.75 H3O0.25] Fe1.84 [(SO4) 1.82 (AsO4) 0.18] [(OH) 2.34 (H20) 3.66] and arsenonatrojarosite [Na0.87 H3O0.13] Fe2.50 [(SO4)1.95 (AsO4)0.05] [(OH)4.45(H20)1.55], being notorious that the arsenojarosite retains more arsenic in their structure, but is deficient in iron.

11:30 AM
Mechanical Characterization of Cellular Ceramic Materials: *Wilson Acchar*[1]; Fernando Barcelos[1]; Luis Pereira[2]; [1]Federal University of Rio Grande do Norte; [2]Federal University of Rio de Janeiro

Porous ceramics have been extensively investigated as structural materials for flow of fluids in many applications, such as filters for molten metals, hot gases, thermal protection systems and heat exchangers. This class of material must have special features: high permeability and mechanical strength. However, these parameters are influenced in different ways by the processing method and the consequent cellular structure. In this work two different types of commercial ceramic filter materials are investigated. Characterization included the evaluation of the strength values as well as the microstructural analyzes of the surface fracture. The results indicate that the strength values are strong dependent on the filament defects.

11:45 AM
Study of Attapulgite for Human Health: *Wilson Acchar*[1]; Tulio Moura[1]; Antonio Costa[1]; Ledjane Barreto[2]; [1]Federal University of Rio Grande do Norte; [2]Federal University of Sergipe

Since the beginning of time, nature has served humanity as a source of various raw materials. Clays are common ingredients in pharmaceutical products both as excipients and active substances. Recently a patented study reports the use of attapulgite as the encapsulating agents both for the protecting the active substance and modulating release into the body. Some clays such as kaolinite, smectites, talc, etc are also used as dermatological protectors. Sepiolite and smectites have the ability to form complexes with organic compounds with absorb ultra-violet radiation, enabling them to be used in sun screens with protection factors. Brazil has a significant reserve of attapulgite located in Teresina, Brazil, making the study of the potential use of this mineral in specils areas very attractive. The objective of this work is to characterize the attapulgite in order to study the potential use of this clay material in the human health.

Computational Thermodynamics and Kinetics: Phase-Field Simulations in Alloys I

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS Structural Materials Division, TMS: Alloy Phases Committee, TMS: Chemistry and Physics of Materials Committee, TMS/ASM: Computational Materials Science and Engineering Committee, TMS: Integrated Computational Materials Engineering Committee, TMS/ASM: Phase Transformations Committee, TMS: Process Technology and Modeling Committee

8:30 AM Invited
Phase-Field Modeling of Evolving Microstructures and Phase Transformations in Solid Oxide Fuel Cells: *Mikko Haataja*[1]; [1]Princeton University

Energy conversion processes in solid oxide fuel cell (SOFC) materials are strongly affected by a nonlinear coupling between mass/charge transport, heat transport, and morphology at nanometer and micrometer length scales in a multi-phase/multi-component system. Furthermore, under continuous operation, these complex morphologies and local compositions evolve over time in response to a multitude of physical, chemical, and mechanical cues at elevated temperatures. In order to understand and predict the stability of morphologies and their spatio-temporal evolution, a mesoscale approach, which accurately incorporates both atomic scale information and evolving microstructures, is required. In the first part of my talk, I will present our recent work on quantifying coarsening kinetics of Ni particles in Ni-YSZ anode materials based on "experimentally-informed" phase-field simulations. In the second part of my talk, I will focus on the development of elastic stresses and resulting mechanical failure in SOFC anode materials driven by re-oxidation of Ni particles.

8:55 AM
Inertia Dominated Criticality in Martensites: Oguz Salman[1]; *Alphonse Finel*[2]; Lev Truskinovsky[1]; [1]CNRS - Ecole Polytechnique; [2]ONERA-CNRS

When driven slowly, many multiparticle systems with long range interactions evolve through a series of discrete events with power law statistics associated with self-organized criticality. Such dynamics has been experimentally observed through acoustic emission in several shape-memory alloys that undergo martensitic transitions characterized by a strain misfit between the parent and the product phases. We present both an overdamped phase field and a Lagrange-Rayleigh modeling of a prototypical martensitic transition, and show that dynamics exhibits intermittency. If the system is sufficiently underdamped, the discrete events (avalanches) self-organize into a critical state that displays scale invariance. Instead, the overdamped system does not show criticality. To explain the role of inertia, we analyze a simple 1D spring model with a double well potential.

9:10 AM
Continuum-Level Simulation of a Displacement Reaction System Based on Computational Thermodynamics and Kinetics: *Hui-Chia Yu*[1]; Chen Ling[1]; Jishnu Bhattacharya[1]; Anton Van der Ven[1]; Katsuyo Thornton[1]; [1]University of Michigan

Current research and development of Li-ion battery cathode materials have mainly focused on intercalation compounds. However, conversion reaction compounds, an alternative to intercalation compounds, has recently drawn increasing attention from researchers because of the potentially larger energy capacity. In this work we examine spinel Li-Cu0.5-TiS2, in which Cu is extruded during lithiation, as model system for conversion reaction. The thermodynamic free energy landscape and kinetic transport coefficients are determined by first principles and kinetic Monte Carlo calculations. The calculated phase diagram shows solid solution and two-phase regions exist in different areas of the composition space. We studied the kinetics and accompanying morphological evolution during charge and discharge in the electrode particles in the framework of Fick's diffusion and phase field model. Because of kinetic constraints, the composition evolution follows different paths during discharge and charge processes, which explains the hysteresis, this material system's interesting and important characteristic, during charge-discharge cycles.

9:25 AM
A Phase-Field Model for δ-Zirconium Hydride Formation in Single- and Polycrystalline Zirconium Alloys: *Tae Wook Heo*[1]; Kimberly Colas[1]; Arthur Motta[1]; Long-Qing Chen[1]; [1]The Pennsylvania State University

Zirconium alloys are extensively utilized as structural materials in nuclear energy industry for nuclear fuel cladding. The formation of hydrides during reactor operation degrades the mechanical behavior of the cladding. We propose a phase-field model for modeling microstructure evolution during δ-hydride formation in Zr alloys including both structural change and hydrogen diffusion. The stress-free transformation strains of multiple variants for hcp-Zr (α) to fcc-hydride (δ) transformation are derived based on the orientation relationship between α and δ phases. The interface between hydride and Zr matrix is assumed to have mixed coherency: basal planes are coherent and edges are incoherent. The elastic strain energy is calculated using Khachaturyan's microelasticity theory. We discuss the habit plane formation, the effects of grain orientations, and the influences of external loads on the morphological evolution of hydrides and compare the hydride morphologies to experimental observations performed on hydrided Zr, using in situ synchrotron radiation diffraction.

9:40 AM
Phase Field Modeling of Coherent Zirconium Hydrides Reorientation under Applied Load: *Lingfei Zhang*[1]; Ludovic Thuinet[1]; Alexandre Legris[1]; Andrée Debacker[1]; Antoine Ambard[2]; [1]UMET; [2]EDF R&D

Mechanical properties of hydrided Zircaloy claddings under external load lie in the center of nuclear reactor safety. Numerous experimental studies revealed hydride reorientation along the radial direction under hoop strength, but until now no sound physical explanations have been proposed. In this work we propose a model based on a micro-mechanical phase field approach under inhomogeneous elasticity assumptions to analyze the influence of an applied stress on the preferential orientation of hydrides either in the basal or prismatic planes. According to a previous experimental work, the fully coherent zêta hydride is considered in this analysis. Our work reveals that under uniaxial stress σ_a parallel to the basal plane, the zêta orientation variants misaligned with σ_a are promoted. Furthermore, beyond a critical stress, orientation outside the basal plane is observed, in agreement with the well known radial reorientation aforementioned.

9:55 AM
Continuum Dislocation Dynamics: Comparison between Models: *Woosong Choi*[1]; Yong Chen[1]; Stefanos Papanikolaou[1]; James Sethna[1]; [1]Cornell University

Many continuum theories of dislocation dynamics have been proposed to bridge the gap in between discrete microscopic simulations and macroscale phenomenology. As of yet, however, these theories had limited success in explaining or predicting the physics of microstructure formation and evolution. Recently, we have shown that a simple isotropic continuum model dynamically form walls and exhibit complicated microstructure formation and evolution similar to experiments. Most other continuum theories have not seen such structures emerging, and to what extent this theory explains the physics remains to be answered. We explore several variants of the current theories which have different microscopic physics as to how slip systems, cross-slip, statistically stored dislocations, explicit or effective short range interactions, etc. are treated. Comparisons among simulation results of these models will be presented, and we will discuss the relevant mechanisms and their consequences in the dynamics of microstructures.

10:10 AM Break

10:30 AM
An Accurate Scheme for Resolving Grain Boundaries in a Phase-Field Model of 3D Grain Coarsening: *David Wu*[1]; Zhidong Leong[1]; Dickson Thian[1]; Carl Krill III[2]; [1]Institute of High Performance Computing; [2]Ulm University

Due to the use of diffuse interface, phase-field model is attractive for simulating grain coarsening because it can easily handle complex morphological transitions by avoiding explicit treatment of boundary conditions at grain boundaries. However, the use of diffuse interface presents challenges for resolving grain boundary positions, which is necessary when comparing phase-field results to sharp interface theories such as von Neumann-Mullins law in 2D and MacPherson-Srolovitz law in 3D. In particular, MacPherson-Srolovitz law is formulated with grain volume, edge length, and mean width, the latter of which is extremely sensitive to grain boundary positions. We present an accurate scheme for resolving grain boundaries and calculating geometric properties of grains from phase-field simulation. Compared to known solutions for symmetric grains, we find that calculated geometric properties, including mean width, are accurate even for very small grains.

10:45 AM
Phase Field Approach to Stress-Induced Solid-Solid and Solid-Liquid Phase Transformations: *Valery Levitas*[1]; [1]Iowa State University

Recent advances in phase field theory and simulations of stress-induced phase transformations are presented, including: 1. Development of new thermodynamic potentials for multivariant martensitic phase transformations for small and large strains for 3D loading. 2. Introducing an athermal threshold in phase field modeling. 3. Developing thermodynamically consistent expression for interface tension, which is also consistent with the sharp interface limit. 4. Introducing a way to control martensite-martensite surface energy through coupling gradients of different order parameters. 5. Developing thermomechanical theory for surface-induced transformations. 6. Developing of a model for coherent solid-melt interface with non-spherical transformation strain. Finite element algorithm is developed and numerous problems for martensitic microstructure evolution and pre-melting and melting of nanoparticles are solved and compared to experiments. In particular, our model describes well experimental data on the width of the molten layer versus temperature for the Al plane surface and on melting temperature versus particle radius.

11:00 AM
Topological Effects in Coarsening of Grain-Boundary-Engineered Microstructures: *Ming Tang*[1]; Bryan Reed[1]; Vasily Bulatov[1]; James Belak[1]; Thomas Lagrange[1]; Joel Bernier[1]; Mukul Kumar[1]; [1]Lawrence Livermore National Laboratory

In FCC metals such as copper, grain boundary character distributions can be engineered by a technique known as grain boundary engineering. By increasing the special boundary (mainly low S boundaries) content in the network, this method is known to significantly reduce the grain growth rate at elevated temperatures, which makes grain-boundary-engineered materials attractive for potential applications under irradiation conditions. Here we applied phase-field simulations to studying the quantitative relation between grain-boundary-engineered microstructures and their coarsening kinetics. It was found that the special boundary population alone is not sufficient to determine the evolution of the grain boundary network. Microstructures with the same special boundary population but different topologies can exhibit different coarsening behavior, which is influenced by topological features such as triple junction and twin-related-domain size distributions. Such findings underline the importance of capturing the correct topology of grain-boundary-engineered networks in simulations to reliably predict their evolution.

11:15 AM
3D Phase Field Simulation of Phase Coarsening in Binary Two Phase System: *Vishal Yadav*[1]; Nele Moelans[1]; [1]Katholieke Universiteit Leuven

A new phase field model for studying phase coarsening in a binary two phase system is proposed. For this alternative model, the relation with physical input data is more straightforward and accurate. Furthermore, an efficient numerical method for large-scale 2D and 3D simulations of phase coarsening in a binary two phase system is implemented. We performed simulations for realistic systems such as Pb-Sn and Al-Si with a range of system properties. The effect of volume fraction, diffusivities, and the number of order parameters on the coarsening rate and particle size distribution is studied. The findings are compared with experimental studies on Pb-Sn and Al-Si. We also studied the growth behavior in 3D.

11:30 AM
A Phase Field Crystal Study of Rapid Solidification and Solute Trapping in Binary Alloys: *Harith Humadi*[1]; Jeff Hoyt[1]; Nikolas Provatas[1]; [1]McMaster University

In this study we have incorporated two time scales into the phase field crystal dynamics to explore different solute trapping properties with various interface pulling velocities. With only diffusive dynamics, we demonstrate that the segregation coefficient, k, vs velocity for a binary alloy is consistent with the model of Kaplan and Aziz where k approaches unity in the limit of infinite velocity. However, with the introduction of wave like dynamics in both density and concentration fields the trapping behavior reproduces the prediction of Galenko et al.. In addition, a Floquet linear stability analysis was performed to determine the appropriate time and length scale needed for the wave dynamics to act on the system with the desired physics.

11:45 AM
Enhancement of Field-Induced Strain Responses in Decomposed Two-Phase Nanodispersions: *Wei-Feng Rao*[1]; Armen Khachaturyan[1]; [1]Rutgers University

The magnitude and hysteresis of strain responses to externally applied fields are essential to advanced functional materials used in high-performance devices. We took into consideration the field-induced extrinsic reorientations of the domain states within the nanosized precipitates of the low-symmetry phase to increase the strain and reduce the associated hysteresis. The two-phase systems are formed at early stages of a precipitation of the low-symmetry phase from the supersaturated cubic solid solution. The macroscopic strain effect caused by this reorientation through small atomic displacements is a giant value determined by the crystallographic parameters of these phases, which can be regarded as giant quasi-elasticity if the reorientation is driven by a stress or super-magnetostriction if both phases are ferromagnetic and a magnetic field is applied. Using 3D and 2D modeling, we formulated conditions leading to a drastic amplification of hysteresis-reduced strain responses that may reach orders of magnitude.

Fully Ab Initio Determination of Free Energies: Where Do We Stand?: *Jörg Neugebauer*[1]; Fritz Körmann[1]; Alexey Dick[1]; Albert Glensk[1]; Blazej Grabowski[2]; Tilmann Hickel[1]; [1]Max-Planck-Institut für Eisenforschung GmbH; [2]Lawrence Livermore National Lab

The combination of accurate first principles calculations with mesoscopic/macroscopic thermodynamic and/or kinetic concepts has quickly advanced in the past few years and allows now to tackle even the complexity of advanced engineering materials. Key to these studies is the highly accurate determination of free energies. In the talk we will show how efficient sampling strategies together with high convergence density-functional theory calculations allow an unbiased and accurate determination of all relevant temperature dependent free energy contributions. While in the past the focus has been mainly on the quasiharmonic contributions (which are computationally most easily to obtain) new advances in methods and computational power provide now for the first time the opportunity to systematically include anharmonic and magnetic contributions. The flexibility and the predictive power of this approach will be discussed for examples relevant to the design and understanding of modern high strength steels.

8:55 AM
Ab-Initio Discovery of Crystal Structures and Phase Diagrams: *Richard Hennig*[1]; William Tipton[1]; Clive Bealing[1]; Kiran Mathew[1]; [1]Cornell University

Predictions of structure formation by computational methods have the potential to accelerate materials discovery and design. Here we present an approach based on evolutionary algorithms coupled to ab-initio relaxations that accurately predicts how atoms arrange into crystal structure and determines the ground state phase diagrams of materials without any prior information about the system. We applied the method to binary Li-Be and elemental Eu under pressure. For Li-Be we discover several stable phases under pressures and observe an unexpected quasi-1D and 2D electronic structure in some of these compounds [1]. For Eu we identify three phase transformations and identify the structure of the superconducting high pressure phase [2]. We currently study the phase behavior of several Li-based systems for battery applications to identify stable and metastable phases and determine the kinetics of Li diffusion in these systems.[1] Nature 451, 445 (2008)[2] Phys. Rev. B 83, 104106 (2011)

9:10 AM
Determinants of Thermal Stability in Nano-sized Binary Alloys: *C. C. Yang*[1]; Y.-W. Mai[1]; [1]The University of Sydney

An extension of the classic thermodynamic theory to nanometer scale has generated a new interdisciplinary theory - nanothermodynamics, which is an indispensable tool for the investigation of size-dependent physicochemical properties in nanocrystals. In this work, a new nanothermodynamic model was established to investigate the size-dependent thermal stability of nanosized binary alloys. It is found that the instability of binary alloys at the nanometer scale is caused by severe bond dangling associated with increased surface/volume ratio. The calculated results are consistent with experimental data and may provide new insights into the fundamental understanding of thermal stability in nanoalloys.

9:25 AM
Fully Ab Initio Determination of Anharmonic Contributions by Efficient Sampling Strategies: *Albert Glensk*[1]; Blazej Grabowski[2]; Tilmann Hickel[1]; Jörg Neugebauer[1]; [1]Max-Planck-Institut, Duesseldorf, Germany; [2]Lawrence Livermore National Laboratory

Using ab initio approaches, temperature dependent thermodynamic free energies are nowadays typically calculated within the quasiharmonic approximation. Numerically highly accurate ab initio calculations for Al including anharmonic contributions on the other hand showed a significant change in the heat capacity and a dramatic effect on the entropy of vacancy formation in Al compared to quasiharmonic results [1]. By developing and implementing highly efficient sampling methods, we are now able to routinely determine anharmonic contributions for metals. Using these methods we were able to systematically improve the ab initio based thermodynamic description of Al-Mg-Si-Cu alloys. Particularly, the influence of anharmonicities on the unary subsystems of these alloys, consequences for the phase diagrams and deviations from quasiharmonic results will be discussed.[1] B. Grabowski et al, PRB 79, 134106 (2009)

9:40 AM
High-Throughput Ab-Initio Calculations of Topologically Close-Packed Phases in Transition-Metal Alloys: *Thomas Hammerschmidt*[1]; Bernhard Seiser[2]; Ralf Drautz[1]; David Pettifor[2]; [1]ICAMS, Ruhr-University Bochum; [2]University of Oxford

Topologically close-packed (TCP) phases play an important role in modern alloys and steels. The formation of TCP phases is attributed to high local concentrations of refractory elements. We present high-throughput ab-initio calculations for a number of binary systems in order to investigate the factors that influence the structural stability of TCP phases in alloys. In particular, we determined the formation energies of the TCP phases A15, σ, χ, μ, C14, C15 and C36 in the binary systems Ta-V/Nb, Re-V/Cr/Nb/Mo, and Co-V/Cr/Nb/Mo. The observed trends in structural stability are captured and explained by simplified models of the electronic structure. We discuss in particular the role of the number of valence electrons, of the size mismatch between the atoms, of magnetism and of the configurational entropy for the stabilization of TCP phases.

Thermodynamics of Unstable Structures: *Vidvuds Ozolins*[1]; [1]UCLA

Materials scientists often need to know the free energy of a material in a structure that has not been measured experimentally and may even be unstable in the bulk form. This problem acquires great importance in the widely used CALPHAD approach to calculating phase diagrams of metallic alloys. Here, a long-standing discrepancy between the empirically derived and first-principles calculated lattice stabilities has been attributed to the existence of dynamical instabilities in many simple metallic structures (bcc, fcc, and hcp), which invalidate the usual definitions of entropy and free energy. We will review the stability criteria, analyze thermodynamic functions in the vicinity of an instability, and discuss the role of dynamical instabilities in phase diagram calculations. Proposals for treating the thermodynamics of unstable phases will be reviewed and recent attempts to find practical solutions to the problem of defining and calculating entropies of unstable phases will be discussed.

10:45 AM
Ab Initio Thermodynamics of the fcc-bcc Transition in Ca Including All Relevant FiniteTemperature Excitation Mechanisms: *Blazej Grabowski*[1]; Per Soderlind[1]; Tilmann Hickel[2]; Jorg Neugebauer[2]; [1]Lawrence Livermore National Laboratory; [2]Max-Planck-Institut fur Eisenforschung

Phase diagrams are the cornerstone of materials design. Traditional approaches to phase diagrams suffer from fundamental difficulties related to experimental input (e.g., unstable phases). The emerging field of ab initio supported phase diagrams is the unrivaled approach to a true advancement in the field. However, while well approved for the T=0K regime, finite temperature ab initio calculations are still facing enormous challenges Particularly ambitious is an accurate description of phase transitions often involving additional complications due to instabilities. In this talk, we present methods to accurately and efficiently deal with these issues. In particular, we focus on the fcc-bcc transition in Ca with bcc being unstable at T=0K. We show the correct treatment of the instability to be crucial for the transition and the limits of standard ab initio approximations (xc-functionals).

11:00 AM
Thermodynamic Modeling of Peirce-Smith Converter Slag at the Chagres Smelter, Chile: N Cardona[1]; P.J. Mackey[2]; P. Coursol[3]; R. Parada[4]; R. Parra[5]; [1]Kingston Process Metallurgy; [2]P.J.Mackey Technology Inc.; [3]Coursol Consultants; [4]Chagres Smelter; [5]University of Concepción

Flash furnace matte at the Chagres smelter in Chile is converted to blister copper in Peirce-Smith converters. The produced slag from each of the two slag blows is transferred to the slag cleaning furnaces (along with flash furnace slag) for cleaning prior to discharge, while the high copper slag from the copper blow is recirculated back to the converter process. The performance of the slag cleaning furnace is dependent in part on the quality of the converter slag. In order to understand the impact of converter slag quality on slag cleaning and to help optimize the slag cleaning operation, thermodynamic modeling of the converter slag, supported by microscopic examination of smelter slag samples, was carried out to characterize the Peirce-Smith converter slag. The results of the investigation are described in this paper.

11:15 AM
Micron-Scale Measurements of Heat Capacity by Time-Domain Thermoreflectance: Xuan Zheng[1]; *Changdong Wei*[2]; David Cahill[3]; Ji-Cheng Zhao[2]; [1]Seagate Technology; [2]The Ohio State University; [3]University of Illinois – Urbana-Champaign

A pump-probe optical technique based on time-domain thermoreflectance is developed for localized measurement of specific heat capacity with a spatial resolution on the order of several microns. Benchmark validation of this method is made on several common materials by a careful comparison between the measured values and the well-accepted literature values. The usefulness of this technique in rapid establishment of composition-phase-property relationships is demonstrated on several diffusion-multiple samples where large amount of solid solution compositions and intermetallic compounds are generated by interdiffusion between the elements. The method together with diffusion multiples provides an efficient way to generate much-needed thermodynamic data for CALPHAD modeling and database construction.

11:30 AM
Quantum Monte Carlo and Statistical Sampling Approach to Reference States for Thermodynamic and Kinetic Models : *D. M. Nicholson*[1]; Randolph Hood[2]; P. R. C. Kent[1]; Fernando Reboredo[1]; Markus Eisenbach[1]; [1]Oak Ridge National Laboratory; [2]Lawrence Livermore National Laboratory

The free energy and diffusivity of reference states form the underpinning of current thermodynamic and kinetic models. As a function of temperature, T, these states may or may not be observable. A uniformly applied ab initio approach holds the greatest potential for a consistent reference state description. We demonstrate the feasibility of using Quantum Monte Carlo for reference state energies at T=0 by presenting energies for: bulk Al as a function of pressure, defects in Al (including transition state energies), and He interstitial formation and binding energies in Al. We further demonstrate the use of Wang-Landau statistical sampling of density functional energies (local approximation) to evaluate magnetic entropy as a function of T in Fe and Fe3C. Work supported by the CDP, Energy Frontier Research Center of U.S. Department of Energy (DOE), Office of Science, ERKCS99 by the Division of Materials Science (DOE), and Division of Scientific User Facilities (DOE).

11:45 AM
Ab Initio Temperature-Dependent Lattice Dynamics for BCC Uranium: *Per Soderlind*[1]; Blazej Grabowski[1]; Lin Yang[1]; Alexander Landa[1]; [1]Lawrence Livermore National Laboratory

The body-centered cubic phase of uranium (or any actinide metal) is stabilized at higher temperatures while first-principle density-functional methods predict it to be unstable at lower or zero temperature. This is a problem when devising models particularly when experimental data are sparse or lacking. Many thermodynamical approaches are available but a recent proposal is a very efficient approach based on a self-consistent procedure to calculate temperature-dependent lattice dynamics from first-principles theory. In this presentation we combine highly accurate all-electron DFT calculations with the self consistent ab initio lattice dynamics (SCAILD) methodology to calculate thermodynamic properties of bcc uranium. This is work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

Defects and Properties of Cast Metals: Hot Tearing

Quantitative Characterization of Damage Evolution during the Solidification of Al Alloys Using Fast Synchrotron Tomography: *Peter D. Lee*[1]; Chedtha Puncreobutr[2]; Thomas Connolley[3]; Richard W. Hamilton[2]; [1]The University of Manchester; [2]Imperial College London; [3]Diamond Light Source Ltd,

Synchrotron sources are now being used relatively routinely to observe the in situ formation of damage in semi-solid metals. Using a number of defects as examples (e.g. porosity and hot tears), methods of quantifying these three-dimensional, time dependent images are discussed. The quantification of the time dependent changes in the morphology of defect structures allows both the relative kinetics, and dominant processes to be determined. Examples are applied to both monolithic and particulate reinforced alloys, illustrating how fast synchrotron tomography can be used to gain significant new insights into the mechanisms controlling defect formation during solidification.

8:55 AM
The Importance of Solidification Structure with Respect to Hot Tearing during Continuous Casting of Steels: *Robert Pierer*[1]; Wolfgang Rauter[2]; Christian Bernhard[1]; [1]Chair of Metallurgy, Montanuniversitaet Leoben; [2]voestalpine Stahl Donawitz GmbH & Co KG

During the solidification of steels, events such as micro/macro segregation as well as the generation of defects and porosity strongly depends on the solidification grain structure. Until now, the relevant literature generally has dealt with the primary or the secondary dendrite arm spacing to characterize the solidification structure. However, these phenomena and particularly the phenomenon of hot tearing during continuous casting of steels occur mainly between primary grains along primary grain boundaries. In this regard, it is very important to note that the primary grain size increases with increasing distance from the surface of the product. Based on theoretical considerations and investigations into the solidification structure of a continuously cast round bloom in combination with the appearance of hot tears, the present study responds to the following questions: How does the primary grain size and subsequently the number of primary grain boundaries, respectively influence the phenomenon of hot tearing and how does the morphology of the solidification structure (i.e. zone of columnar vs. equiaxed grains) influence the extent of open hot tears and hot tear segregations?

9:20 AM
Hot Tearing Susceptibility in DC-Cast Aluminum Alloys: *Nasim Jamaly*[1]; Andre Phillion[1]; Steven Cockcroft[1]; Jean-Marie Drezet[2]; [1]University of British Columbia; [2]Ecole Polytechnique Federale de Lausanne

Hot tearing and loss of dimensional stability are two key defects related to industrial aluminum alloy casting processes. In order to investigate their occurrence, a new semi-solid constitutive law [1] for AA5182 that takes into account cooling rate, grain size and porosity has been implemented into a Direct Chill casting process model for both round billets and rectangular ingots. The semi-solid stress-strain predictions and the extent of strain accumulation at high fraction solid resulting from different casting geometries as well as different processing parameters was then used to demonstrate the relationships between defect formation, microstructure, and processing variables. [A.B. Phillion, S.L. Cockcroft, and P.D. Lee, Model Simul in Mater Sci Eng, Vol.17:055011, 2009].

10:10 AM
Solidification Phenomena during Casting of Stainless Steel/Cast Iron Composites: *Tim Lucey*[1]; Mark Reid[2]; Michael Cortie[1]; Paul Huggett[3]; Ken Moran[4]; Wing Yeung[1]; Richard Wuhrer[1]; [1]University of Technology, Sydney; [2]University of Wollongong; [3]Materials Solutions Pty. Ltd.; [4]Moran Scientific Pty. Ltd

Vacuum casting has been employed in the past to join dissimilar materials such as mild steel and white cast iron however; the requirement for vacuum conditions makes the process restrictive. The interfacial phenomena occurring when a white iron of low melting point is cast onto a steel substrate in an air atmosphere is considered in this study. It has been found that an interfacial layer of austenite is epitaxially solidified on the steel substrate from the liquid phase, which increases in thickness with soak time. In-situ confocal scanning laser microscopy has been employed to study the solidification of this austenitic rim. Carbon diffuses through this layer into the steel substrate through grain boundaries that lie perpendicular to the steel and act as conduits for accelerated atomic transfer into the substrate and allows for the continued solidification of this austenite rim due to the localised increase in liquidus of the alloy.

10:35 AM
Hot Tear Susceptibility of Al-Mg-Si Alloys with Varying Iron Contents: Lisa Sweet[1]; *Mark Easton*[1]; John Taylor[1]; Cameron Davidson[1]; Liming Lu[1]; Malcolm Couper[2]; David StJohn[3]; [1]CAST crc; [2]ARC CoE of Design in Light Metals; [3]School of Engineering, The University of Queensland

Hot tear susceptibility in a cast 0.53Si-0.33Mg-xFe 6060 aluminum alloy was investigated using the CAST Hot Tear rig, designed to simulate hot tearing in DC casting. The rig has two cast bars, one that is used to measure the load response and one which is fixed at both ends to restrain thermal contraction so that hot tearing could be observed if it occurred. The iron (Fe) content, ranging from 0.02-0.5wt pct, was seen to have a major influence on the load response during solidification and the crack rating of these alloys. The findings are discussed in terms of the coherency-coalescence model and are related to the influence of Fe content on the morphology, prevalence and precipitation sequence of the ß-Al5FeSi and \945-AlFeSi Fe-containing intermetallic phases. Observations made of hot tear fracture surfaces show that these phases may play distinctively different roles within the mechanism of hot tearing in these alloys.

11:00 AM
Rules to Prevent and Mitigate Hot Tearing in Al Based Casting Alloys: *Shimin Li*[1]; Kumar Sadayappan[2]; Diran Apelian[3]; [1]Worceter Polytechnic Institute; [2]CANMET- Materials Technology Laboratory; [3]Worcester Polytechnic Institute

Hot tearing is a common and severe defect encountered in alloy castings. Once it occurs, the casting has to be repaired or scrapped, resulting in significant loss. During the last four years, we have worked to quantitatively measure hot tearing in Al cast alloys. We have developed the equipment with our colleagues at CANMET, have studied the key processing variables and we have developed a basic mechanistic understanding. With this knowledge base we are in a position to present a “rule based controls approach” to mitigate or alleviate hot tearing. The rules to prevent and alleviate hot tearing will be reviewed and discussed.

11:25 AM
The Analytical Model of Microsegregation for Solute Elements in Solidifying Mushy Zone of Steel: *Chao Xiao*[1]; Jiongming Zhang[1]; Yanzhao Luo[1]; [1]University of Science and Technology Beijing

The microsegregation resulting in internal cracks in continuously cast strand is studied by using a analytical model in which the transition of ferrite(δ)/austenite(γ) solidification is considered. The effects of C, Si, Mn, P and S on the interdendritic segregation, zero strength temperature(ZST) and zero ductility temperature(ZDT) are discussed. The results show that C content in steel influences the interdendritic segregation, solidus temperature and solidification front temperature significantly. The segregation of P and S increases greatly when the C content increased from 0.1% to 0.5%while that of the other elements are not obviously changed. The changes of C content have a great impact on ZST and ZDT, while the fluctuations of P and S contents only affect ZDT greatly.

Deformation, Damage, and Fracture of Light Metals and Alloys: Session II

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Light Metals Division, TMS/ ASM: Mechanical Behavior of Materials Committee
Program Organizers: Qizhen Li, University of Nevada, Reno; Fuqian Yang, Univ. of Kentucky; Ke An, Oak Ridge National Laboratory

Tuesday AM — Room: Northern A2

Corrosion Damage of Deformed AZ31 Mg Alloy: *Guang-Ling Song*[1]; [1]GM Global Research &Development

Hot-rolled AZ31 sheet, a severely deformed Mg alloy, has great potential applications in the automobile industry. Its significantly refined grains resulting from hot-rolling is believed to be beneficial to the enhancement of its overall corrosion resistance. The alloy has crystallographically orientated grains. Its (0001) crystallographic plane dominated rolling surface is more corrosion resistant than its cross-section surface which is mainly composed of crystallographic planes $(10\bar{1}0)$ and $(11\bar{2}0)$. The microstructures of these two surfaces evolve during heat-treatment, leading to its deteriorated corrosion performance. Surface plastic deformation machining can further improve its corrosion performance due to a combined effect of grain refinement and strong basal texture.

9:00 AM Invited
Relationship of Corrosion Fatigue and Stress Corrosion Cracking Thresholds to Degree of Sensitization in Al-Mg Alloy: *Peter Pao*[1]; Ronald Holtz[1]; Thomas Longazel[1]; Robert Bayles[1]; Ramasis Goswami[2]; [1]Naval Research Laboratory; [2]SAIC

Systematic experimental studies of the corrosion-fatigue threshold, ΔK_{TH}, and stress-corrosion cracking threshold, K_{1SCC}, of Al 5083-H131 heat treated to various degrees of sensitization at temperatures of 70, 100 and 175°C are reported. ΔK_{TH} does not degrade until the ASTM G67 nitric acid mass loss (NAML) exceeds approximately 30 mg/cm^2. The K_{1SCC}, however, degrades continuously with increasing NAML and has dropped by a factor of five when the NAML is 30 mg/cm^2. The degradations of ΔK_{TH} and K_{1SCC} are associated with the growth of a semi-continuous type of grain boundary coverage by ß -Al_3Mg_2. Once the grain boundary is fully covered with ß - Al_3Mg_2, typically in the NAML range of 40 to 50 mg/cm^2, both ΔK_{TH} and K_{1SCC} have already degraded substantially. The aging behaviors of ΔK_{TH} and K_{1SCC} versus NAML are the same, regardless of aging temperature, indicating that only continuity of ß is the dominant effect.

9:30 AM
Fatigue and Corrosion Properties of Mg-Al-Mn Alloy by Super Vacuum Die Cast: *Wei Wen*[1]; Alan A. Luo[2]; Tongguang Zhai[1]; [1]University of Kentucky; [2]General Motors Corporation

AM60(Mg-Al-Mn) alloys fabricated by super vacuum die cast (SVDC) and high pressure die cast (HPDC) were fatigued in four-point bend at room temperature and different humidity. It was found that SVDC alloy had higher fatigue strength than HPDC alloy. Crack initiation was predominantly associated with pore clusters in the surface of SVDC alloy, and with the interfaces between eutectic-phase and the matrix in HPDC alloy. The surface layer that was formed with a low pore density and smaller pores in SVDC alloy accounted for its improved fatigue strength over that of HPDC alloy. Its effects on fatigue properties and corrosion resistance were investigated by comparative experiments using the as-cast sample and the sample with the surface layer being removed. The polarization curves of SVDC sample and HPDC sample were measured in corrosion test to study the effect of SVDC method on corrosion resistance of Mg-alloy.

9:50 AM
Effect of Corrosion on the Strength of Fillet Arc Welded Cu-Lean AA7xxx Joints: *J. Dabrowski*[1]; Dr. M. Bruhis[1]; Dr. J.R. Kish[1]; [1]Cenrtre for Automotive Materials & Corrosion, McMaster University, Hamilton, ON Canada

Heat-treatable AA6xxx (Al-Mg-Si) and AA7xxx (Al-Zn-Mg) Al alloys, with relatively high strength, toughness, energy absorption, weldability and formability, make it possible to design safe, cost-competitive automotive bumper systems to crush in a controlled fashion. One major technical issue preventing widespread utilization of higher strength AA7xxx extruded beam profiles, in the peak-aged T6 condition, is the susceptibility to intergranular corrosion modes, including exfoliation and stress corrosion cracking. These corrosion modes are of particular concern for arc welded (GMAW) lap joints and fillet T joints, which is a common joining technology used to attach extruded heat-treatable Al alloys. A study was undertaken to document the effect of corrosion on the strength and fracture mode of the arc welded joints. The fracture stress and mode was experimentally determined using tensile shear loading experiments. An ARAMIS strain-mapping system based on digital image correlation (DIC) using a CCD camera was used for strain measurement.

10:10 AM Break

10:20 AM
Micro-Shear Stress and Damage Predictions from Hydrostatic Stress Loading of Aluminum Alloys 7075, 7039, and 7020: *John Chinella*[1]; [1]U.S. Army Research Laboratory

Thermodynamics dependent microstructure, phase, and physical model predictions of material characteristics are demonstrated for aluminum alloys 7020 (Al-4.5Zn-1.2Mg), 7039 (Al-4.0Zn-2.8Mg), and 7075 (Al-5.6Zn-2.5Mg-1.6Cu) by direct application of Sente Software's Java Materials Program (JMatPro), mesoscale computation materials engineering software. JMatPro reveals phase constitutions as a function of input composition, temperature, and time and, using material property databases and physical models, calculates temperature-dependent physical and mechanical properties. With secondary application, the elastic bulk moduli for constituent phases and inclusions, derived from Gibbs energy by JMatPro, are used to predict the maximum levels of micro-scale shear stresses under hydrostatic pressure. With comparison to conditions known to cause incipient spall in 7020 alloy, levels of microscale shear stress around inclusions are shown to equal or exceed the level of Von Mises calculated shear yield strength of the alloys, validating that deformation occurs during high-load ballistic spall events, at the initial stages of compression.

10:40 AM

Coupling Experimentation and Computation to Investigate Damage Evolution in High Purity Aluminum: *Matthew Tucker*[1]; John Bingert[1]; Brian Patterson[1]; Cheng Liu[1]; Ricardo Lebensohn[1]; [1]Los Alamos National Lab

Understanding and capturing the intricacies involved in the damage evolution and eventual failure of a component requires a coupling of carefully designed experiments and simulations. In this work, a sample with known initial damage and crystal orientation states is subjected to interrupted tensile testing, while the evolving damage state is characterized ex situ. Micro x-ray computed tomography (XCMT) is employed to follow embedded internal tracer particles allowing for the quantification of localized internal strains. The initial damage state is provided by casting porosity, while the size and shape of each pore is measured at global strain intervals. Particles are embedded to serve as tracers for localized internal strains. Localized surface strains are also measured using more traditional digital image correlation (DIC) techniques. Comparing the surface and internal strains shows the result of the evolving damage state and crystal orientations and helps to elucidate the contribution of local strains from each.

11:00 AM

The Effect of Chemistry and Microstructure on the Deformation and Fracture Behavior of (Ti, Zr)Ni-Based Alloys with Aluminum Additions: *Derek Hsen Dai Hsu*[1]; B. Chad Hornbuckle[2]; Gregory Thompson[2]; Michele Manuel[1]; [1]University of Florida; [2]The University of Alabama

(Ti, Zr)Ni alloys possess the potential for use in a wide range of industries. Applications can include but are not limited to high-temperature shape memory actuators and bulk metallic glasses. The present work reports the mechanical characterization of $Ti_{31.5-x}Zr_{20}Ni_{48.5}Al_x$ (X = 0, 1, 2, 3) alloys. The addition of aluminum to this system changes the microstructure, which subsequently alters the deformation and fracture behavior of these alloys. To determine the relationships connecting microstructure with deformation behavior, advanced characterization techniques including optical microscopy, scanning and transmission electron microscopy, and atom probe tomography are used to examine this quaternary system. This evaluation includes precipitate morphology as a function of chemistry and heat-treatment, and deformation mechanisms such as dislocation, twinning and martensite evolution as a function of strain. The authors would like to acknowledge the support of the NSF under grant number CMMI-0824352 and NASA grant NNX09AO61A from the NASA FAP Supersonics project.

11:20 AM

Investigation of Frequency Effect on Fretting Wear Damage of Titanium Alloy: Qualitative and Quantitative Approaches: *Benjamin van Peteghem*[1]; Siegfried Fouvry[1]; Patricia De Oliveira Campos Neubauer[1]; [1]Laboratoire de Tribologie et Dynamique des Systèmes

In the dovetail blade-disk contact of turbojet engines, the loading cycle is very complex: during startup and shutdown, the normal force and the displacement vary simultaneously. And, during flight, the contact is submitted to small vibrations. In this study, we focused on the largest displacements (i.e. during startup and shutdown), which vary simultaneously with the normal force. In a former study, it has been shown that frequency drives the energy wear rate, and normal force variation drives tribochemical reactions. This new study investigates these two points to define an extended wear law and to formalize the tribochemical behavior of this contact. Frequencies between 0.025 Hz and 5 Hz have been studied, in constant and variable normal force conditions. Two different behaviors were observed, depending on the frequency and the loading. Those behaviors confirm the hypothesis of a major role of oxidation in the wear process induced by fretting.

11:40 AM

Primary Creep in Titanium Alloys: Role of Trace Elements: *Srikant Gollapudi*[1]; Tapash Nandy[1]; Satyanarayana D[1]; Phaniraj C[2]; [1]Defence Metallurgical Research Laboratory; [2]IGCAR

The influence of trace elements viz. Fe and Ni on the primary creep behaviour of Ti-834 alloy was studied. Two Ti-834 alloys, DMR Ti834 and TIMETAL 834 with higher and lower content of (Fe, Ni) respectively were chosen for this study. The creep behaviour of both alloys was studied in the temperature range of 873 – 1023 K at a stress range of 50 - 400 MPa. Subsequent analysis showed that under similar stress and temperature conditions, DMR Ti834 yields a smaller primary creep strain in comparison to TIMETAL 834. The creep activation energy (Q) in the primary creep region was also determined and again found to be smaller in DMR Ti834 (Q = 284 kJ/mol) in comparison to TIMETAL 834 (Q = 399 kJ/mol). The difference in primary creep strain and Q values was rationalized vis-a-vis the Fe, Ni content.

Electrode Technology for Aluminium Production: Bake Oven Design and Improvement

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee
Program Organizer: Morten Sorlie, Alcoa Norway

Tuesday AM — Room: Americas Seminar
March 13, 2012 — Location: Dolphin Resort

Session Chair: André Proulx, Rio Tinto Alcan

8:30 AM

Anode Quality and Bake Furnace Performance of EMAL: Raja Akhtar[1]; *Markus Meier*[2]; Peter Sulger[2]; Werner Fischer[2]; Ralph Friedrich[3]; Thomas Janousch[3]; [1]Emirates Aluminium EMAL; [2]R&D Carbon Ltd.; [3]Riedhammer GmbH

As part of the worldwide biggest greenfield project, the two open top anode bake furnaces of EMAL were started up in 2010 to reach an annual production capacity of 450’000 tons of baked anodes. Two furnaces are installed with 64 sections each having 9 flues and 8 pits that are equipped with 4 fires each. An unprecedented combination of outstanding anode quality and furnace performance figures could be achieved. This document highlights the distribution of key anode properties, furnace productivity and energy consumption. Furnace design and operational challenges to reach today’s standards are discussed.

8:55 AM

Experiences in FTC Design, Operation and Development: *Erik Dupon*[1]; Peter Klut[2]; Edo Engel[1]; [1]Danieli Corus Technical Services; [2]Danieli Corus BV

Over the past decades, emission control has consistently been a major issue for the developed, aluminium consuming world. Environmental facilities like Fume Treatment Centres have been retrofitted to paste plants and carbon bake furnaces throughout the world. The emerged countries have seen a great increase in aluminium consumption and for all greenfield smelters, the addition of FTC’s has been mandatory. Danieli Corus’s experience in FTC’s extends from retrofit projects in e.g. the EU and Australia up to LSTK projects in developing countries such as India. This article describes how existing FTC’s have performed over the past decades in terms of environmental performance and maintenance requirement. For recent projects, specific circumstances of execution in greenfield situations are discussed. In addition, developments in FTC technology and future prospects are presented.

9:20 AM
Boost of Anode Production at Voerdal Aluminium by Advanced and Integrated Control Strategies: Michael Schneider[1]; Christian Krupp[1]; *Detlef Maiwald*[2]; Domenico Di Lisa[2]; [1]Voerde Aluminium GmbH; [2]Innovatherm

Voerde Aluminium GmbH (Voerdal) is operating since more than 40 years a 36 section Kaiser type furnace for the production of anodes. Due to the continuous amperage incease in the potline, the baking furnace capacity had to be increased by 10% in the given boundary conditions of the furnace size and government permission of the maximum flow gas volumes and emissions.Voerdal and the system designer jointly developed new control strategies to ensure the boost of anode production. This was mainly achieved by implementation of new control modules which integrate the FTC feedback values into the overall control strategy. This paper explains the functional principles of these control strategies and describes the phases of implementation. Finally it outlines the actual results achieved.

9:45 AM
New Central Control System Architecture for Anode Baking Furnaces: *Nicolas Fiot*[1]; Xavier Genin[1]; Fabienne Virieux[2]; [1]Solios Carbone; [2]Fives Solios

Conventional anode baking firing and control systems are composed of several mobile pieces of equipment with their own local controller to manage the high speed local tasks. Redundant central control units synchronize the actions of each local controller. A fast real time Ethernet network implementation allows simplifying the existing control system architecture: it uses only one real time central controller and remote Inputs/Outputs for each mobile piece of equipment. The robustness and reactivity of the control as well as the required safety loops are preserved. The maintenance and day to day operation are simplified. Furthermore, real time network and accurate time synchronisation between the pieces of equipment open new perspectives to improve the baking process management and to enhance safety.

10:25 AM
Methods to Improve Fuel Utilization for Open Top Anode Baking Furnaces: Rifu Lin[1]; Shoulei Gao[1]; Lin Tang[1]; Yan Li[1]; [1]Sunstone

As a baking furnace ages, cracks and openings develop in the furnace which allow outside air to enter. Unless proper corrective actions are implemented, gas consumption can increase, final baking temperatures can decrease, and baked anode properties can deteriorate. In this paper, methods are presented for improving the efficiency of fuel utilization for aging furnaces, and thereby lowering fuel consumption, while maintaining or improving anode finishing temperatures and anode properties.

10:50 AM
Energy Saving Technologies for Anode Manufacturing: *Jingli Zhao*[1]; Qingcai Zhao[1]; [1]Jinan Aohai Carbon Products Corporation Ltd.

The energy saving technologies for anode manufacturing are developed and applied in the anode production processes in Jinan Aohai Carbon Products Corporation Ltd. The surplus heat from shaft calciners is recovered for heating coal tar pitch and power generation. The baking furnace structure and the lining materials have been improved so as to get reasonable anode occupation efficiency and less heat loss. The heating curves for anode baking are finely adjusted and controlled for completely burning of the volatiles in the green anodes for less energy input into the baking furnace. Based on the technology application mentioned above a great energy saving and benefit to the plant environment have been achieved in Aohai anode plants.

Electrometallurgy 2012: Session II

Sponsored by: The Minerals, Metals and Materials Society, The Metallurgy and Materials Society of CIM, TMS Extraction and Processing Division, TMS: Hydrometallurgy and Electrometallurgy Committee

Program Organizers: Georges Houlachi, Hydro-Quebec; Antoine Allanore, Massachusetts Institute of Technology; Michael Free, University of Utah; Michael Moats, University of Utah; Edouard Asselin, UBC; Shijie Wang, Rio Tinto Kennecott Utah Copper; James Yurko, Materion Brush Beryllium and Composites

Tuesday AM Room: Europe 5
March 13, 2012 Location: Dolphin Resort

Session Chairs: Georges Houlachi, Hydro-Quebec; Jim Yurko, Materion Brush Beryllium and Composites

8:30 AM
Molten Carbonates in the Energy Field, as Electrolytes, Composite Materials, Fuel Carriers or Reaction Media: *Michel Cassir*[1]; [1]Chimie ParisTech

The unique properties of molten carbonates offer an open scope of applications in the field of energy. These molten salts are in the center of chemical and electrochemical reactions involving carbon and carbonaceous species, carbon dioxide and carbon monoxide, significant for energy generation. Moreover, such media have also an oxidative character; they can dissolve molecular oxygen and oxygen reduced species which may have an important role in waste treatments and homogeneous catalysis. An overview will be given on the principal physicochemical properties of molten carbonates, before focusing on their main known application, the molten carbonate fuel cell (MCFC). Progress in other new fuel cells applications will also be analyzed, such as direct carbon fuel cell (DCFC), hybrid carbon fuel cell (HDCFC) and composite high-temperature fuel cells combining the features of MCFC and solid oxide fuel cell (SOFC). Afterwards, membranes for the separation and capture of CO2 will be reviewed.

8:50 AM
The Equilibrium between Titanium Ions and Metal Titanium in Fluoride-Chloride: *Qiuyu Wang*[1]; Hongmin Zhu[1]; [1]University of Science and Technology Beijing

The equilibrium between titanium ions and metal titanium was investigated in fluoride-chloride molten salt. The electrochemical properties of titanium ions in fluoride-chloride were studied on a molybdenum electrode by cyclic voltammetry (CV) and square wave voltammetry (SWV). The equilibrium constant of the equilibrium between titanium ions and metal Ti was calculated in KCl-NaCl- 2.5wt %K2TiF6 at the temperature of 1073K.

9:10 AM
Surface Area Effects at Liquid-Liquid Interfaces Consisting of a Liquid Metal and an Electrolyte: *Paul Burke*[1]; Brice Chung[1]; Brian Oldfield[1]; Donald Sadoway[1]; [1]MIT

Electrochemical measurements are referenced on the basis of the surface area of the interface between the electrodes and the electrolyte. This area is typically assumed as the apparent geometric area. In the case of liquid electrodes and electrolyte, a perturbation of this interface by vibration or convection can alter the effective surface area. This change in surface area can make the interpretation of electrochemical measurements difficult in systems with liquid electrodes. The current work attempts to quantify this effect by inducing waves at the interface in an electrochemical cell containing liquid electrodes.

9:30 AM
Electrochemical Behavior of Calcium-Bismuth Alloys in Molten Salt Electrolytes: *Hojong Kim*[1]; Dane Boysen[1]; Donald Sadoway[1]; [1]MIT

The electrochemical properties of calcium-bismuth alloys were investigated to determine their utility as electrodes in liquid metal batteries. During battery discharge, calcium from the negative electrode is oxidized to form a cation, which is conducted through the molten salt electrolyte to the positive electrode, where it is electrochemically reduced and alloys with molten bismuth metal. Upon charging, calcium from the molten calcium-bismuth alloy positive electrode is oxidized to form a cation, which returns back to the negative electrode through the molten salt electrolyte where it is electrochemically reduced. The cell potential of Ca||Ca-Bi cells was measured as a function of state of charge and temperature over the range of composition spanning 0 < mole fraction, xCa < 0.25). The electrolyte was a solution of molten CaCl2-NaCl-LiCl-BaCl2. The temperature range was 500°C – 700°C. The composition of the working electrode (Ca-Bi alloys) was varied by coulometric titration.

9:50 AM
Low Temperature Extraction Process for Metals from Metal Oxides Using Ionic Liquids: *Vibha Gill*[1]; Ramana Reddy[1]; [1]The University of Alabama

A fundamental study on development of a low temperature electrochemical technology for extraction of metals from metal oxides using ionic liquids was undertaken. In this presentation electrochemical extraction of Zn from ZnO dissolved in eutectic solvents Urea ((NH2)2CO) and Choline chloride (HOC2H4N(CH3)3+Cl-) in a 2:1 ratio at 80°C is discussed. FTIR studies of ionic liquids with and without ZnO addition were conducted. Reduction potential of Zn metal in these solvents were determined using CV. Electrochemical experiments using EG&G three electrode cell system with Al as cathode, carbon electrode as anode and Pt as a reference electrode. The deposits were characterized using XRD and SEM-EDS. The results showed that pure Zn was deposited on the Al cathode. The current density of 180A/m2 with an efficiency of 87.6% was obtained. The process is a low energy consumption and environmental friendly with no GHG emission.

10:10 AM Break

10:25 AM
Towards Sustainable Metals Production by Molten Oxide Electrolysis: *Donald Sadoway*[1]; [1]MIT

Molten oxide electrolysis (MOE), the electrolytic decomposition of a metal oxide into molten metal and oxygen gas, is a low-carbon route for metals extraction. MOE avoids consumable carbon anodes and halide electrolytes; this eliminates the need for energy-intensive anode manufacture and guarantees the absence of greenhouse-gas emissions as the by-product of the metal-recovery step. In the author's laboratory a variety of metals have been produced by MOE including iron, nickel, chromium, manganese, silicon, and titanium, each by electrolytic decomposition of the related metal oxide. Promising results for a low-cost, oxygen-evolving anode have been obtained. Beyond sustainable metals production, MOE can serve as the inspiration for scalable electrical energy storage in stationary applications. Liquid-metal/molten-salt cells have been shown to operate as rechargeable batteries that have the potential to handle colossal currents thereby enabling us to store off-peak power from the grid for subsequent delivery on demand during high-usage periods.

10:45 AM
Effect of Electronic Current on the Solid Oxide Membrane (Som) Process for Magnesium Production: *Eric Gratz*[1]; Soobhankar Pati[2]; Jarrod Milshtein[1]; Adam Powell[2]; Uday Pal[1]; [1]Boston University; [2]Metal Oxygen Separation Technologies

The solid oxide membrane (SOM) process has been used at 1150 °C to produce magnesium by direct electrolysis of its oxide. Magnesium oxide is dissolved in a molten CaF2-MgF2 ionic flux. An oxygen-ion-conducting yttria-stabilized zirconia (YSZ) SOM membrane separates the cathode and the flux from the anode. During electrolysis, magnesium ions are reduced at the cathode and Mg(g) bubbles out of the flux into a separate condenser. The flux has a small solubility for magnesium which imparts electronic conductivity to the flux. The electronic conductivity decreases current efficiency of the process and also degrades the YSZ membrane. This study investigates different methods for reducing the electronic conductivity of the flux due to magnesium solubility. One effective method shown here is inert gas flushing near the magnesium nucleation site. Potentiodynamic and potentiostatic experiments along with AC impedance spectroscopy are used to characterize the effectiveness of the approach.

11:05 AM
Behavior of Silicon Electrodepositing in Fluoride Molten Salts: *Xin Wang*[1]; Shuqiang Jiao[1]; Hongmin Zhu[1]; [1]University of Science and Technology Beijing

The behavior of silicon deposition electrochemically in a molten high-melting-point fluoride electrolyte was studied at temperatures above the melting point of silicon 1412°C. The corresponding structures and morphologies of the product of deposition were characterized by XRD and SEM. A series of tests has been performed on the electrochemical deposition behavior of Si4+ ions in BaF2-CaF2-Na2SiF6 molten salt. The influence of electrochemical parameters of cathode deposition of silicon was also investigated. The results showed that silicon could deposit on the top of fluoride molten salts. The electrochemical deposition of Si4+ ions in the molten salts was observed to proceed through two reaction steps.

11:25 AM
VITTORIO DE NORA PRIZE: Development of Electrometallurgical Processes for 21st Century Metal Extraction: *Antoine Allanore*[1]; James Yurko[1]; [1]Massachusetts Institute of Technology

The late 19th century development of electrometallurgy enabled the discovery of revolutionary metal processing methods, which are at the core of our technology-oriented societies (electrolytic extraction in molten salts for light and rare-earth metals and aqueous electrowinning for copper, zinc, nickel, etc...), or which proved to be necessary to improve metal sustainability (electric arc furnace for recycling). The 21st century challenges related to metal extraction, particularly environmental ones, have led to a reconsideration of electrochemical extraction processes. This presentation will first briefly present some existing extraction methods, in particular electrometallurgical ones, pointing-out the advantages and issues related to the current state-of-the art. The second part of the talk will present how breakthrough electrochemical processes have recently been developed to adapt to environmental and energy constraints, taking the example of low- and high-temperature electrochemical extraction processes scaled-up for transition and light metals. Technical results related to metal production (Fe, Mn, Ti) and oxygen generation by molten oxide electrolysis will be presented in particular, to emphasize the key environmental and metallurgical advantages of electrochemical techniques. The experience gained developing and up-scaling these processes suggest that a paradigm change of commercial production of metals could potentially be achieved with their implementation.

Emeritus Professor George D.W. Smith Honorary Symposium: Steels I

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS/ASM: Phase Transformations Committee

Program Organizers: Michael Miller, Oak Ridge National Laboratory; Gregory Olson, Northwestern University and QuesTek Innovations LLC; George Krauss, Colorado School of Mines

Tuesday AM — Room: Mockingbird 2
March 13, 2012 — Location: Swan Resort

Funding support provided by: Oak Ridge National Laboratory; QuesTek Innovations LLC; AMETEK, Inc

Session Chairs: George Krauss, Colorado School of Mines; Hans-Olof Andren, Chalmers University of Technology

8:30 AM Invited
Some Atoms I Have Known: A Tale of Two Smiths: *Greg Olson*[1]; [1]Northwestern University

In the early 1980s, Morris Cohen's dream of establishing the long-sought structural mechanism of early aging phenomena in ferrous martensites was brought to fruition through a collaboration with G.D.W. Smith whose 1D atom-probe microanalysis confirmed the theoretical prediction of a Zener-order-induced spinodal instability of the BCT Fe-C solution, and showed that the composition of the resulting high C modulations is of Fe8C stoichiometry, now confirmed by DFT calculations. Combining the atomic capability of G. D. W. Smith with the systems vision of C. S. Smith, a Materials Design Initiative was undertaken in 1985. G. D. W. Smith played a leading role in establishing the matrix overlap correction procedures vital to extending the analysis of multicomponent alloys down to the nm scale of efficient strengthening dispersions. Smith's leadership in 3D atom-probe development ultimately enabled full validation of the first commercial alloys to emerge from this design technology, incorporating "carbides by Smith."

8:55 AM Invited
Microstructural Characterisation of Nanometre Scale Irradiation Damage in High-Ni Welds: *Jonathan Hyde*[1]; Paul Styman[2]; Colin English[1]; George Smith[2]; Keith Wilford[3]; Tim Williams[3]; Robin Boothby[1]; Helen Thompson[1]; [1]National Nuclear Laboratory; [2]Oxford University; [3]Rolls Royce

During service, Reactor Pressure Vessel (RPV) steels harden as a result of the formation of irradiation-induced nanometre-scale microstructural features which act as obstacles to dislocation movement. The hardening may lead to embrittlement and limit the reactor operating life. Microstructural observations of the irradiation-induced features have provided an important contribution to the mechanistic understanding of this degradation phenomenon and to the development of dose-damage relationships. Information from Atom Probe Tomography (APT), which provides information on the spatial distribution of solute atoms within individual grains, and Small Angle Neutron Scattering (SANS), which provides information averaged over many grains, have proved especially informative for characterising well defined solute clusters. In this paper we examine the ability of APT and SANS to characterise the earliest stages of irradiation damage in several neutron-irradiated and thermally-aged RPV steels and discuss the consequences for longer term evolution. The results will be compared with Monte Carlo models.

9:20 AM Invited
Contributions of Atom Probe Tomography to the Understanding of Steels: *Michael Miller*[1]; [1]Oak Ridge National Laboratory

Since the introduction of the computer-controlled atom probe field ion microscope in the early 1970s, significant contributions to the understanding of steels have been made primarily due to its near atomic spatial resolution and the ability to detect carbon and other light elements. Some notable achievements that will be discussed are the solute partitioning between phases in pearlite, the visualization and quantification of carbon segregation to dislocations (Cottrell atmospheres), quantification of the copper-enriched precipitates responsible for the embrittlement of neutron irradiated pressure vessel steels, the low temperature phase separation responsible for the 475° embrittlement of Fe-Cr alloys and the ferrite phase in duplex stainless steels, and the nanoclusters responsible for the remarkable stability of nanostructured ferritic alloys to high dose irradiation. Research supported by ORNL's Shared Research Equipment (SHaRE) User Facility, which is sponsored by the Office of Basic Energy Sciences, U.S. Department of Energy.

9:45 AM
Three Dimensional Characterization of Interfaces in Nanolayered Radiation Tolerant Metallic Thin Films: *Arun Devaraj*[1]; Venkata Rama Sesha R Vemuri[1]; Tamas Varga[1]; Shutthanandan Vaithiyalingam[1]; Satyanarayana V. N.T Kuchibhatla[1]; Chongmin Wang[1]; Thevuthasan Suntharampillai[1]; Charles H Henager[2]; [1]EMSL, Pacific Northwest National Laboratory; [2]Pacific Northwest National Lab

Recent research points to the intrinsically high radiation damage resistance of nanolayered materials with interfaces acting as traps and recombination centers for the radiation-induced point defects. This talk will focus on the unique benefits of atom probe tomography (APT) in characterizing the atomic structure of the interfaces in sputtered nanolayered Ti/Al metallic thin films before and after ion beam irradiation. Coupling APT with Rutherford backscattering spectrometry, aberration corrected scanning transmission electron microscopy, and first principle computations helped quantify changes in intermixing as a function of irradiation dose and layer spacing. These insights were used to investigate whether the internal interfaces in metallic multilayers can be manipulated at the nanoscale to enhance dynamic recombination of radiation-produced defects, or self-healing, so as to reduce radiation damage without compromising other properties.

Ultrahigh Strength Pearlitic Microstructures: Contributions by George D. W. Smith: *George Krauss*[1]; Stephanie Miller[1]; Emmanuel De Moor[1]; David Matlock[1]; [1]Colorado School of Mines

Fully pearlitic patented and cold drawn steel wire constitutes a product with ultrahigh ultimate tensile and torsional strengths for demanding applications, including tire reinforcement, springs, and cable for lifts, elevators, suspension bridges and mooring cables. The wire microstructure is a unique composite of very fine aligned and interspersed lamellar ferrite and cementite in eutectoid or near-eutectoid steels consisting only of iron and carbon and small amounts of other elements, including sometimes vanadium as a microalloying element. This presentation reviews some of the major contributions made by Professor Smith in the characterization of these remarkable microstructures and integrates his work with ongoing research designed to further understand and improve ultrahigh strength steel wire.

10:55 AM Invited
Atom Probe Analyses of Advanced Sheet Steels: *Kazuhiro Seto*[1]; David Saxey[2]; George Smith[3]; [1]JFE Steel Corporation; [2]University of West Australia; [3]Oxford University

Interstitial atom free (IF) steel and precipitation strengthened steel were analysed using a three-dimensional atom probe. We have confirmed that C and B segregate to grain boundaries in IF steel at very first stage of recrystallisation during annealing although P segregates afterwards. This result is important to control the secondary work brittlement observed in IF steel after press forming. Secondly, very fine precipitates in Ti-V bearing hot rolled formable high strength steel were analysed. Banded microstructure containing nanoscale carbides was clearly observed. The average composition of fine precipitates less than 5nm was rich in Fe whereas the fraction of Fe decreased in large precipitates. The distribution of fine precipitates on a single layer was random, and the mean free distance in three-dimension was estimated as approximately 28nm. The increase of yield strength was weaker than calculation from Orowan mechanism.

11:20 AM Invited
Atom Probe Tomography for Industrial Applications: *Harald Leitner*[1]; [1]Montanuniversitaet Leoben

Atom probe field ion microscopy is known as a technique which has the capability of measuring compositional changes on near atomic scale with equal detection efficiency for all elements. Atom probe field ion microscopy has the highest analytical spatial resolution of any microscope, but this technique is still not well-established in industrial research. However, with the development of the three-dimensional atom probe, especially the instruments with large field of view, larger areas can be analyzed and thus the obtained results are more representative for material properties. Furthermore, due to the three-dimensional picture of the analyzed volume, microstructural features are accessible which are not detectable with an one-dimensional atom probe and also other microscopic techniques. In this talk, examples of atom probe investigations on industrial materials such as steels and nickel-base alloys are presented, which gained deeper insight into them by the invention of the three-dimensional atom probe.

11:45 AM
The Application of Atom Probe Tomography to the Identification of Transformation Mechanisms of the Bainite Reaction in Steels: *Francisca Caballero*[1]; Michael Miller[2]; Carlos Garcia-Mateo[1]; Juan Cornide[1]; [1]CENIM-CSIC; [2]ORNL

The bainite transformation of austenite to ferrite between 200–550ºC is controversial. The displacive theory states that bainitic ferrite forms by shear, the transformation is essentially martensitic (i.e. the individual atom movements are less than one inter-atomic spacing) and proceeds by the formation of sub-units. The reconstructive theory states that bainite is a product of a reconstructive transformation (i.e., most of the solid state phase transformation occurs by thermally activated atom movements) and grows by the migration of growth ledges on the broad faces of the interface. This atom probe tomography study tracked the atom distributions during the bainite reaction and has provided experimental evidence on the incomplete transformation phenomenon, the carbon supersaturation of ferrite, the plastic accommodation in austenite, and cluster and precipitation formation. Research supported by ORNL's Shared Research Equipment (SHaRE) User Facility, which is sponsored by the Office of Basic Energy Sciences, U.S. Department of Energy.

12:00 PM
Atom Probe Analysis of Nanoscale Austenite Reversion in Steels: Dirk Ponge[1]; *Dierk Raabe*[1]; Lei Yuan[1]; Pyuck Choi[1]; Jim Wittig[1]; [1]Max-Planck-Institut

We design ultra-high strength and ductile martensitic and TRIP steels via nanoscale austenite reversion. The mechanism works via partitioning and kinetic freezing of C or Mn at martensite-austenite interfaces or via Gibbs adsorption isotherm segregation at martensite-martensite grain boundaries. We apply the method to Mn-based maraging steels and Cr-C-based martensitic stainless steels. Nanoscale austenite reversion leads to a variety of GPa steels at a ductility above 15%.

12:15 PM
Control of p-n Heterojunction Abruptness in Vapor-liquid-solid Grown Semiconductor Nanowires: *Daniel Perea*[1]; Jinkyoung Yoo[2]; Daniel Schreiber[1]; S. Tom Picraux[2]; Theva Thevuthasan[1]; [1]Pacific Northwest National Laboratory; [2]Los Alamos National Laboratory

Efforts to continually scale down the size of electronic components is guiding research to explore the use of nanomaterials synthesized from a bottom-up approach – group-IV semiconductor nanowires being one such material. However, Au-catalyzed synthesis of Si-Ge semiconductor nanowire heterojunctions using the commonly-used vapor-liquid-solid (VLS) growth technique results in diffuse heterojunction interfaces, leading to doubts of producing compositionally-sharp p-n junctions using this approach. However, we have recently reported the ability to increase Si-Ge nanowire heterojunction abruptness by VLS synthesis from a Au(1-x)Ga(x) catalyst alloy. In this work, we have extended the use of a AuGa catalyst alloy to produce more compositionally abrupt p-n junction interfaces compared to using pure Au as directly measured by atom probe tomography. The ability to controllably increase nanowire p-n junction abruptness is important for nanowire applications as tunneling field effect transistors where an increase in device performance is expected from shaper p-n junction interfaces.

Self-Assembly Strategies for Nanoscale Assemblies For Organic Photovoltaic Cells: *Dhandapani Venkataraman*[1]; [1]University of Massachusetts Amherst

In this talk, I will focus on the various self-assembly strategies for the assembly of organic seminconductors into nanoscale segregated structures towards efficient organic photovoltaic devices. Specifically, I will focus on two approaches- one focussed on diblock copolymers and the other focused on using semiconducting nanoparticles for obtaining nanoscale structures. Both these strategies are based in our molecular understanding of the evolution of bulk heterojunction structures.

9:00 AM
Atom Probe Contribution to the Characterization of Cigse Grain Boundaries: *Philippe Pareige*[1]; Emmanuel Cadel[1]; Francois Couzinie-Devy[1]; Nicolas Barreau[2]; John Kessler[2]; [1]Rouen University; [2]IMN

Atom Probe Tomography technique is a nano-scale-sensitive analytic tool allowing 3D chemical analysis with atomic scale resolution. In the present study, high efficiency Cu(In,Ga)Se2 (CIGSe) thin films have been investigated by APT in order to solve interrogations about grain boundaries (GBs) composition. The analyzed CIGSe layers have been grown by co-evaporation on Mo-coated soda-lime glass substrates following the standard 3-stage process. In order to ensure the presence of GB in the analysed volume, location and misorientation of GBs have been determined by electron backscattering scanning diffraction (EBSD). From APT analyses, spatial distribution of CIGSe elements can be imaged at atomic scale; particular attention has been devoted to the composition profiles at the vicinity of the CIGSe GB interface. New results are compared with usual CIGSe GB passivation models.

9:20 AM
Plasma Sprayed Titanium Oxide-Carbon Nanotube Composite Coating for Dye Sensitized Solar Cells: *Cheng Zhang*[1]; Ujwal Chaudhary[1]; Santanu Das[1]; Samarth Thomas[1]; Arvind Agarwal[1]; [1]Florida International University

TiO2 is an attractive material for dye sensitized solar cells (DSSC) because it is inexpensive and non-toxic as compared to the Si-based solar cells. Plasma spraying is an ideal method to produce TiO2 based DSCC due to its high deposition rate and ease of scale-up. In the present study, TiO2-carbon nanotube (CNT) based composite is explored as DSCC material. It has been shown in the literature that carbon nanotubes improve the conversion efficiency of DSSC in many ways. This study investigates the role of CNT addition in terms of phase transformation from anatase to rutile, microstructural properties and photocatalytic properties. TiO2 and TiO2-CNT coatings are prepared by plasma spraying on the stainless steel and FTO glasses. These composite coatings are characterized by X-ray diffraction and scanning electron microscopy. Photocatalytic properties are studied by the MB solution decomposition test.

9:35 AM
Reaction Based Sintering and Applications for Dye Sensitized Solar Cells: *Sukanya Murali*[1]; Dunbar Birnie[1]; [1]Rutgers University

Dye sensitized solar cells have the potential for low-cost manufacturing, but one key challenge is finding a low temperature sintering process for the titania electrode that can be employed on plastic substrates. To address this need, we have used reactive alkoxide solutions to fuse matrix particles together at low temperature. We discuss our efforts to understand where the reacted material locates itself within final microstructures. A silica-titania model system was employed to identify the reacted titania in the matrix. SEM studies and surface area measurements give insight into the effect of the matrix particle morphology on the properties and connectivity of the titania reaction product. SEM, AFM and TEM studies and image analysis of silica-titania sub-monolayers enable identification and measurement of the titania neck widths for varying titania precursor amounts. Geometrical calculations relate the interparticle neck radius to solution concentration. Implications for design of reactively sintered systems are presented.

First-Principles-Based Nanomaterials Design for Solar Energy Storage and Conversion: *Alexie Kolpak*[1]; Jeffrey Grossman[1]; [1]MIT

Large-scale adoption of solar energy storage and conversion technologies requires development of new materials with enhanced efficiency and low cost. With their penchant for exhibiting novel and/or enhanced properties, nanostructured materials offer myriad promising routes toward the development of such materials. In this talk, I will illustrate the potential of this strategy with two examples. First, I will discuss our first-principles-based design of solar thermal fuels composed of chromophore-derivitized carbon nanotubes. These materials can exhibit volumetric energy densities exceeding Li-ion batteries, potentially enabling practical use of this highly renewable, emission-free, and portable solar energy storage and conversion technology. Second, I will discuss our design of photovoltaic (PV) materials that exploit atomic-scale interface properties to drive electron-hole separation and eliminate defect-mediated recombination. Using first-principles computations, I will demonstrate a nanostructured GaAs-based superlattice that could eliminate the need for expensive, high-purity GaAs, potentially enabling replacement of Si with the more efficient GaAs.

10:55 AM
Doped Titanium Oxide Nanotube Arrays with Enhanced Photocatalytic Properties: Z. Xu[1]; Q. Li[1]; S. Gao[1]; *J. Shang*[2]; [1]Institute of Metal Research; [2]University of Illinois

Photocatalytic nanoarrays have attracted much attention because of their potential applications in the low-cost solar cell devices. In this study, self-organized nanotube arrays were made from titanium oxides doped with both anionic and cationic species to improve the photocatalytic properties of titanium oxide nanoarrays. While the cationic additions demonstrated strong influence on the structure of the nanotube arrays, the anionic dopants, such as nitrogen and fluorine, were found to enhance the visible light absorption and the photodegradation efficiency of organic species under the visible light illumination. The enhanced properties were dependent on both the nanotube structural architecture and chemical doping effect.

11:15 AM
New Numerical Method to Calculate the True Optical Absorption of Hydrogenated Nanocrystalline Silicon Thin Films and Solar Cells: *Fatiha Besahraoui*[1]; [1]Oran University

The enhanced optical absorption measured by Constant Photocurrent Method (CPM) of hydrogenated nanocrystalline silicon thin films is due mainly to bulk and/or surface light scattering effects. A new numerical method is presented to calculate both true optical absorption and scattering coefficient from CPM absorption spectra of nanotextured nanocrystalline silicon films. Bulk and surface light scattering contributions can be unified through the correlation obtained between the scattering coefficient and surface roughness obtained using our method.

Fatigue and Corrosion Damage in Metallic Materials: Fundamentals, Modeling and Prevention: Fatigue Life Prediction and Enhancement

8:30 AM Invited
Probabilistic Property-Life Mapping Based P-S-N Experiment Principle of Small Samples: *Liyang Xie*[1]; Jianzhong Liu[2]; [1]Northeastern University, Shenyang, China; [2]Beijing Aeronautic Materials Institute

Based on probabilistically mapping from material property to fatigue life, presented is the principle and method of small sample P-S-N experiment programming and statistically data treatment technique. By integrating the life distribution information at different stress levels, P-S-N equation can be acquired satisfactorily from small samples. The principle and method are based on the existence of the relationship between life distribution and stress level. The key to determine P-S-N equation is to obtain the life standard deviation – cyclic stress relationship, and the opinion to determine this relationship is first to determine the mean life – stress level relationship by test data and assume a reasonable std-stress equation. According to the assumed relationships, tested fatigue lives at different stress levels can be converted into the equivalent lives at the first high stress levels. The relationship can be determined when the equivalent life distribution is identical to the tested life distribution.

8:50 AM

A Probabilistic Approach to Modeling Fatigue Life Variation: *Julian Raphael*[1]; Peter Liaw[2]; Wei Wu[2]; [1]J R Technical Services, LLC; [2]The University of Tennessee

A method of estimating the fatigue-life variation is presented. The approach consists of introducing finite element results and probabilistic material property simulations into a fatigue or fatigue-crack-growth model and then analyzing the data to develop the cumulative distribution function for life expectancy. The justification for this approach stems from the fact that many empirically-derived material constants, such as the fatigue-ductility exponent and the fatigue-ductility coefficient, are calculated by linear regression of a data set whose correlation coefficient is less than unity. The application of the fatigue-life prediction methodology will be discussed.

9:10 AM

A Non-Linear Damage Accumulation Fatigue Model for Predicting Strain Life at Variable Amplitude Loadings Based on Constant Amplitude Strain Fatigue Data: *Peter Huffman*[1]; Scott Beckman[1]; [1]Iowa State University

A novel technique for predicting fatigue life from a variable amplitude strain history using constant amplitude loading data is presented. A critical feature of this reversal-by-reversal model is that the damage accumulation is inherently non-linear. The damage from the next reversal in the variable amplitude loading is predicted by approximating the accumulated damage as coming from constant amplitude loading that has the same strain as the next variable amplitude cycle. A key result of this approach is that overloads at the beginning of the strain history have a much more substantial impact on the total lifetime. The predictions made by this model are compared to experimental results, as well as the predictions made by other methods. This technique effectively incorporates the strain history in the damage prediction and has the advantage over other methods in that there are no arbitrary fitting parameters that require substantial experimental data.

9:30 AM

Fatigue Life Prediction of Friction Stir Welded Profiles: *Meysam Mahdavi Shahri*[1]; Torsten Höglund[1]; Rolf Sandström[1]; [1]Royal Institute of Technology

Friction Stir Welding (FSW) is a low heat input solid state welding technology especially suitable for low melting point metals. FSW technology is seen as providing superior joint integrity compare to those with conventional welding procedures. Euro code 9 is a standard code for fatigue assessment of aluminium structures. However Euro code 9 covers aluminium alloys and welded structures with conventional welding methods but not those with FSW procedure. In the present paper euro code 9 is used to estimate the fatigue life time for different FS welded extruded hollow aluminium profiles. The present study compares fatigue test results from friction stir welded joints with fatigue curves for traditional fusion welded joints in Al 6005 and base material. The result falls in a good agreement with experimental data and FEM predictions. This suggests that Euro code 9 can be used for fatigue assessment of FS welded joints.

9:50 AM

Neural Network Fatigue Life Prediction in Notched Bridge Steel I-Beams from Acoustic Emission Amplitude Data: *Eric Hill*[1]; Fady Barsoum[1]; Jamil Suleman[1]; Andrej Korcak[1]; Yi Zhang[1]; [1]Embry-Riddle Aeronautical University

Ten notched A572-G50 bridge steel I-beams were transversely loaded in three-point bending, and back propagation neural network (BPNN) fatigue life predictions were performed on the acoustic emission (AE) amplitude histogram data taken during fatigue cycling. BPNN fatigue life predictions based on the AE data from the first (0-25%), second (25-50%), and third (50-75%) quarters of the fatigue life data yielded worst case errors of 18.4%, 16.8% and 5.3%, respectively, for training on five beams and testing (predicting) on the remaining five. The worst case prediction errors decreased to -12.4%, -13.4%, and 4.5% when trained on the AE data from six beams and tested on four. Thus, it was found that BPNN prediction accuracy was improved both by using more training data (six beams rather than five) and by training on AE data taken later (third quarter) in the fatigue life of the notched I-beams.

10:10 AM Break

10:20 AM

Effect of Laser Shock Peening (LSP) on the Fatigue Behavior of Ti-6Al-4V ELI Alloy: *Sagar Bhamare*[1]; Sethuraman Subramanian[1]; James Guenes[1]; Leonora Felon[2]; David Kirschman[2]; Seetha Ramaiah Mannava[1]; Dong Qian[1]; Vijay K. Vasudevan[1]; [1]University of Cincinnati; [2]X-Spine Systems Inc.

Based on current bio-medical research that suggest that spinal implants with greater flexibility increase healing rate of spinal fusion, a novel implant rod, made from Ti-6Al-4V ELI was designed to replace current rigid rod, with aim of increasing flexibility and simultaneously enhancing the fatigue strength by applying laser shock peening (LSP) process. Residual stresses generated by LSP were measured using X-Ray diffraction and simulated using finite element method. Residual stress profiles are discussed. Results of four-point bending fatigue tests of both untreated and LSP-treated flexible rods are presented and compared with current design. Additionally, fracture surface of failed samples were characterized by scanning electron microscopy to elucidate the fatigue crack initiation and growth mechanisms. It is found that LSP increases fatigue life of novel design. A strain-life based fatigue life prediction model was developed to simulate fatigue life estimates of LSP treated rods. Effectiveness of life prediction model is discussed.

10:40 AM

Fatigue Behavior of Laser Shock Peened (LSP) Ti6242 Alloy: *Gokulakrishnan Ramakrishnan*[1]; Vibhor Chaswal[1]; James Guenes[1]; Kristina Langer[2]; Dong Qian[1]; S.R. Mannava[1]; Vijay.K. Vasudevan[1]; [1]University of Cincinnati; [2]Air Force Research Laboratory/RBSM, WPAFB

LSP is known to dramatically improve fatigue life by introducing deep residual stresses. Since residual stress is prone to relaxation under thermal and/or mechanical loading, understanding the thermal stability of fatigue life is important. Aerospace alloy Ti6242 was LSP'd using different conditions and the residual stresses were characterized by conventional XRD. Near-surface microstructures and local properties were studied using SEM and nano/micro indentation. The thermal stability of residual stress and microstructure were assessed over a range of temperatures and times. Kinetics of relaxation is modeled using a Zener-Avarami-Wert approach. Static and fatigue tests were conducted at room temperature on the unpeened, LSP-treated and LSP-treated + thermally aged specimens with and without a notch in 3-Point Bend geometry. The fracture surface was subsequently examined by SEM to identify the effect of LSP on crack initiation and growth. The results of the effects of LSP on the fatigue behavior are presented.

11:00 AM

Effect of Grinding Residual Stress on Fatigue Performance of Crankshaft: *Mahesh Dhumal*[1]; Ramchandra Prasad[2]; Suresh Arangi[1]; [1]Bharat Forge Limited; [2]Department of MEMS, Indian Institute of Technology Bombay

In this study, effect of grinding residual stress on fatigue performance of crankshaft has been investigated. The coolant flow rate during grinding was varied to get different values of surface residual stress. The surface residual stress was measured by using the X-ray diffraction technique. Surface residual stress was further correlated with Barkhausen Noise Analysis (BNA) signal. A consistent increase in surface residual stress and BNA signal was observed with decrease in coolant flow rate. Experimental test results showed that the crankshaft ground with maximum coolant flow rate (52 Lit/min) have compressive residual stress at the surface and enhanced fatigue strength. Micromechanism of fracture surface showed that crankshaft with surface compressive residual stresses (406 MPa) had crack initiation at the interface of induction hardened layer and core. On the contrary crack had initiated from surface when surface residual stresses (309 MPa) were tensile in nature.

11:20 AM
Effects of Ultrafast Laser Micromachining on Structure and Mechanical Properties of 316 LVM Stainless Steel: *Hossein Lavvafi*[1]; John Lewandowski[1]; Janet Gbur[1]; Dave Dudzinski[2]; Melissa Young[2]; David Schwam[1]; John J Lewandowski[1]; [1]CWRU; [2]Cleveland Clinic Foundation

Medical devices, such as guide wires, valves, needles, and stents increasingly demand smaller devices made with difficult to machine materials. Some applications often include fine details that are impossible to achieve with rotary tool machining. As a result, there is greater interest in the use of laser machining. Damage caused to the surface while using laser machining can affect the performance of the components. As devices shrink in size, the greater is the need for athermal manufacturing processes. In this study different type of laser with different pulse width were used to machine AISI 316 LVM biomedical grade wires. The mechanical behavior of these wires were evaluated in uniaxial tension, and in cyclic strain-controlled fatigue with the use of a flex tester operated to provide fully reversed bending fatigue. The effects of laser input energy and pulse width on surface quality and subsequent mechanical response will be reported along with plans for future work.

11:40 AM
Fatigue Response of Aluminium Alloy 7075-T6 Bolted Plates at Flight Environmental Conditions: *Reza Hashemi Oskouei*[1]; Raafat Ibrahim[1]; John Mikhail[1]; [1]Monash University

In this paper, fatigue life of aluminium alloy 7075-T6 bolted plates has been studied at flight temperatures. In order to investigate the effect of the environmental temperature on the fatigue life of both lightly and firmly bolted plates, the specimens were clamped with two different tightening torques and then fatigue tested at ambient (25° C), low (-50° C) and high (60° C) temperatures. Both the lightly and firmly bolted plates experienced more fatigue cycles at -50° C. However, the fatigue behaviour at 60° C was different compared to ambient temperature depending on the amount of applied clamping force.

From Macro to Nano, Understanding Mechanical Behavior across Length Scales: A Structural Materials Division Symposium in Honor of Robert Ritchie: Amorphous and Nanocrystalline Materials

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Biomaterials Committee
Program Organizers: Jamie Kruzic, Oregon State University; Brad Boyce, Sandia National Labs; Reinhold Dauskardt, Stanford University

Tuesday AM — Room: Mockingbird 1
March 13, 2012 — Location: Swan Resort

Session Chairs: Brad Boyce, Sandia National Laboratory; Reinhold Dauskardt, Stanford University

8:30 AM Introductory Comments

8:35 AM Keynote
Fracture and Mechanical Behavior of Hybrid Molecular Glass Films: Experiments and Computational Models: *Reinhold Dauskardt*[1]; [1]Stanford University

Hybrid organic-inorganic glass films exhibit unique electro-optical and mechanical properties and have application in emerging nanoscience and energy technologies. We describe computational methods to address the fundamental relationship between their molecular structure and resulting mechanical and fracture properties. Using molecular dynamics and a simulated annealing approach, large distortion-free hybrid glass networks with well-controlled network connectivity can be generated. With this capability along with a novel fracture model and molecular dynamics simulations of elastic deformation, we elucidate the critical effect of network connectivity and nanoporosity on mechanical properties. The accuracy of our computational tools is confirmed through comparison to synthesized hybrid films where the molecular structure, connectivity and nanoporosity is carefully controlled. Having predictive models for how molecular structure affects mechanical properties offers the opportunity for computational design of new hybrids and provides a quantitatively accurate rationale for guiding precursor selection and the molecular design of hybrids with exceptional mechanical properties.

9:15 AM Keynote
Microstructure and Stress State Effects on Fracture of Novel Materials: *John Lewandowski*[1]; [1]Case Western Reserve Univ

The presentation will review the effects of changes in microstructure and/or stress state on the fracture mechanisms of a variety of novel materials. Examples will be taken from work at CWRU with former and present students on composites, metallic glasses, and nano-composite materials. Microstructures can be varied from the micro- to nano-scale depending on processing conditions while changes in stress state can be accomplished via notches, superimposed pressure, and other novel test techniques that can help to delineate the micromechanisms of failure in the manner utilized by Prof. Ritchie and students/collaborators over the years.

9:55 AM
Thermography Study on the Temperature Evolution of Bulk Metallic Glasses under Monotonic and Cyclic Loading: *Peter Liaw*[1]; Gongyao Wang[1]; B. Yang[2]; Y. Yokoyama[3]; C. T. Liu[4]; A. Inoue[3]; [1]University of Tennessee; [2]Shell Companny; [3]Tohoku University; [4]City University of Hong Kong

In-situ monitoring the mechanical damage of the structural materials is important for controlling the failures. Temperature patterns in the structural materials serve as significant fingerprints during loading. The infrared (IR) camera is an excellent tool to study the failure mechanism of the structural materials. Bulk metallic glasses (BMGs) are good candidates for the structural applications because of their great mechanical behavior. In our lab, a state-of-art IR thermography camera is employed to monitor the temperature evolutions in shear bands and cracks of BMGs under monotonic and cyclic loading. With the understanding of the temperature evolutions during mechanical testing, thermography could provide the direct information and evidence of the stress-strain distribution, shear-band formation and growth, and crack initiation and propagation. In-situ visualizations and qualitative and quantitative analyses have been performed through thermography results. Theoretical models are developed to understand the deformation mechanisms of BMGs under monotonic and cyclic loading.

10:10 AM
R-Curve Behavior of Zr-Ti-Cu-Al Bulk Metallic Glass with Extraordinary Fracture Toughness: *Jian Xu*[1]; Qiang He[1]; Evan Ma[2]; [1]Institute of Metal Research, Chinese Academy of Sciences; [2]Department of Materials Science and Engineering, Johns Hopkins University

In this work, we demonstrate a $Zr_{61}Ti_2Cu_{25}Al_{12}$ (ZT1) bulk metallic glass (BMG) that simultaneously combines all the desirable properties including the reasonable cost, robust glass-forming ability, high strength (\963$_y$=1600MPa) and high fracture toughness (K_{JIC}=133 MPavm). In terms of ASTM standard for J-R curve test procedures, R-curve of this BMG was determined, showing K_J as high as ~230 MPavm, comparable to the toughest (Pd-based) BMG recently developed by Caltech. $Zr_{61}Ti_2Cu_{25}Al_{12}$ BMG exhibits a remarkable resistance to crack growth, which results from the crack-tip blunting by multiple-shear events and crack deflection during propagation. As revealed, apparent crack extension under loading for the fatigue pre-crack consists of two contributors, shear-off zone with 150 \181m in length caused by multiple-shear events and subsequent real sub-critical crack propagation.

10:25 AM Break

10:40 AM
Fatigue-Induced Grain Growth as a Precursor to Crack Nucleation: *Brad Boyce*[1]; Henry Padilla[1]; [1]Sandia National Labs

Grain growth is traditionally thought of as a thermally-driven diffusional process. However, even at and below room temperature, nanocrystalline metals can undergo mechanically-induced grain growth. This process is distinct from dynamic recrystallization which is typically thought of as a high-temperature process. The abnormal grain growth process can be induced by monotonic loading at high stresses, or can occur at lower stress under cyclic fatigue loading. In our recent examination of three nanocrystalline nickel alloys, we have consistently observed fatigue-driven grain growth as a precursor to crack initiation, suggesting the possibility of a sequential two-step process. This detrimental fatigue-induced coarsening process may behave athermally, and may not be impeded by traditional metallurgical stabilizers such as solutes or pinning particles. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

10:55 AM
The Role of Free and Grain Boundary Surfaces in the Fatigue of Nanostructured Metals: *Christopher Muhlstein*[1]; [1]The Pennsylvania State University

Nanostructured, thin, metallic films often exhibit high yield and ultimate strengths (i.e., gigapascals in magnitude) that are accompanied by undesirable strain rate sensitivity, low fracture toughness, and poor resistance to fatigue crack growth. These properties have often been attributed to the most obvious structural features of the materials – their grain boundaries. However, emerging evidence suggests that thin film and grain morphology contributions to fracture and fatigue mechanisms are distinct and can often be described by existing (macroscopic) theories. In this presentation I will review the deformation, fracture, and fatigue behavior of platinum to illustrate how various surfaces control crack growth in face-centered cubic metal films.

11:10 AM
The Mechanical Behavior of Highly Nano-Twinned Cu: *Andrea Hodge*[1]; Timothy Furnish[1]; Troy Barbee[2]; [1]University of Southern California; [2]Lawrence Livermore National Laboratory

The ductility and plastic flow behavior of highly aligned nanotwinned copper produced by interrupted magnetron sputtering is presented. Tensile tests were performed at various strain rates at both room and liquid nitrogen temperatures. Higher ductility and strength are reported for all samples tested at 77K. The observed inhomogeneous deformation and shear band propagation are discussed as a function of the testing temperature, decreasing heat capacity at 77K and the low initial dislocation density which leads to a yield peak. Uniformly distributed mobile dislocations introduced by rolling to 20% reduction in thickness eliminated the yield point at both temperatures. The experimental observations clearly demonstrate that the observed yield-point behavior is a direct result of the very low initial dislocation density in these sputtered films as expected for ‘‘ideal" nanoscale microstructural materials.

11:25 AM
Mechanical Properties of Nanotwinned and Nanolayered Metal Films: *Xinghang Zhang*[1]; Yue Liu[1]; Daniel Bufford[1]; Haiyan Wang[1]; [1]Texas A&M University

Nanotwinned metals are attractive as twin interfaces enable high strength and ductility, excellent electrical conductivity and thermal stability. Twin interface is identified in a variety of sputtered fcc metals, such as 330 stainless steel, Cu and Ag films. Both coherent {111} and incoherent {112} twin boundaries are observed. Average twin spacing, on the order of ~ 10 nm, can be achieved by varying deposition conditions. Twin interfaces are effective barriers to the transmission of dislocations, and thus lead to high strength in monolithic metals. Meanwhile twin interfaces are effective sources and sinks for dislocations during deformation. In situ nanoindentation studies reveal that certain twin interfaces are mobile during deformation due to rapid movement of Shockley partials, and consequently detwinning occurs. Finally strengthening mechanisms in highly textured Cu/Ni multilayers will be discussed, wherein both twin and layer interfaces are proven essential in tailoring the mechanical properties of multilayers.

11:40 AM
A Comparative Study of the Mechanical Properties and Fracture of Nanocrystalline (20 nm), Ultrafine Grained (100 nm) and Coarse Grain Polycrystalline (> 1 µm) Ni: *Indranil Roy*[1]; Farghalli Mohamed[2]; [1]Schlumberger; [2]University of California, Irvine

A number of alternatives, often competing, are responsible for the plastic deformation and fracture of crystalline solids. Traversing the length scale of its grain size, from nanocrystalline to microcrystalline we present in this study a comparative analysis of mechanical properties and fracture morphology of nanocrystalline (20 nm), ultrafine-grained (100 nm) and coarse grain polycrystalline (> 1 µm) Ni. Salient observations of the low temperature mechanical behavior and deformation mechanism for ED nc-Ni having average grain sizes of 20 and 100 nm were (a) deformation mechanism started as a local ductile fracture manifested by coalescence of nano / micro dimples with a sudden transition to a brittle mode (b) while work hardening had minimal or no response to the increasing test temperature (T < 0.25 Tm), it was observed to increase with increasing strain rate, however this was more pronounced for the specimens with smaller average grain size of 20nm.

Integrative Materials Design: Performance and Sustainability: Processing and Properties of Advanced Steels & Sustainable Design, Life-Cycle Analyses, and Recycling

Sponsored by: The Minerals, Metals and Materials Society, TMS/ASM: Mechanical Behavior of Materials Committee
Program Organizer: Diana A. Lados, Worcester Polytechnic Institute

Tuesday AM — Room: Europe 2
March 13, 2012 — Location: Dolphin Resort

Session Chair: Diana Lados, Worcester Polytechnic Institute

8:30 AM Invited
Innovation in the Manufacturing of Powder Forged Automotive Connecting Rods: *Ian Donaldson*[1]; [1]GKN Sinter Metals LLC

Powder metallurgy is a proven manufacturing method that owes its market penetration on being a sustainable manufacturing method coupled with the ability to tailor properties through materials and microstructures not achievable via competing technologies. Powder forging (P/F) is a fully dense, well-established method for manufacturing automotive connecting rods. Recent requirements for lighter and higher output engines has led to demands for lighter weight and higher fatigue endurance connecting rods with no degradation in machinability. With the traditional P/F Fe-Cu-C material system, this could be achieved by hardening through phase transformation, but that would result in poor machinability, raising total cost significantly. This study introduces a novel approach for using pre-alloyed Cu to avoid heat treatment or increased processing temperatures while improving chemical homogeneity and mechanical properties over traditional admixed compositions. Aspects of sustainability and integrated design with application of the new alloys will also be presented and discussed.

8:55 AM
New Concepts for Damage Tolerant Steels for High Performance Components: *Margarita Bambach*[1]; Hans Henning Dickert[1]; Wolfgang Bleck[1]; [1]RWTH Aachen University

Failure within the guarantee terms of high performance components such as gear wheels and bearings leads to high warranty costs. In order to prevent premature failure, fail-safe, damage tolerant steels with a high bearing capacity are necessary. Macroscopic failure is usually caused by effects occurring on a microscopic scale, such as crack initiation at non-metallic inclusions. Much effort has been invested in improving the purity grade of the applied steels. However, purity has already reached its technological-economical limits. This work focuses on the development of damage tolerant steels as an alternative to conventional methods for improving the life time of high performance components. Using a suitable combination of strengthening mechanisms, a high-strength, yet ductile matrix with a high work hardening potential will be developed. Thus, stress concentrations at inclusions can be reduced via plastic deformation. As a result, preliminary failure may be avoided and warranty costs may be kept low.

9:15 AM
Design of Novel Steels with Reduced Density: *Jonas Schwabe*[1]; Wolfgang Bleck[1]; Henning Dickert[1]; Alexander Zimmermann[1]; [1]RWTH Aachen

Steels with reduced density enable considerable weight reductions and therefore enable important economical and ecological savings e.g. in transportation industries. High additions of aluminum provoke a great density reduction and increase the strength of the steels as well. However, the unsatisfactory ductility of the high aluminum steels produced so far does not allow industrial mass applications. The present research describes the design of cold rolled flat steels with density reductions of up to 13% - while maintaining a substantial ductility of minimum 20% fracture strain at strengths up to 600 MPa. The combination of their mechanical and physical properties makes these materials attractive for many applications, especially in the automotive industry. Therefore, tests of the corrosion behavior, the deformation behavior under crash conditions, the deformation behavior at low and at high temperatures, the coating behavior as well as tests concerning the applicability of continuous casting were carried out.

9:35 AM
Effect of Pretreatment on the Strength and Formability of Vehicle Hot-Forming Martensitic Steels: *Ying Chang*[1]; Yipeng Gao[2]; Ping Hu[1]; Liang Ying[1]; Zhaohuan Meng[1]; Yunzhi Wang[2]; [1]Dalian University of Technology; [2]OSU

The stress-induced martensitic transformation in steel sheet (Fe-1.3wt%Mn-0.003wt%B-0.8wt%RE, 1.6mm thickness) during hot-forming could improve not only its strength and hardness, but also its formability. Based on experimental testing, theoretical analysis and calculation results, optimal properties (including formability) of the high strength steel (HSS) could be achieved by a rapid-cooling pretreatment to the austenite before hot-forming to enhance the stress-induced martensitic transformation during forming. Comparing with the traditional hot-forming HSS, the microstructure obtained in the pretreated samples consists of more uniform, finer lath martensite and retained austenite. The yield strength of the samples is greater than 1000 MPa, the tensile strength is over 1500 MPa, and the hardness is greater than HV435. No fracture bands are formed during forming. As a consequence of the high strength, the sheet thickness can be reduced up to 35% for automobile applications.

9:55 AM
The Contribution of Niobium Bearing Steels and Enhanced Sustainability: *Steven Jansto*[1]; [1]CBMM-Reference Metals Company

With the ever-growing concern for the environment and resource sustainability, the application of advanced high strength Nb-bearing steels for numerous high strength steel applications have been shown to reduce resource usage and improve the carbon footprint. The conservation and more efficient use of ironmaking and steelmaking raw materials is a global issue for all steel producers. Recent Nb-microalloyed steel applications provide a more efficient product design, reduced steelmaking emissions and less energy consumption per tonne of steel. A sustainability structural steel study presents the positive cost and environmental impact of Nb-microalloyed steel applications. The analysis compares the CO_2 emission reduction and energy savings in the steelmaking process melted via the Basic Oxygen Furnace (BOF) versus the Electric Arc Furnace (EAF) route. The application of Nb-microalloyed structural steels offer the opportunity to reduce the total weight of a given structure, such as a bridge, compared to non-microalloyed steel construction.

10:15 AM Break

10:40 AM Invited
Resource Recovery and Recycling of Materials: Mini-Mills of the Future: *Diran Apelian*[1]; [1]Worcester Polytechnic Institute

Consumption of material goods has created a large supply of scrap that unfortunately is mostly downgraded. The value of scrap is likewise undervalued and sold to various sources, many of them overseas markets. The scenario that exists today is untenable for environmental and economic reasons. The scenario that is sustainable and tenable is to recover and recycle by upgrading our scrap. Mini-Mills that utilizes 100% scrap that are intelligently sorted and processed is the path that we need to follow to produce metallic components. A system analysis for mini mills for light metals will be presented and discussed.

11:05 AM Invited
Engineering Solutions for Sustainability: Materials & Resources: *Brajendra Mishra*[1]; [1]Colorado School of Mines

Integrated engineering solutions to societal challenges in the transportation, energy, recycling, housing, food, water, and health sectors will be discussed. Specific outputs will include: The nucleus of a consensus definition of sustainability as it applies to engineering to provide a common basis for deliberation and action among various disciplines;Delineation of six critical overarching themes for engineering sustainability that provide a unifying framework in formulating strategy and implementing solutions within a diversity of challenges, issues, and stakeholders;Development of a draft Technology and Resources Matrix, designed as a communication tool for guiding research and policy actions within various engineering disciplines. These and other concepts and tools developed through this project lay the foundation for a productive, interdisciplinary dialogue and are intended for use by professional societies, educators, industry leaders, and policy makers to continue building a truly integrated sustainable engineering model.

11:30 AM Invited
Limited Materials Availability: Considering the Importance of Materials Market Dynamics: *Randolph Kirchain*[1]; Elisa Alonso[1]; Frank Field[1]; [1]Massachusetts Institute of Technology

Discussions about the sustainability of materials consumption have become increasingly prevalent. Popular media has even begun to ask: will we run out of X? Economic theory suggests otherwise, but this does not mean that materials availability does not present a risk to specific industries or technologies. This presentation will discuss how disruptions to materials availability can impact industry; methods for screening for those risks; and strategies for mitigating risk – including the redesign of materials and products. Case studies of materials critical to the future of the automotive and energy supply industries will be discussed. These cases point to the importance of market dynamics, including the price sensitivity of supply and demand, in establishing ultimate economic risk from limited availability. Results of selected dynamic market modeling will be used to demonstrate the value materials and materials process design to mitigating the risk of limited materials availability.

11:50 AM Invited
Development of Aluminum Dross Based Material for Engineering Applications: *Chen Dai*[1]; Diran Apelian; [1]WPI

In order to channel Al dross towards an appropriate engineering application, two different types of dross waste were selected from industrial production streams for characterization. Physical and chemical tests indicated that dross waste may be applied directly but better processed with boiled water to reduce crack-causing gases which form during the hydration reaction. Mechanical property evaluations revealed the possibility for dross waste to be utilized as filler in concrete, resulting in 25% higher flexural strength and a 5% higher compressive strength compared to pure cement. In addition, comparisons were carried out between similar size and fraction of dross powder and sand additions to concrete; the results indicate that fine dross powder had a positive effect on mechanical properties of concrete vs. to additions of sand. The opportunities to utilize a waste material as for engineering applications for construction materials will be reviewed and discussed.

12:10 PM Invited
Increasing Use of Secondary Materials in Production Planning: *Elsa Olivetti*[1]; Randolph Kirchain[1]; Gabrielle Gaustad[2]; [1]MIT; [2]Rochester Institute of Technology, Rochester, NY

Increasing the efficient use of secondary (i.e. recycled) resources provides one strategy in moving towards sustainable consumption. Secondary recovery enables energy saving benefits, forestalls depletion of non-renewable resources and avoids the deleterious effects of extraction and beneficiation (recycling does add some impacts of its own). There are several barriers to increased use of secondary materials, particularly in metal systems, that can be addressed through innovative production processing and alloy product design. This presentation will discuss a few of those options including control of incoming compositional variation in secondary materials through explicit incorporation of uncertainty, robust long term batch planning to mitigate compositional accumulation and informed alloy design towards recycling friendly alloys. Research has shown that explicit consideration of operational uncertainties and alloy design that considers the impact of recycling through the use of stochastic programming in production planning can increase the use of secondary materials.

International Smelting Technology Symposium (Incorporating the 6th Advances in Sulfide Smelting Symposium): Current and Emerging Smelting Technologies

Sponsored by: The Minerals, Metals and Materials Society, The Metallurgy and Materials Society of CIM, TMS Extraction and Processing Division, TMS: Pyrometallurgy Committee
Program Organizers: Jerome Downey, Montana Tech of the Univ of Montana; Thomas Battle, Midrex Technologies, Inc.; Jesse White, Elkem Solar Research

Tuesday AM — Room: Northern A3
March 13, 2012 — Location: Dolphin Resort

Session Chair: To Be Announced

8:30 AM
The Path to Technology Development, Ralph Baggaley and the Evolution of Copper Smelting Technology: *Larry Southwick*[1]; Ralph Yardley[2]; [1]L.M. Southwick & Associates; [2]Yardley & Associates

Ralph Baggaley, a Pittsburgh industrialist and associate to George Westinghouse, was instrumental in developing the basic lining and numerous operating features of what became known as the Peirce Smith copper converter. Beginning in the late 1890's Mr. Baggaley conducted literature, laboratory and larger scale research, acquired and was awarded numerous patents, and visited many operating facilities. A book he wrote responding to examiner comments regarding one of these patents, as well as several other documents provide a unique light into the innovation process as practiced by this uniquely creative man. This paper will review and discuss Baggaley's critique of copper converting technology as it existed and was practiced around the turn of the century, and how he came to form, defend and prove his ideas and concepts. One of the authors, Yardley, is Mr. Baggaley great grandson and provided the information which is the core and genesis of this study.

8:55 AM
Processing of Lead, Zinc, Copper and Nickel Concentrates - The Xstrata Technology Approach: *Gerardo Alvear Flores*[1]; [1]Xstrata Technology

Processing of copper, zinc, lead and nickel concentrates is becoming more challenging due increasingly complex mineralogy. Smelters are required to modify their operating flowsheets and strategies to process more complex feed materials economically while meeting stricter environmental regulations. Xstrata operates mines, smelters and refineries around the world. It has developed a number of innovative technologies at various operating sites that provide an economic solution for the production of base metals and silver. These technologies include ISASMELTTM TSL, ISACONVERTTM TSL, IsaKiddTM Tankhouse Technology, BBOCTM and Albion leach technologies. This paper describes process flow sheets that demonstrate how Xstrata's technologies can be combined to treat complex feed materials.

9:20 AM
Ferroalloy Research in Norway – Cooperation between Academia and Industry: *Merete Tangstad*[1]; [1]NTNU

In Norway the ferrosilicon/silicon- and ferromanganese- production is strong with a world market of 4 % / 9 % and 4 % respectively. The research and development work in the academia mirrors the national interest, and hence, there has been an extensive research in the academia within these areas. There are some vital drivers and premises for a successful cooperation. The main driver is a win-win situation for both the industry as well as the academia. For the industry this could be cost-, competence- or environmental- benefits and for the academia, building of competence, educate more students as well as possibilities to publish are important drivers. The results from the cooperation in Norway are basic knowledge regarding thermodynamic- and kinetic-data, as well as reaction mechanisms within core processes. Now, the main interests are the challenges within depletion of raw materials as well as environmental issues.

9:45 AM
Status of the Alcoa Carbothermic Aluminum Project: *Christina White*[1]; Øyvind Mikkelsen[1]; David Roha[2]; [1]Alcoa Norway ANS; [2]Alcoa Technical Center

Significant resources have throughout the years been spent in the investigation of production of aluminium by carbothermic reduction. Due to the technological challenges involved the efforts have not yet resulted in a commercial process. An initiative to overcome issues that prevented previous attempts to succeed was taken by Alcoa through the Advanced Reactor Process. The research program has resulted in technical developments which have resolved many of the previous issues. Also the knowledge about the process has continuously improved through physical and computer modeling as well as by experimentation at various scales. The technical achievements together with improved process understanding have resulted in a reactor design able to continuously operate the process for several weeks at the time, with hundreds of kilograms of alloy in every tap. This paper gives an overview of the status of the project, the modeling efforts done and the remaining technical challenges.

Outotec´s Smelting Solutions in Non-Ferrous Metals Production: *Asmo Vartiainen*[1]; [1]Outotec Oyj

Outotec has in its portfolio a wide variety of smelting solutions for non-ferrous metals. These include flash smelting for primary copper and nickel, flash converting for copper, Ausmelt TSL technology for primary and secondary copper, and for Ni,Sn, Pb, Zn residues and waste, Kaldo TBRC technology for secondary copper, lead and precious metals recovery, slag cleaning technology etc. Outotec provides complete tailored process solutions for customers' needs. Decades of experience have resulted in extensive metallurgical know-how that ensures the most profitable process choice and its optimal performance. Outotec's life cycle technology partnership with the customer spans from the early stages of the process solution design all through the supply and commissioning of the entire process chain with integrated process control and holistic service and support concept. Continuous research and development ensure that the customer is provided with the latest advancements in process and equipment solutions.

10:50 AM
Atlantic Copper PS-Converters: A Continuous Commitment to the Future: *Antonio Martin*[1]; Jesús Hurtado[1]; Francisco Jimenez[1]; [1]Atlantic Copper SA

Atlantic Copper is one of the largest copper producers in Europe. Its production facilities, including a primary copper smelter and an electrolytic refinery, are located in Huelva, on the South-West coast of Spain. These installations enable the smelting of over 1 million tpy concentrates to produce up to 260 ktpy of cathodes and 900 ktpy of sulphuric acid. Since the commissioning in 1970 until today, continuous improvements have been made at the PS-Converters such as several improved designs of primary hoods and scrap chargers, blast air control system, operation with OPC online analysers, design of secondary hoods and other environmental projects. All these modifications have been aimed at increasing the capacity of our smelter while keeping a continuous environmental commitment. This paper describes the modifications and improvements carried out over the years at the Converters and the proposals for future developments at Atlantic Copper

11:15 AM
Improvements on Converter Operating Practice at Mufulira Smelter, Zambia: John Sakala[1]; *Jeyapandian Sasikumar*[1]; Sydney Kwalela[1]; [1]Mopani

With the commisioning of the 850,000 tonnes of Concentrate treated per annum capacity Isasmelt in September 2006 the Converter section became a bottleneck to the high throughput.Over 25% of the Isasmelt downtime was attributted to lack of Converter space. Areas that were negatively affecting converter operations were low Tuyere line campaign lives which were avaraging 150 blows, high reverts generation, low blister copper conversion rates and high converter cycles time. As a result of the interventions carried out, Converter Campaign lives were increased to over 250 blows, Reverts generation was reduced from 22% to 14% of new concentrate treated,Blister Copper conversion rate was increased from 15tph to 19tph and the blowing time was reduced from 5.7 hours to 4.7 hours.

Magnetic Materials for Energy Applications II: Permanent Magnets for Energy Applications

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Magnetic Materials Committee

Novel Synthesis of Rare Earth Permanent Magnets for Energy Applications: *Raju Ramanujan*[1]; P Deheri[1]; S Bhame[2]; [1]Nanyang Technological University; [2]Univ. of Liege

Superior high performance permanent magnets are vital in an enormous variety of energy generation and utilization applications, they can reduce energy consumption and increase energy efficiency. There is also a sustainability and strategic need to reduce rare earth content. Hence, novel synthesis techniques were studied, advantages of chemical synthesis include facile elemental substitution and the ease of obtaining nanoparticles. Challenges arise from high reactivity and differences in electrochemical behavior. Chemical synthesis by sol-gel, auto-combustion and microwave based methods were studied. In the sol-gel method, Nd-Fe-B gel was prepared and annealed to produce mixed oxide powders. Hard magnetic Nd2Fe14B nanoparticles were prepared from these oxides by three step reduction-diffusion. The Henkel plot revealed exchange coupling. The synthesis of exchange coupled 10 nm magnetic nanoparticles by glycine nitrate auto combustion, followed by reduction diffusion, was also carried out. These results and the magnetic properties will be discussed in the presentation.

High Performance Magnets with Less or No Rare Earth: Challenges and Opportunities: *Jinfang Liu*[1]; [1]Electron Energy Corporation

China controls over 95% of the rare earth (RE) market, and recently, started to regulate its rare earth industry by introducing environmental protection policies, shutting down small rare earth mining operations, and imposing export quotas. Reduced supply and increased demand have increased the cost of some RE metals by 300 to 500% in the last 12 months, the most unstable being the price of Dy. The RE supply chain risk leads to a strong desire to develop high performance magnets with less or no RE. This paper will discuss the technical challenges and opportunities ahead, including the process challenges to obtain certain microstructure and texture in order to reach theoretical potential of the nanocomposite magnets.

Synthesis and Characterization (Structural and Magnetic) of Bulk and Nanostructured d-Phase in Mn-Ga System: *Tanjore Jayaraman*[1]; Jeffrey Shield[1]; [1]University of Nebraska

Permanent magnets play a vital role in environment-friendly technologies. Currently due to the demand for rare-earth based permanent magnets it is imperative to explore non-rare earth based magnetic systems. In this work we present the synthesis and characterization (structural and magnetic) of bulk and nanostructured d-phase (L10) in Mn-Ga system obtained by conventional melting, rapid solidification (melt-spinning), and mechanical alloying (ball-milling); followed by a sequential heat treatment process that resulted in the formation of d-phase. The mechanical alloying resulted in the formation of a nanostructured powder comprising metastable disordered phase - a suitable precursor for making powders of the d-phase. Both the disordered and the ordered d-phase show ferromagnetic behavior at ambient temperature; the ordered phase exhibit superior magnetic properties. The structure and magnetic properties of the d-phase were found to be sensitive to the composition, heat treatment cycle and processing route.

Search for New Rare Earth Based Permanent Magnetic Materials: *B. Jensen*[1]; K. Dennis[1]; R. McCallum[1]; [1]Ames Laboratory, US-DOE

There are substantial challenges in researching magnetic materials of the R-TM-X systems (R = rare earth, TM = transition metal) due to synthesis difficulties including high vapor pressure, high reactivity, toxicity, or the refractory nature of the materials. This research focuses on discovering new phases with high anisotropy and high magnetization through closed diffusion couples in which the alloying elements are sealed inside a high purity Fe crucible. Either vapor-solid reactions or powder metallurgy techniques are then employed to isolate a stoichiometric sample based on a potentially magnetic phase found in the diffusion couple. For this research, X = F, Ca, Sr, Se, Zn, Bi, or Cd, TM = Fe, and R = Nd. New ternary phases have been discovered with WDS and EDS, and magnetic transition temperatures have been measured with a SQUID magnetometer and VSM. This work was supported by ARPA-E contract number DE-AR0000046 at Ames Laboratory (USDOE).

Interfacial Characterisation in Nd-Fe-B Permanent Magnets: *Thomas Woodcock*[1]; Gino Hrkac[2]; Thomas Shrefl[3]; Oliver Gutfleisch[1]; [1]IFW Dresden; [2]University of Sheffield; [3]St. Pölten University of Applied Sciences

Nd-Fe-B sintered magnets play an important role in energy applications such as hybrid electric vehicles and wind turbines. Production of Dy-free Nd-Fe-B magnets with high coercivity requires greater understanding of the coercivity mechanism. Detailed characterisation of the structure and composition of interfaces is therefore highly important. Aberration-corrected TEM has been used to obtain highest spatial resolution images of interfaces between the $Nd_2Fe_{14}B$ and Nd-rich grains in Nd-Fe-B sintered magnets and the composition of the grain boundary phase has been measured using STEM-EELS. Atomistic simulations based on these results predict the presence of distorted regions of $Nd_2Fe_{14}B$, leading to local changes in the magnetic anisotropy, which may have a detrimental effect on coercivity. The thickness of the distorted regions was shown to depend on the crystal structure and orientation of the Nd-rich phase. Local orientation changes caused by defects in Nd-rich phases have been observed by HR-TEM and EBSD.

11:20 AM
Effect of Ni Content on the Crystallization Behavior and Magnetic Properties in a Nanocrystalline (Co1-xNiX)88Zr7B4Cu1 Soft Magnetic Alloy: *Billy Hornbuckle*[1]; Billie Wang[1]; Taisuke Sasaki[2]; Maria Daniil[3]; Matt Willard[4]; Greg Thompson[1]; [1]The University of Alabama; [2]National Institute for Materials Science; [3]Naval Research Laboratory ; [4]Naval Research Laboratory

Soft magnetic materials with nanocrystalline microstructures have shown the capacity for use in electric motors. These materials could reduce component sizes, provide higher energy conversion, and allow easier thermal management. (Co,Fe)-Zr-B-Cu based alloys have been one of the systems investigated for these reasons. This study branches from that system by creating a series of (Co1-XNiX)88Zr7B4Cu1 soft magnetic alloys, where X varied from 0 to 1. These were then melt spun into thin ribbons to determine the compositional limitations of amorphization. The activation energy for crystallization decreased with increasing Ni content. TEM imaging and atom probe tomography revealed fine nanocrystallite and boron segregation to the grain boundaries with increasing Ni content. Chemical partitioning between species in the as-spun and primary crystallization heat treatments were correlated to the resulting changes in magnetic properties. As expected, reduction in magnetization and Curie temperature accompanied the substitution of Ni for Co in this alloy series.

11:35 AM
The Effect of Substituting Nb and Hf for Zr in Fe-Co-Ni-Zr-B-Cu Nanocrystalline Soft Magnetic Alloys: *Keith Knipling*[1]; Maria Daniil[1]; Matthew Willard[1]; [1]Naval Research Laboratory

Nanocrystalline soft magnetic materials possess a unique combination of large magnetization and permeability with low core loss, achieved by exchange-coupling of nanoscale ferromagnetic grains through a surrounding amorphous matrix. The effectiveness of exchange-coupling is reduced, however, above the Curie temperature of the intergranular amorphous phase, T_c^{am}, thus limiting the alloys' maximum service temperature. We recently showed that small substitutions of Co and Ni for Fe in Nanoperm-type ($Fe_{88}Zr_7B_4Cu_1$) alloys increases T_c^{am} while maintaining large saturation magnetizations and small hysteretic losses, resulting in improved magnetic properties at elevated temperatures (~250–450 °C). Substituting other early transition metals for Zr is expected to reduce the saturation magnetostriction, λ_s, thereby reducing the hysteretic losses further. In this study, we report on the crystallization behavior and ambient- and elevated-temperature magnetic properties for a series of $Fe_{77}Co_{5.5}Ni_{5.5}Zr_xNb_{1-x}B_4Cu_1$ and $Fe_{77}Co_{5.5}Ni_{5.5}Zr_xHf_{1-x}B_4Cu_1$ alloys (x = 0–7), and correlate the measured hysteretic losses to the measured λ_s

Materials and Fuels for the Current and Advanced Nuclear Reactors: Nuclear Fuels

8:30 AM Invited
Compatibility of Metallic Transmutation Fuels with Fe-Based Alloys: *James Cole*[1]; Thomas O'Holleran[1]; Robert Mariani[1]; Dennis Keiser[1]; J. Kennedy[1]; [1]Idaho National Laboratory

Out-of-pile diffusion couple studies have been conducted over the past several years to better understand the complex phase evolution that occurs when U, Pu-based metallic nuclear fuel with and without minor actinides (Am, Np) and rare earth fission products (Ce, La, Pr, Nd) contacts Fe-based cladding alloys at elevated temperature. These studies are being performed to support in-pile tests of similar fuels and bound the expected behavior in terms of formation of brittle or low-melting point phases due to interdiffusion of fuel constituents into the cladding and cladding constituents into the fuel. The complex phase evolution observed will be discussed in terms of available equilibrium phase diagram data and the relation to anticipated in-pile behavior.

9:00 AM
Advanced Fuels with Fission Product Getters to Suppress Fuel-Cladding Chemical Interactions: *T. O'Holleran*[1]; R. Mariani[1]; Randall Fielding[1]; P. Hansen[1]; T. Hyde[1]; J. Kennedy[1]; [1]Idaho National Laboratory

Rare earth fission products in metallic fuels are known to exacerbate undesirable fuel-cladding chemical interactions with steel cladding that can lead to premature failure. Rare earth fission products produced during irradiation migrate to the fuel – cladding interface where they can depress solidus temperatures leading to breach of cladding. Furthermore, recycled fuel for a fast burner reactor used to destroy actinides may contain several percent rare earth fission products prior to reactor insertion, leading to fuel – cladding chemical interactions at the outset. This paper describes the selection of additives to complex rare earth fission products during both fuel production and irradiation. It also describes the fabrication and characterization of experimental fuels to test these concepts. Preliminary results indicate effective gettering of (surrogate) rare earth fission products in as-fabricated fuel doped with rare earths. In fuels fabricated without rare earths, the getter forms intermetallics with other constituents.

9:20 AM
Reducing Fuel Cladding Chemical Interaction by Pinning Lanthandide Fission Products in Metallic Fuel: *Gerald Egeland*[1]; Thomas Hartmann[1]; Robert Mariani[2]; Rory Kennedy[2]; Steve Hayes[2]; [1]University Nevada Las Vegas; [2]Idaho National Lab

Fast reactor metallic fuels produce significant lanthanide fission products which have been shown to diffuse to the fuel periphery and interact with the cladding. With the drive for higher burn-up fuels, this effect increasingly becomes a limiting factor with risk of a cladding breach. To test viability of pinning several lanthanides , palladium was chosen as the pinning dopant based its thermodynamic stability of the lanthanide alloys and its fuel compatibility. Iron was chosen as the base for standard cladding materials. Three lanthanides were tested, neodymium, cerium, and praseodymium, along with their 1:1 palladium alloys, against iron in diffusion couples. These experiments show the effects of palladium alloys versus the pure lanthanides on iron.

9:40 AM
Nanofluid-Based Coatings to Mitigate Fuel Cladding Chemical Interactions (FCCI): *Vahid Firouzdor*[1]; Lucas Wilson[1]; Kumar Sridharan[1]; Brandon Semerau[1]; Benjamin Hauch[1]; Todd Allen[1]; [1]University of Wisconsin-Madison

Diffusion barrier coatings and liners have been proposed for the inner surface of fuel claddings for mitigation of fuel cladding chemical interactions (FCCI) in Advanced Burner Reactors (ABR). We are developing methods to deposit diffusion barrier coatings of Ti, Zr, and V and their respective oxides, and yttria-stabilized zirconia (YSZ) using electrophoretic deposition (EPD) of nanofluid precursors. The coatings have been evaluated using diffusion couple studies using cerium as a surrogate for uranium, as well as by SEM and x-ray diffraction techniques. To obtain the best coating quality, process parameters including, the solution chemistry, nanoparticle concentration, voltage, current, and post-coating sintering are being studied. By using co-axial EPD technique uniform coatings have been successfully deposited on the inside surface of cladding sections up to twelve inches in length. Diffusion couple experiments show excellent reduction in diffusion of cerium into steel using the barrier of YSZ and TiO2 coatings.

10:00 AM
Microstructural and Chemical Charaterization of High Burn-Up Mixed Oxide Fuel: *Melissa Teague*[1]; Brian Gorman[2]; Steven Hayes[1]; Jon Carmack[1]; [1]Idaho National Laboratory; [2]Colorado School of Mines

The increasing demand for cost effective green energy has led to a renewed interest in nuclear energy, including the commercialization of fast breeder reactors (FBR's). For FBRs to become economically competitive with current light water reactors (LWRs) the average burn-up of fuel assemblies in an FBR will need to exceed ~150 GWd/tHM (~15% FIMA). A secondary reason for interest in FBR in is their potential to be used to "burn" or transmute long-lived transuranic isotopes contained in spent nuclear fuel produced by the current fleet of LWR. Currently fast reactor performance is largely defined by the limitations of the materials involved in reactors, especially the metallic or mixed oxide ($(U, Pu)O_2$) fuel itself. Problems include fission gas generation, changes in thermal conductivity, microstructure changes within the fuel, fuel swelling, and fuel cladding chemical interaction (FCCI). Microstructural and chemical analysis of MOX fuel with burn-ups of 5-24% FIMA will be presented.

10:20 AM Break

10:30 AM
Interdiffusion Kinetics in U-Zr: *Vincenzo Lordi*[1]; Mark Wall[1]; Luke Hsiung[1]; Ron Foreman[1]; Patrice Turchi[1]; [1]Lawrence Livermore National Lab

The design of reliable advanced nuclear fuels, particularly for high burn-up applications, requires a detailed understanding of degradation mechanisms and kinetics. Phase evolution under operating conditions must be well understood, ideally both experimentally and in simulations. For various advanced U-based fuels, interdiffusion of Zr, both from coatings and also the fuel alloy, is fundamental. In this study, we assess U-Zr interdiffusion data for use in kinetic evolution models and compare to experimental measurements on diffusion couples. The variation of diffusion rates with radiation damage (displacements per atom) is investigated using Zr ion implantation from an ion accelerator to model long-term damage. Damage profiles and dosages from the ion implanter are calibrated with Monte Carlo models of the implantation process. Prepared by LLNL under Contract DE-AC52-07NA27344.

10:50 AM
Forming Process Development for Al-clad U-10Mo Monolithic Fuel Plates: *Kester Clarke*[1]; David Alexander[1]; Jill Wright[2]; Pavel Medvedev[2]; Richard Williamson[2]; [1]Los Alamos National Laboratory; [2]Idaho National Laboratory

A significant goal for the Global Threat Reduction Initiative (GTRI) is converting high performance research reactors from highly enriched (HEU) to low enriched (LEU) uranium, requiring development, qualification, and production of monolithic LEU-10Mo foils. These foils are to be co-rolled with Zr and clad with 6061Al using hot isostatic pressing (HIP). Some reactor designs require a forming/bending operation after HIP processing. The selected method for bending fuel plates is press brake-type forming with solid punches and flexible bottom dies. Small scale trials with multi-layer fuel foils have been performed. Important results include springback evaluation as a function of DU-10Mo and 6061 Al thickness and metallographic examination of the bond zone integrity as a function of bending radius. Plate relaxation as a function of time and temperature was also evaluated, which may be critical to in-reactor performance. Finally, finite element (FE) analysis of forming the multi-layer fuel plate has been performed.

11:10 AM
Characterization of Freeze-Cast Scaffolds as a Novel Fuel Form: *Clarissa Yablinsky*[1]; Joan Burger[2]; Amanda Lang[1]; Philipp Hunger[2]; Thomas Gage[1]; Ulrike Wegst[2]; Todd Allen[1]; [1]University of Wisconsin; [2]Drexel University

With advanced reactor designs requiring better fuel performance, the search for different fuel forms is essential to increasing the materials possible for fast reactor use. In this study, a novel fuel form, created by a directional solidification process, is being researched because of the ability to load different fuels within a longitudinal pore structure in a controlled fashion. Scaffolds of 316 stainless steel and aluminum oxide with different pore sizes and geometries were created and infiltrated with a fuel surrogate, cerium dioxide. The structure, mechanical, and thermal properties of the scaffolds were characterized in both their porous and filled state. Monte Carlo N-Particle modeling was performed in order to test criticality requirements for the fuel and reactor.

11:30 AM
Transport Studies with Porous Metal Fuels: *Robert Mariani*[1]; Curtis Clark[1]; Thomas O'Holleran[1]; Blair Park[1]; Randall Fielding[1]; J. Kennedy[1]; [1]Idaho National Laboratory

Metal nuclear fuels develop significant porosity above approximately 2% burnup (heavy metal basis). Since surfaces can facilitate more rapid transport than the bulk fuel alloy, it is important to characterize the transport of fuel constituents, fission products, and cladding components in porous fuel bodies. Special-effects, out-of-pile tests were therefore designed and are being implemented to assess the significance of porosity on transport, which may be critical to understanding the fuel behavior and to modeling. We describe methods of preparing porous alloy fuels, which included atomizing the alloys into spherical or flake powders. Powders were subsequently sintered and prepared as diffusion couples with reactive counterparts, such as iron. These experiments are a crucial supplement to the traditional bulk diffusion and transport experiments for understanding and modeling fuel properties. We will summarize the rationale and need, experimental plans, recent developments, and future steps.

11:50 AM
Production Scale-Up of Cylindrical Compact Fabrication: *Eric Shaber*[1]; Jeffrey Phillips[1]; [1]Battelle Energy Alliance/INL

Multiple process approaches have been used historically to manufacture cylindrical nuclear fuel compacts. Scale-up of fuel compacting was required for the NGNP Project to achieve an economically viable automated production process capable of providing a minimum of 10 compacts/minute with little or no rejects. In addition, the scale-up effort was required to achieve matrix density equivalent to baseline historical production processes, and allow compacting at fuel packing fractions up to 46 vol%. The scale-up approach of jet milling, fluid-bed overcoating, and hot-press compacting adopted in the U.S. Advanced Gas Reactor (AGR) Fuel Development Program involves significant paradigm shifts to capitalize on distinct advantages in simplicity, yield, and elimination of waste. The scale-up effort is nearing completion with the process installed and operable using nuclear fuel materials. Final process testing is in progress to certify the process for manufacture of qualification test fuel compacts in 2012.

Materials Design Approaches and Experiences III: High Strength High Toughness Steels

Multi-Scale Modelling to Aid Alloy Design: *Matthias Militzer*[1]; [1]The University of British Columbia

Computational materials science tools have great potential to aid the development of new alloying concepts and processing routes. Industrial process models are currently at least in part based on empirical material parameters to describe microstructure evolution and resulting material properties. Modelling across different length and time scales is a promising approach in order to develop next generation process models that can rigorously account for the role of alloying elements. Atomistic simulations can be used to gain insight into interfacial properties (e.g. interface mobility) and the interaction of alloying elements with moving interfaces (i.e. solute drag). Phase field models that operate on the length scale of microstructures (the so-called meso-scale) provide an important bridge to link atomistic simulations with the macro-scale of process models. The potential and challenges of this multi-scale modelling approach will be illustrated for phase transformations in advanced low-carbon steels.

9:00 AM Invited
Integrated Computational Materials Design: From Genome to Flight: *Greg Olson*[1]; [1]Northwestern University

The historic first flight on December 17,2010 of the Ferrium S53 Stainless Landing Gear Alloy represents the first fully computationally designed and flight qualified material. This achievement was made possible by the founding of a multidisciplinary research consortium in 1985, which was in turn inspired by the emergence in 1984 of ThermoCalc as a second-generation CALPHAD software and database system offering a new level of accuracy raising the possibility of true materials design. The steady improvement in accuracy of tools and databases has continued to broaden materials design capability, and its integration with the efficient probabilistic framework of the AIM methodology has continued to accelerate the design and qualification cycle. The higher accuracy of new simulation tools has demanded higher fidelity microstructural characterization now enabled by a suite of 3D tomographic tools integrated under the recent ONR/DARPA "D3D" Digital Structure initiative.

9:30 AM Invited
Multi-Scale Microstructure Design of High Performance Structural Steel: *Chengjia Shang*[1]; [1]University of Science and Technology Beijing

Steel is key structural material. The mechanical properties of steel generally relate with alloys, phases and other microstructure. Ferrite/pearlite and bainite/matensite are the common phases in steel, with the phase transformation temperature decreasing, strength of steel would increasing and the transformation phases are changed from ferrite/pearlite to bainite/matensite. Ferrite is a kind of soft phase that with high uniform elongation, therefor, multi phases(ferrite/bainite or matensite) can play combination roles to modify the strength and ductility. Although, the strength of multi phase steel would be decreased by volume fraction of ferrite, the multi scale precipitates could strengthen either ferrite or bainite/matersite. In this paper, a multi phase and multi scale precipitation controlled steel was designed, the process of how to control the multi phase and multi scale precipitate will be introduced and the excellent properties of such high performance steel will be revealed.

10:20 AM Invited
A Coupled Thermodynamics-Genetic Algorithm Approach For the Design of High Strength Stainless Steels: *Sybrand Van Der Zwaag*[1]; Wei Xu[1]; [1]Technical University Delft

Up to recently the design of advanced (stainless) steels proceeded via an emperical route. In this work we present an coupled thermodynamic - genetic algorithm approach to the design of precipitation hardened martensitic stainless steels. In this alloy design process not only the formation of a maximum amount of desirable precipitates but also the absence of detrimental phases is taken into account. The model can handle a simultaneous optimisation of alloy composition and heat treatment temperatures. Finally,by adding a cost factor to the various alloying elements the most optimal solution to a low cost high strength stainless steel grade can be determined.

10:50 AM
Material Design and Prediction of Deformation Response of Stainless Twinning Induced Plasticity Steels: *Linda Mosecker*[1]; Alireza Saeed-Akbari[1]; Wolfgang Bleck[1]; [1]Department of Ferrous Metallurgy RWTH Aachen University

The high-manganese (HM) twinning induced plasticity (TWIP) steels offer excellent mechanical properties applicable to auto industries due to high energy absorption and excellent strain hardening behavior. Nevertheless, the application of conventional austenitic stainless steels in auto industries with similar mechanical properties and deformation mechanisms to HM-TWIP steels is limited mainly due to the higher costs of the alloyed nickel. Therefore, the replacement of nickel by manganese has been found advantageous to achieve an attractive property/cost balance. In the present study, a CALPHAD-based methodology using the sublattice model was employed to develop mechanism maps by which the activation/suppression of deformation induced mechanisms was predicted. In addition, the accuracy of the developed maps was investigated by checking the deformation response of experimental and published results on Fe-Cr-Mn-N-(C) steels. The given strategy supplies critical information for the material design of stainless TWIP steels on the basis of a thermodynamic approach.

11:10 AM
Materials Design Over the Decades, How Far Have We Come?: *Charles Kuehmann*[1]; Herng-Jeng Jou[1]; Jason Sebastian[1]; Chris Kern[1]; [1]QuesTek Innovations LLC

Computational materials design methods have been in development since the 80's as computational tools, approaches and systems have emerged. Early examples were established within the Steel Research Group/Northwestern University, focused on steel alloys due to the comparative wealth of data and model development available, focused, in large part, on absolute performance enhancements over incumbent alloys. Through the last two decades of technical maturity, these methods are now being applied to more diverse systems, with designs additionally focused on lower cost, enhanced reliability and minimized process variation. An example of this is the ultra-high-strength, ultra-high toughness Ferrium M54 steel, designed, protoyped, scaled to commercial production and completed an AMS specification, in less than 4 years for the Navy by QuesTek Innovations LLC. Accelerated Insertion of Materials (AIM) techniques forecast probabilistic property minimums expected from manufacturing capabilities. Modeling capability is being applied to accelerate the implementation and qualification of M54 in flight critical components for aircraft.

11:30 AM
Formation and Morphology Control of TCP σ Phase in Austenitic Heat Resistant Steels: *Harumi Inatomi*[1]; Masao Takeyama[1]; [1]Tokyo Institute of Technology

σ phase is considered as detrimental phase in the austenitic heat resistant steels, but it could be a promising strengthener for long-term creep strength if the precipitation kinetics and morphology are appropriately controlled, just like Laves phase. In this study, formation process of σ phase in fcc γ phase in the carbon-free Fe-Cr-Ni alloys has been examined at 1073 K. The σ phase forms through the transformation from non-equilibrium bcc α phase with higher Cr content (α-Cr) precipitated prior at γ grain boundaries, and the precipitation kinetics of the σ phase in the γ matrix is sluggish. The kinetics of the σ phase formation becomes further sluggish when formation of the α-Cr phase is suppressed. The morphology of σ phase, thus, can be controlled through the precipitation kinetics of the prior α phase in γ matrix. Some of the examples of the σ phase morphology will be presented.

11:50 AM
Changes of Work-Hardening-Rate in Advanced High Strength Austenitic Steels by the Applied Deformation and Material Parameters: *Alireza Saeed-Akbari*[1]; Wolfgang Bleck[1]; [1]RWTH Aachen University

The recently developed high-strength austenitic steels within Fe-Mn-C and Fe-Mn-Al-C systems offer superior strain hardening behavior due to the activation of mechanisms like mechanical twinning, deformation-induced martensite formation, and planar dislocation glide. In the present work, variations in the work-hardening-rate diagrams of austenitic high-manganese steels are studied by changing parameters like grain-size-distribution, applied strain rate, temperature, chemical composition, and finally SFE. In addition, different scenarios are reviewed where changing one parameter by keeping others as constant values are shown to make certain alterations in the strain hardening behavior of these materials. The given discussions make it possible to predict the materials response across an extensive range of applied deformation parameters in high-manganese iron-based systems to facilitate the materials design/selection process.

Materials in Clean Power Systems VII: Clean Coal-, Hydrogen Based-Technologies, and Fuel Cells: Fuel Cells

Fuel Flexibility and Microstructural Change in Anode during Operation of Solid Oxide Fuel Cells: *Koichi Eguchi*[1]; Hiroki Muroyama[1]; Toshiaki Matsui[1]; [1]Kyoto University

The durability and reliability of solid oxide fuel cells need to be improved before the commercialization. Nickel- yttria-stabilized zirconia (YSZ) cermet is widely used as an anode in SOFCs. The fuel cells are often deteriorated with concentrated hydrocarbon or steam at elevated temperatures. In this study, then, the microstructural change in cell components with an elapsed time was quantified by the FIB–SEM technique to elucidate the degradation of anode. Carbon deposition was sometimes observed with a supply of hydrocarbon fuels to the anode. Morphology and type of carbon were affected by the deposition condition. The degradation behavior was significantly dependent on the fuel humidity and cermet composition. When H2 fuel with concentrated H2O was supplied to the anode, the current density decreased gradually soon after the discharge, followed by a sudden drop in current density.

9:00 AM
Study of Microstructure and Electrical Conductivity on (Ce0.9Nd0.1)1-xMxO2-Δ Electrolytes for Intermediate-Temperature Solid Oxide Fuel Cells: *Fanzhi Meng*[1]; N. Trubaki[1]; Defeng Zhou[2]; Yanjie Xia[3]; Jian Meng[3]; [1]University of Toyama; [2]Changchun Technology of University; [3]Changchun Institute of Applied Chemistry, Chinese Academy of Sciences

The Ce0.8Nd0.2O2 with doped MoO3 was prepared through modified sol-gel method. The ionic conductivity was studied in air using an impedance spectroscopy. The results showed that the MoO3 can form a thin amorphous film around particles, which reduces the interparticle friction, and increases the contact area of particles in a compact solid. And this promotes mass diffusivity in the matrix. This leads to the further increase in densification and decrease in the volume fraction of grain boundary. The total and grain boundary conductivity gradually increases due to the decrease of the grain boundary resistance. It shows that the sample Ce0.8Nd0.2O2 with doped MoO3 has the higher ionic conductivity ($\sigma t=4.33\times10^{-3}$ S.cm^{-1}, $\sigma gb=5.06\times10^{-3}$ S.cm^{-1}) at 600°C. It is obvious that total conductivity enhances one point five times than the sample without MoO3 doping. The MoO3 dopants are the perfect sintering promoter for the NDC system.

9:20 AM Invited
Thermal Stability and Structural Evolution of LSM/YSZ Composite Cathode for SOFC by In-Situ Neutron Diffraction: *Ke An*[1]; Ling Yang[1]; Rebecca Mills[1]; Lu Cai[1]; [1]Oak Ridge National Laboratory

Lanthanum-strontium-manganese oxides (LSM) and yttria-stabilized zirconia (YSZ) are widely used as cathode and electrolyte for solid oxide fuel cells (SOFCs). Thermal stability and reliability of LSM/YSZ heavily depends on the concentration of Y2O3. Therefore, it is obvious to understand the degradation of ionic conductivity by studying LSM/YSZs' structural/phase evolution at elevated temperature. Neutron scattering is superior for this purpose because the large cross-section of all components makes it possible to differentiate different phases and to derive the structural evolution during annealing by Rietveld refinement. On VULCAN instrument at the world most intense pulse based Spallation Neutron Source, a series of LSM/YSZs of 6-10% Y2O3 were heated up to 1500°C at 2C/min, meanwhile simultaneous in-situ neutron diffraction and electrochemical impedance spectroscopy were measured to correlate the structural/phase change to electrochemical degradation. The thermal stability and the structural evolution of the LSM/YSZs at elevated temperatures will be presented.

9:50 AM
Relationship between Cathode Performance and Impurity Concentration for Solid Oxide Fuel Cells: *Teruhisa Horita*[1]; DoHyung Cho[1]; FangFang Wang[1]; Taro Shimonosono[1]; Haruo Kishimoto[1]; Katsuhiko Yamaji[1]; Manuel Brito[1]; Harumi Yokokawa[1]; [1]AIST

Impurities coming from gases can deposit and react with cell components in Solid Oxide Fuel Cells (SOFCs). Especially, chromium and sulfur poisonings are the critical issues for long-term operation. The chromium vapors (CrO3 etc.) can deposit on the porous cathodes and they are reduced to Cr2O3 at the electrochemically active sites. To relational the Cr deposition and electrochemical degradation at cathodes, we have determined the Cr concentration in cathodes by using Secondary Ion Mass Spectrometry (SIMS). From the cathode degradation tests under Cr vapor supply, it was found that the electrochemical active sites were high Cr-concentration, and the degradation trends were different among different cathodes. The sulfur poisoning test was also examined at several candidate cathodes. Cathodes were exposed to dilute SO2 and the cathode performance was examined for long-term operation. It was found that the poisoning proceeded from the cathode surface and morphological change affected the performance.

10:10 AM Break

10:20 AM
Possibility of Metal Film Supported Electrolyte for Proton-SOFC: *Kenichi Kawamura*[1]; Taku Kitahara[1]; Shun Kawamura[1]; Mitsutoshi Ueda[1]; Toshio Maruyama[1]; [1]Tokyo Institute of Technology

In operation of proton-type SOFC, the electrolyte conducts not only proton but also oxide ion. When dense metal used as anode, H2O might be produced at the interface between anode and electrolyte and destroy the electrolyte. In this presentation, I will shows the oxygen permeability of Sr(Ce,Y)O3 and Pd-CeO2 composite and evaluate the possibility of p-SOFC with metal film anode.

10:40 AM
Advanced Conductive Coating Performance at the Long-Term SOFC Operating Condition: *Jung Pyung Choi*[1]; Jeffry Stevenson[1]; Scott Ryan[1]; Matt Chou[1]; Gordon Xia[1]; [1]Pacific Northwest National Laboratory

From the cost and long term performance with safety, metal supported planar SOFC is considering as best design. The ferritic stainless steel interconnects are generally used, due to their low-cost, chromia scale-forming behavior, and good thermal expansion match to other stack components. However, volatile Cr-containing species, which originate from the oxide scale, can poison the cathode material in the cells and subsequently cause power deterioration in the device. MnCo spinel coating has been developed for preventing cathode poisoning. This paper will summarize development of coating method and optimization of the advanced MnCoO spinel material using design of experiment methodology with Taguchi and ANOVA analysis. Then, observed the thickness effect on electrical conductivity with long-term test. The results of this work demonstrate the possibility of automated mass production of dense conductive spinel-coated interconnect materials.

11:00 AM
Transition Metal Doping of Manganese Cobalt Spinel Oxides for Coating SOFC Interconnects: *Jeffrey Fergus*[1]; Yingjia Liu[1]; Jason Ganley[1]; Dileep Chakkathara Janardhanan Nair[1]; William Tilson[1]; Adam Dekich[1]; [1]Auburn University

Manganese cobalt spinel oxide coatings have been shown to be effective for preventing chromium volatilization for interconnect alloys, and the associated cathode poisoning, in solid oxide fuel cells. During high temperature exposure a reaction layer consisting of chromium-containing spinel forms due to reaction with the chromia scale formed on the alloy. The electrical conductivity of this reaction layer is much lower than that of the coating material and thus can increase the overall area specific resistance (ASR) of the system. The approaches to reducing the ASR are to reduce the thickness and/or increase the electrical conductivity of the reaction layer, which includes both the high-chromium spinel phase and the chromia scale. In this paper the effects of transition metal dopants on the amount and properties of reaction products formed during the reaction of spinel oxide coating materials with chromia are presented.

11:20 AM
The Effect of Cerium Oxide Nanoparticle Oxidation State on the Degradation Mitigation of 1100 EW Nafion® Composite Membranes: *Benjamin Pearman*[1]; Nahid Mohajeri[1]; Darlene Slattery[1]; Len Bonville[1]; Diego Diaz[1]; Sudipta Seal[2]; Michael Hampton[2]; [1]Florida Solar Energy Center - UCF; [2]University of Cental Florida

During operation, polymer electrolyte membranes used in hydrogen fuel cells degrade, causing a decline in their long-term performance which can ultimately result in catastrophic membrane failure. The membranes' exposure to radicals, thought to be formed from hydrogen peroxide, is considered the origin of this chemical degradation. To inhibit the destructive effect of these radicals, the addition of chemical mitigators to membranes has been proposed. Cerium oxide, a compound well-known for its ability to easily switch back and forth between its Ce(III) and Ce(IV) oxidation states, shows radical scavenging behavior that is dependent on the initial ratio of those two oxidation states.In this work,

TUESDAY AM

cerium oxide nanoparticles, of various concentrations were added to 1100 EW Nafion® membranes and subjected to degradation experiments, such as liquid Fenton tests, gaseous Fenton tests and accelerated durability runs. The effect of the Ce(III)/Ce(IV) ratio of the nanoparticles on the improved membrane stability was analyzed.

11:40 AM

The Electrochemical Properties of TiAlCrN Coated Stainless Steel with PEMFC Environment: *Min-Seok Moon*[1]; Kee-Do Woo[2]; Myung-Han Yoo[3]; Shin-Jae Kang[4]; Joon-Hyuk Song[3]; [1]Chonbuk National University, Jeonju Institute of Machinery Carbon Composites; [2]Chonbuk National University; [3]Jeonju Institute of Machinery and Carbon composites; [4]Chonbuk National University, Jeonju Institute of Machinery and Carbon composite

Recently, new energy sources have gained expectation due to hiking oil prices and limits on reserves of fossil fuels. However, increasing global warming and air pollution due to using the fossil fuels have been emerged as social issues. The TiAlCrN coating on STS is not applied to develop the advanced metallic bipolar plate for PEMFC. It will be expected to improve the corrosion resistance on PEMFC environment. The aim of this investigation is to develop the cheap metallic bipolar plate coated with TiAlCrN. The mechanical and electrochemical properties of the TiAlCrN coated specimens were measured. The TiAlCrN coated STS304 has better fuel cell performance such as corrosion resistance, ICP and ICR than other experiment materials, except single cell durability. TiAlCrN coated specimen has been satisfied electrochemical property for DOE target.

8:30 AM

New Developments in Lorentz Force Velocimetry: *Andre Thess*[1]; Yurii Kolesnikov[1]; Christian Karcher[1]; Rico Klein[1]; Michael Gramss[1]; Dandan Jian[1]; Christiane Heinicke[1]; André Wegfrass[1]; Christian Resagk[1]; Xiaodong Wang[1]; Thomas Boeck[1]; Thomas Froehlich[1]; Falko Hilbrunner[1]; Christian Diethold[1]; Ilko Rahneberg[1]; Michael Werner[1]; Bernd Halbedel[1]; [1]TU Ilmenau

Lorentz force velocimetry (LFV) a non-contact technique for velocity measurement in electrically conducting fluids. This technique is based on exposing the fluid to a magnetic field and measuring the force acting upon the magnetic-field-generating system. In the present communication we will describe the physical principles of LFV and report results of recent developments aiming both at a better understanding of the fundamental aspects of LFV and the development of new applications. The survey will include results of the application of LFV to local velocity measurement, calibration of Lorentz force flowmeters for application in secondary aluminium industry, time-of-flight LFV as well as the application of LFV to the measurement of velocities in poorly conducting fluids. Acknowledgment: The work is supported by the German Research Foundation (DFG) as a Research Training Group “Lorentz force velocimetry and Lorentz force eddy current testing”

8:55 AM

Non-Contact Measurements in Liquid Metal Free-Surface Flow Using Time-of-Flight Lorentz Force Velocimetry: *Dandan Jian*[1]; Christian Karcher[1]; [1]TU Ilmenau

Surface velocity measurement is a big challenge in metallurgy. Due to chemical aggressiveness of metal melts at high temperature, only non-contact measurement techniques can be applied. One of such techniques is Lorentz force velocimetry (LFV). It is based on the measurement of the Lorentz force acting on a magnet system. This force is proportional to the flowrate or local velocity and the electrical conductivity of the melt. We present a series of model experiments that demonstrate the feasibility of using an arrangement of two identical measuring devices called Lorentz force flowmeters, termed time-of-flight technique. In this case the free-surface velocity may be purely determined by cross-correlating the two force signals of the two flowmeters. In a first experiment we measure free-surface velocities using GaInSn as a low-melting model melt.

9:20 AM

Microstructure and Mechanical Properties of Friction Stir Welding Zone in SS400(SPHC) Plate: *Kwang-jin Lee*[1]; Sang-Hyuk Kim[1]; Ik-Hyun Oh[1]; Kee-Do Woo[2]; [1]Korea Institute of Industrial Technology; [2]Chonbuk National University

Conventional fusion welding of the most metallic materials produces to defects such as porosity, created metallic compound. However, solid state joining processes as friction stir welding don’t form weld pool. Consequently, the defects decrease remarkably and mechanical properties improve in general welding. So, The FSW is a potential candidate for the joining of dissimilar and high melting temperature materials. However, to apply FSW in high melting temperature materials such as steel or Ti alloys etc., the tool with super heat-resisting and abrasion resistance is needed. So, Spark plasma sintering method was selected to fabricate tool material using WC powder. FSW was carried out by 600rpm of tool rotation and 420mm/min of travel speed. Microstructure of the welding zone was precisely investigated by using OM, SEM and TEM. Vickers-hardness, tensile test and impact test were carried out to analyze the mechanical properties of the joint.

9:45 AM

Modeling of Pulsed-Laser Superalloy Powder Deposition Using Moving Distributed Heat Source: *Manas Mahapatra*[1]; Leijun Li[2]; [1]Indian Institute of Technology Roorkee; [2]Utah State University

A three-dimensional finite element model with moving heat source was developed for pulsed-laser powder deposition process. Experiments were conducted to study the repairing of superalloy components using the PLPD process. During the experiments, IN 625 powder was deposited on superalloy substrate similar to IN 738. The process was modeled using three-dimensional finite element analysis. Element birth and death technique was used in the finite element model for simulating the deposition of powder layer on the substrate. Moving distributed heat source was used in the thermal model for realistic simulation of the process. Temperature dependent thermal material properties including enthalpy were used for the powder and the substrate in the transient thermal analyses. The fusion zones and peak temperature distributions of the deposits were predicted from the transient thermal analyses.

10:10 AM

Heat Transfer Characteristics of Magnetite under Microwave Irradiation: *Zhiwei Peng*[1]; Jiann-Yang Hwang[1]; Matthew Andriese[1]; Zheng Zhang[1]; Xiaodi Huang[1]; [1]Michigan Technological University

A simplified finite-difference time-domain (FDTD) algorithm for modeling microwave propagation in magnetic dielectric materials was developed and employed to study the microwave dissipation in magnetite. Heat transfer during microwave heating of magnetite was subsequently investigated by solving heat transfer differential equation using explicit finite-difference (EFD) method. It is observed that temperature of magnetite surface increases rapidly in the first minute due to the rapid strength decays in both electric and magnetic fields within a short distance along the path of microwave dissipation. A temperature peak, initially formed at the surface of the sample slab, migrates inward as heating time extends and microwave power increases.

10:35 AM Break

10:50 AM
Effect of Microwave Curing on GFRP Composites: *T Srinath*[1]; P Martin Jebaraj[1]; Rajaiah K[1]; [1]Dr. Ambedkar Institute of Technology

Optimizing matrix for preparation of composites Manufacturing by lay-up and rolling with curing methods namely room temperature, microwave and analysis by Matrix Digestion Test is undertaken in this work. Microwave curing was done on several fluids like water, milk and SAE 90 grade oil. Later resin was tried out at different time intervals. Lay-up specimens were tried for curing in both methods. Except for mat, other specimens showed right response for curing. Rolled specimens cures faster as compared to hand lay-up specimens. This is due to the right compaction which goes into the rolled specimen. Microwave curing initiates at micro level and the results indicate this trend with roving performing better in rolling and electron beam curing than fabric which is denser thereby implying that the wetting of individual strands of glass fiber is a must for proper bonding and thereby faster curing.

11:15 AM
Experimental and Numerical Approach for Surface Finish during Laser Machining of Alumina: *Hitesh Vora*[1]; Sameer Paital[1]; Sandip Harimkar[2]; Sandra Boetcher[1]; Narendra Dahotre[1]; [1]University of North Texas; [2]Oklahoma State University

High energy infrared lasers have popularly emerged as a potential tool for bulk material removal of structural ceramics. Despite of having this popularity the actual implementation of this technology is not making inroads into actual application due to the undesirable surface finish generated during laser machining. Addressing this issue via multiphysics modeling and thereby controlling the surface finish by selection of appropriate laser processing parameters is discussed herein. In the current study, the machining of alumina is investigated by using a JK 701 pulsed Nd:YAG laser. The surface roughness of the machined surfaces was characterized using an optical profilometer. A finite element model is developed using COMSOL(TM)multiphysics to understand the influence of physical phenomena such as recoil pressure, Marangoni convection, surface tension, and cooling rates over the surface morphology of alumina and eventually establish the relationship between the surface finish and process parameters of laser machining.

11:40 AM
Refinement Effect of Pulse Magneto-Oscillation on Solidification Structure of Medium Carbon Steel: *Yufeng Cheng*[1]; Zhengxin Yin[1]; Xin Cao[1]; Yongyong Gong[1]; Renxing Li[1]; Qijie Zhai[1]; [1]Shanghai University

This paper investigated the refinement effect of pulse magnet-oscillation (PMO) on the solidification structures of medium carbon steel S45C in metal mould. The induction coil was positioned at the middle of ingot. The results showed that solidification structure of the treated ingot was remarkable modified, forming a large volume of fine globular grains comparing with the untreated ingot. Further experimental investigation and theoretical analysis demonstrated that the reason for grain refinement of solidification structure was that PMO promoted nucleation near mould walls and agitated nuclei into the melt, eventually leading to a transition from columnar crystal to equiaxed crystal.

12:05 PM
Research on Solidification Structure Refinement of SUS430 Ferritic Stainless Steel by Electric Current Pulse: *Xin Cao*[1]; Zhenxing Yin[1]; Yufeng Cheng[1]; Renxing Li[1]; Yongyong Gong[1]; Qijie Zhai[1]; [1]Shanghai University

The influence of electric current pulse (ECP) on the solidification structure of SUS430 ferritic stainless steel (FSS), which is widely used on behalf of the excellent properties and relatively low cost, has been investigated. The parallel electrodes were inserted into the free melt surface to constitute a current loop. The different influences of three parameters on solidification structure were studied by changing the peak current value, frequency and treating time respectively. The results indicated that the ECP significantly increased the number of equiaxed grains of SUS430 FSS. The as-cast structure without ECP treating was almost wholly columnar, while the number of equiaxed grains of the specimen, which was treated 3min with a peak current of 400kIA, increased to 2698 in the observed surface. To get the best refinement, an optimum range of these three parameters is required and the peak current value plays the most important role.

Ground-Based Studies of the Structure and Properties of High Temperature Liquids for Upcoming ISS Experiments: *Ken Kelton*[1]; [1]Washington University

Studies of electrostatically-levitated supercooled liquids have demonstrated strong short- and medium-range ordering in transition metal and alloy liquids, which can influence phase transitions like crystal nucleation and the glass transition. It is also related to the liquid properties. In well ordered liquids, for example, we recently demonstrated local maxima in the expansivity of liquids that form bulk glasses and a specific heat maximum at a temperature above the glass transition temperature in a Zr58.5Nb2.8Cu15.6Ni12.8Al10.3 liquid (Vit 106a). Planned ISS experiments will allow a deeper investigation of these results as well as the first investigations of a new type of coupling in crystal nucleation in primary crystallizing liquids, resulting from a linking of the stochastic processes of diffusion linking with interfacial-attachment. Select ground-based studies and the planned ISS investigations will be discussed. Supported by NASA (NNX07AK27G & NNX10AU19G) and the National Science Foundation (DMR-08-56199).

9:05 AM Invited
Thermophysical Properties Measurement of High-Temperature Liquids under Microgravity Conditions in Controlled Atmospheric Conditions: *Masahito Watanabe*[1]; Shumpei Ozawa[2]; Akitoshi Mizuno[1]; Taketoshi Hibiya[3]; Hiroya Kawauchi[1]; Kentaro Murai[1]; Suguru Takahashi[2]; [1]Gakushuin University; [2]Tokyo Metropolitan University; [3]Keio University

Microgravity conditions have advantages of measurement of surface tension and viscosity of metallic liquids by the oscillating drop method with an electromagnetic levitation (EML) device. We are planning measurements of the surface tension and viscosity in ISS using MSL-EML facilities developed by ESA under the controlled oxygen partial pressure conditions. The measurements will be performed by the international collaboration team including our science team. For the preparation of ISS experiments, we performed the precise observation of surface oscillations of levitated metals liquids by on-board flight experiments under the controlled oxygen partial pressure. These measurements were also performed with the change of currents to coils in order to detect the difference of surface oscillation frequency and dumping time by the electromagnetic force. Base on the present result, we discuss about the improvement of the analysis of surface oscillations to obtain the surface tension and the viscosity for precisely measurements in ISS.

9:40 AM
Microgravity Research on Bulk Metallic Glasses and Composites: *Douglas Hofmann*[1]; [1]NASA JPL/Caltech

Bulk metallic glasses (BMGs) are a novel class of amorphous metals which were developed by the Caltech group during microgravity flights on the Space Shuttle and International Space Station under NASA's Microgravity Research Program. The development of these alloys lead to a commercial industry for BMGs including applications such as golf clubs and cell phone cases, among many others. Recent efforts have focused on the development of BMG composites; metal matrix composites reinforced with a ductile phase to improve ductility and fracture toughness. This talk focuses on the study of these alloys under the current NASA ESMD program. A discussion about processing BMG composites in the semi-solid region, along with experimental data obtained using the JPL/Caltech electrostatic levitation platform will be presented. These amorphous materials offer not only a chance to do interesting microgravity science, but also an opportunity to contribute to a wide range of NASA spaceflight hardware.

Detachment of Tertiary Dendrite Arms during Controlled Directional Solidification in Aluminum – 7 wt% Silicon Alloys: Observations from Ground-based and Microgravity Processed Samples: *Richard Grugel*[1]; Robert Erdmann[2]; James Van Hoose[3]; Surendra Tewari[4]; David Poirier[2]; [1]Marshall Space Flight Center; [2]University of Arizona; [3]Qualis/Jacobs; [4]Cleveland State University

Electron Back Scattered Diffraction results from cross-sections of directionally solidified aluminum – 7wt% silicon alloys unexpectedly revealed tertiary dendrite arms that were detached and mis-oriented from their parent arm. More surprisingly, the same phenomenon was observed in a sample similarly processed in the quiescent microgravity environment aboard the International Space Station (ISS) in support of the joint US-European MICAST investigation. The work presented here includes a brief introduction to MICAST and the directional solidification facilities, and their capabilities, available aboard the ISS. Results from the ground-based and microgravity processed samples are compared and possible mechanisms for the observed tertiary arm detachment are suggested.

10:55 AM
Microstructure Formations in the Two Phase Region of the Binary Peritectic Organic System TRIS-NPG: *Andreas Ludwig*[1]; Johann Mogeritsch[1]; [1]University of Leoben, Dep. Metallurgy

In order to prepare for an onboard experiment on ISS on isothermal coupled peritectic growth (PCG), systematic directional solidification experiments were done with TRIS-NPG organic peritectic alloys. It turned out that under specific conditions isothermal PCG were obtained for alloys within the hypo-peritectic region either by (i) reducing the growth velocity from above the critical value for morphological stability of both solid phases to a value below, or by (ii) long-time growing with a constant velocity below the critical value for morphological stability of both solid phases. The later happens via island banding, where nucleation and lateral growth of the peritectic phase compete with growth of the primary phase. Interphase spacings and the widths of alpha and beta lamellae were measured as function of growth velocity for a fixed composition and as function of composition for a fix growth velocity.

11:20 AM
Thermodynamics of Metal-Gas Eutectic Solidification and Potential Effects of Gravity on Microstructural Evolution: *Douglas Swenson*[1]; Paul Sanders[1]; Amber Lifer[1]; Helen Ranck[1]; [1]Michigan Technological University

Porous metals may be fabricated by saturating the metal liquid with a soluble gas species, followed by solidification during which the gas comes back out of solution. Under appropriate solidification conditions, cooperative growth of solid metal and aligned, tubular gas pores occurs. Additionally, it is possible to tailor the microstructure by changing processing conditions, such as by introducing an insoluble gas species that increases the total pressure and affects the volume fraction of pores. In the literature, there is no complete thermodynamic description of such a process. Here, such a description is presented, showing explicitly the effects of both inert and soluble gases on corresponding phase equilibria and porosity of metal-gas systems. The analysis is applied to several common metal-hydrogen systems, based on available literature data. Finally, potential effects of gravity upon microstructural development are discussed.

11:45 AM
Three-Dimensional Phase Field Modeling of Directional Solidification under Microgravity Conditions with Quantitative Experimental Comparison: *Damien Tourret*[1]; Alain Karma[1]; Rohit Trivedi[2]; Bernard Billia[3]; Nathalie Bergeon[3]; Jean-Marc Debierre[3]; Rahma Guerin[3]; [1]Northeastern University; [2]Iowa State University; [3]Institut Matériaux Microélectronique Nanosciences de Provence, UMR CNRS 6242

We present the first quantitative comparison of three-dimensional phase-field simulations with solid/liquid interface dynamics observed during directional solidification of succinonitrile (SCN)-camphor alloys conducted on the International Space Station. A massively parallel implementation of a quantitative phase-field model on Graphics Processing Units (GPU) is used to simulate large systems of many cells in 3D on experimentally relevant length and time scales. The simulations reproduce an experimentally observed oscillatory mode of cellular hexagonal array structure and show excellent agreement with observed behaviors, such as: (i) the period of the oscillations, (ii) a coordinated motion of three groups of cells of the hexagonal array structure and (iii) tip splitting events, enabling the adjustment of the average cell spacing. Microgravity was crucial in uncovering this oscillatory behavior, normally altered by convection effects under terrestrial conditions. Ongoing work focuses on understanding the mechanism of oscillations and the influence of the array structure and growth parameters.

Mechanical Behavior at Nanoscale I: Deformation Mechanisms at Nanoscale

Shear Banding Mechanism in Nano-Twinned Cu–Al Alloy: C.S. Hong[1]; N.R. Tao[1]; X.X. Huang[2]; *K. Lu*[1]; [1]Chinese Academy of Sciences; [2]Riso National Lab

Microstructural evolution during shear banding in a nano-twinned Cu–Al alloy processed by means of dynamic plastic deformation was investigated using TEM and high-resolution TEM. The development of a shear band was found to include a nucleation stage followed by thickening. The nucleation consists of initiation of localized deformation, evolution of a dislocation structure, and transformation of the detwinned dislocation structure into a nano-grained structure. Increasing shear strains leads to thickening of shear bands at the expense of the adjoining twin/matrix lamellae, of which the mechanism is carefully characterized. Grain sizes in the well-developed shear bands are found to be obviously larger than the original twin thickness. Experimental observations will be analyzed in comparison with computational simulations.

9:00 AM Invited
Stochastic Effects in Deformation and Fracture of Nanowires: Andreas Sedlmayr[1]; Reiner Mönig[1]; Steven Boles[1]; Gunther Richter[2]; *Oliver Kraft*[1]; [1]KIT; [2]Max-Planck-Institut für Intelligente Systeme

In several studies, nanowires made of different materials with thickness of 100 nm and below were found to have strength of the order of the theoretical strength of the respective material. It has been argued that this relates to a more or less defect free state of the nanowires after fabrication. In this paper, we present tensile tests on nanowires inside a dual beam SEM/FIB. In Au nanowires, significant amounts of plasticity at high stresses in excess of 1GPa were found. The recorded data show a weak size dependence with a large scatter in the strength values. Different modes of failure were observed which include twinning as confirmed by EBSD indicating activity of partial dislocations. However, the scatter in the strength data suggests that nucleation of partial dislocations occurs at imperfections at the nanowire surface. These observations are discussed considering a weakest-link approach for describing the statistical effects.

9:30 AM
Plasticity in BCC Pillars Observed In-Situ by Laue Diffraction: *Helena Van Swygenhoven*[1]; Julien Zimmermann[1]; Cecile Marichal[1]; Steven Van Petegem[1]; [1]Paul Scherrer Institute

In-situ Laue diffraction is applied on bcc pillars, with the aim to understand the difference in size effect between bcc and fcc single crystals. Mo pillars obtained from a directionally solidified NiAl-Mo eutectic were investigated in the as-grown, in the 11% pre-strained conditions, and after FIB milling. Careful analysis of the diffraction patterns show that the diffraction peaks move initially along a rotation direction corresponding to slip on (1 1 2) plane with streaking along a [1 1 1] direction, the choice of the (112) plane being influenced by pre-existing strain gradients. A similar analysis is performed on W single crystal pillars, a material with a much higher Tc. The Laue diffraction analyses are complemented by SEM slip trace and TEM dislocation analysis. The slip behavior of single bcc pillars is discussed in terms of Tc, the role of FIB damage and the initial presence of dislocations due to pre-straining.

9:50 AM
Discrete Plastic Deformation in Gold Nanowires: *Scott Mao*[1]; He Zheng[1]; Christopher R. Weinberger[2]; Jianyu Huang[2]; [1]University of Pittsburgh; [2]Sandia National Lab

Through in-situ HRTEM observations, we show that the tensile deformation behavior of sub-ten-nanometer Au nanocrystals is drastically different from that of the bulk counterpart. In sharp contrast to the scenario that plasticity is mediated by dislocation emission from Frank-Read sources and multiplication in bulk materials, partial dislocations emitted from free surfaces, which produce fresh surface steps after they annihilate at the free surfaces, dominate the deformation of Au nanocrystals. Stress-relief caused by the surface-mediated plastic deformation is directly visualized. Additionally, these experiments verify that the crystallographic orientation (Schmid factor) is not the only factor in determining the deformation mechanism of nanometer-sized Au. After failure, the Au nanocrystal shows a phase transformation from face-centered-cubic (FCC) to body-centered-tetragonal (BCT) structure. The transformation is facilitated by surface stresses, which are able to drive the <001> crystal along the Bain path from FCC to BCT.

Deformation Mechanisms in Small Scale Al: An In-Situ TEM Study: *Frederic Mompiou*[1]; [1]CEMES-CNRS

Metals with reduced dimensions demonstrate a clear trend of strengths that scale as a power-law of their size. Because both dislocation nucleation and motion are constrained in these materials, alternate plasticity mechanisms are expected.In sub-micron monocrystalline Al fibers, where the initial dislocation microstructure is well characterized, we have shown, using in-situ TEM, that the multiplication of dislocations through spiral sources directly causes an increase of the yield stress as the fiber section is reduced. This situation contrast with the brittle behavior of fibers containing no or few initial defects. These observations and measurements bridge the gap between strength of whiskers and the strengthening of micropillars with size. In nanocrystalline and UFG Al, dislocation mechanisms can be shut down in specific conditions. We have found that the coupling of the grain boundary migration with stress can be an efficient deformation process. The strain produced can be measured and tentatively modeled.

10:50 AM Invited
Stochastic Behavior of Dislocation Nucleation in Solids with Defects: *David Bahr*[1]; Yoonkap Kim[1]; Christine Joseph[1]; Benjamin Revard[1]; Iman Salehinia[1]; [1]Washington State University

Examining the onset of plasticity in small volumes of materials using nanoindentation requires consideration of two size scales; that of the indenter (and hence stress fields and gradients) and that of the spatial variation in defect location. In this study we examine the effect of vacancies, solid solution impurities, and defects generated by FIB damage on the onset of plasticity in FCC, BCC, and HCP metals. In general the distribution of yield points suggests that multiple defects often control the measured range of incipient plasticity. In most of these systems we are able to also distinguish yield event that correspond to non-uniform deformation processes but are clearly not dislocation nucleation. Using a combination of tip radius and loading rate variation and composition variation it is shown that extremes in yield conditions are likely controlled by defect position relative to the tip size.

11:20 AM
Nanovoid Generation and Growth in Metals: Dislocation Mechanisms: *Marc Meyers*[1]; Yizhe Tang[1]; Eduardo Bringa[2]; Bruce Remington[3]; [1]University of California, San Diego; [2]Univ. Nac.Cuyo; [3]Lawrence Livermore National Laboratory

The cooperative emission of shear loops creates the geometrically necessary dislocations responsible for the generation and growth of nanovoids in FCC and BCC metals. The extremities of the dislocation shear loops remain attached to the void surface. In copper, partial dislocation loops generate extended stacking faults that impede cross slip. In tantalum, prismatic loops can form by reaction of multiple shear loops sharing the same <111> slip direction, or by cross slip of the two screw components of a single shear loop in different slip planes. Twinning can also occur. The effect of void-size on the initiation stress was found to be significant. The defect nucleation stress decreases with increasing void size (up to 30 nm radius void in tantalum). This void-size dependent plasticity is also modeled based on dislocation mechanics, and a good agreement is found. In real metals, there is a hierarchy of defects giving rise to voids.

11:40 AM
Deriving Deformation Mechanisms in Nanocrystalline AuCu Thin Films from *in situ* Synchrotron-Based XRD and SEM Tensile Tests: *Jochen Lohmiller*[1]; Patric Gruber[1]; Ralph Spolenak[2]; [1]Karlsruhe Insitute of Technology; [2]ETH Zurich

A prerequisite to exploit the unique combination of high strength and high ductility of nanocrystalline (nc) materials is a thorough understanding of the underlying deformation mechanisms. *In situ* tensile tests were conducted with a synchrotron-based X-ray diffraction setup and in a SEM on nc gold and gold-copper thin films adherent to polymer substrate. The use of compliant substrate enables macroscopically homogeneous and cyclic deformation of the nc films. Shear banding, film fracture and specific deformation texture formation are identified in the comprehensive study and allocated to different stages of deformation. This allows deriving a series of deformation mechanisms dependent on the applied strain. The results also show composition dependent behavior, in which the proneness to localized deformation and texturing is increasing with enhanced copper contents, whereas the most ductile films with no or low copper contents did not crack up to maximum strains of 30%.

12:00 PM
Characterization of Deformation Mechanisms during Cold Rolling of Nanocrystalline Nickel: *Jorg Wiezorek*[1]; Andreas Kulovits[1]; [1]University of Pittsburgh

Microstructural evolution of nanocrystalline Nickel in response to cold rolling has been studied by X-ray diffraction (XRD) and transmission electron microscopy (TEM). Glide of individual dislocations emitted and absorbed by grain boundaries (GB) facilitated the necessary orientation and shape changes of grains. Global and local texture changes during cold deformation were determined by combining XRD and TEM measurements. Grain size changes were monitored quantitatively using a novel computer controlled orientation imaging system in the TEM, which is based on precession illumination. Initially during cold rolling the dislocation-GB interactions alter locally the GB character. High angle GB transform into low angle GB and subsequently dissolve, leading to grain coarsening, e.g. by coalescence. At large thickness reductions, coarsened grains facilitate a deformation mechanism change where grain interior dislocation-dislocation interactions instead of dislocation-GB interactions mainly facilitate plastic deformation inclusive of strain hardening.

12:20 PM
Probing the Relation between Indentation Characteristics and Dislocation Substructure: Lin Li[1]; Myoung-Gyu Lee[2]; *Peter Anderson*[1]; [1]The Ohio State University; [2]POSTECH

Novel indentation studies [1] show that large (>50%) drops in indentation load correlate with major instabilities in dislocation substructures. We study this phenomenon using a finite element based scheme in which an Al grain is discretized into patches ~dislocation cell size. At a critical resolved stress, a cell can spontaneously shear along any of the 12 {111}/<110> slip systems. This imparts a burst of plastic strain that can trigger large multi-cell avalanches. Large experimental load drops are reproduced when the scale of indentation ~ substructure scale and the magnitude of strain burst ~ critical resolved shear stress/elastic shear modulus. For the Al grain, this corresponds to strain bursts of 4 to 8%, equivalent to 4 to 8 dislocations propagating across ~30 nm cells. This study shows how key features of the dislocation substructure are revealed through nanoindentation traces. [1] Minor, AM, et. al., Nature Mater., (2006) 5, 697.

Mechanical Behavior Related to Interface Physics: Microscopic Characterization of Interface Mechanical Response

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Materials Processing and Manufacturing Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Nanomechanical Materials Behavior Committee

Program Organizers: Jian Wang, Los Alamos National Laboratory; Nathan Mara, Los Alamos National Laboratory; Izabela Szlufarska, University of Wisconsin-Madison ; Zhiwei Shan, Xi'an Jiaotong University

Tuesday AM — Room: Oceanic 1
March 13, 2012 — Location: Dolphin Resort

Session Chairs: Andrew Minor, UC Berkeley & LBL; Scott Mao, University of Pittsburgh

8:30 AM Keynote
Understanding Dislocation Interactions with Interfaces: Josh Kacher[1]; Ben Eftink[1]; *Ian Robertson*[1]; [1]University of Illinois

Interfaces serve both as sources and sinks for dislocations. Despite this important role we are still learning about the relationships between dislocations and grain boundaries as well as with interfaces between dissimilar metals, and how the relationships scale dimensionally. For example, coarse-grained copper deforms primarily through dislocation slip. However, in copper-silver eutectic alloys it has been observed that the primary deformation mechanism is deformation twinning, with twinning in copper being driven by that in silver. This talk will emphasize how coupling of electron microscopy techniques, including conventional analysis, time resolved and electron tomography, with computational tools is providing new insight as to how dislocations and deformation twins are generated at and interact with interfaces, and how these interactions affect the mechanical response of the material to deformation.

9:00 AM Keynote
Probing the Origin and Evolution of Strength in Small Volumes with In Situ TEM Nanomechanical Testing: *Andrew Minor*[1]; [1]UC Berkeley & LBL

Recent progress in both in situ and ex situ small-scale mechanical testing methods has greatly improved our understanding of mechanical size effects in volumes from a few nanometers to a few microns. This talk will describe our recent results from in situ TEM compression and tensile testing of FCC, BCC and HCP metals to illuminate the origin of size-dependent yield strength behavior and fundamental deformation structures in nanoscale samples. In addition, comparing in situ compression and tensile testing has led to some interesting observations regarding the evolution of flow strength in nanoscale samples during testing. Lastly, this talk will comment on recent progress related to in situ TEM nanoscale mechanical testing methods and their relevance to bulk mechanical properties.

9:30 AM
Direct Observation of Dislocation Confined Layer Slip in Multilayers: *Nan Li*[1]; Jian Wang[1]; Jianyu Huang[2]; Amit Misra[1]; [1]LANL; [2]Sandia National Lab

Using in situ nanoindentation in a transmission electron microscope (HRTEM), we have studied the confined layer slipping behavior of threading dislocations in Cu/Nb multilayers with individual layer thickness of ~ 20 nm. The observations indicate that Cu-Nb interface can act both as dislocation source and barriers for slip transmission. These findings provide insights in understanding the plastic deformation mechanisms, the high strength, and work hardening of multilayer systems. This project is supported by the DOE, Office of Science,Basic Energy Sciences, Division of Materials Science and Engineering.

9:45 AM
In Situ Observation of Dislocation Assisted Stress Driven Grain Boundary Migration: *Zhangjie Wang*[1]; Zhiwei Shan[1]; Ju Li[2]; Jun Sun[1]; Evan Ma[3]; [1]Center for Advancing Materials Performance from the Nanoscale (CAMP-Nano) & Hysitron Applied Research Center in China (HARCC), State Key Laboratory for Mechanical Behavior of Materials, Xi'an Jiaotong University; [2]Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, Massachusetts Institute of Technology; [3]Department of Materials Science and Engineering, Johns Hopkins University

Grain boundary (GB) hardening has been an efficient way to tailor the mechanical properties of metals and alloys by introducing GBs as the obstacles to dislocation motion. However, with the decreasing of the grain size, the recent published works indicate that the stresses driving GB migration manifested as grain growth in nanocrystalline materials [such as Science, 1686, (2009)]. In our present work, we compressed the Al nanopillar (D˜200nm) with one GB inside a TEM. The in situ quantitative testing shows that under 800MPa contact stress, the GB are not mechanically static structures anymore and it migrated out of the pillar finally. Initially, high density dislocations are piled-up against the GB. However, the GB was broken down under high stress state upon the crash of flood-like dislocations. The in situ quantitative examination of a specific and representative GB allows the further understanding of the GB behavior in nanocrystalline materials.

10:00 AM
The Influence of Grain Boundary Structure upon Damage Evolution at Grain Boundary Interfaces: *Alejandro Perez-Bergquist*[1]; Christian Brandl[1]; Juan Escobedo[1]; Carl Trujillo[1]; Ellen Cerreta[1]; George Gray III[1]; Timothy Germann[1]; [1]Los Alamos National Laboratory

In a prior work, it was found that grain boundary structure strongly influences damage evolution at grain boundaries in copper samples subjected to either shock compression or incipient spall. Here, several grain boundaries with different grain boundary structures, including a S3 (10-1) boundary, are interrogated via conventional transmission electron microscopy (TEM) and high-resolution transmission electron microscopy (HRTEM) to investigate the effects of atomic-scale structural differences on grain boundary strength and mobility. Boundaries are studied both before and after shock compression at a peak shock stress of 10 GPa. Results of the TEM and HRTEM work are used in conjunction with MD modeling to propose a model for shock-induced damage evolution at grain boundary interfaces that is dependent upon coincidence.

10:15 AM Break

10:25 AM Keynote
Surface and Interface Controlled Plasticity and Phase Transition in Nometer-Sized Au Crystals: *Scott Mao*[1]; He Zheng[1]; Jianyu Huang[2]; Christopher R. Weinberger[2]; [1]University of Pittsburgh; [2]Sandia National Lab

We report the in-situ TEM observation on surface and interface controlled deformation and phase transition. In sharp contrast to the scenario that plasticity is mediated by dislocation emission from Frank-Read sources and multiplication in bulk materials, partial dislocations emitted from free surfaces, which produce fresh surface steps after they annihilate at the free surfaces, dominate the deformation of Au nano-crystals. Stress-relief caused by the surface-mediated plastic deformation is directly visualized. After failure, the Au nanocrystal shows a phase transformation from face-centered-cubic (FCC) to body-centered-tetragonal (BCT) structure. The transformation is facilitated by surface stresses, which are able to drive the <001> crystal along the Bain path from FCC to BCT. The central theoretical prediction that plastic deformation in nanometer-sized crystals is dominated by surfaces has been directly verified using in-situ HRTEM.

10:55 AM Keynote
Grain Boundaries and Strength in Nanostructured Metals Produced by Plastic Deformation: *Xiaoxu Huang*[1]; Niels Hansen[1]; [1]Risø National Laboratory for Sustainable Energy, Technical University of Denmark

Nanostructured metals produced by plastic deformation are characterized by high angle boundaries, low angle dislocation boundaries and interior dislocations and strengthening mechanisms are strongly related to interactions between dislocations and boundaries of various misorientations and structures. In particular, the narrowly spaced high angle boundaries act as sinks of dislocations or as dislocation sources, which will control the strengthening mechanisms. The effect of dislocation structures on the strength and ductility of nanostructured metals processed by plastic deformation to very high strains has been investigated by varying the dislocation structure either by annealing or by additional plastic deformation. It has been found that the yield strength increases after annealing and decreases after additional deformation. These unusual observations are interpreted by introducing dislocation source limited strengthening in the former case and dislocation softening in the latter case.

11:25 AM
Twinning in Bulk Nanolayered AgCu under High Strain Rate: *Ben Eftink*[1]; Owen Kingstedt[1]; Buyang Cao[1]; Doug Safarik[2]; John Lambros[1]; Nathan Mara[2]; Ian Robertson[1]; [1]University of Illinois; [2]Los Alamos National Lab

Materials with heterophase interfaces show increased strength and potential for enhanced irradiation resistance. Bulk $Ag_{60}Cu_{40}$ cast eutectic exhibits a layered structure resulting in a high density of heterophase interfaces. This study investigates the mechanical response of a AgCu cast eutectic after compression at strain rates on the order of 10^3 s^{-1}. TEM analysis of the deformed microstructure shows twinning in both silver and copper layers. Twins are observed to run parallel to some interfaces and to extend from both sides of others. This latter result suggests twinning in silver facilitates twinning in copper. The deformation behavior exhibited during high strain rate loading will be discussed in terms of defect interactions with interfaces and dislocation-based deformation mechanisms.

11:40 AM
Interfaces and Mechanical Properties of Highly Textured Cu/Co Multilayers: *Yue Liu*[1]; Youxing Chen[1]; Haiyan Wang[1]; Ji Chen[2]; Xinghang Zhang[1]; [1]Texas A&M University; [2]Liaoning Shihua University

Certain metallic multilayers have shown superior properties, including the achievement of close-to-theoretical strength, fatigue resistance, excellent thermal stability and radiation tolerance. In this study, we investigate the interfaces and mechanical properties of sputtered, highly textured FCC(100)Cu / FCC(100)Co and FCC(111)Cu / HCP(0001)Co multilayers with individual layer thickness, h, varying from 1 to 200nm. Coherency along interfaces in the immiscible systems are increases gradually when h decreases to below 10nm, and fully epitaxial films form when h is 2.5nm or less. In FCC(100) Cu/Co multilayers, TEM studies reveal high density of inclined stacking fault in Co, whereas in FCC(111) Cu / HCP(0001)Co multilayers, high density stacking fault and twins are observed. Large discrepancy of size dependent indentation hardnesses in the two systems are observed at all h. The difference in strengthening mechanisms in the systems are discussed and compared to those of highly textured Cu/Ni multilayer systems.

11:55 AM
Deformation and Spallation of Shocked Cu Bicrystals with S3 Coherent and Symmetric Incoherent Twin Boundaries: *Weizhong Han*[1]; Sheng-Nian Luo[1]; Timothy C Germann[1]; Davis L Tonks[1]; [1]Los Alamos National Lab

Grain boundaries (GBs) play a critical role in the mechanical performance of metals and alloys. Given the vast number of GB types, it is highly desirable to investigate some elemental processes in order to guide materials design. In this investigation, we perform molecular dynamic (MD) simulations of Cu bicrystals with S3 coherent twin boundaries (CTB) and symmetric incoherent twin boundaries (SITB) under shock wave loading. It is revealed that the shock response of the Cu bicrystals strongly depends on the GB characteristics. At shock compression stage, elastic shock wave can readily trigger GB plasticity at SITB, while not at CTB. The SITB can induce considerable wave attenuation such as elastic precursor decay. At the tension stage, spallation tends to occur at CTB while not at SITB due to the high mobility of SITB. In addition, twinning is a mechanism in inducing surface step during shock.

Mechanical Performance of Materials for Current and Advanced Nuclear Reactors: Characterization and Modeling of Disolcation Structures in Nuclear Materials

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Nuclear Materials Committee

Program Organizers: Nicholas Barbosa, National Institute of Standards & Tech; Greg Oberson, United States Nuclear Regulatory Commission; Matthew Kerr, United States Nuclear Regulatory Commission; Elaine West, Knolls Atomic Power Laboratory; Stuart Maloy, Los Alamos National Laboratory; Osman Anderoglu, LANL

Tuesday AM — Room: Swan 1

8:30 AM Invited
Understanding the Dislocation Processes and Interactions Responsible for Creating Defect-Free Channels in Deformed Irradiated Metals: Josh Kacher[1]; Grace Liu[1]; *Ian Robertson*[1]; [1]University of Illinois

The microstructure of deformed irradiated materials is characterized by cleared channels within a field of irradiation-produced defects. Through a combination of characterization of bulk deformed irradiated stainless steel and in-situ deformation in a transmission electron microscope of irradiated metals, the source of the dislocations responsible for creating the channels, the interaction of dislocations with individual defects and grain boundaries, and channel widening mechanisms have been discovered. This talk will show for stainless steels, the dislocations responsible for creating the channels are generated anew from grain boundaries and stress concentration sites; dislocation progress through the defect field is erratic and intermittent; the channel width reflects the width of the source and complex cross-slip reactions; and dislocation pile-ups form in the grain interior and at dislocation sources as well as at grain boundaries. The complex configuration of dislocations in cleared channels is revealed by using electron tomography.

9:00 AM
Planar Dislocations and Dislocation Channeling in Unirradiated and Irradiated Austenitic Stainless Steels: *Young Suk Kim*[1]; Sung Soo Kim[1]; Dae Whan Kim[1]; [1]Korea Atomic Energy Research Institute

Tensile tests were conducted on 316L stainless steel with nitrogen over a temperature range of RT to 750°C at strain rates of 2x10-4/s. The 316L stainless steel (SS) showed serrated flow in a temperature range of 400 to 600°C where a linear increase of strain hardening was accompanied. Using neutron diffraction, the lattice contraction due to atomic ordering was seen to occur in the 40% cold-worked 316 SS on aging at 400°C. TEM microstructures showed the formation of planar dislocations in 316L SS upon tensile testing at 400°C where SRO and serrated flow appeared. This study demonstrates that SRO is the cause of planar dislocations and serrations in austenitic stainless steels. Given that neutron irradiation produces dislocation channeling and softening after yielding in austenitic stainless steels above some fluences, the cause of dislocation channeling and softening in irradiated 304 stainless steels is discussed with short range ordering.

9:20 AM
Incorporation of Dislocation Climb in Crystal Plasticity Models: *Alankar Alankar*[1]; Alfredo Caro[1]; Ricardo Lebensohn[1]; [1]Los Alamos National Laboratory

This work presents an improved plasticity model for single crystals deforming by a combination of dislocation glide and climb. A constitutive framework based on dislocation densities has been implemented in a viscoplastic self-consistent (VPSC) formulation. Accounting for the explicit evolution of edge and screw dislocations densities enables the instantaneous determination of the climb tensor, which depends on the average character of the mobile dislocations. Mobilities of dislocations accommodating deformation by climb and glide, which depend on their interaction with point defects, are determined using kinetic Monte Carlo simulations.

9:40 AM
Polycrystalline Modelling of the Behaviour of Neutron Irradiated Zirconium Alloys and Comparison with TEM Observations: *Fabien Onimus*[1]; [1]CEA

The deformation mechanisms of recrystallized zirconium alloys are strongly affected by neutron radiation resulting in dramatic change of the macroscopic mechanical behaviour. It is especially observed, using transmission electron microscopy, that the dislocation channelling process in the basal plane is the main deformation mechanism after irradiation. A polycrystalline modelling that takes into account both the specific post-irradiation deformation mechanisms as well as the texture of the material has been developed. This physically based model reproduces the mechanical behaviour of the material for both monotonic and cyclic tests. The slip systems activities have been computed for more than 40 grains that were observed by TEM. The activation of basal slip, observed in many of these grains, is very well predicted by the modelling. Moreover, the activation of (c+a)-pyramidal slip observed only in few grains is also well predicted showing the reliability of the modelling.

10:00 AM
The Interaction Energy between Point and Line Defects in BCC Iron: *Erin Hayward*[1]; Blas Uberuaga[2]; Chaitanya Deo[1]; Carlos Tome[2]; [1]Georgia Institute of Technology; [2]Los Alamos National Laboratory

The interaction of dislocations with point defects, such as vacancies, interstitials, or impurities, is important for understanding the processes of dislocation climb, creep, and embrittlement. In irradiated materials, the abundance of point defects may enhance these phenomena. The interaction between a dislocation and a given point defect is often described by the interaction energy, a measure of favorability of the positioning of the defect with respect to the dislocation. We calculate the interaction energy between a screw dislocation and various types of point defects in body-centered cubic iron using atomistic methods. These results are compared to energies found using isotropic and anisotropic elastic continuum theory. We find important differences between the results of atomistic and continuum methods, especially near the core, and conclude that anisotropic fields perform significantly better than their isotropic counterparts. Stability of point defects in the presence of a dislocation core will be discussed.

10:20 AM Break

10:35 AM
The Effect of Crowdions on the Dislocation Bias Factor: *Alexander Barashev*[1]; Stanislav Golubov[1]; Bachu Singh[2]; Roger Stoller[1]; [1]Oak Ridge National Laboratory; [2]Riso National Laboratory

The observed void swelling rates in metals irradiated with 1 MeV electrons are smaller than the theoretical predictions by an order of magnitude. The attempts to solve this problem all considered three-dimensional (3-D) diffusion of both vacancies and self-interstitial atoms

(SIAs) and failed. First principle calculations demonstrated that in metals with the bcc crystal structure the crowdion is more stable than the dumbbell configuration of the SIAs, hence the 1-D migration of SIAs should be realized. Recently we have proposed that this may account for the small dislocation bias factors. In this paper, a quantitative model is developed. It is shown that the crossover between the crowdion- and dumbbell-controlled kinetics occurs when dumbbells are much more stable than crowdions. This explains low swelling levels even in fcc metals and sheds light on the possible reasons for the higher swelling levels observed in fcc as compared to bcc metals.

10:55 AM
Atomic-Scale Study of Strengthening Due to Inclusion-type Obstacles in Iron: *Yury Osetskiy*[1]; Roger Stoller[1]; [1]ORNL

Voids and He-bubbles, secondary phase and oxide particles in oxide dispersion strengthened (ODS) alloys are common obstacles to dislocation glide in commercial materials for nuclear industry. All these obstacles present a family that can be treated as inclusion-type. In this presentation we discuss results of extensive atomic-scale modeling of moving dislocation interaction with the above spherical obstacles embedded into bcc-iron matrix. We simulated a ½<111> edge dislocation gliding in the plane intersecting obstacles of diameter from 1 to 6nm at different distances to their equator. Different interaction mechanisms were observed depending on the dislocation glide plane position and temperature. The strength of different obstacles was compared, the conditions of maximum strength were investigated and the results were discussed in the view of existing experimental data.

11:15 AM
Microstructural Evolution and Dislocation Density Analysis of HT9 Steel Irradiated in the FFTF: *Paula Mosbrucker*[1]; Donald Brown[1]; Levente Balogh[1]; Stuart Maloy[1]; Thomas Sisneros[1]; [1]Los Alamos National Laboratory

HT9 steel is a ferritic/martensitic alloy being considered for use in fuel cladding in fast reactors in order to achieve high fuel burnup. The microstructural evolution, texture, and dislocation density of an HT9 duct were examined following the six-year irradiation of a fuel assembly in the Fast Flux Test Reactor Facility (FFTF). Material obtained from several positions within the assembly produced samples with a wide range of irradiation dose and irradiation temperature history. Synchrotron x-ray diffraction measurements were performed at beamline 1-ID at the Advanced Photon Source. Using the Convolutional Multiple Whole Profile (CMWP) fitting technique of evaluating dislocation contribution to line broadening, we show that irradiation temperature, rather than dose, most significantly controls dislocation density, with higher temperatures correlating to lower dislocation densities. Further, neutron diffraction texture measurements show larger texture evolution at higher doses. The results of synchrotron XRD deformation experiments and annealing experiments will also be presented.

11:35 AM
A Multiscale Investigation of the Interaction between Edge Dislocations and Voids in BCC Iron: *Sylvain Queyreau*[1]; Jaime Marian[1]; Anasthasios Arsenlis[1]; Brian D. Wirth[2]; [1]Lawrence Livermore National Laboratory; [2]University of Tenessee

This work focuses on the strengthening associated to voids –vacancy clusters- which are formed in bcc Iron under irradiation. The dislocation-void interaction is complex and difficult to reproduce in traditional mesoscopic simulations. This is why we propose a new coupling between Dislocation Dynamics and continuum mechanics that accounts for different mechanisms observed in atomic simulations. (i) The dislocation shearing generates a surface step at the void surface synonymous of an increase of potential energy. (ii) A part of the dislocation line energy is recovered inside the empty void. And (iii) a remote interaction stress (image stress) is inherent to the presence of internal free surfaces. This latter is calculated using the non-singular expressions for dislocation stress fields given in a recent publication. Our simulations suggest that ii and iii lead to larger contributions to the strengthening, although the temperature dependence is controlled by the variation of the surface energy i.

11:55 AM
Effects of 3He in ErT2: *Gillian Bond*[1]; Clark Snow[2]; James Browning[3]; Mark Rodriguez[2]; James Knapp[2]; Ryan Wixom[2]; Peter Schultz[2]; Donald Cowgill[2]; [1]New Mexico Tech; [2]Sandia National Laboratories; [3]Oak Ridge National Laboratory

An overview will be presented of a long-term experimental study of 3He in ErT2 that has been carried out over the last several years. The goal of the study has been to elucidate the evolution of helium bubbles and their impact on the properties of ErT2, including swelling and hardening. The helium bubbles that form in ErT2 have a plate-like morphology and lie on {111} planes. Bubble nucleation is already completed by a He/M ratio of ~ 0.018, and the plate-like bubbles then grow in size until a He/M ratio of ~ 0.3 after which bubble linkage becomes extensive. As the bubbles begin to link, the lattice swelling decreases along with the hardness. The study includes transmission electron microscopy (TEM), X-ray diffraction (XRD), and nano-indentation (NI), and the data have been used as input for concurrent modeling efforts.

Nanocomposites: Energetic & Catalytic Nanocomposites

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Composite Materials Committee

8:30 AM Invited
Synthesis, Reactivity and Mechanical Properties of Aluminized Fluorinated Acrylic (Alfa) Nanocomposites: *Christopher Crouse*[1]; Christian Pierce[1]; Jonathan Spowart[1]; [1]Air Force Research Laboratory

We report the synthesis and characterization of an aluminized fluorinated acrylate (AlFA) reactive composite material as a model system to explore the possibility for improving the mechanical properties of nanoparticle/fluoropolymer composites. Chemical functionalization of nano-Al followed by the in situ polymerization of a fluorinated methacrylate monomer was used to prepare the composites with particle loadings up to 70 wt%. Composites with 60 wt% particle content or less demonstrated thermoplastic behavior and were amenable to extrusion. Direct chemical bonding of the polymer matrix to the embedded particles is anticipated to yield improvements in the strength of these materials. Initial quasi-static compression tests displayed a two-fold increase in the compressive strength for AlFA-50 composite over the neat polymer. A combination of high strain rate (gas gun) experiments and combustion studies were also performed to explore the reactive properties for the new composite materials.

9:10 AM
Silicon-Based Nanocomposites for Energetic Applications: *Paul Redner*[1]; Neha Mehta[1]; Karl Oyler[1]; Gartung Cheng[1]; Christopher Csernica[1]; Jesse Sabatini[1]; Jay Poret[1]; Zhaohua Luan[1]; Russell Broad[1]; Deepak Kapoor[1]; [1]US Army, RDECOM-ARDEC

Nanoscale and nanostructured energetic materials are enabling technologies for defense applications. Many current and future requirements cannot be achieved by using more conventional materials only. By exploiting the "tunable" nature of nanocomposites, one can adjust the energy output, light output, strength of materials, and sensitivity to various stimuli. This is accomplished via altering the constituents, particle or grain size, surface area and surface characteristics of the material. Porous silicon is being explored as a novel fuel to replace a variety of materials in energetic formulations for the above-stated reasons. A matrix of formulations was generated in which magnesium was replaced by silicon and barium chromate was replaced with more environmentally friendly oxidizers in order to improve upon a legacy first fire mixture. The materials were tested for impact, friction, and ESD sensitivity and characterized based on light output and color, burn time, and ignition temperature. Results will be discussed.

9:30 AM Invited
Synthesis and Characterization of Nanoscale & Nanostructured Pyrophoric Nanocomposites: *Chris Haines*[1]; Lauren Armstrong[1]; Zac Doorenbos[2]; Kendall Mills[1]; Darold Martin[1]; Jay Poret[1]; Deepak Kapoor[1]; [1]US Army ARDEC; [2]Innovative Materials & Processes LLC

We have taken both a bottom-up and top-down approach to synthesizing pyrophoric materials for DoD applications. The bottom-up approach utilizes an inductively-coupled plasma (ICP), inert gas condensation process to synthesize nanoscale powders comprised of metals like aluminum, iron, manganese, and alloys thereof which are inherently pyrophoric. The top-down approach employs mechanical alloying (MA) of binary, tertiary, and quaternary alloys comprised of aluminum, iron, manganese, titanium, and magnesium. The high surface area (and resultant nanostructured lamellae) of these MA materials also exhibited pyrophoricity. The influence of processing parameters and chemical composition on the tunability of combustion properties of these materials will be presented. The infrared (IR) spectral performance of select materials will also be discussed.

10:10 AM
The Kinetics of Intermolecular Reactive Composites: *Mathew Cherukara*[1]; Karthik Vishnu[1]; Alejandro Strachan[1]; [1]Purdue University

Intermolecular Reactive Composites have generated significant interest in fields as diverse as defence, reactive joining and medicine. However, the mechanisms that govern the propagation of the reactions are poorly understood, limiting their application. We use molecular dynamics to simulate the exothermic reaction of Ni/Al nano-laminates (both crystalline and amorphous) at different temperatures, periodic lengths and nanostructures. We show that the reaction is diffusion controlled in the bulk phase but the introduction of defects like porosity or a free surface speed up the reaction enormously and lead to ballistic transport. We also study the response of amorphous Ni/Al samples and we find that they exhibit faster and more energetic reactions than their crystalline counterparts.

10:30 AM Break

10:50 AM
Bio-Conjugation of Catalytic Nanoparticles: *Robert Draper*[1]; Soumen Das[1]; David Reid[1]; [1]University of Central Florida

This research explores the possibility of using bio-conjugation to disperse nanoparticles into composite matrices for catalytic purposes. Solid state catalysis is often rate limited by the solid diffusion of catalyst particles to reaction sites, making uniform dispersion of catalysts a desirable trait in solid composite reactions to reduce the overall diffusion distance of the catalyst particles per unit weight. One of the more prevalent methods of nanoparticle conjugation involves DNA based templating, such as Watson-Crick Base Pairing, methods that are not suitable for aggressive solvents, or for conjugating many types of particles. Here we explore a novel method using Protein A and Immunoglobulin affinity for biomolecule based nanoparticle conjugation with application to dispersion of catalytic particles in a solid matrix.

11:10 AM
Comprehensive and Sustainable Recycling of Polymer Nanocomposites: *Jiahua Zhu*[1]; John Zhanhu Guo[1]; Suying Wei[1]; [1]Lamar University

A coupled process to recycle the polystyrene(PS)/Ni@NiO nanocomposites is introduced to synthesize ferromagnetic core@shell Ni@C nanoparticles (NPs) and simultaneously to produce useful chemical radicals or liquid fuels. The PS nanocomposites reinforced with core-shell Ni@NiO NPs are prepared by the solvent extraction method. The Ni@NiO NPs are found to have significant catalytic effects on the pyrolysis of PS. The pyrolysis pathway changes from radical generation and ß-scission for PS to radical generation, recombination and hydrogenation for the nanocomposites. GC/MS results confirm the same gas products from pure PS and its Ni@NiO nanocomposites. However, for the liquid products, more saturated products were obtained from the nanocomposites than that of pure PS due to the catalytic hydrogenation of the Ni NPs. A significantly large magnetization (25.0 emu/g) and high specific surface area (236.68 m2/g) were observed in the formed core-shell NPs, and these NPs can be stabilized in acid for a long time.

11:30 AM
Photocatalytic Degradation of TOC by Fe2O3/TiO2 Coated on Light Ceramic: *Ju Hua*[1]; [1]Harbin Institute of Technology

Anatase titanium oxide (TiO2) films were prepared by a conventional sol-gel method on ceramic substrates as an inexpensive photocatalyst for degradation of hydroquinone in water. Investigation of the crystallinity and crack of the Fe2O3/TiO2 Coated on Light Ceramic by XRD and SEM showed that the proper heat-treatment temperature was 400°C, and the as-obtained film displayed best photocatalytic activity among the prepared samples from different calcination temperatures. The prepared inexpensive photocatalyst also displayed good reproducibility, with the photocatalytic activity being maintained at about 54% after 4 cycles. A pseudo-first order reaction model was discovered for the photocatalytic mechanism of the Fe2O3/TiO2 Coated on Light Ceramic.

11:50 AM
Colloidal Ag-Pt/TiO_2 Nanocomposites for Photocatalysis: *Bijith Mankidy*[1]; Vinay Gupta[1]; Babu Joseph[1]; [1]University of South Florida

Novel methods to fabricate nanostructured composites have inspired the design and development of new nanocomposites for advanced applications in catalysis, sensors, and medicine. We will demonstrate a colloidal self-assembly route to synthesize Ag-Pt/TiO_2 nanocomposites for photocatalysis. Here, Ag-Pt bimetallic nanoparticles are surface immobilized on TiO_2 that are prepared using polymeric templates. Pt acts as charge carrier traps and suppresses recombination of photoexcited electron-hole pairs leading to improved quantum efficiency. By alloying Pt and Ag, bimetallic nanoparticle possesses enhanced ability in light harvesting due to the surface plasmon resonance character of Ag, where otherwise photosensitization is achieved by addition of chemical dyes. Another benefit of using AgPt over chemical dyes is that dyes are destroyed during the photoreaction by either photo- or thermal decomposition. In contrast, nanoparticles have higher stability. The nanocomposites are characterized using a combination of several techniques such as dynamic light scattering technique, UV-vis absorption spectroscopy, and TEM.

12:10 PM
Nanodiamond – Polypyrrole Conductive Composite as Working Electrode for Cholesterol Electrochemical Detection: *Pedro Villalba*[1]; Punya Basnayaka[1]; Manoj Ram[1]; Ashok Kumar[1]; [1]University of South Florida

Enhanced properties of nanocomposites material make them a promising candidate for highly sensitive chemical and biological sensors. Under this study, we have electrochemically synthetized nanodiamond (ND) – polypyrrole (PPy) composite as active substrate for cholesterol oxidase (Chx) enzyme functionalization. ND-PPy/Chx structure was used as a working electrode in three electrode for electrochemical cholesterol detection. The ND-PPy films, before and after enzyme immobilization, were thoroughly characterized by using different techniques. The detection mechanism is based on the production of H2O2 after the reaction of cholesterol molecule in presence of the Chx attached to the sensor surface. During reaction cholesterol is reduced to 4-Cholesten-3-One. Later, the H2O2 molecule is separated into water molecules and free electron that can be amperometrically measured. The calibration curve of cholesterol concentration has been studied using the novel electrode ND-PPy films for different known concentration of the analyte under steady state and dynamic conditions.

Neutron and X-Ray Studies of Advanced Materials V: Centennial: In Honor of Prof. G. Kostorz

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee, TMS: Chemistry and Physics of Materials Committee

Program Organizers: Rozaliya Barabash, Oak Ridge National Laboratory; Xun-Li Wang, Oak Ridge National Laboratory; Gernot Kostorz, ETH Zurich; Lyle Levine, National Institute of Standards and Technology; Peter Liaw, Univ of Tennessee; Yandong Wang, Beijing Institute of Technology; Brent Fultz, California Institute of Technology

From Diffuse Scattering to Ground State Structures: *Bernd Schoenfeld*[1]; [1]ETH Zurich

Local atomic arrangements of alloys are successfully determined quantitatively from diffuse scattering using x-rays and neutrons. Binary alloys are nearly exclusively investigated as the number of pair correlation functions rapidly increases for multicomponent systems. Choosing alloys in states of thermal equilibrium, effective pair interaction (EPI) parameters are determined that allow plausible ground state structures to be discussed. We shall present the situation in some recently investigated binary systems. For Pt-Rh and Au-Pd no ordered structures are experimentally known and a comparison will be done with results from electronic structure calculations. As long-period superstructures are indicated for Au-Pd, small differences in the respective ordering energies are decisive. For Ni-Pt and Fe-Pd ordered structures are well known and order-disorder transition temperatures determined from EPI parameters will be compared with direct experimental findings.

In Situ Small-Angle X-Ray Scattering Studies of Formation, Aggregation and Dissolution of Nanoparticles in Suspension for Environmental Health and Safety: *Andrew Allen*[1]; Matthew Martin[1]; Robert MacCuspie[1]; Vincent Hackley[1]; Jan Ilavsky[2]; [1]NIST; [2]Argonne National Laboratory

Solution-mediated nanoparticle formation and interaction processes are of considerable current importance. Not only are solution-mediated reaction routes increasingly exploited for the formation of non-agglomerated and mono-dispersed nanoparticle systems, but the dispersion quality and stability of nanoparticle suspensions under changing solvent conditions are critical for environmental health and safety applications. To gain insights into the relevant processes, small- and ultrasmall-angle X-ray scattering (SAXS and USAXS) measurements, made in situ and in real time using a remote-controlled, isothermal, circulating fluid flow cell at a 3rd generation synchrotron source, have provided representative, quantitative microstructure characterization over length-scales ranging from less than 1 nm to several micrometers. Results will be presented to illustrate the application of such in situ SAXS and USAXS studies to a nucleating solid phase from solution, to agglomerate formation in the presence of increasing salt concentration, and to the progressive dissolution of nanoparticles under acidic conditions.

Size-Dependent Transitions in Nanostructured Zirconia-Scandia Solid Solutions. A High Temperature Synchrotron Diffraction Study: *Aldo Craievich*[1]; Paula Abdala[2]; Diego Lamas[3]; [1]Institute of Physics - USP; [2]ESRF; [3]Facultad de Ingenieria - Universidad Nacional del Comahue

The cubic (c) phase of ZrO2-Sc2O3 ceramics exhibits high ionic conductivity, making this material a good candidate as electrolyte for IT-SOFCs. In microcrystalline ZrO2-Sc2O3 ceramics, the cubic phase is stable only above 600ºC. Contrarily, rhombohedral phases - stable below 600ºC - have a rather low ionic conductivity. Interestingly, rhombohedral phases can be avoided in nanomaterials with average crystallite size, D, below 30 nm. ZrO2-Sc2O3 nanopowders with 10-14 mol% Sc2O3, average sizes in the 35-100 nm range, and different fractions of c (or pseudo-cubic t”) and rhombohedral beta and/or gamma phases, were studied by synchrotron X-ray diffraction. Strong size effects were noticed for the beta-c/t” transition while a not so well defined trend was observed for the gamma-c/t” transition. The temperatures of beta-c/t” and c/t”-beta transitions are decreasing linear functions of 1/D. These results indicate that the size dependences of both transition temperatures are well described by the classical Jesser-Couchman equation.

9:35 AM
Depth-Dependent Plastic and Elastic Strain Gradients from Polychromatic Microdiffraction: *Rozaliya Barabash*[1]; [1]Oak Ridge National Laboratory

Depth-dependent (3D) measurements of the plastic and elastic strain distributions are now possible with differential-aperture X-ray microscopy (DAXM). This method is ideal for studies of mesoscale evolution of strains and defects. This talk will describe two examples of DAXM applications for 3D studies of plastic/elastic response of the materials under external stress fields: (*) The first example mainly demonstrates formation of rotational (deviatoric) strains in a twinned Ni crystal. Crystal plasticity analysis together with finite element simulations confirm the experimentally observed trends in the plastic response of the matrix and the twin. (**)The 2nd example mainly shows the 3D residual elastic strain distribution in Metal/Matrix composites (MMC). Research supported by the U. S. Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division. X-ray microbeam measurements were performed at 34-ID-E at the Advanced Photon Source.

Kinetics of Nano Quasicrystal Formation from Zr-Based Metallic Glass Ribbons and Its Implication to the Heterogeneous Metallic Glass Structure: *Hiroshi Okuda*[1]; Yusuke Maezawa[1]; Ryo Arao[1]; Shojiro Ochiai[1]; Junji Saida[2]; [1]Kyoto University; [2]Tohoku University

Structure of stable Zr metallic glasses has been intensively examined using various methods and approaches. In the present work, kinetics of nano-quasicrystalization in Zr-Pt / ZrCuPt glass ribbons has been examined by a combined use of Anomalous Small and Wide Angle X-ray Scattering (ASWAXS) and time-resolved SWAXS methods. Anomalous SAXS analysis is powerful in discussing the compositional and density fluctuation/ partitioning of heterogeneous stucture, and time-resolved SWAXS is useful for discussing the relationship between the compositional heterogeneity and (quasi)crystalline domains. By measuring the intensity from a small-angle region up to a diffraction peak continuously, we analyzed them with the same sensitivity and resolution. ASAXS results suggested formation of solute enriched zone during precipitation in the ternary alloy system. Contrast analysis for as-quenched and annealed samples was made to discuss the heterogeneity in the glass and the precipitated samples.

10:10 AM Invited
In-Situ Diffraction Studies of Microstructural Changes during Deformation and Irradiation: *Ralph Spolenak*[1]; [1]ETH Zurich

In-situ diffraction studies offer detailed in deformation studies that may otherwise be missed by interrupted experiments. This paper will illustrate the advantages of this method by three case studies: a. fracture of thin brittle coatings on ductile substrates, b. the deformation behavior of metal thin films at high plastic strains from uniform deformation to shear banding and eventual texture changes and c. the collective rotation of grains in thin metal films under the influence of high energy self-ion irradiation. Results will be presented of both x-ray and electron diffraction.

10:30 AM Invited
Online Microcomputed X-Ray Computer Tomography of the In-Vivo Biodegradation of Mg Implants: Victor Wessels[1]; Stefan Fischerauer[2]; Tanja Kraus[2]; Annelie-M. Weinberg[2]; Richard Kickinger[3]; Anja Hänzi[1]; Peter Uggowitzer[1]; *Jörg Löffler*[1]; [1]ETH Zurich; [2]Medical University Graz; [3]University of Applied Sciences Wels

Bioresorbable implants degrade in the body over time and thus do not require surgical removal after they have served their purpose. Mg-alloys show in this context a particularly attractive combination of mechanical, electrochemical and biological properties, but they produce hydrogen during degradation which may cause problems. We will present in this talk the bone and tissue response to degrading Mg pin implants in growing rat skeletons by continuous in-vivo microcomputed x-ray computer tomography (µCT). With this technique, implant degradation, gas evolution, and bone/tissue response can be monitored simultaneously; it further has the great advantage of being noninvasive, so that no animals need to be sacrificed. The µCT studies show that bone recovers completely after implant degradation, even in the case of massive gas formation and preceding alterations of the bone. These studies also show that Mg generates enhanced bone neoformation, giving evidence for its good osteoconductivity and osteoinductivity.

Combined Use of Small-Angle X-Ray and Neutron Scattering: SAS in Color: *Masato Ohnuma*[1]; Yojiro OBA[1]; Koppoju Suresh[1]; Powel Kozikowski[1]; [1]National Institute for Materials Science

Thanks to the distribution of glassy carbon for intensity calibration [1], we are now able to get SANS and SAXS data in absolute unit quite easily. Since the scattering contrast between X-ray and neutron shows large difference, we can extract the information about chemical compositions of heterogeneity embedded in matrix from the intensity ratio between SANS and SAXS. We call this method "alloy contrast variation (ACV)". The ACV method is especially powerful to discuss whether the matrix elements are in the nano-size heterogeneity or not. In contrast, the effects from matrix cannot be ignored in other techniques like TEM or atom probe when the size of heterogenieity is below 2~3 nm. In this talk, we'll show some application results of ACV method in different alloys. Ref[1] F. Zhang, J. Ilavsky, G. Long, J. Quintana, A. Allen and P. Jemian : Metall. Mater. Trans. A, 41A(2010), 1151.

Cascade Dynamics Information Possible from Sub-Picosecond X-Ray Scattering: *Bennett Larson*[1]; Jon Tischler[1]; Roger Stoller[1]; [1]ORNL

The collision of 2-MeV neutrons or 50-keV ions with a lattice atom results in the deposition of 10's of kilovolts of kinetic energy within a few nanometer radius. According to molecular dynamics simulations, the "cascade" of subsequent ion collisions generates several thousand vacancy-interstitial pairs on sub-picosecond time scales. The availability of sub-picosecond 10-keV x-ray pulses from the Linac Coherent Light Source (LCLS) provides the capability to probe cascade dynamics experimentally. Here we present numerical simulations of time-slice x-ray diffraction patterns based on molecular dynamics calculations for 25-keV primary knock-on cascades in Fe at room temperature. The time dependent diffraction patterns will be correlated with the real-space cascade dynamics from the molecular dynamics simulations. Techniques for interpreting the diffraction patterns in terms of local defects and shock induced pressure waves will be discussed. *Research sponsored by the U.S. DOE, BES, Materials Sciences and Engineering Division, "Center for Defect Physics," an EFRC

Mechanics of Magnetic Shape Memory Alloys across the Length Scales: *Peter Müllner*[1]; [1]Boise State University

Magnetic shape-memory alloys (MSMAs) deform via the motion of twin boundaries, driven by a magnetic field or by a mechanical force. Deformation mechanisms are reviewed with attention to different length scales. At the atomic length scale, twinning dislocations are the agent of deformation. Burgers vector and step height of twinning dislocations were characterized using transmission electron microscopy. At the mesoscopic length scale, groups of twinning dislocations form disclination dipoles. In hierarchically twinned martensite, groups of disclination dipoles control localized deformation at even larger length scale. Grain boundaries suppress twin boundary motion, requiring MSMAs to be prepared as single crystals. Grain boundaries were replaced by porosity in polycrystalline metallic foam. Here, at macroscopic length scale, deformation is governed by the plastic compatibility of architectural elements. At the sample scale, when the interaction of the sample with the surrounding apparatus impacts deformation, all mechanisms contribute to the deformability of the sample.

Phonons in Martensite and Austenite NiMnGa - Its Relation to Ferromagnetic Shape Memory: *Winfried Petry*[1]; Semih Ener[1]; Jürgen Neuhaus[1]; [1]Technische Universität München (Munich University of Technology)

NiMnGa is the archetype of ferromagnetic shape memory alloys, which have the potential to serve as sensors, actuators or in magnetic refrigeration. Subtle changes in composition of this alloy create drastic changes in the structural and magnetic properties. We present extensive phonon measurements in the austenite as well martensite phase accompanied by structural characterisation, as function of composition, temperature and magnetic field. For example the off-stoichiometric alloy $Ni_{49}Mn_{32}Ga_{19}$ transforms at 380 K within its ferromagnetic phase from L21 (austenite) to five layered martensite and is very well suitable for ferromagnetic shape memory applications. Phonons in the austenite reveal the atomistic mechanism of the transformation. Phonons in the martensite explain the extremely low twinning stress, which is essential for functionality. Calculations of the electronic structure of Ni_2MnGa in both phases (Entel et al. Mater. Sci. Forum 635, (2010), 3) explain the phonon anomalies observed around the structural phase transition.

Multiple Whole X-Ray Line Profile Analyses for Investigating the Role and Nature of Dislocations
in Plastic Deformation of Semicrystalline Polymers
: *Michael Zehetbauer*[1]; Florian Spieckermann[1]; Gerald Polt[1]; Harald Wilhelm[2]; Michael Kerber[1]; Sigrid Bernstorff[3]; Erhard Schafler[1]; [1]University of Vienna; [2]Laboratory of Polymer Engineering LKT-TGM; [3]Sincrotrone Trieste

Recent publications on semicrystalline polymers show that the method of Multiple whole X-ray line Profile Analysis (MXPA) not only allows for a correct separation of size and strain broadening but also clarifies whether the latter arises from dislocations or not. Thus, these analyses contribute to the long-lasting dispute whether dislocations are present in the crystalline phase and whether their strain-dependent evolution rules the macroscopic deformation. Besides existency, density and arrangement of dislocations, the low symmetry and high anisotropy of the polymer crystals even allow for an identification of the specific dislocation types and populations -

provided that the elastic constants are known. Results from several in-situ synchrotron experiments are presented which span semicrystalline polymers like PP, PET, and the biodegradable P3HB. The microstructural data which also comprise the crystal size and the crystallinity provide a good basis to quantitatively describe the macroscopic mechanical properties in terms of microscopic deformation mechanisms.

Energy-Dispersive Synchrotron Diffraction – a Versatile Method for Advanced Materials Characterization: *Christoph Genzel*[1]; [1]Helmholtz-Zentrum Berlin für Materialien und Energie

Energy-dispersive (ED) diffraction experiments performed on polycrystalline materials are characterized by a fixed geometrical setup and the possibility to record complete diffraction patterns simultaneously under well-defined but arbitrary scattering angles and for different measuring directions with respect to the sample reference system. Employing high energy white synchrotron radiation allows for structural analysis with excellent time and/or spatial resolution as well as for the use of complex large and heavy sample environments. With selected examples taken from measurements on the beamline EDDI@BESSY II the broad variety of applications for ED diffraction is demonstrated. With photon energies between about 10 and 120 keV EDDI is particularly dedicated to the analysis of property gradients (residual stress, texture, microstructure and composition) in the highly stressed surface layer of technical components, but also to in-situ monitoring of thin film growth. For data processing single line profile analysis and whole pattern Rietveld refinement can be applied.

Pb-Free Solders and Other Materials for Emerging Interconnect and Packaging Technologies: Effects of Ultrafine Joints and Alloy/microstructure Relationships

Linkages between Microstructure and Mechanical Properties of Ultrafine Interconnections: Zhiyong Wu[1]; *Zhiheng Huang*[1]; Hua Xiong[1]; Paul Conway[2]; [1]Sun Yat-Sen University; [2]Loughborough University

Microstructures within ultrafine interconnections, which change rapidly during manufacturing and evolve continuously in service, have to be taken into account to accurately predict the reliability of electronic packaging, e.g. 3D electronic packaging. This work emphasizes the size and geometry effects on the properties of solder bumps with diameters of about 20 microns by taking into account the microstructures simulated using a phase field method. Irregular boundaries of the solder bumps can be dealt with in the model due to the flexibility in geometries provided by the finite element method. Size and geometry effects on the microstructural evolution and subsequent mechanical property will be discussed by coupling the phase field and mechanical modeling techniques. With the size geometry effects included, the microstructure and properties of solder joints from both experimental and modeling will be compared and the results are expected to highlight the significance of microstructure engineering in ultrafine interconnections.

8:55 AM
Silver Addition Effects on the Ni-Sn Interfacial Reaction for 3D IC Applications: *J. J. Yu*[1]; H. Y. Chuang[1]; M. S. Kuo[1]; W. L. Shih[1]; C. Kao[2]; [1]National Taiwan University ; [2]National Taiwan University

For 3D IC applications, solder volume is extremely small in the chip-to-chip micro joining process. For this reason, solder joints can contain a large portion of intermetallic compounds (IMCs), which results in many peculiar properties. This study aims to uncover effects caused by the miniaturisation of solder volume on the Ni-Sn solid state reactions. When pure Sn is used for, a number of voids were observed at the interface. The void formation is considered as a result of volume shrinkage during the Ni-Sn reactions. Interestingly, an addition of 2.4 wt. % Ag in Sn can effectively avoid the formation of voids. The mechanism will be also discussed.

9:15 AM
Effect of Minor Alloy Additions on the Interfacial Reactions with Low Solder Volume for 3D IC Applications: *Ting-Li Yang*[1]; C. Robert Kao[1]; [1]National Taiwan University

Three dimensional integrated circuits (3D ICs) technology has received a lot of attention due to its high packaging density and better performance. It is well known that minor alloy additions to solders have pronounced effects on the interfacial reactions between solder and substrate. These alloy elements might substantially change the reaction rate and the morphology of the reaction products. Accordingly, it is of interest to investigate the effects of minor additions within the regime of small solder volume. In this study, two extreme types of alloy elements which include inert element, Bi, and a highly reactive element, Zn will be studied. Sandwich structures of Cu/Sn/Cu, Cu/Sn10Bi/Cu, and Cu/Sn0.4Zn/Cu were prepared by chip-to-chip bonding process. The solder thickness between Cu substrate was controlled at 10μm ±1μm. High temperature storage tests were conducted by isothermal aging at 120 °C. Also, the microstructure evolution was also examined during annealing.

9:35 AM
Preferred Orientation of 30 \956m Fine Pitch Sn2.5Ag Micro-Bumps Studied by Synchrotron Polychromatic X-Ray Laue Microdiffraction: *Tian Tian*[1]; Kai Chen[2]; Martin Kunz[2]; Nobumichi Tamura[2]; Tao-Chih Chang[3]; Chau-Jie Zhan[3]; King-Ning Tu[1]; [1]UCLA; [2]Lawrence Berkeley National Laboratory; [3]Industrial Technology Research Institute

Synchrotron radiation white beam x-ray microdiffraction was employed to study the grain size and orientation of fine pitch Sn2.5Ag micro-bumps. The indexation results of Laue patterns show that mostly there is one dominated grain orientation in a single micro-bump. Moreover, a statistics study basing on the characterization of 72 micro-bumps, shows that the [001] direction, which is the fast diffusion path for Ni/Cu atoms, is tend to be parallel to the substrate of the test vehicle. This property shows a stability after reflow processes in a statistics view.

9:55 AM
Thermomigration on 3D IC Pb-Free Micro Bump: *Wei-Cheng Jhu*[1]; Fan-Yi Ouyang[1]; [1]National Tsing Hua university

Due to the demands for high performance and miniaturization, packing technology is moving from 2D IC to 3D IC. In 3D IC, joule heating will be serious and heat will accumulate between stacking chips. In order to effectively remove heat, a temperature gradient will be established across the packages. When a difference of 2°C generates across a micro-bump of 20um in diameter, the temperature gradient will be 1000°C / cm, which has been reported to cause serious thermomigration failure. In this paper, we have successfully designed a novel experiment to establish various temperature gradients across the micro-bump to study the failure mechanism and microstructure change on thermomigration. Furthermore, in-situ infrared microscopy was also used to confirm the temperature gradient and temperature distribution in the solder joints.

10:15 AM

Effects of Small Solder Volume on the Cu/Sn/Cu Interfacial Reactions for 3D IC Applications: *Meng Hsin Chen*[1]; Hsin Yi Chuang[1]; Ting Li Yang[1]; C. Robert Kao[1]; [1]National Taiwan University

This study reveals the miniaturized solder volume effect on the interfacial reactions for 3D IC micro jointing. Cu/Sn(10\149;m)/Cu sandwiches were subjected to the solid-liquid and solid state reactions. The results show that the miniaturized solder volume has less impact on types IMC. In solid-liquid reactions at 250°C for 15 min, nearly the entire Sn phase was transformed into IMC. Cu6Sn5 grains growing from the opposite interfaces impinged on each other and merged into a single grain. In solid state reaction at 150°C, Sn was consumed after 1008 h of aging. The vertically contacted Cu6Sn5 grains remained exhibiting different orientations instead of merging into a single crystal. The detailed microstructure evolution and the IMC growth kinetics are discussed in the present work.

10:35 AM Break

10:45 AM

Volume Shrinkage Induced by Interfacial Reaction in Micro Ni/Sn/Ni Structure: *C. Li*[1]; H. Chuang[1]; M. Kuo[1]; C. Kao[1]; [1]National Taiwan University

In 3D-IC, solder joints of a few microns in size are used to connect Si dies in the third dimension. Theoretically, there is 10.5% shrinkage in volume when Ni reacted with Sn to form Ni3Sn4. If it indeed occurs, solder joints would be in a highly stressed state and prone to failure. In this study, alpha-stepper and SEM (scanning electron microscope) analysis were carried out to measure the actual volume shrinkage for Ni/Sn/Ni sandwich structures during an isothermal aging at 180°C for 0-7 days. The results showed there was about 7.3% shrinkage in volume and the remaining 3.2% shrinkage was released by forming voids in Ni3Sn4 layer. The internal stress and the forming of voids in small scale Ni/Sn/Ni sandwich structures during solid state aging might induce potential reliability issues.

11:05 AM Invited

The Effect of Doping Nd on the Oxidation Resistance and Wettability of Sn-0.7Cu Solder: *Jian Zhou*[1]; Yi-Li Fang[1]; Xu Chen[1]; Yang-Shan Sun[1]; Feng Xue[1]; [1]Southeast University

In the present paper, the oxidation behavior of Sn-0.7Cu solders doping with Nd was studied. By checking gain in weight of solders heated at 250°C or 300°C, Sn-0.7Cu-300ppmNd was found less oxidation formed at the surface than that of Sn-0.7Cu and other solders. The oxide surface of solders was investigated by Auger electron spectroscopy (AES). The results showed that the oxide layer thickness at the surface of Sn-0.7Cu-300ppmNd was much thinner than that of Sn-0.7Cu. Neodymium oxide and tin oxide formed on the Sn-Cu-Nd solders. It was indicated that Neodymium oxide layer prevented O atom from diffusion into the solder inner, so the solders doped with Nd shows improved oxidation resistance. Wetting balance method was used to measure wettability of the solders on Cu substrate. The experimental results showed that minute amount of Nd addition to Sn-0.7Cu solder can increase the wetting force and decrease the wetting time.

11:30 AM

Single-Joint Shear Strength of Micro Cu Pillar Bumps with Different Amounts of Intermetallics: *Yu-Jen Chen*[1]; C. Robert Kao[1]; [1]National Taiwan University

This study investigates the effects of intermetallics on the single-joint shear strength of micro Cu pillar bumps with SAC405 solder caps. The correlation between the shear strength and the intermetallic compound after aging at 180°C for 150, 300, 500, 750 hours is studied. Microstructure characterization reveals that Cu6Sn5 was scallop-type after reflow, and Cu6Sn5 transforms to planar-type after 150 h of aging. Microvoids are observed at Cu3Sn/Cu interface after aging, and the amount of voids increases with aging. According to the shear test results, the shear strength decreased with aging. The formation of a planar Cu6Sn5 layer is the major factor leading to a sharp decrease of the joint strength.

11:50 AM

Interfacial Reactions in the Sn-Co-Cu/Ni Couples: Chih-Ming Chen[1]; *Chia-Ming Hsu*[1]; Sinn-Wen Chen[1]; [1]National Tsing Hua University

The Sn-Co-(Cu)/Ni couples reacted at 180°C and 210°C were prepared. In the Sn-0.05wt%Co/Ni and Sn-0.5wt%Co/Ni couples, the reaction products were continuous Ni3Sn4 phase layer, and discontinuous (Ni,Co) Sn4 phase. In the Sn-0.7wt%Cu-0.05wt%Co/Ni andSn-0.7wt%Cu-0.5wt%Co/Ni couples, the reaction product was the Cu6Sn5 phase in the early stage. With longer reaction time up to 100 hours, Ni3Sn4 phase was formed between the Cu6Sn5 and Ni substrate. Detachment of Cu6Sn5phase in the solder was observed with even longer reaction time to 500 hours, and the results are similar to those in the Sn-0.7wt%Cu/Ni couples. Reaction couples with current stressing were also prepared, and polarity effect was observed. In the Sn-Co/Ni couples, growth enhancement of Ni3Sn4and (Ni,Co)Sn4 were observed at the interface which electron flow from Sn toward Ni.In the Sn-Co-Cu couple, due to the polarity effect, the different grow rates of Cu6Sn5 and Ni3Sn4were found between two different interfaces.

12:10 PM

Microstructural Evolution in SnAgCu Solders and Effect on Constitutive Response During Creep: *Babak Talebanpour*[1]; Praveen Kumar[2]; Zhe Huang[1]; Chien-Hung Wen[1]; Indranath Dutta[1]; [1]Washington State University; [2]Indian Institute of Science

Microstructure of a Sn-Ag based solder continuously evolve during storage and service because of its low melting temperature. This necessitates development of a microstructurally adaptive creep model to accurately predict reliability of solder joints. This work presents a systematic study of microstructural evolution in two Sn-Ag-Cu solder alloys, namely Sn-1.0%Ag-0.5%Cu and Sn-3.0%Ag-0.5%, subjected different thermo-mechanical excursions. Quantitative microscopy is utilized to identify the key thermo-mechanical history dependent length parameter associated with the evolving microstructure, including precipitate size, inter-precipitate spacing, proeutectic grain size and eutectic-channel width, of Sn-Ag-Cu solders. A microstructurally adaptive creep model was developed using this length parameter, where in situ changes in the above microstructural features are considered. Contributions of eutectic and proeutectic regions in the total creep response of the solder were incorporated by treating the solder as a composite with two different micro-constituents. Comparisons between modeling and experiments will be presented.

Phase Stability, Phase Transformations, and Reactive Phase Formation in Electronic Materials XI: Interfacial Reactions of the Pb-free Solder Joints

Kinetics of Solid-State Reactive Diffusion in the Sn/(Ni-X) System: *Masanori Kajihara*[1]; [1]Tokyo Institute of Technology

Tin-base solders are widely used in the electronics industry. If a multilayer Au/Ni/Cu conductor is interconnected with the Sn-base solder, the Au layer quickly dissolves into the molten solder during soldering, and then the Ni layer is directly contacted with the solder. Owing to reactive diffusion at the interconnection between the Ni layer and the solder, Ni-Sn compounds are formed during soldering, and then gradually grow during energization heating at solid-state temperatures. However, the Ni-Sn compounds are brittle and possess high electrical resistivities. Thus, the growth of the compounds deteriorates the electrical and mechanical properties of the interconnection. Addition of alloying element X into Ni may inhibit the compound growth and hence the deterioration of the interconnection. To examine influence of the addition on the compound growth, the kinetics of the solid-state reactive diffusion in the Sn/(Ni-X) system was experimentally observed at temperatures of 433-473 K in the present study.

8:50 AM Invited

Properties of Au-Ge Based Alloys for High Temperature Lead Free Solders: *Christian Leinenbach*[1]; Shan Jin[1]; Fabrizio Valenza[2]; Donatella Giuranno[2]; Rada Novakovic[2]; Hans-Rudolf Elsener[1]; Jiang Wang[1]; Simona Delsante[3]; Gabriella Borzone[3]; Andrew Watson[4]; [1]Empa-Swiss Federal Laboratories for Materials Science and Technology; [2]National Research Council (CNR) – Institute for Energetics and Interphases (IENI); [3]University of Genova; [4]University of Leeds

Low melting Au based alloys offer a combination of high corrosion and creep resistance as well as good electrical and thermal conductivity. Despite their high price, Au alloys are of special interest for high temperature solder applications where these characteristics are essential, e.g. special MEMS devices or in space technology. The alloying system Au-Ge is of particular interests due to a deep eutectic point at 360°C, but information on Au-Ge alloys as solder material is limited. In this work, the feasibility of Au-Ge based alloys as high-temperature lead free solder will be presented. Beside the experimental study and thermodynamic assessment of a number of important alloying systems (Au-Ge-Cu, Au-Ge-Ni, Au-Ge-Sn, Au-Ge-Sb, Au-Ge-Si) wetting and soldering tests using eutectic Au-Ge alloy and relevant substrates were performed. Sound joints with a high strength could be produced. The application of eutectic Au-Ge alloy as solder material for highly loaded components was finally demonstrated.

9:10 AM

Study of Intermetallic Compound Growth of Sn-2.3Ag Solder Micro-Bumps during Solid-State Aging: *Tao-Chi Liu*[1]; Yi-Sa Huang[1]; Chin-Hsing Tang[1]; Chih-Rong Chen[2]; Chih Chen[1]; [1]National Chiao Tung University; [2]Integrated Service Technology Inc

We investigate the relationship between the aging duration and microstructure of intermetallic compounds (IMCs) in SnAg microbumps with about ten microns bump height. Three structure, including Cu/solder/Cu, Ni/solder/Cu, and Cn/Ni/solder/Cu were prepared and studied. Contrary to traditional packaging, the growth rate of IMCs is the key concern for electronic reliability of 3D-stacked ICs. In this study, aging tests at 150°C up to 1000 hr were performed on the above three sets of microbumps. The results illustrate that the IMCs on the Cu UBM can be grown above 100 hours at 150°C aging, the thickness of Cu6Sn5 is 2.24 microns; and Cu3Sn is 1.09 microns. Eventually the micro-bump was fully transferred to brittle IMCs within 500 hours aging. Nevertheless, for Cu/Ni/solder/Cu microbumps, The Ni3Sn4 IMC on the Ni side was only about 1 micron after aging for 1000 hr. The results will be presented in the conference in details.

9:25 AM

Reflow and Solid-State Reactions between SnAgCu-xNi Solder and Au/Pd/Ni Surface Finish: *Bo-Mook Chung*[1]; Yong-Ho Baek[1]; Jaeho Choi[2]; Joo-Youl Huh[1]; [1]Korea University; [2]Gangneung-Wonju National University

Recently, electroless Ni/electroless Pd/immersion Au (ENEPIG) was introduced as an alternative surface finish to electroless Ni/immersion Au (ENIG) in electronic packaging industry owing to its superior solder joint reliability. However, when the EP layer is relatively thick, Pd atoms resettle as $PdSn_4$ near the solder/Ni interface during the reflow and aging processes and deteriorate joint reliability. In this study, we have examined the effect of Ni addition to Sn-3.0Ag-0.5Cu solder on Pd resettlement during the reflow and solid-state aging processes. Solder balls (φ 450 m) of Sn-3.0Ag-0.5Cu-xNi (x=0~0.5 wt.%) were reflowed on ENEPIG finished pads (φ 400 μm) with a 0.3-μm-thick EP layer at 250°C for 120 s. Solid-state aging was carried out at 150°C for pre-determined times. In the presentation, the results for the intermetallic growth and Pd resettlement during the reflow and aging reactions will be discussed with respect to the effects of the Ni contained in solder.

9:40 AM

Effect of Interfacial Compound Layer on Pd Resettlement during Reflow and Solid-State Reactions between Sn-rich Solder and Ni Substrate: *Yong-Ho Baek*[1]; Bo-Mook Chung[1]; Jaeho Choi[2]; Joo-Youl Huh[1]; [1]Korea University; [2]Gangneung-Wonju National University

Electroless Ni/electroless Pd/immersion Au (ENEPIG) surface finish is now becoming a preferable choice in electronic packaging industry to achieve reliable solder joints with SnAgCu (SAC) solders. In this study, we have examined how Pd resettlement depends on the intermetallic compound (IMC) phase, Ni_3Sn_4 or Cu_6Sn_5, formed at solder joints during the reflow and solid-state aging treatments. For Pd resettlement during the reflow process, solder balls (φ 450 μm) of Sn-3.5Ag, SAC302 and SAC305 were reflowed on the ENEPIG finished pads (φ 400 μm). For Pd resettlement during solid-state aging, two kinds of diffusion couples, Pd(1 μm)/Sn-1.0 wt% Cu(60 μm)/Ni and Pd(1 μm)/Sn(60 μm)/Ni, were prepared by electroplating and then aged at 150°C to monitor IMC growth and Pd resettlement at the solder/Ni interface. In the presentation, we will discuss a possible mechanism of how Pd resettlement can be controlled by changing the IMC layer formed initially at the solder/Ni joints.

9:55 AM
Employment of a Bi-Layer of NiP/Cu as a Diffusion Barrier Layer for Cu bump/Sn Bonding Structures for the 3D Integration Applications: *Byunghoon Lee*[1]; Haseok Jeon[1]; Hoo-Jeong Lee[1]; [1]Sungkyunkwan University

Cu bump /Sn layer/Cu bump is a widely-adopted bonding structure for 3D integration; nevertheless, a strong material interaction between Cu and Sn that occurs during manufacturing processes and under actual usage conditions is potentially a serious problem for both thermal and mechanical reliabilities. Here, we propose the introduction of a bi-layer of plated Ni(P) and Cu as a diffusion barrier. The Ni(P) layer with a thickness of 1um serves to prevent Cu diffusion whereas the Cu layer with a thickness of 0.5um is expected to react with Sn and form Cu6Sn5, which would subsequently suppress a reaction between Ni and Sn. We deposited the bi-layer barrier using a wet process, electroless-plating for Ni(P) and electroplating for Cu. We examined the effects of the barrier on the thermal stability and bonding morphology using SEM and TEM. Then we carried out lap-shear tests to characterize the mechanical properties.

10:10 AM Break

10:25 AM Invited
The Impacts of Palladium Addition on Phase Formation, Microstructure Evolution and Mechanical Reliability in Sn-Ag-Cu/ENEPIG and Sn-Ag-Cu-Pd/ENIG Solder Joint: Chien Fu Tseng[1]; I-Dai Wang[1]; Tae-Kyu Lee[2]; Kuo-Chuan Liu[2]; Chih-Yuan Cheng[3]; Jim Wang[3]; *Jeng-Gong Duh*[1]; [1]National Tsing Hua Univ; [2]Cisco Systems Inc.; [3]Shenmao Technology Inc.

Interfacial reactions of ENIG (electroless nickel and immersion gold) and ENEPIG (electroless nickel, electroless palladium and immersion gold) jointed with Sn-3.0Ag-0.5Cu solder were investigated in this study. It was found that Pd mainly dissolved into Cu6Sn5, which further suppressed the growth of intermetallic compound (IMC) in the Sn-3.0Ag-0.5Cu/ENEPIG solder joint. In addition, with slower growth of Cu6Sn5, less columnar Kirkendall voids would form in the Ni3P layer. This study aims to figure out the interfacial variations between ENIG and ENEPIG surface finishes after jointed with lead free solder. Alternatively, a new solder alloy, Sn-3.0Ag-0.5Cu-xPd (x=100, 250, 500 ppm), was developed and jointed with ENIG surface finish in order to explore the effects of Pd on the solder joint. Similar to Sn-3.0Ag-0.5Cu/ENEPIG solder joint, the Pd doing in solder also resulted in slower IMC growth and less columnar voids formation during solid and liquid state reaction. Moreover, the mechanical property showed that the Pd added solder joint was superior to that without Pd addition via the high speed impact tester. The Pd effects on phase formation, microstructure evolution and mechanical testing were investigated and summarized in this study. Finally, the detailed mechanism of Pd addition in interfacial reaction of solder joints will be proposed and discussed.

10:45 AM
The Interfacial Reaction between Diffusion Barrier and Thermoelectric Materials under Current: *Li-Chen Lo*[1]; Albert T. Wu[1]; Tai-Ying Lin[1]; [1]National Central University Department of Chemical and Material Engineering

This paper investigated the interfacial reaction between the diffusion barrier, Ni, and the thermoelectric materials. Ni is a good barrier between Pb-free solder and n-type bismuth telluride (Bi2Te2.5Se0.5) thermoelectric material to prevent the rapid formation of brittle SnTe intermetallic compound (IMC). Instead of SnTe, Ni3Sn4 and NiTe formed at the interfaces. These IMCs would affect the mechanical and electrical properties of the thermoelectric module. Different current densities were applied to the system to investigate the electromigration behavior of the systems at various temperatures. The results suggested that the variation of the thicknesses of the IMCs not only depended on the polarity; it was affected by the localized increase in temperature due to the Peltier effect. The kinetics of the atomic motion will be discussed.

11:00 AM
Interfacial Reactions of the Sn-xZn/Au Couples: *Yee-Wen Yen*[1]; Hsien-Ming Hsiao[1]; Cheng-Kuan Lin[1]; [1]National Taiwan Univ of Science & Tech

The interfacial reactions of the Sn-xZn/Au couples were investigated. When the Zn content was less than 3 wt%, the Au-Sn binary and a few Au-Sn-Zn ternary intermetallic compounds (IMCs) were formed at the interface. Both binary Au-Sn and Au-Zn and Au-Sn-Zn ternary IMCs were formed at the Sn-5Zn/Au interface. When the Zn content was greater than 7 wt%, the Sn-xZn/Au couples were completely transferred to the Au-Zn system. The n value of the Sn-xZn/Au (x< 5 wt%) couples were between 0.25-0.33. The Sn-xZn/Au (x=7 to 15 wt.%) couples also have the similar results when the aging times were less than 144 h. The n value of the Sn-50Zn/Au couple was 0.5, the reaction mechanism was diffusion-controlled. The n value of Sn-90Zn/Au couple was 0.19. The results indicated that the adding the Zn into the Sn-Zn alloys would change the reaction systems from the Au-Sn to Au-Zn systems.

11:15 AM
Asymmetrical Microstructure on the Two Joint Interfaces of Flip-chip Cu/Sn/Cu Solder Joints: Cheng-Yi Liu[1]; *Yu Jin Hu*[1]; [1]National Central University

In this study, we observed an asymmetrical microstructure between the joint interfaces of Cu/Sn/Cu flip-chip solder joints. A serious Cu-Sn compound phase accumulated near the bottom interface of the Cu/Sn/Cu flip-chip solder joints. On the contrary, no obvious Cu-Sn compound phase can be found near the upper interface of the Cu/Sn/Cu flip-chip solder joints. We believe that this asymmetrical microstructure could be caused by the solidification process after reflowing process. During the solidification process of the flip-chip solder joint, the upper joint interface, i.e., close to the chip side, would be cooling earlier than the bottom interface. So, there is the liquid/solid interface run across the Cu/Sn/Cu solder joint. The liquid/solid line bring the Cu-Sn compounds down to the bottom joint interface. In this talk, the detail microstructure evolution of the solder joint during the cooling process would be discussed.

11:30 AM
Influence of Stress on the Microstructural Development of Sn-Ag-Cu Solder Alloy during Aging: *Choong-Un Kim*[1]; Huili Xu[1]; Tae-Kyu Lee[2]; Hong-Tao Ma[2]; Kuo-Chuan Liu[2]; [1]The University of Texas at Arlington; [2]Cisco System Incorporation

The close linkage between the microstructure of solder and its joint reliability has spurred extensive studies. While many studies have investigated evolution of Sn grain structure with aging, they usually neglect the fact that 1) aging induced change in grain structure is coupled with stress state of joint and 2) stress state can vary significantly depending on the location of joint in the electronic packaging, Our investigation, conducted primarily on Sn-Ag-Cu alloys in PBGA packaging structure, reveals that Sn structure development during aging is indeed affected significantly by stress state (shear, triaxial), and, as a result, Sn structure exhibits strikingly different crystallographic and metallurgical features depending on the joint location in the packaging structure (center, edge and outer corner of package). This paper introduces experimental evidences supporting the unique variation in Sn grain structure with aging and joint location, and the analysis on the stress state leading to such variations.

11:45 AM
Effect of Bump Height on Interfacial Reaction of Cu/SnAg/Ni Structure: *Yi-Sa Huang*[1]; Chin-Hsing Tang[1]; Chih Chen[1]; [1]National Chiao Tung University

Intermetallic compound (IMC) growth of Cu/Sn2.3Ag/Ni solder joint after reflow was observed in this study. The bump height of the solder joints are 10, 20 and 40 μm. In 40 μm-height solder joint, $(Cu, Ni)_6Sn_5$ as IMC grows rapidly on both sides. In 20 μm-height one, IMC grows slower on Ni side but faster on Cu side. However, the IMC growth information has a different trend when bump height reduces to 10 μm. $(Cu, Ni)_6Sn_5$ on Ni side stops growing as reflow time increases. Compositional analysis was performed to measure the element concentration in the as-fabricated solder joint. Cu concentration and Ni concentration increase when bump height reduces. In the 10 μm-height solder joint, average Cu concentration is 2.44 at. %, and average Ni concentration is 1.57 at. %. The concentrations are speculated as the main factor which affects the interfacial IMC growth rate on the solder joint.

Phase Transformations and Deformation in Magnesium Alloys: Phase Transformations and Deformation

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS/ASM: Phase Transformations Committee

Key Issues in Thermodynamic Mg Alloy Database: *Rainer Schmid-Fetzer*[1]; [1]Clausthal University of Technology

Key issues in a large thermodynamic Mg database (20 components, over 450 assessed phases) are consistency, coherency and quality assurance. These issues concern extension, maintenance and updating of the database. For example, merging published assessments of additional binary or ternary subsystems requires scrutinizing the structural modeling especially of pertinent solid phases. First of all it must be checked if a given thermodynamic description is correct in producing the intended stable phase diagram. Also the thermodynamic properties, such as enthalpies of formation and absolute entropies must be checked for realistic values, considering also systematic trends as observed for binary Mg-RE phases. Metastable phases must be assessed with realistic values. These are also the standards for own assessments in combination with key experiments. The second focus of this presentation is on the database application by predicting phase formation during solidification and heat treatment in multicomponent magnesium alloys from thermodynamic calculations.

Grain Refinement of Magnesium Alloys: Theoretical Developments and Their Application: *David StJohn*[1]; Ma Qian[1]; Mark Easton[2]; [1]University of Queensland; [2]Monash University

This paper covers developments that have occurred since our Metallurgical and Materials Transactions publication on the Grain Refinement of Magnesium Alloys associated with the previous special symposium on this topic in 2005. Since that time we have developed the Interdependence Theory which provides a new perspective for the study of grain refinement. It is a new model for analyzing grain refinement mechanisms and predicting grain size outcomes. After an introduction to the Interdependence Theory we will revisit the refinement of Mg-Al and Mg-Zr alloys as well as reviewing the broader research on grain refinement of magnesium alloys. Consideration will also be given to reported grain size variations observed in high pressure die cast alloys and ultrasonically treated alloys, both of which exhibit a relationship to the growth restriction factor Q defined by the alloy chemistry. Finally, we discuss the implications of the theory regarding directions for future research.

9:25 AM Invited

Enhancement of Precipitation Hardening of Magnesium Alloys by Microalloying: *Kazuhiro Hono*[1]; C. L. Mendis[1]; T. T. Sasaki[1]; T. Ohkubo[1]; T. Bhattacharjee[1]; [1]National Institute for Materials Science

The age-hardening responses of rare-earth free magnesium alloys are too low to give extra hardening after wrought processes; however, microalloying to Mg-Zn, Mg-Ca, and Mg-Sn alloys lead to substantial enhancements of age hardening responses. We have systematically worked on the microalloying effect of rare-earth free Mg alloys to investigate the feasibility of developing age hardenable wrought alloys. In this talk, we overview our recent TEM/STEM and 3D atom probe studies on micoralloyed Mg-Zn, Mg-Sn and Mg-Ca alloys, and discuss how peak aged microstructure can be refined by microalloying based on TEM/STEM and 3D atom probe studies.

Modeling Nucleation and Growth during Co-Precipitation in Mg-RE Alloys: Yipeng Gao[1]; Hong Liu[2]; Jianfeng Nie[2]; *Yunzhi Wang*[1]; [1]The Ohio State University; [2]Monash University

Most light alloys are strengthened by precipitation hardening and the size, shape, spatial orientation, coherency state and spatial distribution of precipitates determine the deformation mechanism and mechanical behavior of these alloys. To assist in alloy design, a new modeling framework based on the phase field approach is developed. It is able to use ab initio calculations, CALPHAD database and crystallography of phase transformations from theoretical models and TEM characterizations as direct inputs, and treat nucleation and growth events involving simultaneously displacive and diffusional processes and heterogeneous nucleation near pre-existing lattice defects such as dislocations, grain boundaries and second-phase particles. Using ß1 and ß' precipitation in WE54 as an example of the Mg-RE series alloys, we show that the activation energy, critical nucleus configuration and precipitation sequence can be determined using this new approach. These are critically important parameters for alloy design but extremely difficult to determine experimentally.

Mg-M-RE Alloys Containing LPSO Structures with Synchronization of Stacking and Chemical Modulations: *Yoshihito Kawamura*[1]; Michiaki Yamasaki[1]; Eiji Abe[2]; Koji Hagihara[3]; [1]Kumamoto University; [2]The University of Tokyo; [3]Osaka University

New heat-resistant wrought Mg-M-RE alloys that are duplexes of a-Mg phase and a novel phase with a long period stacking ordered (LPSO) structure, have been developed in Japan. The M element is Co, Ni, Cu, Zn, or Al, and the RE (rare earth) element is limited to Y, Gd, Tb, Dy, Ho, Er, or Tm. Four kinds of LPSO structures are found in these alloys: 10H, 18R, 14H, and 24R, in which the M and RE elements are enriched in two atomic layers on basal planes at intervals of 5, 6, 7, and 8, respectively. Also, these structures can be called "Synchronized LPSO Structures", because the stacking and chemical modulations are harmonized. These synchronized LPSO phases have more preferable mechanical properties than the a-Mg phase and exhibit kink deformation, which further improves the mechanical properties drastically.

10:50 AM

On the Structure, Transformation and Deformation of Long-Period Ordered Structures in Mg-Y-Zn Alloys: Yuman Zhu[1]; Allan Morton[2]; *Jian-Feng Nie*[1]; [1]Monash University; [2]CSIRO

Ternary Mg–Y–Zn alloys have attracted increasing attention due to their promising mechanical properties and unique microstructures. The microstructure of the Mg–Y–Zn alloys contains predominently precipitates of metastable 18R and/or equilibrium 14H long-period ordered structures, depending on the processing conditions of the alloy.

Such 18R and 14H structures are also found in other magnesium alloys such as Mg–Gd–Zn, Mg–Gd–Y–Zn, Mg–Dy–Zn, Mg–Ho–Zn, Mg–Er–Zn and Mg–Y–Cu. This presentation will provide an overview of recent results on the characterisation of the structure, transformation and deformation of the 18R and 14H structures using high-angle annular dark-field scanning transmission electron microscopy and electron diffraction. These recent experimental results will also be discussed in the context of precipitation in other Mg-RE-Zn alloy systems and the design of alloys for higher strength.

Creep Mechanism in a Mg-6Al-3Ca-0.3Mn Alloy: *Tomoyuki Homma*[1]; S. Nakawaki[1]; Shigeharu Kamado[1]; [1]Nagaoka University of Technology

High temperature resistant Mg-6Al-3Ca-0.3Mn (mass%) alloy has been developed by gravity casting technology. After the solidification, network-shaped compounds form on grain boundaries, suppressing grain boundary sliding. When the Mn-containing alloy is subjected creep deformation, fine and equiaxed Al-Mn type particles distribute in the matrix during the primary creep region. The number density of the fine particles increases as the creep time increases. Due to the presence of the precipitates, threshold stress appears in a strain rate-applied stress diagram. The detailed creep mechanism will be clarified.

11:40 AM Invited

Deformation in Magnesium from First-Principles: *Dallas Trinkle*[1]; Joseph Yasi[1]; Louis Hector[2]; [1]University of Illinois, Urbana-Champaign; [2]General Motors R&D Center

Predictive modeling of strength from first-principles electronic structure methods offers great promise to inform Mg alloy design. Simulating the mechanical behavior for new alloys requires an understanding of mechanisms for deformation at atomic-length scales, with accurate chemistry, extended to larger length- and time-scales. Modern computational approaches can now investigate dislocations from first-principles, and compute interactions with solutes across the periodic table. We can predict metallurgical trends with changes in size and chemical misfits, and connect those to predictions of mechanical behavior through predictive models. Comparing alkali, alkali earth, and transition metals with rare earth solutes provides new connections between electronic structure and mechanical behavior. Moreover, the computational approach provides a blueprint for attacking new challenges in deformation behavior beyond solute strengthening and softening.

12:05 PM

In-Situ Neutron Diffraction Study of Aging of a Mg-Y-Nd-Zr Alloy (WE43): Effects of Precipitation on Individual Deformation Mechanism Strength and Activity: *Sean Agnew*[1]; F. Polesak[1]; Bjorn Clausen[2]; [1]University of Virginia; [2]Los Alamos National Laboratory

There is an outstanding question regarding why the age hardening response of Mg alloys is not nearly as good as many competing Al alloys. A recent hypothesis is that it is due to precipitate geometry, since many commercial Mg alloys form either basal plate-shaped precipitates or c-axis aligned rod-shaped precipitates. These are among the least effective shapes to obstruct basal slip. It is further proposed that prismatic plate-shaped precipitates would be most effective for strengthening Mg alloys. The Mg-Y-Nd-Zr alloy, WE43, is an alloy which does form prismatic plate shaped precipitates during aging. In-situ neutron diffraction and crystal plasticity modeling are employed to explore the effect of these precipitates on the strength and hardening responses of basal slip, {10.2} extension twinning, and non-basal slip. The results confirm that basal slip is responsible for yielding in this cast alloy, and that the basal slip mechanism is most affected by the precipitation.

Randall M. German Honorary Symposium on Sintering and Powder-Based Materials: Powder Technology

Sponsored by: The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Powder Materials Committee

Program Organizers: K. Morsi, San Diego State University; Fernand Marquis, Naval Postgraduate School; John Meyer, Iowa State University; Ahmed El-Desouky, San Diego State University; Eugene Olevsky, San Diego State University

8:30 AM Keynote

Nanostructured Metals: Synthesis and Behavior from the Nanoscale to the Microscale: *Enrique J. Lavernia*[1]; [1]University of California, Davis

Bulknanostructured materials and composites have matured into a new class of materials that can be synthesized using various methods, including mechanical alloying of powders in liquid nitrogen (cryomilling). Results from various groups around the world reveal considerable improvements in the physical performance of a variety of cryomilled Al alloys, as well as interesting reports of novel deformation mechanisms. Their inherently low plasticity has been addressed via the introduction of additional size scales. In this lecture, recent results are reviewed and discussed with particular emphasis on the following topics: recent findings in the area of cryomilled materials; primary consolidation and secondary processing methods; microstructural evolution from nanostructured powders to bulk materials during consolidation; and mechanical behavior of consolidated materials. The deformation behavior and the underlying mechanisms of cryomilled materials are discussed in an effort to shed light into the fundamental behavior of ultrafine grained and nanostructured materials.

Improved Understanding of Gas and Melt Flow Manipulation for Enhanced Control of Powder Yields from Close-Coupled Gas Atomization Processing: *Iver Anderson*[1]; Joel Rieken[2]; John Meyer[2]; David Byrd[1]; Andrew Heidloff[1]; [1]Ames Laboratory; [2]Iowa State University

Significant progress in design of discrete-jet close-coupled (DJ-CC) gas atomization nozzles and melt feed tubes has helped achieve powder particle size control and efficient use of gas flow energy for gas atomization of metal and alloy powders. Powder yield characterization and high-speed video observations of atomization trials were performed from Ar atomization of special ferritic stainless steel and other selected metals and alloys. Also, gas atomization flow simulations using surrogate fluids, e.g., water, and schlieren gas flow visualization and aspiration measurements were conducted for Ar and N2 and a range of parameters for DJ-CC nozzles. Closed wake gas flow patterns were found most effective for enhanced fine powder processing and open wake flow with slotted “trumpet bell” pour tubes were utilized to gain close size control (standard deviation < 1.6) over an order of magnitude of particle diameters (50-500µm). Supported by USDOE-FE and Carpenter Technologies, Inc., through contract no. DE-AC02-07CH11358.

9:50 AM Invited
Production, Characterization and Application of Mono-Size Alloy Droplets: *Teiichi Ando*[1]; [1]Northeastern University

Mono-size alloy droplets are produced by controlled capillary jet breakup, a droplet generating process, also used in ink-jet printing technology. With Rayleigh instability controlled through the decoupled process parameters of jet diameter, mass flow rate and perturbation frequency, mono-size droplets of desired diameter can be generated at high rates with essentially full yield. The uniform size of droplets assures nearly identical solidification paths for all the droplets generated under fixed process conditions. This permits precise prediction of the motion and thermal and solidification behaviors of the droplets through rigorous process and metallurgical modeling, which is applicable to industrial thermal spray processes as well. Uniform droplets can be in-flight solidified or deposited on a substrate to produce various forms of materials with novel rapid solidification microstructures. Areas of industrial applications are discussed.

TEM Guided Microstructural Design of MgH2 Powders and Thin Film Alloys with Room Temperature Volumetric Hydrogen Cycling Ability: *David Mitlin*[1]; Peter Kalisvaart[1]; Mohsen Danaie[1]; Shu Tao[2]; Ben Zahiri[1]; Helmut Fritzsche[3]; [1]University of Alberta and NINT NRC; [2]Eindhoven University of Technology; [3]SIMS-CNBC NRC

This presentation is separated into two sections: We will first discuss our recent cryogenic stage transmission electron microscopy (TEM) – based findings on the MgH2 to Mg (and vise versa) phase transformation in high-energy milled powders. We show that both reactions are nucleation limited, rather than core shell, and identify the dominant metal - hydride orientation relationships. By performing cryo-TEM on ball milled powders we discovered deformation twins in the microstructure. Density functional theory (DFT) analysis demonstrates that the twins significantly affect the kinetics of hydrogen diffusion. In the second portion of the presentation we highlight our recent alloy design efforts for both “bulk” thin films and thin film multilayers. The research culminates in the creation of several classes of catalysts that enable for relatively rapid room temperature volumetric sorption over multiple cycles. The same catalysts allow for ultra-rapid 250+ cycles elevated temperature absorption/desorption at pressures of 1-3 atm.

10:55 AM
Effect of Pre-Consolidation Solidification Structure in Novel Gas Atomization Precursor Powder Approach for Efficient Production of Ni-based Oxide Dispersion Strengthened (ODS) Alloys: *John Meyer*[1]; Joel Rieken[1]; Iver Anderson[2]; [1]Iowa State University; [2]Ames Laboratory, US DOE

Oxide dispersion strengthened (ODS) Ni-base superalloys have been considered promising candidate materials to combat the challenging operating conditions of future thermal power plants. Traditional processing (i.e. mechanical alloying) of Ni-based ODS materials is very time, energy and cost intensive as well as susceptible to contamination. Gas atomization reaction synthesis with a reactive (Ar/O_2) atomization gas was developed as a simplified route for processing of ODS precursor powders. The pre-consolidation microstructure and amount of solute trapping as a result of rapid solidification were investigated using x-ray diffraction coupled with electron microscopy to determine how it affects the distribution and size of the yttrium-enriched nanometric oxide dispersoids formed during the internal oxygen exchange reactions upon consolidation. The resulting spacing was expectedly similar to the as-atomized solidification structure, a trend observed in similar Fe-based ODS alloys produced via this process. Supported by Carpenter Technology and USDOE-FE-ARM Program through Ames Laboratory contract no. DE-AC02-07CH11358.

11:10 AM
Effect of Rapid Solidification and Heat Treatment on D2 Tool Steel: *Pooya Delshad Khatibi*[1]; Hani Henein[1]; Douglas Ivey[1]; [1]University of Alberta

It is believed that excellent mechanical properties of D2 steels can be achieved from reduced microsegregation and a good distribution of carbides during the solidification. An understanding of the evolution of microsegregation and carbide formation during rapid solidification is necessary to control the microstructure. Impulse Atomization (IA) has been employed to produce rapidly solidified (RS) powders of D2 steel in helium and nitrogen cooling gases. The resulting powders were sieved into different size ranges and the microstructures and phases were examined using SEM, XRD and neutron diffraction. In addition to a substantial refinement of grain size, rapid solidification also suppressed the martensitic transformation and produced supersaturated retained-austenite. Different annealing tests were carried out on the as-atomized powders. SEM images showed a good distribution of precipitated carbides after annealing. The effect of annealing on the RS powders was evaluated using Vickers microhardness measurements and the precipitated carbides were characterized using TEM.

Advantages of Long Term Al Recycling Batch Planning in a Constrained Secondary Material Market: *Tracey Brommer*[1]; Britt Elin Gihleengen[2]; Elsa Olivetti[1]; Randolph Kirchain[1]; [1]Massachusetts Institute of Technology; [2]Norsk Hydro

The sizable energy savings resulting from remelting secondary materials during aluminum production reduce environmental impact and cost. Economic savings result from the lower cost of secondary materials and reducing alloying additions. Strong market demand for secondary materials has restricted material availability for industrial remelters. Optimizing production on a charge by charge basis may lead to non-optimal allocation of secondary materials. Effective use of secondary materials as a means to reduce cost and master alloy consumption is improved by optimization over a longer time horizon. Expanding the optimization time horizon allows the explicit calculation of the optimal allocation of raw materials for each alloy in the production portfolio. In this investigation, the authors evaluate the advantages of optimizing over a longer time horizon using performance metrics of cost, raw material allocation, and out of specification rate.

8:50 AM
Mechanical Dross Processing: The Approach to Zero Waste from Smelter and Secondary Dross: *David Roth*[1]; [1]GPS Global Solutions

Mechanical dross treatment was the standard method of dross treatment before the advent of the tilt type rotary furnace. There were four predominant systems used. The first three are no longer used because of maintenance and technical aspects of the equipment and aluminum recovery issues. The classical impact crusher systems are used today for high volume dross processors. The RT Metal/Reclaimer manufactured by DIDION has now allowed small volume dross generators the ability to use this type of technology. This paper will discuss the past systems and how the RT Metal/Reclaimer System brings dross recycling without the use of salt fluxes to the individual casting and melting facilities, significantly improving the environment and reducing land fill materials.

9:10 AM

Recycling of Aluminium Alloy Scraps by Pressure-Assisted Investment Casting for Aluminium Foam Manufacture: *Seksak Asavavisithchai*[1]; Areeya Srichaiyaperk[1]; Natthida Jareankieathbovorn[1]; [1]Chulalongkorn University

Recycling of ADC12 alloy scraps for fabrication of open-cell aluminium foams has been conducted via pressure infiltration method of replication process. The scrap, up to 50 wt.%, was melted with pure aluminium billet, followed by infiltration in a replicated mold of polyethylene foam structure. Compared with the pure aluminium foam, the compressive strength and hardness are higher for the foams with recycled scraps. The increase in foam mechanical properties is due to the presence of Si hard phase in Al matrix. The strength and hardness of the foams also increase with increasing contents of the scraps.

9:30 AM

In-Process Separation of Mill Scale From Oil at Steel Hot Rolling Mills: *Naiyang Ma*[1]; [1]ArcelorMittal

High oil concentration is one of the major barriers for recycling of mill scale of steel hot rolling mills. It is of vital importance to find cost-effective technologies of reducing oil concentration in mill scale in order to recycle the mill scale without causing detrimental effects on production and environment. This paper discusses in-process separation of mill scale from oil at steel hot rolling mills. Formation of mill scale and status of oily wastewater at hot rolling mills are reviewed in the first place. A mathematical model is then formulated to relate oil concentration in mill scale to physical properties of mill scale, chemical and physical properties of wastewater and interacting parameters between mill scale particles and wastewater. From this model, three approaches of in-process separation of mill scale from oil are derived: (1) avoiding contacts between mill scale particles and oily wastewater, and (2) maintaining low oil concentration in wastewater, and (3) collecting mill scale in upper streams of wastewater flows. In-process separation of mill scale from oil might have advantages of lower capital cost, lower operating cost and less additional environmental concerns, compared to other strategies of separating mill scale from oil.

9:50 AM

Recycling of Electric Arc Furnace Dust: *Vicente Sobrinho*[1]; Vitor Telles[2]; Felipe Grillo[2]; Jose Oliveira[1]; Jorge Alberto Tenorio[2]; Denise Espinosa[2]; [1]IFES; [2]USP

This research aims to study the process of incorporation of the metal iron in electric arc furnace dust (EAFD), from a steel mill producing long steel by liquid iron in addition to the changing temperature of 1400 degree Celsius altering experimental conditions such as how to add the EAFD. Previously, the EAFD will be characterized using the following techniques: chemical analysis, X-ray diffraction, scanning electron microscopy (SEM) and Energy Dispersive Spectroscopy (EDS) microanalysis. After characterization, the EAFD to be added to the bath of liquid iron. The achievement of fusion experiments in laboratory scale, will take place in a vertical tubular furnace with temperature control. The fusion experiments to assess the incorporation of the metal iron will use graphite crucibles. It is expected that the results obtained at the end of the research allow the evaluation of the iron metal incorporation of eletric arc furnace dust in pig iron bath.

10:30 AM

Recycling of Electric Arc Furnace Dust in Iron Ore Sintering: *Victor Telles*[1]; Denise Espinosa[1]; Jorge Tenório[1]; [1]University of Sao Paulo - USP

The purpose of this work was to study the reutilization of the steelmaking dust, derived from steel production in the electric arc furnace, in iron ore sintering process aiming zinc elimination. In each sintering process were collected sintered samples, these materials were analyzed by chemical analysis using atomic absorption spectrophotometry in order to determine the zinc content. Samples of not sintered mixtures were also characterized by chemical analysis aiming to determine the initial amounts of zinc, i.e. in order to check the zinc amounts present in the mixture before the sintering process. The comparation among the zinc contents of samples sintered and not sintered allowed to determine the elimination of zinc during the experiments. Results showed that the zinc elimination in the process is proportional to the ratio reducer/waste. Zinc removal was lower when the reducer/waste ratio was decreased.

10:50 AM

Extraction of Iron Oxide and Concentration of Titanium Compounds in Bauxite Residue: Edilson Magalhães[1]; Emanuel Macêdo[1]; José Antonio Souza[1]; João Nazareno Quaresma[1]; Danielly Quaresma[1]; *Luis Venancio*[1]; [1]Federal University of Pará

The production of alumina from bauxite using the Bayer process generates the residue known by red mud. This material can be used as a source for concentration and recovery of valuable metals such as titanium. The greatest difficulty of concentrating titanium compounds is the large amount of iron oxide present in red mud > 30% by weight. This paper shows the extraction of the iron oxide, increasing the concentration of the titanium compounds. The red mud is leached with H2SO4 at 20% and 30% concentration and temperature range of 60°C, 80°C and 90°C.Analysis of the leached and concentrated was made to verify the effectiveness of the iron oxide extracting process and the titanium compounds concentration viability.

11:10 AM

Pyrometallurgical Approaches for Utilization of Smelting Slag from Cobalt Concentrate: *Jeongsoo Sohn*[1]; Kang-In Rhee[1]; Soo-Kyung Kim[1]; [1]Korea Institute of Geoscience and Mineral Resources

Although a few countries only mine and produce for cobalt, cobalt is used for many applications such as secondary battery, cemented carbide, super alloy, catalyst, magnet, and pigment and so on. There is serious problem that by product (slag) is produced in the course of cobalt ore smelting. That is a major reason to induce the environmental pollution. It is necessary, therefore, to find a utilization of slag as well as to develop eco-friendly efficient smelting technology. For these purposes, reductive smelting of cobalt ore process, eco-friendly leaching process, customized cobalt compound manufacturing process, especially recycling of smelting slag process were proposed. For recycling of smelting slag process, in this study, a novel approach of directly recycling the liquid slag to prepare small drop size ball as can be used for various applications using slag atomizing technology was proposed.

11:30 AM

Heat Treatment of Black Dross for the Production of a Value Added Material - A Preliminary Study: *Reza Beheshti*[1]; Shahid Akhtar[2]; Ragnhild E. Aune[3]; [1]KTH; [2]NTNU; [3]NTNU,KTH

The potential use of Black Dross (BD) as a raw material in the production of refractories, fluxing agents and glasses is the main motivation of the present study. Heat treatment experiments were carried out in Ar, and under reduced pressure (20Pa), to evaluate the salt removal efficiency. The chemical composition of the BD after heat treatment was investigated by SEM-EDS and XRD analyses. Based on the present results, it was established that the salt starts to evaporate at \8776 1273 K in Ar, and under reduced pressure. The salt removal efficiency in a 20 g sample was found to increase in both cases as a function of time and temperature. Moreover, in Ar the chloride concentration was lowered to 0.3 wt% after heat treatment at 1573 K for 10 hours. Under reduced pressure, however, 0.2 wt% residual chloride was obtained after 8 hours at 1473 K.

11:50 AM
Development of Synthetic Flux for Basic Oxygen Steel Making Using Waste Oxides of Steel Plant: *Jagannath Pal*[1]; S. Ghorai[1]; P. Venkatesh[1]; D. P. Singh[1]; M. C. Goswami[1]; D. Bandyopadhyay[1]; S. Ghosh[1]; [1]Council of Scientific and Industrial Research, National Metallurgical Laboratory

In BOF operation, burnt lime as flux often creates problem due to its high melting point (2700ºC), poor dissolution, fines generation and hygroscopic nature. Since Fe2O3 and 22% CaO form eutectic at 1230ºC, in current study, a pre-fused synthetic flux in form of sinter was prepared from LD sludge and lime fines as source of iron oxide and CaO respectively. Mixture of aforesaid fines were pelletized into micropellets (2-6mm) that were strengthened by an innovative treatment using steel plant's waste gas rendering excellent handling properties. The treated micro-pellets were subsequently sintered in a 7-9 kg capacity pot sintering set-up without coke breeze. The produced sinter contains upto 45% CaO and exhibits suitable handling properties, low softening point (1180 ºC) and quick dissolution (27-32 sec/g). Being non-hygroscopic it is suitable for storage, handling and charging. Flux prepared through this cokeless sintering has high potential as a flux material in BOF process.

12:10 PM
Addition of Electric Arc Furnace Dusts in Hot Metal: *Felipe Grillo*[1]; Denise Espinosa[1]; Jose Oliveira[2]; Jorge Tenório[1]; [1]University of Sao Paulo - USP; [2]Federal Institute of Espírito Santo

The aim of this work was evaluation of the recovery of Zn and Fe of the EAFD added to the hot metal in the form of a briquette at temperature of 1500°C. the EAFD was agglomerated by cold briquetting and introduced in the hot metal. This study utilized a bench-scale equipment to melt, during this process to kept a flow rate of inert gas above the bath. Were collected periodically metal samples and the samples were analyzed for determination of the content of total silicon and carbon by chemical analysis. Zinc oxide, zinc ferrite and other oxides were reduced and were volatized and collected by a cleaning system of dust (baghouse) located on top of the oven. More than 98% of iron were recovered from EAFD during the test. It was possible to produce a dust containing about 68% zinc by means of adding of EAFD.

Science and Engineering of Light Metal Matrix Nanocomposites and Composites: Metal Matrix Composites

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division
Program Organizers: Xiaochun Li, University of Wisconsin-Madison; Alan Luo

Tuesday AM — Room: Macaw 2
March 13, 2012 — Location: Swan Resort

Slow-Shot High Pressure Die-Casting (SS-HPDC) Process for AE44 Magnesium Single-Cylinder Engine Block with Short-Fiber Reinforcement in the Bore: *Bin Hu*[1]; Pan Wang[1]; Bob Powell[2]; Xiaoqin Zeng[3]; [1]Genral Motor China Science Lab; [2]General Motors Global R&D Center; [3]Shanghai Jiao Tong University

Single-cylinder magnesium engine blocks with short fiber reinforcement in the bore region were prepared by low shot speed, high pressure die casting to infiltrate the fiber preforms and produce sound castings. The magnesium alloy was AE44 and the cylindrical preforms were made with silica-bonded Saffil fibers. The slow shot, high pressure die casting process (SS-HPDC) was intended to simulate squeeze casting. SS-HPDC process is a promising means for casting the blocks, which were free of porosity could be subjected to T4 and T6 heat treatments without blistering. Processing parameters were identified and optimized. These included the pouring temperature, 760°C; the die temperature, 275°C preform preheat temperature, 750°C and the intensification/infiltration pressure, 90MPa. Their relative contribution to the quality of the cast blocks is discussed and suggestions for further optimization are made.

8:50 AM
Compressive Properties of Al-B4C Composites over the Temperature Range of 25 - 500 °C: *Srinu Gangolu*[1]; A Rao[2]; N Prabhu[1]; V Deshmukh[2]; B Kashyap[1]; [1]Indian Institute of Technology Bombay; [2]Naval Materials Research Laboratory

Aluminum - Boron carbide (B4C) composites containing 0, 5, 10, and 15 wt% B4C were produced by stir casting at 900°C. Compression tests done from room temperature to 600°C and at strain rates of 10-4 and 10^{-2} s^{-1}, exhibit a decrease in flow stress with increasing temperature and decreasing strain rate. The effects of temperature and strain rate on deformation behavior were analyzed to identify the regimes of different operating mechanisms. The role of particulates on strengthening and transition to different mechanisms of deformation were discussed in terms of dislocation activity, diffusion and other high temperature processes. Rolling was done to vary the grain sizes and incorporate the same towards understanding mechanism for deformation in the form of constitutive relationship.

9:10 AM
Mechanical Properties of a Spherical Particle Reinforced Aluminum Composite after Metal Working: *William Harrigan*[1]; [1]Gamma Technology

Particle reinforced aluminum composites can be processed by conventional metalworking techniques such as extrusion, forging and rolling. Composites have been made by Gamma Technology with spherical alumina particles. These composites have properties that are similar to composites made with irregular shaped particles. The spherical particles reduce the tool wear during machining operations leading to reduced cost of part manufacture. Composites made with the spherical particles have been extruded, forged and ring rolled. This study looks at the mechanical properties of the composite at several stages of metal working. Tests were conducted after several levels of forging, after several levels of extrusion and after combinations of extrusion, forging and ring rolling. The study documents the development of uniform microstructure and the accompanying uniform mechanical properties.

9:30 AM
Effect of Processing on the Dynamic Response of a Silicon Carbide Reinforced Aluminum Metal Matrix Composite: *Brandon McWilliams*[1]; Tomoko Sano[1]; Jian Yu[1]; Chian Yen[1]; [1]US Army Research Laboratory

Microstructure based finite element simulations are conducted to investigate the effects of processing on the dynamic deformation response of ceramic particle reinforced aluminum metal matrix composites (MMC). Samples were obtained from as-cast and hot-rolled MMC plate which had been reduced to various thicknesses. During rolling, ceramic particles fracture leading to a change in particle morphology and particle size distribution in the composite. This combined with a break up of inclusions formed in the casting process leads to dramatically different material response in rolled MMC plate versus the as-cast material. To implement these materials in design applications, a complete understanding of how these microstructures evolve and their effect on properties is required. The modeling approach in this work is used to predict the stress-strain response and explore high rate damage and failure mechanisms of the MMC. In-situ SEM, and macro scale mechanical test results are used to validate the modeling.

9:50 AM
Fabrication and Characterization of Al-SiC Composite Foam: *Geo Harrison*[1]; Ganapathy Subramanian[1]; Vinoth Kambli[1]; Pradeep Kumar[1]; [1]College of Engineering Guindy, Anna University

Metal matrix composite foams have very low density, high stiffness and good impact resistance. These properties enable them to be used in various automotive and structural components. Al-SiC composite foams are prepared by dispersion of fine Silicon carbide powder in molten aluminum, followed by blowing of an inert gas and simultaneous stirring. The well dispersed inert gas bubbles form numerous micro-voids during solidification of the composite. A fine Al-SiC composite foam with homogeneous micro-structure is manufactured by this process. The impact resistance, stiffness and the mechanical behavior of the Al-SiC are analyzed subsequently.

Aluminum Metal Matrix Composite via Direct Metal Laser Deposition: Processing And Mechanical Characterization: *Benjamin Waldera*[1]; Samar Kalita[1]; [1]Advanced Engineered Materials Center - University of North Dakota

Aluminum metal matrix composites (Al-MMCs) have shown favorable material characteristics for aerospace applications such as airframes, reinforcement materials and joining elements. Similarly, carbide Al-MMC coatings can greatly improve surface performance of aluminum components. In this research, such coatings were developed from a powder blend of pure aluminum, chromium carbide and tungsten carbide nickel alloy, premixed at 2:1:1, on AA 7075 plates through direct metal laser deposition. Microstructure of the carbide Al-MMC was studied by optical and scanning electron microscopy. The hardness and the reduced Young's modulus were assessed through depth-sensing instrumented indentation using a Hysitron-TI950 Nanomechanical Tester. The carbide Al-MMCs demonstrated good interfacial bonding and improved modulus and hardness. A maximum hardness and reduced modulus of 2.47 GPa and 87.43 GPa, respectively, were recorded for the composite. Hardness and reduced modulus of AA 7075 substrate were 1.45 GPa and 70.63 GPa, respectively. This talk will present our recent findings.

10:45 AM
A Microstructure-Sensitive Fatigue Model for SiC Reinforced AA6061 Metal Matrix Composites: *Andrew Brammer*[1]; J Jordon[1]; [1]The University of Alabama

In this work, a microstructure-sensitive fatigue model is proposed for a SiC reinforced metal matrix composites (MMC's). The fatigue model proposed here was correlated to a discontinuously particulate-reinforced 6061 aluminum alloy tested under stress amplitude controlled fatigue conditions. Experimental results show that the 6061 was strongly influenced by volume fraction of the particulate reinforcement, particularly under high cycle fatigue. The model presented here characterizes the fatigue damage of the MMC into three distinct stages: crack incubation, microstructurally/physically small crack growth, and long crack growth. In this model, the influence of particle volume fraction, nearest neighbor distance and subsequent matrix strength are captured in the three stages of the model. The model showed good results in correlating the fatigue behavior of various percentages of reinforced-particulate. The model illustrated that particle fraction is indeed the controlling factor in fatigue lifetimes and this conclusion was supported by fractography analysis of failed specimens.

11:05 AM
Damage Evolution Model for Hybrid Metal Matrix Composites: *Jessica Dibelka*[1]; Scott Case[1]; [1]Virginia Polytechnic Institute and State University

In this study, two types of alumina fiber reinforcement, continuous Nextel™ fabric and discontinuous Saffil paper, were used to produce aluminum matrix composites. One of the composites created was a hybrid composite consisting of both reinforcements. This hybrid composite displayed high strength similar to the Nextel™ fabric-reinforced composite while maintaining a reasonable strain to failure typical of the Saffil paper-reinforced composite. Additionally, the hybrid composite exhibited progressive rather than catastrophic tensile failure. When the maximum strength of the composite was reached, the stress dropped 10% and was sustained for a considerable amount of strain before ultimate failure. A modeling framework is presented to describe the progressive damage and ultimate failure of these composites. This framework combines fiber/matrix-scale models for stiffness and strength with layer-level models for stress redistribution. Excellent predictions are obtained for initial failures, with reasonable predictions obtained for subsequent damage events.

11:25 AM
Numerical Simulation of Pressure Infiltration Process for Making Metal Matrix Composites: Effect of Process Parameters: Bo Wang[1]; *Krishna M. Pillai*[1]; [1]University of Wisconsin-Milwaukee

A three-dimensional finite difference model is developed for simulating the pressure infiltration process (PIP) for making metal matrix composites (MMCs) where liquid metal is injected under pressure into a mold packed with reinforcing fibers. The infiltration of liquid (pure) metal into the fibrous preform under a constant applied pressure is modeled using the Darcy's law after assuming fully saturated flow behind the liquid-metal front. The concomitant solidification and heat transfer processes are modeled using a suitable energy equation. The simulation allows one to study the effect of process parameters on the PIP infiltration process through evolution of flow-front during filling, solidification pattern, and pressure and temperature distributions. In this study, the effects of the inlet (applied) pressure and the gate size on the infiltration process are studied. The simulation results for such metal infiltration into porous preforms can be used to optimize the PIP and other related manufacturing processes (such as squeeze casting) for making MMCs.

11:45 AM
A Parametric Study of Hot Rolling of an Aluminum MMC via ANSYS and LS-DYNA: *Charles Mansfield*[1]; Nathan Mutter[1]; Ali Gordon[1]; [1]UCF

Material, geometric, and contact properties all play a role in the consequent mechanical characteristics of hot rolled plates; however, previous numerical parametric simulations have yet to incorporate variability over all of these processing parameters. Hot rolled aluminum metal matrix composites (MMCs) have been identified for high value components of next generation structural applications. Determining the thermo-mechanical processing parameters that optimize the strength and ductility of this class of materials is a means to increase the usability of these materials in practical applications. With the aid of a command line formatted input file for ANSYS and LS-DYNA, this numerical study simulates the effects of plate geometry, roller parameters, and contact parameters on the mechanical response of the plate. Based on the study, models that link processing parameters to (1) the stress-strain response in the plate and (2) accumulation of damage in the plate are developed.

8:30 AM
High Frequency EM Purification of Silicon: Lucas Damoah[1]; *Lifeng Zhang*[1]; [1]Missouri University of Science and Technology

The use of electromagnetic field to remove suspended particles from metals such as aluminum by pushing to the boundary has been well studied. However, the potential of this method is yet to be exploited for the removal of inclusions from silicon. This study investigates and discusses new results on the effect of processing parameters such as composition, coil current, and frequency on the removal of inclusions from silicon under high frequency AC electromagnetic field.

8:55 AM
Mono-Like Ingot/Wafers Made of Solar-Grade Silicon for Solar Cells Application: Sergey Beringov[1]; Timur Vlasenko[1]; Sergiy Yatsuk[1]; Oleksandr Liaskovskiy[1]; *Iryna Buchovska*[1]; [1]Pillar Group

Working with solar-grade silicon for solar cells application usually meets some difficulties in comparison to polysilicon produced by Siemens method: higher impurities content leads to lower yield, worse electro-physical parameters and poor performance in solar cells application. However some adjustments in ingot production can show significant improvements in quality of final product: crystalline wafers and cells. Recent investigations have shown that solar-grade silicon is suitable for high effective production process such as mono-like multicrystalline wafer production. Production-scale lots made at Pillar show promising results for solar-grade silicon application: high-quality wafers with significantly big crystalline grains of <100> orientation.

9:15 AM
Preparation and Characterizations of Hydrogenated Microcrystalline Silicon Germanium Thin Films Prepared by RF Magnetron Sputtering: *C. H. Chang*[1]; C. W. Chang[2]; H. S. Chen[1]; J. P. Chu[1]; [1]National Taiwan University of Science and Technology; [2]Industrial Technology Research Institute

We have investigated the effects of H2/Ar mixture during deposition and post-annealing temperature on crystal structure, microstructure as well as properties of hydrogenated microcrystalline silicon germanium (μc-Si0.8Ge0.2:H) thin films. μc-Si0.8Ge0.2:H. thin films were deposited on glass substrates by radio frequency magnetron co-sputtering of Si and Ge in H2/Ar gas mixture. The electrical and optical properties of μc-Si0.8Ge0.2:H thin films, analyzed with Hall effect measurement and VIS-NIR spectrum, respectively, have been evaluated. The results indicate that the crystallite size, electrical properties and optical properties depend on the annealing temperature. The properties of μc-Si0.8Ge0.2:H thin films will be discussed in light of results obtained.

9:35 AM
Removal of Phosphorus from Silicon Melts by Vacuum Refining: *Buhle Xakalashe*[1]; Jafar Safarian[2]; Merete Tangstad[2]; [1]Mintek; [2]NTNU

Induction vacuum refining testwork has been carried out to study the effect of iron on phosphorus removal from silicon melts. The experiments were carried out through vacuum induction melting of high purity silicon with additions of phosphorus and iron at temperatures ranging between 1773 K and 1873 K and at a pressure of 0.5 Pa. Holding times varied between 0 s and 7200 s. ICP-MS was the primary analytical technique employed for sample analysis. The experimental results showed that phosphorus can be decreased from 15.5 ppmw to 1.5 ppmw at a temperature of 1873 K and holding time of 7200 s. The removal of phosphorus from silicon via induction vacuum refining seems to be independent of iron concentration for iron concentrations of up to 5000 ppmw. The rate constants for phosphorus removal were determined to be 8.4x10-6m/s and 2.5x10-6m/s at 1873 K and 1773 K, respectively.

9:55 AM
Thermodynamics of Phosphorous Distribution between Si and Fe–Si in Solvent Refining of Silicon: *Leili Tafaghodi Khajavi*[1]; Mansoor Barati[1]; [1]University of Toronto

This study involves employing solvent refining as a purification process in which silicon recrystallization takes place from a super–saturated iron-silicon melt. It is believed that iron will act as the impurity "getter" and purified silicon crystals will grow from the alloy melt, while the impurities are segregated to the liquid alloy. Phosphorous is a problematic impurity to remove since its segregation coefficient in pure silicon is relatively large. To assess the feasibility and efficiency of phosphorous removal through solvent refining, it is critical to study its equilibrium distribution between solid Si and the Fe–Si alloy phase. The distribution of phosphorous between solid silicon and iron-silicon melt at 1483-1583 K was measured to evaluate the impurity removal potential of each alloy. Interaction parameter between phosphorous and iron was calculated by varying the concentration of phosphorous in Si.

10:15 AM Break

10:35 AM
Imaging Techniques for the Characterization of Multi-Crystalline Silicon Bricks and Wafers: *Steve Johnston*[1]; Fei Yan[1]; Katherine Zaunbrecher[2]; Mowafak Al-Jassim[1]; Omar Sidelkheir[3]; Alain Blosse[3]; [1]National Renewable Energy Laboratory; [2]Colorado State University; [3]Calisolar

Imaging techniques are applied to multi-crystalline silicon wafers and solar cells throughout the production process. Photoluminescence imaging, both band-to-band and defect-band, is used to characterize defects and wafer quality at all process steps. These steps include bricks sawn from ingots, wafer sawing, cleaning and texturing, emitter diffusion, edge isolation and glass removal, anti-reflective coating/passivation, and metallization of finished cells. Bricks, wafers, and cells can be imaged at a rate commensurate with in-line measurement, giving spatial information to characterize quality and defect content. Photoluminescence images on silicon bricks can be correlated to lifetime measured by photoconductive decay and could be used for high-resolution characterization of material before wafers are cut. The defect areas in as-cut wafers are compared to imaging results from electroluminescence and lock-in thermography, and cell parameters of near-neighbor finished cells, showing correlations to efficiency, open-circuit voltage, short-circuit current, and fill factor.

10:55 AM
Silicon PV Wafers: Correlation of Mechanical Properties and Crack Propagation with Defects and Stresses: *Khaled Youssef*[1]; Meirong Shi[1]; Prashant Kulshreshtha[1]; George Rozgonyi[1]; [1]North Carolina State University

The interactions between a propagating crack and crystal growth induced impurities, defects, and residual stresses have been evaluated in thin CZ Si wafers. Nanoindentation was used to evaluate the influence of fast pulling rate and the associated defects and precipitates on the hardness and fracture toughness. Our results showed that defects and stresses associated with fast solidification rates reduce wafer toughness by about 45% and therefore play a major rule in thin wafer breakage. In addition, supporting the nanoindentation results, micro-Raman spectroscopy, FTIR, and AFM profiling were used to investigate phase transformations. A modified brittle-to-ductile fracture mechanism was identified. The phase transformation results indicate that a judicious choice of stress and impurity will facilitate a beneficial change of brittle semiconducting Si to a meta-stable ductile metallic Si phase via deformation. This finding offers the possibility of reducing damage/cracks created during the cutting process by enhancing the ductile mechanisms of cutting.

11:15 AM

Thermodynamics on Boron Rejection during Metallurgical Grade Silicon Oxidation by Silicon Dioxide: *Yaqiong Li*[1]; Yi Tan[1]; Jiayan Li[1]; Shenrui Wu[1]; Yao Liu[1]; [1]Dalian University of Technology

A metallurgical grade silicon (MG-Si) refining concept process was presented. Under vacuum conditions, silicon was selectively oxidized by high purity silicon dioxide to form gaseous silicon monoxide while impurities with low vapor pressure in MG-Si were rejected in residue; Then high purity silicon was obtained from the disproportionation of condensed silicon monoxide; and by-produced silicon dioxide was recycled for the oxidation step. Thermodynamics on boron rejection during the oxidation were studied in this work. In the temperature range of 1200-1800K, the saturated vapor pressure of boron, and the Gibbs free energy changes, the equilibrium partial pressures of silicon monoxide and boron oxides of potential reactions were calculated. And the effect of boron activity in MG-Si was also discussed. The results indicated that boron in MG-Si can be rejected during the oxidation and it shows the potential for the further development of the new refining process.

11:35 AM

On the Segregation of Impurities in Solar Silicon: *Kader Zaidat*[1]; Abdallah Nouri[1]; Yves Delannoy[1]; [1]Grenoble-INP

The exponential increase of the photovoltaic market leads to a shortage of high purity Si raw material and the producers are currently using less and less pure Si. However the quality of Si photovoltaic cells depends on the purity of the material and on the grain structure of the ingot from which the wafers are cut. It is necessary to control the segregation of impurities in the grown ingot in order to optimize the cell properties as a function of the raw material purity.We have developed a Bridgman set-up in order to study the solidification of photovoltaic Si under independently controlled solidification parameters: growth rate, thermal gradient, purity and convection. Segregation can be controlled by forced convection which is induced by a travelling magnetic field in order to homogenize or segregate the rejected impurities such as carbon and metallic elements.

11:55 AM

Effect of Solute Hydrogen on Toughness of Feed Stock Polycrystalline Silicon for Solar Cell Applications: *Mohamad Zbib*[1]; Megan Reynolds[1]; Uttara Sahaym[1]; Grant Norton[1]; David Bahr[1]; Wayne Osborne[2]; [1]Washington State University; [2]REC Silicon

Polycrystalline silicon grown via fluidized bed reactors, mainly used for solar applications, produces mm sized granular beads and 100 nm size powders. Three commercial polysilicon products from different manufacturers were examined. This paper focuses on the relationship between solute hydrogen and mechanical behavior of FBR silicon. Fourier transform infrared spectroscopy was used to identify hydrogen in as grown and annealed samples, and indentation techniques were used to determine mechanical properties. FTIR was able to distinguish between solute H and H impurities accumulated during sample preparation. Annealing decreased solute hydrogen and led to an increase in toughness by 20% in samples with solute H in the as grown condition. The toughness of all samples ranges between 0.74 and 0.97 MPa-m$^{0.5}$. However, annealing increases the crystallite size between 20% to 50%, which lowers the toughness. Removing solute hydrogen and increasing crystallite size exhibit competing effects on the toughness of FBR silicon.

Solid-State Interfaces II: Toward an Atomistic-Scale Understanding of Structure, Properties, and Behavior through Theory and Experiment: Interface Interaction with Defects

On the Feasibility of Designing Interfaces Immune to Helium Damage: *Michael Demkowicz*[1]; Abishek Kashinath[1]; Amit Misra[2]; Nan Li[2]; [1]Massachusetts Institute of Technology; [2]Los Alamos National Laboratory

Helium implanted into materials operating in fusion reactor environments leads to bubble formation, accelerates void growth, and degrades mechanical properties. Drawing on atomistic modeling and experiments, I will propose a strategy for mitigating these effects by trapping He at interfaces, addressing in particular the relation of interface structure to He trapping and He clustering. I will show that, under some conditions, the effect of He on interface mechanical properties such as tensile strength and shear resistance is tolerable. Finally, I will discuss the potential for designing interfaces immune to He damage by modifying interface structure. This material is based upon work supported by the Los Alamos LDRD program and the Center for Materials at Irradiation and Mechanical Extremes, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number 2008LANL1026.

Effect of Nanoparticle-Matrix Interfaces on Cavity Formation in ODS Ferritic Steels under Dual-Beam Irradiation: *Luke Hsiung*[1]; [1]Lawrence Livermore National Laboratory

Structures of oxide nanoparticles/clusters and their role in the formation of radiation-induced cavities in ODS ferritic steel have been studied using high-resolution transmission electron microscopy (HRTEM) techniques. The ODS steel contains partially or fully crystallized oxide nanoparticles larger than ~2 nm and amorphous nanoclusters smaller than ~2 nm. The crystal structure of crystalline nanoparticles is mainly Y4Al2O9 (YAM) with a monoclinic structure. Crystalline nanoparticles larger than 20 nm tend to be incoherent with the matrix, and crystalline nanoparticles smaller than 10 nm tend to be coherent/semi-coherent with the matrix. Unimodal distribution of helium-filled cavities (bubbles) was found to form in (Fe + He) dual-beam irradiated ODS steel as a result of the dispersion of high-density nanoparticles/clusters. HRTEM observations of preferred formation of helium bubbles at the particle-matrix interfaces reveal the crucial role of nanoparticles/clusters in the suppression of bubble-to-void conversion (void swelling) in the irradiated ODS steel.

9:30 AM
Interface Microstructure Evolution of Heterogeneous Systems under Vacancy Supersaturation: *Enrique Martinez Saez*[1]; Jeffery Hetherly[1]; Alfredo Caro[1]; Michael Nastasi[1]; [1]LANL

A new hybrid Molecular Dynamics-kinetic Monte Carlo (MD-kMC) algorithm has been developed in order to study the microstructure evolution of heterogeneous systems in a vacancy-supersaturated environments. The algorithm takes into account both chemical and stress fields. Migration barriers are calculated using a linear approximation in which final and initial energies are obtained from MD. The approximation makes the algorithm fast enough to be able to handle hundreds of vacancies. Therefore, we are able to observe void formation in twist boundaries in Fe and Cu, characterized by different sets of screw dislocations. We have captured as well the jog formation in an edge dislocation dipole in Fe. Incoherent interfaces have been also studied. The de-mixing process after a displacement cascade event for the case of the Cu-Nb system in the presence of a Kurdjumov-Sachs interface is reported. This material is based upon work supported as part of the Center for Materials at Irradiation and Mechanical Extremes, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, and by the LANL LDRD Office.

9:50 AM
Interface Structures, Defects, and Mechanical Properties at fcc-bcc Interfaces from "Tunable" Potentials: *Xiang-Yang Liu*[1]; Richard Hoagland[1]; Jian Wang[1]; Blas Uberuaga[1]; Michael Demkowicz[2]; Michael Nastasi[1]; Amit Misra[1]; [1]Los Alamos National Lab; [2]Massachusetts Institute of Technology

Nanolayered Cu-Nb composites exhibit high strength and enhanced radiation damage tolerance. To understand the relevance of interface structures to interface properties in general fcc-bcc systems, "tunable" potentials offer a fairly simple way to selectively vary parameters independently. In this work, the parameterization of the EAM interatomic potentials in fcc-bcc system is modified to understand the interface structures, defects, and mechanical properties. We change the dilute heats of mixing between Cu and Nb and investigate the effect on interface structures, defect formation energies, and influence on both the interfacial shear strength and the active shear plane at the interface. To understand the interface behavior in different lattice misfit geometries, the relative lattice constants ratio between Cu and the bcc crystal is varied, to examine effects on interface dislocations and defect formation energetics. Defect-interface interactions are studied with MD and other methods, to predict the radiation damage tolerance of these interface systems.

Defect-Interface Interactions in Oxide Ceramics: *Blas Uberuaga*[1]; [1]Los Alamos National Laboratory

It is well established that interfaces and grain boundaries can act as efficient sinks for radiation-induced defects. Recently, we showed that, in Cu, interstitials are preferentially loaded into grain boundaries during collision cascades and that these interstitials, trapped at the boundary, interacted over relatively long distances and short times to help annihilate vacancies remaining in the bulk of the crystal. Here, we explore these phenomena in oxide ceramics. Using a combination of molecular dynamics, molecular statics, and accelerated molecular dynamics, we examine the ability of boundaries in oxides to absorb interstitials during damage production and the subsequent emission of those interstitials to annihilate vacancies. We find similarities but also important differences to the behavior observed in Cu. In particular, strong electrostatic effects present themselves, leading to complex defect-interface interactions.

10:50 AM
On the Solute/Interface-Interaction in the Framework of a Defactant Concept: *Reiner Kirchheim*[1]; [1]University of Göttingen

Willard Gibbs Adsorption Isotherm and Carl Wagner's definition of excess solute at surfaces and grain boundaries were both extended to include other crystalline defects like dislocations and vacancies. Thus solute segregation to dislocations and vacancies and other crystalline defects gives rise to a reduction of their formation energies, too and are called defactants. Under which conditions zero values could be attained, will be discussed. Special emphasis is paid to the segregation of carbon at iron grain boundaries which is experimentally determined by atom probe tomography and which is used to design nanocrystalline steel by ball milling. It will be shown that the excess carbon corresponds to about one monolayer of cementite and that this excess is independent of the character of the large angle grain boundary. Thus solute/solute-interaction plays an important role in grain boundary segregation although often neglected during modelling.

11:10 AM
Interface Facets Identified with Singularity in Interfacial Structures: *Wenzheng Zhang*[1]; Xinfu Gu[1]; [1]Tsinghua University

Theoretically, candidates of interface facets can be searched according to local minima of interfacial energy in 5D, but this is a nontrivial task. Simple rules in terms of measurable delta g vectors have proved useful for identifying interface facets. In this work, the association of these rules with singularity in the interfacial energy is elucidated with singularity in the interfacial defect structures. While singularity of ledge defects usually leads to rational facets, singularity of dislocation structure is permitted by special interface geometry, usually described with irrational indexes. Interfacial facets defined by singular interfaces usually serve as the terrace planes of growth ledges, so their structures are essential to understanding overall interface migration. Though the description with defect singularity appears lack of atomic details in a relaxed structure, it offers a practical starting point for time-efficient atomic–scale modeling of singular interfaces in real materials.

11:30 AM
On the Factors Governing the Sink Strength of Semicoherent fcc-bcc Interfaces: *Kedarnath Kolluri*[1]; Michael Demkowicz[1]; [1]Massachusetts Institute of Technology

Using atomistic modeling of fcc-bcc interfaces, we investigate the factors that govern the sink strength of interfaces to radiation-induced point defects. The sink strength depends on point defect absorption, emission, and recombination at interfaces. We find that point defects and point-defect clusters are trapped at interface misfit dislocation intersections and misfit dislocation kinks. Trapped defects migrate from trap to trap along misfit dislocations. In addition, migration of untrapped point defects is confined to regions between misfit dislocations. Furthermore, density of defects accommodated by an interface depends on interface misfit dislocation network's ability to reconstruct. The prospect of predicting sink strength of semicoherent interfaces is discussed. This material is based upon work supported as part of the Center for Materials at Irradiation and Mechanical Extremes, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number 2008LANL1026.

11:50 AM
Energetics of Point Defect and Impurity Segregation to Grain Boundaries in Fe: *Mark Tschopp*[1]; Kiran Solanki[2]; Nathan Rhodes[3]; [1]MSU/CAVS; [2]Arizona State University; [3]University of Florida

Quantifying how point defects and impurities interact with grain boundaries is important for understanding segregation of solute and impurity atoms in metals. The research objective herein is to understand the energetics of the interaction between point defects/impurities and grain boundaries in BCC Fe and quantify the associated uncertainties.

Molecular statics simulations were used to sample a wide array of grain boundary sites and structures. The present results provide detailed information about the interaction energies of vacancies, self-interstitial atoms, and impurities with grain boundaries in iron. Certain grain boundaries have properties different from the remainder of boundaries. Moreover, the formation energies were also found to depend on the local atomic structure and the distance from the center of the boundary. Such studies provide insight into the process of grain boundary segregation and the structure of grain boundaries, which can lead to re-engineering grain boundaries for materials by design applications.

Symposium in Memory of Patrick Veyssière: Understanding the Mechanisms Controlling Plastic Flow: Screw Dislocations-lattice Friction

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division

Program Organizers: Georges Saada, LEM CNRS ONERA; Dennis Dimiduk, Air Force Research Laboratory; Hael Mughrabi, University Erlangen-Nuernberg; Haruyuki Inui, Kyoto University

Tuesday AM — Room: Europe 6
March 13, 2012 — Location: Dolphin Resort

The Role of the Initial Dislocation Density in Controling Size-Affected Flow Response: *Jaafar El-Awady*[1]; Michael Uchic[2]; Dennis Dimiduk[2]; Satish Rao[3]; Christopher Woodward[2]; [1]Johns Hopkins University; [2]Air Force Research Laboratory; [3]UES Inc.

We report experimental and 3-dimensional discrete dislocation dynamics (DDD) measurements to characterize the effect of starting dislocation density on size-affected flow response. Microcrystals were FIB-milled into a 23% pre-strained bulk Ni single-crystal. The strength-scaling exponent was -0.18, which is considerably lower than that measured for microcrystals with moderate initial dislocation densities. DDD simulations also show a reduction in power-law exponent with increasing initial dislocation density. However, while previous experimental studies suggested that Taylor hardening law fails at micron and submicron length scale, DDD simulations show that the strength-dislocation density response in fact follows a power-law relationship with an exponent equal to -0.2. Also, Taylor hardening is recovered above a size-dependent critical dislocation density. We finally discuss the role of this critical dislocation density in controlling the size-affected flow response, and rationalize the results based on the the stochastics of an existing dislocation network in microcrystals.

Atomistic Simulations of Intersection Cross-Slip Nucleation in Face-Centered Cubic Materials: *Satish Rao*[1]; Dennis Dimiduk[2]; Michael Uchic[2]; Triplicane Parthasarathy[1]; Jaafar El-Awady[3]; Christopher Woodward[2]; [1]UES Inc.; [2]Air Force Research Laboratory; [3]Johns Hopkins University

Embedded atom potentials and molecular-statics simulations of screw character dislocation intersections with forest dislocations, in FCC Ni and Cu and L12 Ni3Al, illustrate a mechanism for cross-slip nucleation. 3-dimensional dislocation dynamics simulations accounting for Shockley partials qualitatively reproduce the atomistic results for the same dislocation intersections. Investigations using the Nudged Elastic Band Method and an approximate Escaig-stress technique showed the activation barrier for a screw dislocation to transfer from the glide-plane or the cross-slip-plane to a partially cross-slipped state. The intersections form Glide, Lomer-Cottrell or Hirth locks, having cross-slip activation energies that are a factor of 3- 20 lower than those for the Friedel-Escaig mechanism. The activation barrier for cross-slip is linearly proportional to (d/b)ln(v3*d/b)0.5, where ‘d’ is the spacing of the Shockley partial dislocations and ‘b’ is the screw dislocation Burger’s vector. These results suggest a preference for cross-slip at selected screw dislocation intersections in FCC materials.

Kinetics of Screw Dislocations in Fe and Fe Alloys at Low Temperatures: *Daniel Caillard*[1]; [1]CNRS

Pure iron exhibits a discontinuity in the temperature dependence of stress and activation volume, which indicates a possible change of mechanism at around 200-250K. This discontinuity has never been satisfactorily explained, in spite of recent atomistic calculations. In addition, its vanishing upon alloying may help to understand the corresponding softening and hardening effects. To interpret such behaviour, in situ experiments have been carried out first in pure Fe, between 110K and 300K. The videos show two kinds of motion, below and above 200K, which have been related to this change of mechanism. The two behaviours have been compared with results of atomistic calculations and mechanical tests, and modelled. Similar experiments in Fe containing various concentrations of C, P, Si and Cr also show various kinds of screw dislocation motion, which allow us to account for the complex softening/hardening effects of solute atoms.

A New Type of Dislocation Source in BCC Molybdenum: *Qing-Jie Li*[1]; Xiang-Dong Ding[1]; Zhi-Wei Shan[1]; Ju Li[2]; Jun Sun[1]; Evan Ma[3]; [1]Center for Advancing Materials Performance from the Nanoscale (CAMP-Nano) & Hysitron Applied Research Center in China (HARCC), State Key Laboratory for Mechanical Behavior of Materials, Xi’an Jiaotong University; [2]Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, MIT; [3]Department of Materials Science and Engineering, Johns Hopkins University

Due to the lattice symmetry of BCC metals, screw dislocation plays a critical role in their plastic deformation. Usually, the low mobility and self-multiplication of screw dislocations lead to a different mechanical behavior from FCC metals. In the present work, by means of molecular dynamics simulations, we show a new self-multiplication mechanism of screw dislocation in BCC Molybdenum, i.e., double-kinks mechanism. During the motion at a certain stress level, we found screw dislocation can form a dislocation dipole with the thickness of three atomic layers, which can be opened into a dislocation loop at a critical stress. The formation of dislocation dipole is related to the collision and interaction of different kinks which originated from the broken symmetry. This new mechanism may broaden our understanding of the mechanical behavior of BCC metals in both macro- and meso- size scale. Key words: BCC Molybdenum, screw dislocation, self-multiplication

Elevated Temperature Deformation Mechanisms in Ta2C: *Nicholas De Leon*[1]; Billie Wang[1]; [1]The University of Alabama

Tantalum carbides, an ultra-high temperature ceramic, exhibit an interesting duality of mechanical responses with temperature; classical ceramic brittle behavior at low temperatures but significant plasticity at elevated temperatures. While the plastic deformation mechanisms of the rock-salt structured TaC phase have been thoroughly defined, the hexagonal like \149; -Ta2C phase, with its CdI antitype structure, has not been extensively investigated and is the scope of this work. Ta2C specimens were mechanically tested at 1600°C and characterized using dynamical diffraction transmission electron microscopy (TEM) and high resolution transmission electron microscopy (HRTEM) techniques. Density functional theory was also used to compute the stacking fault energies on the basal, prism and pyramidal planes. The two major deformation mechanisms experimentally identified were dislocation slip and stacking faults. Both basal and secondary a/3<11-23>{10-11} non-basal slip were predicted and observed. The basal plane faulting was shown to preferentially occur between the Ta-Ta metallic bonds.

11:00 AM Invited
Screw Dislocations in Zirconium: an ab Initio Study: *Emmanuel Clouet*[1]; [1]SRMP, CEA Saclay

Plasticity in zirconium is thought to be controlled by screw dislocations gliding in the prismatic planes of the hexagonal close-packed structure. This prismatic and not basal glide is observed for a given set of transition metals like zirconium and is known to be related to the number of valence electrons in the d band. We used ab initio calculations based on the density functional theory to study the core structure of screw dislocations in zirconium. Dislocations are found to dissociate in two partial dislocations, each with a pure screw character. The dissociation distance observed in the simulations agrees well with the one predicted by elasticity theory using the calculated stacking fault energy. The Peierls barrier have also been calculated for a screw dislocation gliding in a prismatic plane. A low value, ~0.3 +/- .1 meV/A, has been obtained. The Peierls stress deduced from this barrier is compatible with experimental data.

Experimental Study and Finite Element Computation of the Single Crystal Behavior of Zirconium: Cyril Lebon[1]; *Fabien Onimus*[1]; Eva Héripré[2]; Laurent Dupuy[1]; Ludovic Vincent[1]; Xavier Feaugas[3]; [1]CEA; [2]Ecole Polytechnique; [3]University of La Rochelle

The mechanical behaviour of zirconium alloys, used as cladding of nuclear fuel for water reactor, is well known. However there is yet no single crystal constitutive law for zirconium.In order to determine the single crystal behaviour, a zirconium alloy (containing 100 ppm oxygen) with millimetre grains is used. Tensile specimens are machined to obtain only one grain, well orientated for prismatic slip, in the gauge length. The specimens are covered by a speckled paint. During the tests, the in plane deformation is monitored. Thanks to digital image correlation, the strain field tensor is deduced and resolved along the slip systems giving the shear strain on prismatic planes. The single crystal behaviour for prismatic slip is deduced. Strain rates jumps and relaxation tests are also conducted with the same method to measure the activation volume. Finite elements computations of the full specimens are then performed using the fitted constitutive law.

Atomistic Simulations of Kinks on 1/2<110> Screw Dislocation in Magnesium Oxyde: *Philippe Carrez*[1]; Patrick Cordier[1]; [1]Lab. UMET CNRS-UMR8207

In lattice friction materials, dislocation move by formation and migration of kink pairs. Plastic deformation of MgO involves a single 1/2<110> Burgers vector associated with two potential slip plane families {110} and {100}. Whereas 1/2<110>{110} is characterized by a relatively low lattice friction, 1/2<110>{100} shows higher lattice friction and a strong sensitivity of shear stresses to temperature. Here we propose theoretical calculations of structure, geometry and formation energy of kinks on 1/2<110> screw dislocation in MgO for both slip systems. In this study, we used pairwise potentials of Buckingham form which satisfactorily reproduce screw dislocation core structure. Then, isolated kinks are introduced into large simulation cell. Using periodic boundary conditions and fixed surfaces, kink formation energies are extracted from simulations. Preliminary results performed for 1/2<110>{110} are consistent with the experimental kink energy of 1.2 eV.

Formation of Transformation Texture in Supertransus Heat Treated Ti-6Al-4V Sheet: Gordon Sargent[1]; Adam Pilchak[1]; Kacey Kinsel[1]; *Lee Semiatin*[1]; [1]US Air Force Research Laboratory

Texture formation in alpha/beta titanium alloys can result from deformation and/or phase transformation. A number of investigations and analyses of deformation-texture formation in such materials have been performed. However, much less effort has been expended to understand or model transformation-texture evolution associated with the non-random selection of alpha variants during the decomposition of the metastable high-temperature beta phase. In this presentation, past research related to variant selection in alloys such as Ti-6Al-4V will be summarized. Subsequently, recent work to establish the effect of process variables on variant selection during the cooling of Ti-6Al-4V sheet following beta annealing will be described. These process variables comprise soak time at peak temperature/beta grain size, cooling rate, stress state during cooling (i.e., unconstrained vs constrained conditions), prestrain prior to cooling, and imposed strain during cooling.

9:00 AM Invited
Variant Selection during Alpha Precipitation in Ti-6Al-4V under the Influence of Local Stress – A Simulation Study: Rongpei Shi[1]; *Yunzhi Wang*[1]; [1]Ohio State University

Variant selection of alpha (HCP) phase during its precipitation from beta (BCC) matrix plays a key role in determining the microstructural state and mechanical properties of alpha+beta titanium alloys. In this work, precipitation of semi-coherent alpha plates from beta matrix in Ti-6Al-4V (wt.%) under the influence of local stress is investigated by using a three-dimensional phase field model. The model is fully quantitative, not only being linked directly to available thermodynamic and mobility databases, but also incorporating the crystallography of BCC to HCP transformation, elastic anisotropy, and defect structure at the alpha/beta interfaces. The volume fraction and spatial distribution of different alpha variants are found to correlate strongly with the stress distribution within a polycrystalline sample. If the grains are highly textured, specific variants may percolate through the entire sample, leading to microtexture.

9:30 AM
Role of Grain-Boundary Characteristics on the Evolution of Allotriomorphic Alpha in Titanium Alloys: *Vikas Dixit*[1]; G.B. Viswanathan[2]; W.A.T. Clark[1]; Hamish L. Fraser[1]; [1]The Ohio State University; [2]Air Force Research Laboratory

Grain-boundary alpha (GBA) has an important role in microstructural evolution and mechanical properties, such as, fatigue and fracture toughness, in alpha/beta titanium alloys. Various grain-boundary parameters, such as, misorientation angle, the orientation of grain-boundary plane and also Burgers orientation relationship (OR) may control the evolution of this phase. In the present work, two methods to determine the orientation of an interfacial plane with respect to one of adjacent crystals have been developed using FIB, EBSD and TEM and their accuracy has been validated. Subsequently these methods have been utilized to determine the inclination of grain boundary plane relative to neighboring grains in Ti-550 alloy-system. Results indicate a correlation amongst the growth of GBA and various parameters including the misorientation angle, Burgers OR with neighboring prior-beta grains and most notably the inclination of the GB plane. The contribution of these factors on variant selection occurring at grain-boundaries will also be presented.

9:50 AM

Phase Separation and Its Subsequent Influence on Alpha Nucleation in Titanium Alloys: *Soumya Nag*[1]; Arun Devaraj[1]; Yufeng Zheng[2]; Robert Williams[2]; Jaimie Tiley[3]; Hamish Fraser[2]; Rajarshi Banerjee[1]; [1]University of North Texas; [2]The Ohio State University; [3]Air Force Research Laboratory

In titanium alloys precipitation of a phase within the ß matrix can occur at various heterogeneous nucleation sites that are closely associated with competing instabilities inherent within the ß phase. In this study advanced characterization techniques such as synchrotron-based in situ x-ray diffraction, aberration-corrected high-resolution (S)TEM, and atom probe tomography have been coupled to investigate such instabilities and its influence on the early stages of a precipitation in a ternary Ti-5Al-20Mo alloy. During isothermal annealing, the nature of phase separation (compositional partitioning), presumably resulting from a miscibility gap, within the ß phase of this ternary alloy, has been investigated in detail. Subsequently, the solute-depleted regions within the matrix nucleate the stable a phase, leading to a homogeneous distribution of highly refined precipitates. These and related results will be presented.

10:10 AM

Morphological, Structural and Compositional Evolution during the Decomposition of Martensite in Ti-2wt%Mo: *Yufeng Zheng*[1]; Robert Williams[1]; Rongpei Shi[1]; Yunzhi Wang[1]; Hamish Fraser[1]; [1]The Ohio State University

The Binary Ti-Mo system is a good example to study various phase transformations of beta isomorphous (monotectoid) alloys. In this work, Ti-2wt% Mo is used to study decomposition of martensite during tempering. Precipitates were found homogeneously distributed within the parent martensitic plates and to have various morphologies and compositions depending on tempering time and temperature. The effect of tempering on the structure, composition, and morphology of this precipitates was investigated systematically through SEM, TEM and STEM characterization techniques, in conjunction with EDS and EELS for chemical analysis. Phase field simulations were also carried out to study the factors that could influence the morphology of the precipitates.

10:30 AM Break

Recent Studies on the Evolution of Microstructure in Ti-Based Alloys: *Peter Collins*[1]; Peyman Samimi[1]; Iman Ghamarian[1]; Brian Welk[2]; Dan Huber[2]; Rajarshi Banerjee[1]; Hamish Fraser[2]; [1]University of North Texas; [2]The Ohio State University

It is well known that the microstructural features of alpha+beta and beta Ti-based alloys have a strong effect on the mechanical properties. As models relating structure to properties continue to mature, it is becoming increasingly important to understand the effect of composition and processing on the evolution of microstructure in Ti-based alloys. Therefore, this paper presents recent advances in assessing the earliest and intermediate stages of microstructural evolution – specifically the effect of composition and processing on these stages. A series of state of the art two-dimensional and three-dimensional characterization techniques have been employed in this study of the evolution of microstructure. Of specific interest are the evolution of grain boundary alpha, equiaxed alpha particles, eutectoid phases, and intragranular alpha precipitates.

11:20 AM

Microstructures in Solid-State Welds of Martensitic and Non-Martensitic Transforming Titanium Alloys: *Thomas Broderick*[1]; Adam Pilchak[2]; Jonathan Orsborn[3]; Taylor Pratt[1]; Andrew Woodfield[1]; Hamish Fraser[3]; [1]General Electric Aviation; [2]AFRL Materials and Manufacturing Directorate; [3]The Ohio State University

Subscale components made of similar and dissimilar titanium alloys were fabricated using solid-state welding techniques. Process conditions exposed these alloys to very high transients and gradients in temperature and mechanical deformation. The associated graded microstructures ranged from highly metastable, mechanically deformed microstructures at the joined interface, to partially dissolved and lightly worked microstructures from lesser exposures slightly displaced from the joined interface, to unaffected, original microstructures of the parent metals at a distance further from the joined interface. Subsequent residual stress relief and aging heat treatments resulted in subscale components containing quenched and aged, solution and aged and over aged microstructures in one joined structure. These microstructures were examined using optical, SEM/EBSD and TEM imaging techniques. An interpretation of how as-welded and heat treated microstructures formed was developed according to the potential of transients to cause local changes in phase composition, phase stability and activation of transient martensitic transformation paths.

11:40 AM

Microstructure and Mechanical Properties of a Copper Containing Three Phase Titanium Alloy: *Srikant Gollapudi*[1]; Tapash Nandy[1]; Rajdeep Sarkar[1]; Ashok Gogia[1]; Sankarasubramanian R[1]; Chinta Babu U[1]; [1]DMRL

In this study we attempt to improve the strength of titanium alloys by utilizing the precipitation hardening technique, a route that is relatively unexplored in titanium alloy development. It was found that copper satisfies the conditions necessary for precipitation hardening in titanium alloys and hence the following alloy, Ti–6Al–1.5V–2.5Cu (TAVC), was chosen for our studies. It was decided to ascertain the performance of this alloy in comparison to a standard titanium alloy, Ti–6Al–4V (TAV). The higher, albeit limited strengthening, of TAVC vis-a-vis TAV was attributed to the formation of metastable precipitates of Ti–Cu which were revealed by TEM studies. The Mott–Nabarro model was able to rationalize the strengthening provided by the precipitates.

12:00 PM

Recrystallization Behavior in Ti-13Cr-1Fe-3Al Alloy after Severe Plastic Deformation: *Masato Ueda*[1]; Hikaru Matsuhira[1]; Yuji Takasaki[1]; Masahiko Ikeda[1]; Yoshikazu Todaka[2]; [1]Kansai University; [2]Toyohashi University of Technology

Ti-13Cr-1Fe-3Al alloy was developed as an affordable priced titanium-based material for general use. Up to now, we've investigated mechanical properties, microstructures and heat treatment behaviors in the alloy. The grain size was refined to around 20 μm by thermo-mechanical treatments, dispersions of titanium boride or yttrium oxide, and so on. This means the grain size reaches the limit of conventional techniques in this alloy. Severe plastic deformation (SPD) has received considerable attention as a useful procedure for significant refinement of microstructures in metallic materials. In this study, recrystallization behavior was investigated in the Ti-13Cr-1Fe-3Al alloy after high-pressure torsion (HPT), which is an SPD procedure. Vickers hardness rapidly increased with the number of turns (N) and saturated around 440 after N= 5. The HPT-processed specimen for N=10 was fully recrystallized at 1023 K for 0.3 ks. Equiaxed crystals could be observed and the size reached 6 μm.

8:30 AM
The Development of China's Copper Primary Smelting Technology: Kaixi Jiang[1]; Lan Li[1]; Yaping Feng[1]; Haibei Wang[1]; Bang Wei[1]; *Xiaoping Zou*[2]; [1]Beijing General Research Institute of Mining and Metallurgy; [2]Beijing General Research Institute of Mining & Metallurgy

China is currently the world's largest copper producer. In the last five years, 950kt/y smelting capacity was commissioned. Currently, about 1200kt/y smelting capacity is under construction and about 2000kt/y smelting capacity is under feasibility study. Ausmelt/ISA smelting and flash smelting technologies were commonly adopted in China. After the double-flash-smelter was first adopted in 2004, three new double-flash-smelters are scheduled. Recently, two new smelting technologies were developed in China. One is an improved bath side-blown smelting process, and another is SKS bottom-blown process. Both technologies have been in practice for over 3 years and have achieved good technical performance. Approximately 500kt/y new smelting capacity in China and India will adopt these technologies. Both technologies have advantages of low investment cost, low energy consumption and high flexibility for complex raw materials. This paper reviews "green" copper smelting projects in China and introduces the practices of the two new Chinese smelting technologies.

8:50 AM
New Process for Treating SCF Flue Dust at Atlantic Copper: *Guillermo Rios*[1]; Joan Viñals[2]; Alba Sunyer[2]; Cristina Arbizu[1]; [1]Atlantic Copper; [2]University of Barcelona

Atlantic Copper is one of the largest copper producers in Europe. Its production facilities are located in Huelva (Spain) and treat over 1 million tpy concentrates to produce up to 260 ktpy cathodes and 900 ktpy of sulphuric acid. During the copper concentrate smelting the slag coming from the Flash Furnace and the PS converters is treated in an electrical slag cleaning furnace. As a result of the treatment of the off gases from this furnace, approximately 2,000 tpy of a Zn rich filter cake are produced and sent to authorized waste managers. This paper describes the characterization of this material and the preliminary results of a new process to recover zinc as a pure zinc hydroxicarbonate while lead is collected as an indium rich anglesite phase. The behavior of impurities (Cd, As, Tl, Sn, Sb, Bi, Cu, Se, Te) in the leaching, solution purification and precipitation steps are reported

9:10 AM
Direct Leaching Alternatives for Zinc Concentrates: *Kurt Svens*[1]; [1]K. R. Svens Consulting Incorporation

As the zinc consumption is gradually increasing all the time in the world, many zinc plants are looking for possible expansions. As the sulphuric acid market as well as the fertilizer market in many areas is saturated, the costs for the roasting-acid plant section of the zinc plant will create problems when making the feasibility calculations for the possible expansions. For solving the customers' situation two proven zinc concentrate direct technologies are available. A third one, which is possible, is not having any industrially proven application in the zinc area.

9:30 AM
The Effect of Polytetrafluoroethylene on Pressure Oxidation of Chalcopyrite: Jin Nuo[1]; *Eduard Guerra*[1]; [1]Laurentian University

The use of polytetrafluoroethylene, PTFE, as a solid sorbent for elemental sulfur during pressure oxidation of chalcopyrite was investigated. The effect of agitation, PTFE particle size and lingin sulfonate addition were evaluated using leaching conditions that were otherwise similar to those employed in the CESL process. The effects of these factors, and their interactions, on chalcopyrite oxidation are explained in terms of interfacial forces and solid-solid interactions. Using relatively fine PTFE powder with vigorous agitation resulted in ca. 100% copper extraction in less than 90 minutes without the need for grinding of the flotation concentrate.

9:50 AM
The Effect of Complexing Agents and the Anode Material on the Kinetics of Electro-Assisted Reduction of Chalcopyrite: Eliezer Martínez-Jimenez[1]; *Gretchen Lapidus-Lavine*[1]; [1]Universidad Autonoma Metropolitana-Iztapalapa

Electro-assisted reduction has shown to be an effective pretreatment to render chalcopyrite less refractory towards oxidative leaching. In this process, chalcopyrite is selectively converted to chalcocite or copper metal in an electrolytic cell at ambient conditions, while ferrous ion is leached into solution. However, the reaction velocity is hampered by the formation of a ferrous sulfide passivating layer on the solid surface, especially at elevated solid to liquid ratios. In the present work, several strategies for overcoming this problem were evaluated. On one hand, specific ligands for the ferrous ion were added in order to increase its solubility and, on the other, an anode material, which promotes the oxidation of the sulfide ion, was chosen. Leaching tests showed citric acid to be an effective ligand for both ferrous and ferric ions and, in combination with a lead-silver anode, significantly increased the kinetics of chalcopyrite reduction.

10:30 AM
Nickel Smelter Slag Microstructure and Its Effect on Slag Leachability: Ilya Perederiy[1]; *Vladimiros Papangelakis*[1]; Indje Mihaylov[2]; [1]University of Toronto; [2]Vale Base Metals Technology Development

Nickel slags differ in chemical composition and microstructure. Slow cooling promotes crystallization and growth of crystalline fayalite and magnetite, and vitreous silica. Slag granulation yields either an amorphous solid or highly intergrown crystalline silicate and oxide phases. Smelter slags contain Ni, Co and Cu as dissolved oxides and matte inclusions. Extraction of the entrapped metals by High Pressure Oxidative Acid Leaching (250°C, 70 g/L initial H2SO4, up to 90 psi O2, 45 min) dissolves the metal bearing minerals. The impact of slag microstructure on the accessibility of these minerals to leaching is discussed.

10:50 AM
Characterization of Aluminum Cathode Sheets Used for Zinc Electrowinning: *Neil Gao*[1]; Daniel Liu[1]; Maura Malone[1]; [1]Teck Metals Ltd.

Corrosion is the primary failure mode for aluminum (Al) cathode sheets used in Teck's Trail Operations zinc electrolytic plant. It was observed that the corrosion performance of Al cathodes from different suppliers varied considerably. This suggests that the material properties of Al cathodes have a strong influence on corrosion resistance. In the current study, various types of Al alloys, including 1050, 1060, 1070, H1S and 1090, were characterized through chemical analysis, corrosion testing, mechanical testing and metallography. The results were discussed with a focus on the effects of impurity elements and second phase particles on corrosion resistance. The findings were used to improve the Al cathode sheet specification and to develop a standardized screening procedure which details qualification steps for comprehensive evaluation prior to a plant trial.

11:10 AM
Mechanical Pretreatment of Lead Based Alloy Anode for Zinc Electrowinning: *Taro Aichi*[1]; Rie Sato[1]; Makoto Muramatsu[2]; Hideyuki Takahashi[2]; Kazuyuki Tohji[2]; [1]Dowa Metals and Mining Co., Ltd.; [2]Tohoku University

There have been many ways to condition the lead based alloy anode for zinc electrowinning, namely electrochemical method, chemical treatment and physical treatment. Some of the advantages of physical treatment are its productivity and the variety. In this report, some physical treatments including blasting with silica, alumina, steel grid, and zinc cut-wire were tested. Laboratory tests confirmed there were differences in the formation of anode scale during electrowinning and the suppression of lead dissolution from those anodes.

11:30 AM
Duplex Stainless Steel Corrosion in a Zinc Plant Purification Filter Application: *Timothy Moore*[1]; Michael Heximer[1]; Dominic Verhelst[1]; [1]Teck Metals Ltd

Teck's Trail Operations recently installed new pressure filters in the cold stage purification step in the zinc leaching plant. Alloy 2205 duplex stainless steel was chosen as the material of construction as it was in use in the hot stage purification stage. Within a year of commissioning, an unacceptably high rate (greater than 1 mm/y) of corrosion was observed on the weld heat affected zone (HAZ). Laboratory and field tests were conducted to establish the conditions under which the corrosion was occurring. The tests isolated the aggressive conditions to a unique combination of materials present during the filter regeneration stage. Further, the change of the duplex grain structure of the alloy during welding resulted in the HAZ being more susceptible to the corrosive environment. A new material of construction was recommended as a result of the investigation.

Ultrafine Grained Materials VII: Mechanical Response

Some Common Features of Ultrafine Grained and Nanocrystalline Bcc Metals Produced by Severe Plastic Deformation: *Qiuming Wei*[1]; Laszlo Kecskes[2]; Suveen Mathaudhu[3]; Brian Schuster[2]; [1]University of North Carolina at Charlotte; [2]US ARL; [3]US ARO

In this work, we attempt to provide an updated overview on some common features of ultrafine grained (UFG, grain size ranging from 200 nm to 1000 nm) and nanostructured (NS, grain size smaller than 200 nm) metals with body centered cubic (bcc) structures produced via severe plastic deformation (SPD) such as equal channel angular extrusion (ECAE), ECAE followed by cold rolling, or high pressure torsion. Microstructures were analyzed by TEM of EBSD. Tungsten, tantalum, niobium and iron were studied. Mechanical properties were evaluated both at quasi-static and dynamic loading. Some common features were identified for these UFG/NS bcc metals. For example, all show elastic-nearly perfectly plastic stress strain behavior and much elevated flow stress. It was found that in the UFG regime, they also exhibit reduced strain rate sensitivity, opposing the behavior of fcc metals. Such has rendered most of these metal to show plastic instability under dynamic loading.

8:50 AM
Dynamic Loading of Ultrafine-Grained Aluminum: *Matthias Hockauf*[1]; Lothar Meyer[2]; Martin Wagner[1]; [1]Chemnitz University of Technology; [2]Nordmetall Research and Consulting GmbH

The work-hardening behavior of aluminum 99.7 (soft annealed) and of the aluminum alloy AlMgSi (peak-aged) was investigated. Equal-channel angular pressing (ECAP) was used to introduce an ultrafine-grained microstructure that was carefully analyzed by electron microscopy. Compression tests were performed at strain rates between 10^{-4} and 10^{3} s^{-1}. Our results show that the ECAP strain path and the resulting dislocation structures affect both the post-ECAP yielding and the hardening response. Furthermore, the precipitates of the alloy have significant influence on strain rate sensitivity. Quasi-static (10^{-4} s^{-1}) and dynamic (10^{2} s^{-1}) tensile tests agree well with the compression experiments. The on-set of necking occurs at the end of hardening in stage III. Compared to its influence on flow stress, the influence of strain rate on ductility is rather small. However, uniform elongation and elongation to failure are slightly increased for the ultrafine-grained materials during dynamic tensile loading.

9:05 AM
Quasi-Static and Dynamic Compressive Mechanical Behavior of Friction Stir Processed Ultrafine Grained Al-Mg-Sc Alloy: *Nilesh Kumar*[1]; R. Mishra[1]; R. Howell[2]; K. Cho[2]; [1]Missouri University of Science & Technology; [2]Weapons and Materials Research Directorate

Al-Mg-Sc alloy was subjected to friction stir processing (FSP) to obtain ultrafine grained (UFG) microstructure. Quasi-static and dynamic compression tests were carried out on UFG alloy at strain rates between 10^{-4} to 10^{4} s^{-1}. Dynamic compression tests were carried out using split-Hopkinson pressure bar. Strain rate dependence of the flow stress was studied. The evolution of the deformed microstructure has been investigated using electron backscatter diffraction and transmission electron microscope. In general, very limited study exists on high strain rate deformation behavior of UFG face centered cubic materials and in particular, no work exists on the deformation behavior of FSP UFG alloys. This work is an attempt to bridge the gap in the literature.

9:20 AM
Anisotropic Mechanical Properties of Commercially Pure Aluminum Processed by Equal Channel Angular Extrusion: *Pei-Ling Sun*[1]; Sheng-Jie Huang[1]; Chung-Yi Yu[2]; Po-We Kao[3]; [1]Feng Chia University; [2]China Steel Corporation; [3]National Sun Yat-Sen University

Commercially pure aluminum AA1050 was subjected to equal channel angular extrusion (ECAE) to a total strain of ~8 at room temperature. Post-ECAE annealing was then conducted on the samples. Compression tests were performed on the ECAEed and annealed samples along different loading directions at room temperature. Both the as-ECAEed and annealed samples show anisotropic mechanical properties, in which the highest compressive stress appears to be along the transverse direction of ECAE. This is attributed to the strain path change effect. Shear bands were observed on the annealed sample surface after compression tests. The presence of shear bands on the annealed sample surface may be attributed to the lower dislocation density after annealing treatment. When the annealed samples were compressively tested, inhomogeneous deformation occurred by the form of shear band deformation.

9:35 AM Invited
Tensile Properties and Fracture Mechanisms of Ultrafine Cu Alloys Subjected to Severe Plastic Deformation: *Zhefeng Zhang*[1]; P. Zhang[1]; X. H. An[1]; Y. Z. Tian[1]; S. D. Wu[1]; T. G. Langdon[2]; [1]Institute of Metal Research; [2]University of Southern California

The mechanical properties and fracture mechanisms of Cu, Cu-Al, Cu-Zn and Cu-Ag alloys subjected to either equal-channel angular pressing (ECAP) or high-pressure torsion (HPT) were investigated. It is found that both the tensile strength and uniform elongation of Cu-Al and Cu-Zn alloys subjected to ECAP increase simultaneously with increasing alloy contents (Al or Zn); whereas there is a peak uniform elongation when the two Cu alloys are processed by HPT. The tensile fracture behaviors of Cu and Cu-Zn alloys changed from necking to necking + shearing then to shear fracture with increasing the number of ECAP passes. Then the macroscopic and microscopic tensile shear fracture mechanisms are analyzed by considering the competitive relationship between the slipping strength and the critical shear strength. As well as the size and density of dimples on the fracture surfaces. Finally the strengthening and toughening mechanisms of ultafine materials are discussed.

9:55 AM
Microstructure and Tensile Strength of Grade 2 Ti Processed by Equal-Channel Angular Pressing and Cold Rolling: *Vitor Sordi*[1]; Megumi Kawasaki[2]; Maurizio Ferrante[1]; Terence Langdon[2]; [1]Federal University of Sao Carlos; [2]University of Southern California

The potential for strengthening of commercially pure titanium using severe plastic deformation constitutes an alternative to the use of complex Ti alloys for many medical or industrial applications. In this work, rods of grade 2 Ti were processed up to six passes by Equal-Channel Angular Pressing (ECAP) at 573K, followed by cold rolling at room (CRRT) or subzero (CRLT) temperatures. After 4 passes of ECAP the grain size was refined down to sub-micron scale, and subsequent CR led to further refinement of structure. Characterization included Vickers microhardness measurements and tensile tests performed at room temperature and in the temperature range 573-773 K. Results show that the tensile strength in this temperature range can be significantly improved using these processing techniques. At room temperature, the ultimate tensile strength of pure Ti after ECAP+CRLT is similar to that of many Ti alloys, while maintaining adequate levels of elongation to failure.

10:10 AM
Strain Rate Sensitivity of Ultrafine Grained and Nanocrystalline Metals via Instrumented Nanoindentation: *Ivan Romero*[1]; L. J. Kecskes[2]; Suveen Mathaudhu[3]; Qiuming Wei[1]; [1]University of North Carolina at Charlotte; [2]U.S. Army Research Laboratory; [3]Army Research Office

Plastic deformation mechanisms are the object of many studies, especially the thermodynamics and kinetics of the plastic deformation of metals and their changes along grain size. Strain rate sensitivity (SRS) is an indicator that gives information on the plastic deformation that can be obtained by means of the jump test in conventional mechanical testing or by nanoindentation as here presented. Different works have been presented in order to characterize the effects of strain rate in metals since the 1960s; during the last decade works on the untrafine (UFG) and nanocrystalline (NC) regime has been done with the aim of identifying the trend of metals according to their crystal structure, i.e., FCC, BCC and HCP metals, and the influence of the production methods such as severe plastic deformation or powder metallurgy. In this study, nanostructured bulk metals are probed in order to extract information about their SRS via instrumented nanoindentation.

Ductility and Strategies for Improving Ductility of Bulk Nanostructured Materials: *Yonghao Zhao*[1]; [1]Nanjing University of Science and Technology

The limited ductility of bulk nanostructured materials has emerged as an important obstacle to widespread application of bulk nanostructured materials, despite their other attributes, such as ultra high strength levels, in some cases. This talk will first analyze the intrinsic and extrinsic reasons for the low ductility of the bulk nanostructured materials, and then summarize effective strategies for improving the poor ductility of bulk nanostructured materials. Finally we report on recent successful results by applying some of these strategies in nanostructured NiFe and 7075 Al to obtain both high strength and ductility. Keywords: Nanostructured materials, ductility, microstructures

11:00 AM
True Stress-True Strain Relationships until just before Fracture of Ultrafine-Grained Ferrite-Cementite Steels: *Noriyuki Tsuchida*[1]; Tadanobu Inoue[2]; [1]University of Hyogo; [2]National Institute for Materials Science

True stress-true strain relationships until just before fracture were estimated by stepwise tensile test and the Bridgman correction in ultrafine-grained ferrite-cementite steels with average ferrite grain sizes less than 2 μm. The estimated true stress-strain relationships were different from the nominal stress-strain curves including the conventional tensile properties. In the nominal stress-strain curves, strength increased and elongation decreased with decreasing the grain size. However, the balance between true stress and true strain just before fracture became larger with decreasing of the grain size in the true stress-true strain relationships. The estimated true stress-strain relationships for the ultrafine-grained steels suggest that the grain refinement strengthening can improve true stress and true strain until fracture.

11:15 AM
Micromechanical Testing of Nanocrystalline and Ultra Fine Grained bcc Metals: *Jonathan Ligda*[1]; Brian Schuster[2]; Qiuming Wei[1]; [1]UNC Charlotte; [2]Army Research Laboratory

We report on recent investigations into the mechanical properties of nanocrystalline (NC) and ultra-fine-grained (UFG) body centered cubic metals processed via high pressure torsion (HPT). The microstructures were characterized using synchrotron x-ray diffraction and transmission electron microscopy. The mechanical properties were investigated using site-specific nanoindentation along with micro- tension and compression. These samples have an inherent gradient in microstructure and properties resulting from the HPT processing. Grain sizes vary as a function of radial position on the bulk HPT disk; with increasing distance from the center of the disk, grains transition from UFG to the truly NC regime. W and Ta show a Hall-Petch dependence on hardness well into the NC regime. NC Ta specimens have been shown to retain some significant tensile elongation. Specimens with the smallest grain sizes show a distinct transition to localized plastic deformation.

11:30 AM
The Effect of High Strain Rate on the Mechanical Properties of Nanoporous Metal: *Tanvir Ahmed*[1]; Alan Jankowski[1]; [1]Texas Tech University

Porous metals are being used in energy absorption devices and renewable-energy system applications. Micro-scratch measurements at high strain rate show that nanoporous metals have an enhanced strain-rate sensitivity in comparison to their dense counterparts. Rate-dependent tribological tests are conducted to measure the sensitivity of porous metal coatings at the micro- and nano-scale to investigate differences in the operative deformation mechanism at high strain rate. Results for microporous silver indicate the strain-rate sensitivity exponent increases significantly as the strain rate is increased beyond the regime dominated by solution effects and dislocation-based deformation. Similar results are presented for nanoporous gold and aluminum coatings for comparison with dense nanocrystalline counterparts. The morphological effects from porosity are assessed in structural stability and operative deformation mechanisms at high strain rates. The features of length scale are evaluated using electron microscopy, and the mechanical behavior is assessed by the micro- and nano- scratch hardness methods.

11:45 AM
Influence of Cryogenic Processing on the Mechanical Properties of High-Purity Copper: *Joel House*[1]; James O'Brien[2]; Philip Flater[1]; Robert De Angelis[3]; Richard Harris[1]; Michael Nixon[1]; [1]Air Force Research Laboratory; [2]O'Brien and Associates; [3]University of Florida

Wang et al (Nature, 2002) demonstrated that cold rolling at cryogenic temperatures could be used to increase the toughness of high-purity copper. Increased material strength was attributed to extremely fine grain structure (grain size \149; 300 nm), in combination with deformation twinning. The current research seeks to extend that characterization by processing copper using Equal Channel Angular Pressing (ECAP) at cryogenic temperatures. After processing, a series of experiments were conducted to characterize the materials response to low temperature annealing (175-275°C) and to characterize the mechanical properties in the as-worked and annealed conditions. The mechanical property characterization included low strain rate and high strain rate loading in both tension and compression. Results of the mechanical property experiments will be discussed in the context of the features of the microstructures that have been characterized using optical microscopy, scanning electron microscopy, and electron-backscattered diffraction.

12:00 PM
Occurrence and Elimination of Yield Point Phenomena in Nanostructured Metals: *Xiaoxu Huang*[1]; Jacob Kidmose[1]; Tianlin Huang[2]; Qingshan Dong[2]; Niels Hansen[1]; [1]Risø National Laboratory for Sustainable Energy, Technical University of Denmark; [2]Chongqing University

In ultrafine grained aluminum produced by plastic deformation and annealing, the tensile stress-strain curves show an unexpected yield drop, which is detrimental to the formability. The underlying mechanism is related to lack of mobile dislocations in the microstructure. In order to remove the yield drop, two procedures have been explored. One is to introduce extra dislocations by plastic deformation and the other is to add incoherent particles in order to increase the density of potential dislocation sources. Both routes are successful as they can remove the yield drop. This effect is discussed based on detailed strength and structural observations.

Stability and Microstructural Evolution of Grain Boundaries in Severely Deformed Metals: *Gerhard Wilde*[1]; Sergiy Divinski[1]; Harald Rösner[1]; [1]University of Muenster

Severe plastic deformation causes grain refinement due to the creation of large dislocation densities and the subsequent or concurrent socialization into cell- and grain boundaries. Here, detailed grain boundary diffusion studies after different thermomechanical treatment were performed to analyze the rates of atomic transport and the specific excess energy density of such grain boundaries in severely deformed pure metals like Cu, Ni, Ti and Ag. Additionally, the radiotracer analyses are combined with high resolution transmission electron microscopy and local strain field analyses with atomic resolution via geometric phase analysis to examine the stability and the time – and temperature – dependent evolution of grain boundaries in severely deformed metals. The comparison indicates that the theoretical and computational studies can capture important aspects of the properties and the evolution of such grain boundaries even quantitatively, but that they are not in agreement with the entire set of the experimentally observed behavior.

8:50 AM
Thermal Stability in Nanostructured fcc Metals: The Role of Twin Interfaces and Vacancies: *Christopher Saldana*[1]; Alexander King[2]; Srinivasan Chandrasekar[3]; [1]Pennsylvania State University; [2]US Department of Energy, Ames Laboratory; [3]Purdue University

In this study we show that nano-scale twinned microstructures produced by low-temperature, severe plastic deformation of pure copper exhibit both strength and thermal stability. Twinned microstructures store less energy in their interfaces than other nanostructured materials, but also appear to exhibit lower vacancy supersaturations, reducing the driving force and mobility for microstructure evolution. While similar combinations of strength and thermal stability are observed in the case of deformed silver, the same behavior is not observed in aluminum and nickel. This suggests that, in applications where thermal stability is critical, the preferred strengthening of certain pure metals may be different from the conventional approach of pushing microstructure refinement to nano-scale equiaxed grain morphologies.

9:05 AM
X-Ray Diffraction Study of Thermal Stability of Several Materials Prepared by ECAP and HPT: *Radomir Kuzel*[1]; Zdenek Matej[1]; Milos Janecek[1]; Ondrej Srba[1]; [1]Charles University in Prague, Faculty of Mathematics and Physics

XRD studies of ECAP and HPT materials (mainly Cu, Cu-Zr, Mg) were performed after annealing and by in-situ measurements in high-temperature chamber for samples prepared by different number of passes and number of revolutions, respectively. Strong changes were found for ECAP samples while no dependence was observed in the latter case when differences were found along the radius of disc-shape specimen. In-situ measurements were focused not only on temperature dependence but also on time evolution of the diffraction line widths. The latter were measured at temperatures where significant drop of line widths was observed in isochronal annealing. The widths were decreasing with time but after relatively short time they reached saturated values and for their further reduction an increase of temperature was necessary. Evaluation in terms of dislocation densities, correlation and crystallite size was performed by our own software Mstruct developed for total powder diffraction pattern fitting.

9:20 AM Invited
Stabilization and Mechanical Properties of Nano-Crystalline Copper by Alloying with Tantalum: *Kris Darling*[1]; Laszlo Kecskes[1]; David Foley[2]; Suveen Mathaudhu[3]; [1]ARL; [2]Texas A&M University; [3]ARO

The thermal stability of nanocrystalline Cu 10at% Ta prepared through high energy cryogenic mechanical alloying was studied. Nanocrystalline Cu 10at% Ta maintains a mean grain size of 150nm after annealing at 97% of it melting point. Powder samples were consolidated by high temperature equal channel angular extrusion (ECAE). Post processing analysis revealed fully consolidated samples exhibiting high hardness (4-3GPa), low porosity (<1%) without evidence of prior particle boundaries. Samples were tested mechanically under various testing methods. The results are reported here.

9:40 AM
Stability and Grain Growth Mechanisms in Sintered Tungsten: *Brady Butler*[1]; James Paramore[1]; Kristopher Darling[1]; Micah Gallagher[1]; Eric Klier[1]; Heidi Maupin[1]; [1]U.S. Army Research Laboratory

One common method for achieving ultrafine grained tungsten microstructures is through the addition of particulate phases. These dispersoids operate via a kinetics based pinning mechanism to reduce the mobility of grain boundaries during the final stages of sintering. In recent years an alternative grain refinement mechanism based on increasing the thermodynamic stability of grain boundaries has been proposed for a number of alloy systems. In this paper, the principle of solute segregation as a means of reducing grain boundary energy and thereby reducing the driving force for grain growth is investigated. The application of thermodynamic stabilization techniques for producing ultrafine grained microstructures is demonstrated in a tungsten system and compared to previous results in other alloy systems. In particular, the relationships between thermodynamic stability, densification and grain growth are established.

9:55 AM
Processing and Thermal Stability of Nanocrystalline Tungsten Alloys: *Tongjai Chookajorn*[1]; Christopher Schuh[1]; [1]Massachusetts Institute of Technology

Thermal stability is a major practical concern for nanocrystalline metals, as they contain a large volume fraction of interfaces which promote structural coarsening and therefore loss of properties at elevated temperature. In the case of refractory metals, powder-route processing via high energy milling is the processing method of choice to form a high-strength nanocrystalline structure, but the subsequent need to consolidate at elevated temperature introduces a unique requirement for nanostructure stability if bulk nanocrystalline material is to be produced. Here we describe our work on the processing of nanocrystalline tungsten alloys, with a focus on the problem of nanostructure stabilization through alloying effects such as grain boundary segregation and phase separation. Thermal stability of the nanocrystalline structure is studied as a function of alloying additions, and contact with theoretical models for nanostructure stability is also made.

10:10 AM
The Effect of Deformation Texture on the Thermal Stability of UFG HSLA Steel: *Enrico Bruder*[1]; [1]TU Darmstadt

UFG microstructures produced by SPD are far from the thermodynamic equilibrium thus being prone to undergo coarsening processes at elevated temperatures. Theoretical and experimental investigations revealed that the stability against discontinuous grain growth in UFG metals strongly depends on the fraction of high angle grain boundaries (HAGBs), meaning that discontinuous grain growth does not occur if the fraction of HAGBs exceeds a certain level. The present work focuses on the impact of strong deformation textures on the thermal stability of UFG microstructures in ferritic steels processed by linear flow splitting. It shows that the expected correlation between thermal stability and fraction of HAGBs is valid up to moderate texture intensities, whereas a strong deformation texture promotes discontinuous grain growth in spite of a high fraction of HAGBs. EBSD measurements show that this effect is based on strain induced boundary migration causing a progressive orientation pinning which destabilizes the microstructure.

10:40 AM Invited
GB Segregations in UFG Alloys Processed by SPD: *Xavier Sauvage*[1]; Nariman Enikeev[2]; Julia Ivanisenko[3]; Artur Ganeev[2]; Ruslan Valiev[2]; [1]University of Rouen, CNRS; [2]IPAM-USATU; [3]INT - Karlsruher Institut für Technologie (KIT)

UFG alloys processed by SPD exhibit very specific grain boundaries that are characterized by long range elastic stresses and enhanced free volumes. To minimize the excess energy associated to these specific boundaries, some solute elements may segregate and cover them. Such segregations may significantly affect the mechanical behavior or the thermal stability. Therefore a systematic study was carried out to clarify the mechanisms and especially the role of defects created during SPD. GB segregations were characterized thanks to Atom Probe Tomography in an Al-Mg alloy and in a steel processed by HPT. In the AlMg alloy, heterogeneous distribution of Mg was found along boundaries with local concentrations up to 30at.%, while in the steel, the carbon concentration along the boundary was much lower and more regular. These data will be discussed with a special emphasis on the GB structure and on the mechanisms involved during SPD.

11:00 AM
Low-Temperature Thermal Stability of Cold-Rolled Nanostructured Aluminum: *Tianbo Yu*[1]; Niels Hansen[1]; Xiaoxu Huang[1]; [1]Risø National Laboratory for Sustainable Energy, Technical University of Denmark

Commercial purity aluminum deformed to high strains was annealed at relatively low temperatures (from room temperature to 220°C), and the evolution of microstructure was characterized using transmission electron microscopy (TEM) and electron backscattered diffraction (EBSD). Triple junctions in a lamellar nanostructure with an average spacing 200~300 nm are classified into three categories based on the structural morphology, and a relationship is formulated between the density of triple junctions and the boundary spacing. Based on TEM and EBSD observations, thermally-activated triple junction motion is identified as the key process during recovery of highly-strained aluminum, leading to removal of thin lamellae and widening of microstructure. A mechanism for recovery by triple junction motion is proposed, which can underpin the general observation that a lamellar structure formed by plastic deformation coarsens into a more equiaxed structure during annealing at low temperatures.

11:15 AM
Conditions for Stabilization of Binary Nanocrystalline Alloys against Grain Growth and Phase Separation: *Heather Murdoch*[1]; Chris Schuh[1]; [1]MIT

Many nanocrystalline materials are limited in their application by their propensity for grain growth due to the energy associated with their large volume fraction of grain boundaries. Several methods have been proposed to stabilize nanoscale structure; among these grain boundary segregation is appealing as it lowers the thermodynamic driving force for grain growth. This approach to stabilization has been used with some success in various binary metal alloys; however, in many such cases the precipitation of a second phase triggers a rapid loss in stability. Adapting a recent model developed by Trelewicz and Schuh for nanocrystalline stabilization via grain boundary segregation, we examine the conditions under which an alloying element can support a nanoscale grain structure that is thermodynamically stable against second phase formation. We ascertain the materials properties required for stabilization of a nanocrystalline structure, and delineate alloys in which grain boundary segregation is not a viable stabilization strategy.

11:30 AM Invited
Enhancement of Strength and Stability of Nanostructured Ni by Small Amount of Solutes: *Hongwang Zhang*[1]; Ke Lu[1]; Reinhard Pippan[2]; Xiaoxu Huang[3]; Niels Hansen[3]; [1]Institute of Metal Research; [2]Austrian Academy of Science; [3]Risoe National Laboratory for Sustainable Energy

Plastic deformation is an effective method to fabricate bulk nanostructured metals and alloys with high strength, however, with limited thermal stability. Foreign elements in solid solution can have a beneficial effect by reducing both dynamic and thermal recovery and thereby increasing the strength at ambient temperature and the thermal stability at elevated temperatures. Here we report exploratory investigation on a comparison of polycrystalline Ni with a purity of 99.7% (with 0.14% Ti) and 99.967wt% deformed by high pressure torsion to a strain of 100. The presence of Ti solute atoms i) decreases the structural scale from 130 to 42 nm, ii) increases the flow stress from 1000 to 1700 MPa, and iii) increases the recrystallization temperature from 150oC to 500oC. The effect of solute on dislocation storage during deformation and on mobility of dislocations and boundaries during annealing are discussed. The strengthening mechanisms and their superposition are also analyzed.

11:50 AM
Processing of Thermally Stable, Ultrahigh-Strength Mg-Alloys: Kristopher Darling[1]; Laszlo Kecskes[2]; *Suveen Mathaudhu*[2]; [1]U.S. Army Research Laboratory; [2]U.S. Army Research Office

Advanced nanocrystalline alloys have shown remarkable property improvements, particularly, order-of-magnitude strength increases, when compared to their coarse-grained counterparts. However, a major obstruction to the widespread application of such materials is the degradation of properties via rapid grain growth at even ambient temperatures. Conventional methods for circumvention of this problem at low temperatures have largely steered toward kinetically pinning the boundaries with disperoids, or through misorientation of grain boundaries, yet even these methods have limited utility at elevated temperatures needed for routine sintering and forming operations. In this work, we will present a synergistic approach to the development of thermally stable nanostructured Mg-alloys which incorporates elements of predictive modeling of suitable alloy systems, fabrication of nanostructured alloy powders by high energy ball milling and consolidation of the powders at elevated temperatures to bulk ultrahigh strength alloys.

12:05 PM
Applying Equilibrium Segregation Theories to Inhibiting Grain Growth: *Brian VanLeeuwen*[1]; [1]The Pennsylvania State University

This work reviews the assumptions of the popular Langmuir-McLean segregation isotherm and Guggenheim-Fowler segregation isotherm. It is concluded that these should not be applied to the study of grain growth inhibition in nanocrystalline alloys because they assume constant interfacial area. An amended isotherm that does not make this assumption is proposed.

12:20 PM
High-Pressure Torsion-Induced Grain Refinement/Growth in Coarse-Grained/Nanocrystalline Cu Powders: *Haiming Wen*[1]; Troy Topping[1]; Enrique Lavernia[1]; Rinat Islamgaliev[2]; Ruslan Valiev[2]; [1]University of California, Davis; [2]Ufa State Aviation Technical University

Severe plastic deformation (SPD) is widely used to achieve exceptional grain refinement in coarse-grained metals to obtain ultrafine or nanocrystalline (nc) grain size. Deformation-induced grain growth in nc metals has been reported during various plastic deformation processes. However, very few studies have compared or related the two opposite processes (i.e. grain refinement and grain growth). In this study, high pressure torsion (HPT) was used to process coarse-grained or nanocrystalline Cu powders. The results showed that significant grain growth from an average grain size of 46 nm to 90 nm occurred in cryomilled nanocrystalline Cu powders. In comparison, HPT resulted in exceptional grain refinement in coarse-grained Cu powders and also attained an ultimate grain size of ~ 90 nm. The associated mechanisms for the grain refinement/growth were ascertained, and microstructure and mechanical behavior of the samples obtained from the two processing routes were compared and discussed.

2012 Functional and Structural Nanomaterials: Fabrication, Properties, Applications and Implications: 1-Dimensional Nanomaterials and ZnO

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS: Nanomaterials Committee
Program Organizers: Jiyoung Kim, University of Texas; David Stollberg, Georgia Tech Research Institute; Seong Jin Koh, University of Texas at Arlington; Nitin Chopra, The University of Alabama; Terry Xu, UNC Charlotte

Tuesday PM — Room: Pelican 1
March 13, 2012 — Location: Swan Resort

Session Chair: Seung Hyuck Kang, Qualcomm

Energy Generation and Storage Applications of TiO2 Nanotubular Arrays by Atomic Layer Deposition and Nanotemplating: *Hyunjung Shin*[1]; [1]Kookmin University

Tubular structures of oxides in nanometer have attracted much attention as the most promising 1-D materials for many applications. High crystalline quality of TiO_2 NT arrays templating by atomic layer deposition (ALD) onto anodic aluminum oxides (AAO) and subsequent annealing will be presented. The optimum boosting condition of crystallization has been attained. More than half of micron-meter long anatase single grains resembling the physical properties of the bulk in NTs were obtained, and the most defective form was able to be prepared by pinning the grain growth at the thinnest wall thickness. The former was utilized in high efficient dye-sensitized solar cells, producing photovoltaic cells exceeding conversion efficiency of ~6%, and the high efficiency results were ascribed to the minimization of defect sites. The latter was found to be using in Li-ion battery application, resulting in fast charging up to ~2000 C as well as high charging capacity.

2:35 PM
High Performance TiO_2 Nanotubes-Based Biosensors for Streptavidin Detection: *Mingun Lee*[1]; Antonio Lucero[1]; Taewook Kim[1]; Jie Huang[1]; Moon Kim[1]; Jiyoung Kim[1]; [1]University of Texas at Dallas

Biosensors composed of a single tinanium dioxide (TiO_2) nanotube were fabricated to detect streptavidin – a popular test vehicle for demonstrating feasibility of a biomolecule-based protein detector. Streptavidin detection is facilitated by functionalizing the nanotubes with biotin or its derivatives via self-assembled alignment in phosphate buffered saline (PBS). The presence of streptavidin is noted by the conductance shift in the nanotubes due to biotin-stpretavidin pair bonding occurring on its surface. Our biosensors have achieved detection limit of 10pM, and did not exhibit any change in conductance when exposed to chemicals other than streptavidin, which indicates high sensitivity and selectivity; with further study and modifications, they are likely become highly effective at detecting not only proteins, but other bio-substances as well. This research was supported by a grant (code #:2010K000351) from 'Center for Nanostructured Materials Technology' under '21st Century Frontier R&D Programs' of the Ministry of Education, Science and Technology, Korea.

2:55 PM
Nano Boron Carbide in Fabric for Improvement of Ballistic Performance: David Stollberg[1]; *Juan Aguilar*[1]; [1]Georgia Tech Research Institute

Kevlar fiber is widely used for body armor due to its high strength, tenacity, and energy absorption. Kevlar-based armor systems are often enhanced by adding Boron Carbide (B4C) plates. B4C is used because it is relatively light weight, extremely hard, and has good energy dissipating mechanisms upon impact. One of the main issues with these armor systems is that they are heavy and cumbersome, making it difficult for soldiers to operate while wearing them. Consequently, they are often considered unsuitable for routine wear. The purpose of this study was to improve the ballistic and puncture resistance of protective fabrics (Kevlar and Nomex) by incorporating B4C in a way that does not significantly increase weight or reduce flexibility. This was achieved by depositing nano-thickness films of B4C on the fabrics. The effect of functionalization with carbon nanotubes (CNT) was also explored. The resulting modified fabrics were tested, showing improved puncture resistance.

3:15 PM
Size Dependent Transition of Deformation Mode in Gold Nanowire: A Molecular Dynamics: *Pil Ryung Cha*[1]; Na-Young Park[1]; Ho-Seok Nam[1]; Seung-Cheol Lee[2]; [1]Kookmin University; [2]Computational Science Research Center,Korea Institute of Science and Technology

Inspired by recent experimental results [1] for the deformation behavior of Au nanowire with the diameter of ~100 nm, we have conducted the molecular dynamics (MD) simulations for the deformation of single-crystalline <110>/{111} Au nanowires with various diameters under tensile loading. Our MD results demonstrate size-dependent transition of the deformation mode from fracture by the localization of slip to transformation to <100>/{100} nanowire by twin propagation unlike previous MD researches which have shown the tensile deformation by the localization of slip in Au nanowire. The transition arises from the competition between irreversible slip behavior and pseudo-elasticity represented by twin propagation. Below a critical size, <110>/{111} nanowires showed irreversible behavior by slip localized in the transformed region as soon as a twin region (transformed <100>/{100} wire) formed, which was caused by the yield stress of the transformed <100>/{100} region lower than the flow stress associated with twin propagation.

3:35 PM
Synthesis and Investigation of Growth Mechanisms of Functional Inorganic Oxide Nanomaterials: *Yuanbing Mao*[1]; [1]University of Texas-Pan American

One of the remaining challenges in preparing nanomaterials is to develop large scale, controllable, reliable and simplistic synthetic methods. Hence, we present our recent work on the large scale synthesis of luminescent RE doped oxide nanoparticles, including Er:Y2O3 and Er:La2(ZrxHf1-x)2O7, and magnetic double perovskite La2BB'O6 by molten salt synthesis. Their luminescent and magnetic properties have been systematically studied. Moreover, to better control the property and device performance of nanomaterials, growth kinetic and mechanistic information of structure changes should be pursued to provide feedback for the development of new "designer" materials to meet the future challenges. In this presentation, we start with ex situ studies of titanium-based oxide nanomaterials, and then focus on advanced luminescent nanomaterials. Specifically, we present our recent investigation of in-situ time-resolved synchrotron x-ray diffraction (XRD) and absorption spectroscopy (XAS) analyses on the synthesis of rare-earth doped metal oxide nanostructures, including Er:Y2O3 nanotubes and nanoparticles and Er:La2(ZrxHf1-x)2O7 nanoparticles.

4:10 PM
Ultrafine ZnO Nanoparticles Synthesized by Ultraviolet Decomposition Process in Ambient Air: Growth Mechanism and Photoresponsive Activities: *Jyh Ming Wu*[1]; Hsin-Hsien Yeh[2]; Hong-Ching Lin[2]; [1]Feng Chia University; [2]Industrial Technology Research Institute

Zinc oxide nanostructures have been considered as promising materials for applications of sensors, photovoltaic cell,and photocatalysis. In this work, the different solvents such as isopropylalcohol (IPA), acetone, and denatured ethanol were used to prepare a single precursor of $Zn(AcAc)_2•H_2O$. The single crystalline ZnO nanoparticles were formed as $Zn(AcAc)_2•H_2O$ was irradiated under a ultraviolet lamp (λ~380 nm, 75-150mW/cm^2) in ambient air. High-resolution transmission microscopy image and selected-area diffraction pattern revealed that the nanoparticles were single crystalline and belongs to wurtize-structure ZnO. The particles size of ZnO is ~7-9 nm based on Debye-Scherrer formula and HRTEM investigation. Water molecular was found to be acted as key compoments during the formation process. As-synthesized ZnO nanoparticles have been investigated using UV lamp (λ~365nm, 2.33mW/cm^2). A superior photocurrent to dark current ratio was achieved ~764. As-developed UV-light decomposition process under ambient air is very simple, large-area, and with short process time.

4:30 PM
P-Type Conductive Behaviors of AlN Co-Doped ZnO Films Deposited by the Atomic Layer Deposition: *Yu-Mi Kim*[1]; Kwang-Seok Jeong[1]; Ho-Jin Yun[1]; Seung-Dong Yang[1]; Sang-Youl Lee[1]; Hi-Deok Lee[1]; Ga-Won Lee[1]; [1]Chungnam National Univ.

AlN co-doped ZnO (ANZO) films were deposited by the atomic layer deposition (ALD) system on glass substrates at the low temperature of 200 °C. To find out an optimal film condition for the p-type conductive behaviors, the experimental study is carried out by varying N doping concentration (2 at%, 15 at%), 4 kinds of different process sequences and post-annealing temperatures from 300 °C to 700 °C under N2 ambient. The structural, optical and electrical characteristics of ANZO films with different process sequences are investigated, respectively. The ANZO films with NH4OH concentration of 2 at% and sequence D (DEZ-NH4OH-TMA-NH4OH) show excellent p-type behavior with a high mobility and a hole concentration of 32.41 cm2V-1s-1 and about 2.72×1016 cm-3 at post-annealing temperature of 500 °C, respectively.

4:45 PM
Zinc Oxide Nanorods by the Pulsed Plasma in Liquid and Their Photocatalytic Property: *Emil Omurzak*[1]; Kengo Taniguchi[2]; Tsutomu Mashimo[2]; [1]Kumamoto University ; [2]Kumamoto University

Wurtzite-type ZnO (w-ZnO) nanorods were synthesized using the pulsed plasma in liquid method. The pulsed plasma submerged into a liquid enables us to synthesize metastable, high-temperature phase nanocrystalline materials by rapidly quenching from the plasma state. Pulsed plasma generated by electrical discharge between two electrodes made of pure metallic zinc rods submerged into water resulted in production of the w-ZnO nanostructures. Synthesized ZnO nanostructures were of rod shape with a diameter of about 20 nm and length up to 150 nm. UV-Visible absorption spectroscopy analysis of the synthesized ZnO nanorods showed a blue shift (about 0.19 eV) of absorption peak (350 nm) comparing to that of the commercial sample. Photoluminescence spectrum of the sample at the room temperature showed two peaks at 381 nm and 535 nm. Photocatalytic property of the synthesized ZnO nanoparticles was higher than that of the commercial photocatalyst TiO2 under the visible light. Purer ZnO without metallic Zn could be synthesized by using the SDS and CTAB surfactant materials. In addition, morphologies of the nanorods produced using different surfactants were different from each other.

5:05 PM
ZnO Nanowires Grown on ZnO Thin Film Deposited by Atomic Layer Deposition: *Mikhail Ladanov*[1]; Paula Algarin Amaris[1]; Pedro Villalba[1]; Garrett Matthews[1]; Manoj Ram[1]; Jing Wang[1]; Ashok Kumar[1]; [1]University of South Florida

Currently, ZnO nanowires are studied for their applications in a wide variety of devices. Control over the properties of ZnO nanostructures, such as size, shape and density is required. In this work the atomic layer deposition (ALD) technique was used to deposit the seeding layer of ZnO, which was then post-processed using rapid thermal processing. ZnO nanowires were grown using hydrothermal method on the seeding layer. We studied how the annealing of ZnO thin films grown by ALD affect properties of ZnO nanowires grown on this film using the hydrothermal method. ZnO thin films were characterized by means of AFM and grazing incidence XRD, while ZnO nanowires were characterized by means of XRD and SEM. Results suggest strong correlation between properties ALD thin films modified by rapid thermal annealing and resultant ZnO nanowires. Changes in density, size and degree of vertical orientation in ZnO NW are shown.

5:20 PM
Deposition of Organic and Inorganic Hybrid Laminates Using Ozone Based Atomic Layer Deposition: *Sunwoo Lee*[1]; Jie Huang[1]; Mingun Lee[1]; Pil-Ryung Cha[1]; Jiyoung Kim[1]; [1]The University of Texas at Dallas

Recently, organic materials have been attracting attention due to their low cost and flexibility. However, they have many issues such as electrical instability and short life time. Therefore, a hybrid stack has been developed to compensate for the many issues of organic materials while maintaining their flexibility and functionality. A novel technique for building an organic and inorganic stack has been introduced by M. M. Sung et al. using a modified ALD method.1 It has the advantage of minimizing the defects during growth of organic and inorganic films because the hybrid films are deposited by an in-situ process through the sequential, self-limiting surface reaction similar to ALD. This research has been partially funded through Korea-US collaboration R/D program by MKE-COSAR-KETI. References [1]. B. H. Lee, et al., J. Am. Chem. Soc., 129, 16034 (2007).

2012 Symposium on Surfaces and Heterostructures at Nano- or Micro-Scale and Their Characterization, Properties, and Applications: Energy and Catalysis

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Materials Processing and Manufacturing Division, TMS: Energy Conversion and Storage Committee, TMS: Nanomaterials Committee, TMS: Surface Engineering Committee, TMS: Young Leaders Committee, TMS: EMPMD Council

Program Organizers: Nitin Chopra, The University of Alabama; Ramana Reddy, The University of Alabama; Arvind Agarwal, Florida International University; Sandip Harimkar, Oklahoma State University; Jiyoung Kim, University of Texas at Dallas; Christopher Matranga, National Energy Technology Laboratory

Tuesday PM — Room: Pelican 2
March 13, 2012 — Location: Swan Resort

Characterization and Modeling of 3D Photovoltaics: *Jonathan Guyer*[1]; Daniel Josell[1]; [1]NIST

First Generation (thick layers of crystalline silicon) and Second Generation (thin films of CdTe, CIGS, etc.) PV devices are both well established, with well defined techniques for fabrication and characterization. Third Generation PV encompasses a wide diversity of materials and nanostructures and commercially viable technologies and means of fabrication are yet to be determined. Many of the proposed structures have considerable microstructural variability that complicate interpretation of macroscopic device measures. We are developing idealized, three-dimensionally patterned templates that can serve as test structures to enable measurement of critical device and materials properties. Initial heterostructures are based around electrodeposited CdTe. To guide and interpret the experimental measurements we are developing open source models of carrier and light transport within arbitrary 2D and 3D device geometries. This talk will compare experimental measurements with simulation results and discuss how the model is used to guide new device geometries.

More Efficient Polymer Solar Cells by Doping with Ferroelectric Dipoles: Kanwar Nalwa[1]; John Carr[1]; Rakesh Mahadevapuram[1]; Hari Kodali[1]; Baskar Ganapathysubramanian[1]; *Sumit Chaudhary*[1]; [1]Iowa State University

A key requirement for realizing efficient organic photovoltaic (OPV) cells is the dissociation of photogenerated electron-hole pairs (singlet-excitons) in the donor polymer, and charge-transfer-excitons at the donor-acceptor interface. However, in modern OPVs, these excitons are typically not sufficiently harnessed due to their high binding energy. Here, we show that doping the OPV active-layers with a ferroelectric polymer leads to localized enhancements of electric field, which in turn leads to more efficient dissociation of singlet-excitons and charge-transfer-excitons. Bulk-heterojunction OPVs based on poly(3-hexylthiophene):[6,6]-phenyl-C61-butyric acid methyl ester were fabricated. Upon incorporating a ferroelectric polymer as additive in the active-layer, power conversion efficiencies increased by nearly 50%, and internal quantum efficiencies approached 100% – indicating complete exciton dissociation at certain photon energies. Similar enhancements in bilayer-heterojunctions, and direct influence of ferroelectric-poling on device behavior showed that improved dissociation was due to ferroelectric dipoles rather than any morphological change.

Effect of Annealing and Additives on Defects and Recombination in Polymer Photovoltaic Layers: Yuqing Chen[1]; Rakesh Mahadevapuram[1]; *Sumit Chaudhary*[1]; [1]Iowa State University

Various types of annealing treatments and solvent additives are used in polymer photovoltaics to control nanomorphology and improve device efficiencies. Though their morphological effects are known, it is not clear how they affect the defects and carrier recombination rates/mechanisms. Our experiments reveal some unintuitive results in this regard. Defect densities in the polymer domains are a stronger function of unintentional oxygen dopants rather than the annealing. In fact thermal or solvent annealing enhance oxygen diffusion, which creates even more defects. However, these defects in annealed films do not have much effect on the final device efficiencies and carrier recombination rates. Performance is a stronger function of other structural parameters like domain sizes in the phase separated photovoltaic blends. On a side note, oxygen dopants actually increase the hole concentration, which in turn improves hole mobility and charge transport, and further improves the devices.

Raman Studies of Hybrid Nanostructures for Solar Energy Applications: *Sonal Padalkar*[1]; KunHo Yoon[2]; Lincoln Lauhon[2]; [1]Northwestern University ; [2]Northwestern University

Raman microspectroscopy was employed to study the optical response of Si nanowires decorated with Au nanoparticles prepared by two different methods. In one approach, Au nanoparticles were drop-cast on Si nanowires, while in the second approach Au nanoparticles were grown directly on Si nanowires from solution. Raman spectra and spatial maps were obtained from both types of nanowires for varying nanowire and nanoparticle geometries. A low particle density was maintained to resolve the single nanoparticle responses. Both enhancement and suppression of the Raman scattering was observed depending on the sizes of the nanowire and nanoparticle. Other features of the Raman spectra showed measurable changes including the line shape, peak position and width. Insights into the trends in the Raman enhancement and suppression were gleaned from finite difference time domain modeling. Raman spectra and modeling provide a sensitive measure of the light harvesting properties of metal-semiconductor hybrid nanostructures.

4:10 PM Invited
Developing Titania/Ferroelectric Heterostructures for Solar Photolysis: *Gregory Rohrer*[1]; Paul Salvador[1]; Li Li[1]; Andrew Schultz[1]; Yiling Zhang[1]; [1]Carnegie Mellon University

A series of photochemical reactions have been conducted on thin titania films supported by ferroelectric substrates (BaTiO3 and BiFeO3) with a wide range of orientations. For all of the orientations and both phases of titania, the thinnest films have reactivities equal to or greater than the bulk-like films, suggesting that the charge separating characteristics of the substrate have the potential to increase the reactivity of titania. When titania is supported by the narrower bandgap ferroelectric BiFeO3, photochemical reactions on the titania surface can be stimulated by visible light with an energy smaller than titania's bandgap. Finally, the efficacy of the dipolar field effect is demonstrated by measurements of hydrogen evolution rates from a composite catalyst comprised of BaTiO3 particles coated with mesoporous titania. The rate of hydrogen evolution from the composite catalyst exceeds the rate of hydrogen evolution from the BaTiO3 or the mesoporous titania alone.

4:45 PM
Photocatalytic Activity of Heterostructured Powders: Nanostructured TiO_2 Shells Surrounding Microcrystalline (Ba,Sr, Pb)TiO_3 Cores: *Li Li*[1]; Paul Salvador[1]; Gregory Rohrer[1]; [1]CMU

Heterostructured photocatalysts were prepared to have nanostructured (ns) TiO_2 shells surrounding microcrystalline (mc) (Ba,Sr,Pb)TiO_3 cores. The shells were 50 nm thick and were composed of nanocrystalline, nanoporous, predominantly anatase TiO_2. The mc-(Ba,Sr)TiO_3/ns-TiO_2 core-shell photocatalysts annealed at 600 °C had the highest rates of UV photochemical hydrogen production from water/methanol solutions, rates much greater than those for ns-TiO_2 or mc-(Ba,Sr)TiO_3 alone. The mc-$PbTiO_3$/ns-TiO_2 core-shell photocatalysts displayed more efficient degradation rate for methylene blue than its components alone under visible light. The improved photocatalytic properties are attributed to the isolation of three processes: light absorption and low scattering in the mc-core, charge separation at the core-shell interfaces, and hydrogen production on the nanostructured TiO_2. The annealing temperature, coating thickness and Pt loading amount are discussed, respectively. Such heterostructured powders represent a new strategy for the design of photocatalysts and the use of nanostructured catalytic coatings.

5:05 PM Invited
Deactivation Mechanism and Hole Scavenging in Heterostructured Visible Light Active CO_2 Photoreduction Catalysts: *Christopher Matranga*[1]; Congjun Wang[1]; Robert Thompson[1]; Paul Ohodnicki[1]; [1]US DOE- NETL

The design of heterostructured photocatalysts for converting CO_2 into value-added chemicals is an increasingly active area of research in the scientific literature. While many new techniques are being reported for improving the visible light activity of CO_2 reduction catalysts, the hole left in the photocatalyst after electron transfer continues to lead to deactivation, particularly in heterostructures of semiconductor nanocrystals and metal oxides. The fate of the hole in the valence band of semiconductor nanocrystals forming a series of PbS/TiO_2 and CdSe/TiO_2 photocatalysts has been evaluated with X-ray photoelectron spectroscopy and the resulting oxidation of the nanocrystal sensitizer has been characterized. The use of sacrificial hole scavengers based on amine, alcohol, and other chemistries has been evaluated and shown to extend catalyst lifetimes significantly. The mechanism of photocatalytic deactivation and its prevention with hole scavengers will be discussed. Reaction data will also be presented illustrating extended catalyst lifetimes and product distributions.

5:40 PM
Multicomponent Metal-Carbon Junctions in 1-D Geometry: *Junchi Wu*[1]; Paaras Agrawal[2]; Nitin Chopra[1]; [1]The University of Alabama; [2]Northridge High School

Vertically aligned and axially heterostructured metal nanowires with uniform diameters (~267-279 nm) and micron-scale lengths were fabricated by combining template process with wet-chemical deposition process. Subsequently, carbon nanotubes (CNTs) were selectively grown on the nanowires resulting in metal-carbon junctions. The length of nanowires and CNT could be controlled by varying the growth duration. The heterostructures were characterized by scanning electron microscopy (SEM), X-ray diffraction (XRD), transmission electron microscopy, Raman spectroscopy and microscopy, and cyclic voltammetry (CV) and ac electrochemical impedance spectroscopy (EIS).

3rd International Symposium on High Temperature Metallurgical Processing: Alloy and Materials Preparation

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Energy Committee, TMS: Pyrometallurgy Committee
Program Organizers: Tao Jiang, Central South University; Jiann-Yang Hwang, Michigan Technological University; Patrick Masset, TU Freiberg; Onuralp Yucel, Istanbul Technical University; Rafael Padilla, University of Concepcion; Guifeng Zhou, Wuhan Iron and Steel

Tuesday PM Room: Southern II
March 13, 2012 Location: Dolphin Resort

Session Chairs: Rafael Padilla, University of Concepcion; Jianliang Zhang, University of Science and Technology Beijing

2:00 PM
Future Considerations for Further Processing of Cobalt Alloy at Nchanga Smelter: *Humphrey Chikashi*[1]; Credo Ng'uni[1]; [1]Konkola Copper Mines

A pyrometallurgical route for producing a sellable, higher value and an easier to treat product from cobalt alloy recovered from the flash smelting slag is introduced and explored in this paper. Theoretical analyses as well as results from actual plant trials of the process are presented. Cobalt content upgrade procedure discussed is done at minimum initial investment and operating cost. The method also offers advantages such as reduced size of downstream hydrometallurgical units to recovery cobalt to metallic form. Results of leaching tests conducted on the cobalt rich slag are also presented and discussed.

2:15 PM
Improving Hot Workability of Ledeburitic Tool Steels: Matevz Fazarinc[1]; Goran Kugler[1]; Iztok Perus[1]; *Milan Tercelj*[1]; [1]University of Ljubljana

Ledeburitic tool steels are highly alloyed steels, used for specific applications but are characterized by low hot workability. Selecting the right process parameters for these types of steels for improvement of their intrinsic hot workability is thus necessary. Inappropriate selection results in the occurrence of unusual carbides, in terms of type, shape and their distribution. Beside the secondary carbides also other brittle phases precipitated on grain boundary accelerate cracking at lower and medium temperatures of the working range. The main reason for decreased workability at lower temperatures of the working range is appearance of cracks around the carbides. On the other hand, upper limit of temperature range is predominately related to eutectic carbides and phases with low melting point. The aim of this work was to determine the necessary condition for improvement of the intrinsic hot workability.

2:30 PM
Influence of Elements Segregation on Creep Properties of A Single Crystal Nickel-Based Superalloy: *Chao Zhang*[1]; Sugui Tian[1]; Xingfu Yu[1]; Zheng Zeng[1]; Chen Liu[1]; [1]Shenyang University of Technology

Single crystal nickel-base superalloy is prepared by using the various withdrawing rates. By measuring creep properties and microstructure observation, the influence of the element segregation on creep properties of the superalloys is investigated. Results show that the dendrite spacing and the segregation extent of the elements decrease with the enhancing withdrawing rate. The superalloy with smaller dendrite spacing has lower segregation of the elements and better creep resistance. The dislocations climbing over the rafted γ' phase is thought to be the deformation mechanism of the alloy during steady state creep. In the later stage of creep, the fact that some dislocations shear into the rafted γ' phase may twist the rafted γ' phase. As the creep goes on, the initiation and propagation of the cracks occur up to occurring creep fracture, which is thought to be the fracture mechanism of the superalloy during creep.

2:45 PM
Preparation of High Titanium Ferrous with Low Oxygen Content Prepared by Enhanced Reduction: Zhang Ting'an[1]; *Dou Zhihe*[1]; Niu Liping[1]; Zhang Hanbo[1]; Lv Guozhi[1]; Liu Yan[1]; Li Yan[1]; He Jicheng[1]; [1]Northeastern University

Rutile, ilmenite and Al-Ca complex reducer were used to prepare high titanium ferrous alloy by enhanced reduction. The effects of the complex reducer compositions and lag types on the reduction process were investigated. The alloys were characterized by XRD,SEM and chemical analysis. The results indicate that the alloys consist mainly of $TiFe_2$, $AlTi_3$ and Al_2O_3. The oxide inclusions exist in alloy which results directly in the high oxygen content and micro-structural defects. The titanium and oxygen contents decrease in alloy, but the aluminum content increases while the mass ratio of calcium in the complex reducers increases. When the mass ratio of Al/Ca in the Al-Ca complex reducers varies from 6:1 to 5:1, the titanium, oxygen and aluminum contents vary from 63.75% to 55.00%, from 3.01% to lower than 2.0% and from 10.72% to 14.00% respectively.

3:00 PM
Preparing Aluminum-Scandium Alloys Using Direct Hall Reduction Process: *Chunyang Gruan*[1]; Jilai Xue[1]; [1]Unversity of Science and Technology Beijing

Al-Sc Alloys have showed many advanced properties for a wide range of industrial application, which is usually produced using thermal reduction process. This work is aimed to develop an electrochemical process to make Al-Sc alloy using industrial Hall aluminum reduction cells. The investigations have been carried out in a lab cell where NaF/AlF_3-Al_2O_3-LiF as electrolyte, Sc_2O_3 as raw material, and liquid aluminum as cathode were used at operating temperature of 950□. The resulting Al contained 0.2 – 0.6 wt % Sc that is the common range in its content for advanced applications. However, a small fraction of Sc was found from thermal reduction at Al-melts interface. SEM-EDS and ICP-AES analysis showed a uniformed distribution of Sc at varying locations of the Al-Sc alloy sample.

3:15 PM
Production of Fe-Cr-Ni-Ti Alloys by Metallothermic Processes: *Cem Colakoglu*[1]; Onuralp Yücel[2]; [1]Istanbul Technical University; [2]Istanbul Technical University

This study consist of Fe-Cr-Ni-Ti alloys production by metallothermic reduction of Fe_2O_3-Cr_2O_3-NiO-TiO_2 powder mixtures. Metallothermic reactions were realized by using a stainless steel SHS reactor. Different ratios of Cr/Ni/Ti were carried out in the metallothermic experiments, and addition of excess stoichiometric amount of metallic Al and Al_2O_3 powders were added to the initial mixture to decrease the adiabatic temperature and specific heat of the system. The raw materials, alloys and slags were characterized by using XRD (X-Ray Diffractometry), and Scanning Electron Microscobe (SEM).

3:30 PM Break

3:40 PM
Production of $NbAl_3$ Powders through Sodium Reduction of Oxides in Molten Salts: *Chao Du*[1]; Na Wang[1]; Yao Zhang[1]; Shuqiang Jiao[1]; Hongmin Zhu[1]; [1]University of Science & Technology Beijing

Na_2NbAlO_5 was synthesized using Nb_2O_5 and $NaAlO_2$ as raw materials in molten NaCl-$CaCl_2$ by a solid reaction. With an addition of sodium into the melts, Na_2NbAlO_5 was subsequently reduced to form $NbAl_3$ intermetallic compound with a particle size of 50-300nm.

3:55 PM
Recrystallization of L-605 Cobalt Superalloy during Hot-Working

Process: *Julien Favre*[1]; Yuichiro Koizumi[1]; Akihiko Chiba[1]; Damien Fabregue[2]; Eric Maire[2]; [1]IMR Tohoku University; [2]INSA de Lyon

Co-20Cr-15W-10Ni alloy (L-605) is a cobalt-based superalloy combining high strength with keeping high ductility. The aim of this work is to get maximal grain refinement with a homogeneous microstructure after the hot-working process to obtain optimal in life mechanical resistance. Microstructure was observed after high-temperature deformation to determine optimal deformation conditions for obtaining the targeted microstructure. High-temperature deformation behavior is studied by compression tests at temperatures from 1000°C to 1200°C and a strain rate range of 0.001 s^{-1} to 10 s^{-1}. Microstructure observations revealed the occurrence of dynamic recrystallization for all deformation conditions. For strain rates lower than 0.1 s^{-1} or higher than 1 s^{-1}, dynamic recrystallization lead to a homogeneous microstructure with a grain size about 10 µm. Deformation at temperatures lower than 1100°C and strain rates about 1s^{-1} resulted in a heterogeneous microstructure with grain size lower than 1 µm.

4:10 PM
Research on Inclusions in CuCr Alloy Prepared by Thermit Reduction: *Dou Zhihe*[1]; Zhang Ting'an[1]; Zhang Zhiqi[1]; Niu Liping[1]; Lv Guozhi[1]; Liu Yan[1]; He Jicheng[1]; [1]Northeastern University

CuCr alloy can be extensively used as lead frame of electric contact and high strength conductor. We proposed aluminothermy reduction electroslag remelting to prepare the large scale CuCr alloy. But there are pores and oxide in the CuCr alloy prepared by aluminothermy reduction process. This paper anlysed the inclusions in CuCr alloy.The ratio of reactant, additive, electromagnetic stirring and the temperature of mold were considered. The slags and CuCr alloy are respectively analyzed by XRD and SEM. The results show that when the additive is Na3AlF6, the slag is consist of Al2O3 and Cr. when the additive is CaF2, the slag is consist of Al2O3, Cr, CaF2 and CaAl4O7. The inclusions in CuCr alloy are mainly Al2O3 and pores which disperse in Cu-rich zone and Cu-Cr phase interface. When 5% CaF2 and 5% KClO3 are added , there are less pores and inclusions ,and the microstructure is more better .

4:25 PM
Settling of Inclusions in Top-cut SoG-Si Scraps under Electromagnetic Field: *Lucas Damoah*[1]; Lifeng Zhang[1]; [1]Missouri University of Science and Technology

Increasing demand for Solar Grade Silicon (SoG-Si) due to rising interest in renewable energy has lead to increased SoG-Si top–cut scraps generated from the multi-crystalline silicon making process. In the current study, experiments under high frequency, high voltage, electromagnetic field were performed and the results showed that SiC inclusions settled within a short time to the bottom of the crucible and the characteristic rod-like morphologies of Si3N4 inclusions were not detected.

4:40 PM
Study and Application of the Taphole Clay with High Strength and Friendly Environmental Surroundings in a New Blast Furnace with 3800M3 Volume: *Guotao Xu*[1]; Yue Wang[1]; Yafei Xiong[1]; Huaiyuan Li[1]; Shuzhong Li[1]; [1]Wuhan Iron and Steel Group Company

The composition, properties and structure of taphole clay with high strength and friendly surrounding used in a new blast furnace with 3800 M3 volume was studied. The developed taphole clay had been applied in the blast furnace for four months, pouring times were 11-13 every day, flowing rate of hot iron was 7.5 t/min and the consumption of taphole clay was 0.49Kg per ton iron, which can make the new blast furnace attach the designed production quickly and decrease the cost of hot iron. The taphole clay is easy to be opened in the channel of hot iron which can be remained in stable shape under the corrosion of slag or hot iron, and it dose not produce poisonous smoke in yellow or dark color in the use process. The development of new taphole clay is useful to improve the work surrounding of the blast furnace.

Advances in Surface Engineering: Alloyed and Composite Coatings: Session IV

*Sponsored by:*The Minerals, Metals and Materials Society, TMS Materials Processing and Manufacturing Division, TMS: Surface Engineering Committee
Program Organizers: Sandip Harimkar, Oklahoma State University; Srinivasa Bakshi, Indian Institute of Technology Madras; Arvind Agarwal, Florida International University

Tuesday PM — Room: Macaw 1
March 13, 2012 — Location: Swan Resort

Session Chair: To Be Announced

2:00 PM
The Roles of Diffusion Factors in Electrochemical Corrosion of TiN and CrN (CrSiCN) Coated Mild Steel and Stainless Steel: *Feng Cai*[1]; Qi Yang[2]; Xiao Huang[1]; [1]Carleton University; [2]National Research Council Canada

Noble coating on steel components is an effective solution to preventing corrosion attacks. However, through-coating defects, such as pin holes, voids and growth defects play a detrimental role in the degradation of the coating-substrate system. They allow corrosive media to be in contact with the metal substrate, initializing pitting corrosion and eventually resulting in coating failure. This research studies the correlation between coating defects and corrosion behavior of the TiN and CrN (CrSiCN) coated mild steel and stainless steel. Electrochemical impedance technique is used to reveal the corrosion behavior. The results revealed that in a coating-substrate system, two critical factors controlling the corrosion resistance, the effective diffusion coefficient and diffusion layer thickness, which are found to be related to coating microstructure. Denser and thicker coating structures are expected to have lower effective diffusion coefficients and greater effective diffusion layer thicknesses; and showed high electrochemical impedance and resistance to electrochemical corrosion.

2:20 PM
Effect of Electroplating Parameters on "HER" Current Density in Ni-MoS2 Composite Plating: *Ebru Saraloglu Guler*[1]; Ishak Karakaya[1]; Erkan Konca[2]; [1]Middle East Technical University; [2]Atilim University

Nickel composites with co-deposited insoluble solid lubricant MoS2 particles have been reported to reduce friction. The aim of this study was to analyze the influence of the electroplating parameters and interaction effects on the optimum plating current density by factorial and mixture designs for three types of mineral processing surfactants (sodiumlignosulfonate, depraminC, ammoniumlignosulfonate). The parameters and ranges were; MoS2 (0-30 g/l), temperature (30-50 ºC), pH (2-4) and surfactant (0-1 g/l). Electrodeposition was carried out from a typical Watts bath containing leveler, wetting agent and brightener by using a potentiostat. The peak current densities were extended to higher values and the peaks on linear sweep voltammograms became noticeable by increasing the scan rate from 20 to 100mV/s over the range 0 to 2.5 V. Increasing MoS2, pH decreased whereas temperature increased peak current densities for all three surfactants. Addition of sodiumlignosulfonate and depramin C decreased, but ammoniumlignosulfonate increased the peak currents.

2:40 PM
Production of Ceramic Layers on Aluminum Alloys by Plasma Electrolytic Oxidation in Alkaline Silicate Electrolytes: *Alex Lugovskoy*[1]; Aleksey Kossenko[1]; Barbara Kazanski[1]; Michael Zinigrad[1]; [1]Ariel University Center of Samaria

Plasma electrolytic oxidation (PEO) is a technology allowing obtaining hard wear- and corrosion-resistant in the form of thick and highly-adhesive oxide layer on aluminum surfaces. The process can be performed in several types of electrolyte, of which the alkaline silicate electrolytes were employed in this study. Silicate electrolytes passivate aluminum alloys, favor micro-arc discharges and contain silicate ions, which modify the technological properties of the coating. The influence of the silicate index of sodium silicates and of their concentration in the electrolyte on the composition, structure and properties of the oxide layer was studied. Electrolyte properties, electrochemical process parameters and the properties of the resulting coating were studied and compared. Optimal electrolyte compositions for the obtaining of hard and corrosion resistant ceramic layer were found. A plausible mechanism of the process was proposed.

3:15 PM
Wear Properties of Plasma Sprayed Y-PSZ Coated 6063 Aluminum Alloy: *Eray Erzi*[1]; Selim Yildirim[1]; Suat Yilmaz[1]; [1]Istanbul University

Thermal spray methods and especially plasma spray method have an increasing importance and being widely used by industries. This method depends on the purpose of spraying powder based coating materials to a surface. Light alloys like aluminum alloys have some disadvantages like low mechanical strength and wear resistance Aim of this study is investigating the wear resistance behavior of coated and uncoated T6 heat treated 6063 Aluminum alloys. Coatings were made by plasma spray method and %8 Y-PSZ was used as coating material. Weartests were done by pin-on-disc method with three different load parameters and results were discussed comparatively.

3:35 PM
Slurry Erosion Behavior of Thermally Sprayed Cr_3C_2-NiCr Coatings: *V. N. Shukla*[1]; R. Jayaganthan[1]; B. V. Manoj Kumar[1]; V. K. Tewari[1]; [1]IIT ROORKEE

High velocity oxy fuel (HVOF) technique was employed to deposit Cr_3C_2-NiCr coating of ~250 µm thickness with average bond strength of ~10000 psi and microhardness of ~8.3 GPa on 310 stainless steel substrate in the present work. The microstructure of the coating consisted of uniformly distributed Cr_3C_2-rich ceramic grains attached with NiCr-rich binder phase. The erosion behavior of the coated samples was studied using 10 and 20 wt% alumina particle concentration in water at normal impact angle for 10 hours. Erosion results indicated a severe loss of material using 20 wt% alumina particle concentration. SEM characterization of the worn coated surface has revealed smearing or cutting of soft binder phase followed by ceramic grain removal, while no change in the phase evolution of surface was observed after erosion. Erosion with 20 wt% of alumina particles in slurry increased crack initiation, and resulted in larger pull-outs and fracture of ceramic grains.

3:55 PM
The Electrochemical Behavior of Surgical Grade 316L SS with and without HA Coatings in Simulated Body Fluid: Tejinder Singh[1]; Harjinder Singh[2]; Hazoor Singh[3]; *Harpreet Saheet*[4]; [1]Gulzar Institute of Engineering & Technology, Ludhiana, Punjab, India; [2]Govt Medical College; [3]Yadvindra College of Engineering, Talwandi Sabo, Bathinda, Punjab, India; [4]Indian Institute of Technology Ropar

ASTM recommended surgical grade 316L SS stainless steel is one of the most widely used material in orthopedic implants. It has been reported that stainless steel is often susceptible to pitting corrosion. The main aim of this study is to evaluate the corrosion behavior of uncoated and HA coated 316L SS in simulated body fluid conditions. HA coating was produced using thermal spraying technique. The coatings were characterized by XRD, SEM/EDS and electrochemical techniques. The corrosion resistance of 316L SS was found to improve after the deposition of HA coating.

4:15 PM
Modification Research on the Influence on Corrosion Film Properties of Pb-Ca-Sn Alloys of with Addition of Bi, Ag and Zn: *Lei Xu*[1]; Li Jun Liu[1]; Pei Xian Zhu[1]; [1]Kunming University of Science and Technology

The influences of Bi, Ag and Zn addition on the electrochemical corrosion film properties of Pb-Ca-Sn(Ca=0.08%, Ca=1.2%) alloys were studied in this paper. And the electrochemical properties of corrosion film were investigated respectively by XRD,SEM, Tafel curve test and cyclic voltammetry (CV) test when the Pb-Ca-Sn alloys were in 1.28g/mL H2SO4 solution. The results show that: the effects of different elements on the electrochemical corrosion film properties of Pb-Ca-Sn alloys are different and obvious. More specific, the corrosion film becomes thicker and the grain size is big when Bi is added, and besides the corrosion film contains more PbO; However, the corrosion film becomes thiner and grain size is fine when Ag and Zn are added, and the corrosion film contains more PbO2.

Alumina and Bauxite: Hydrate Precipitation, Calcination and Environment

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee

2:00 PM
Growth and Agglomeration of Boehmite in Sodium Aluminate Solutions: *Wang Zhi*[1]; Zhang Juan[1]; Xu Rongguang[1]; Guo Zhancheng[1]; [1]Institute of Process Engineering

Boehmite precipitation is a new alternative way from sodium aluminate solutions to alumina, however, the too low particle size becomes one bottleneck for this methods replacing the current production route. Growth and agglomeration of crystals are the main factors influencing product size. The results show that the growth rate of boehmite is in a low range from 0.08 to 2.4 µm/h. Thus, agglomeration of boehmite is a major means to enlarge the particle size of precipitation products from sodium aluminate solutions. By means of laser particle size analyzer and powder attrition index analyzer, the agglomeration efficiency was represented by combining agglomeration degree and attrition index. The influences of seed ratio (SR), temperature, the molar ratio of Na2O to Al2O3 (MR) and organic additives on agglomeration were investigated. The alcohol type additives PPG increases precipitation ratio and agglomeration degree, but reduces the strength of products and makes attrition index increase.

2:15 PM
Physical Simulation on Mixing Uniformity in Seed Precipitation Tank: *Liu Yan*[1]; Zhao Hongliang[1]; Zhang Ting'an[1]; Zhao Qiuyue[1]; Wang Shuchan[1]; Gu Songqing[1]; He Jicheng[1]; Zhang Chao[1]; [1]Northeastern University

The suspension and dispersion of Al(OH)3 particles in seed precipitation tank, which may affect the quality and output of alumina besides the deposit on the bottom of the tank, is one of the key steps in Bayer process. In order to solve these problems, the solids concentration profiles of Al(OH)3 particles were investigated by cold water experiments under simulated industrial conditions. The results showed that, the mixing uniformity in the whole tank was improved with the increase of impeller off-bottom clearance when the impeller of small diameter (D/T =0.5~0.6) was used, and it deteriorated when the impeller (D/T =0.65~0.7) was enlarged. The mixing effects can be improved by increasing the impeller diameter and stirring speed, meanwhile the influence of impeller off-bottom clearance was weakened. But the impeller diameter and stirring speed should be controlled in appropriate ranges for the consideration of power consumption and mixing efficiency.

2:30 PM
Kinetics of Boehmite Precipitation from Supersaturated Sodium Aluminates Solutions with Ethanol-Water Solvent: *Wang Zhi*[1]; Xu Rongguang[1]; Liu Yang[1]; Guo Zhancheng[1]; [1]Institute of Process Engineering

Boehmite was prepared from supersaturated sodium aluminates solutions with ethanol-water solvent. The results of thermo-gravimetric analyzer and XRD showed that the product was mixture of boehmite and gibbsite, and the mass ratio of gibbiste and boehmite varied greatly with different process conditions. This work presents the effects of mass ratio of ethanol and temperature on the precipitation rate and phase compositions of alumina hydrate. The ratio of AlOOH in the product increased significantly with the increase of mass ratio of ethanol because the precipitation of gibbsite was restrained. When the solvent was pure ethanol, the ratio of AlOOH in the product reaches the peak of 90%. Ethanol reduces the free caustic concentration and increases initial supersaturation coefficient significantly. The boehmite activation energy of precipitation in ethanol solvent was 13.7 kJ/mol, indicated that ethanol reduces effectively energy barrier of boehmite from sodium aluminate solutions and it was controlled by diffusion process.

2:45 PM
Effect of Crystal Growth Modifier on the Structure of Sodium Aluminate Liquors Analyzed by Raman Spectroscopy: *Jianguo Yin*[1]; Wangxing Li[2]; Zhanwei Liu[2]; Zhaohui Su[2]; Zhonglin Yin[2]; Wentang Xia[1]; [1]Chongqing University of Science and Technology; [2]Zhengzhou Research Institute of Chalco

It has been proved that crystal growth modifier (CGM) can improve particle size distribution (PSD) and intensity of the alumina products. Yet few researches have been focused on whether CGM has an effect on the structure of sodium aluminate liquors. Effect of CGM on the structure of synthesized sodium aluminate liquors was studied. It is shown that there is no new characteristic peak and obvious shift in the Raman spectrum of the liquors after adding a certain CGM. By constructing a comparison function and using calculation function of the software of Raman spectrometer, it is found that CGM might have micro effect on the structure of the liquors by changing the concentration of principal ion Al(OH)4- of the liquors. The results might be helpful for R&D and application of CGM.

3:00 PM
Precipitation Area Upgrade at ETI Aluminum: *Murat Kayaci*[1]; Bekir Çelikel[1]; Gokhan Kursat Demir[1]; Meral Baygül[1]; Carlos Suarez[2]; [1]Eti Aluminyum; [2]Hatch

ETI Aluminum is an integrated facility that produces sandy alumina by processing boehmitic bauxite. With the development of aluminum smelting technology and greater attention given to environmental protection, the quality requirements of alumina are much strict. ETI has initiated a study to meet smelter grade alumina specifications of its internal electrolysis customer. The old precipitation circuit at ETI alumina refinery was converted to sandy alumina. The change involved modifications to existing tanks and flows to obtain proper hydrate agglomeration. The challenge has been to improve and control particle size distribution without losing precipitation yield and product quality. ETI has been able to reduce its minus 44 micron particles from approximately 40 % to 6-8 % by means of controlling the precipitation circuit parameters such as, alumina supersaturation, seed charge, temperature and classification. Improvements in hydrate occluded soda and attrition index were obtained.

3:15 PM
Flash -and CFB Calciners, History and Difficulties of Development of Two Calcination Systems: Hans-Werner Schmidt[1]; *Fred Williams*[2]; [1]Outotec GmbH; [2]CMIS Corporation

In the last 40 years, stationary calciners have permanently replaced rotary kilns in existing alumina refineries and are being installed in all new Greenfield alumina refineries. In the 1960's two separate and different approaches to stationary alumina calciners were going through research and development. Alcoa developed a fluid flash system and VAW, together with Lurgi (today Outotec) the Circulating Fluid Bed (CFB) calciner. Both developments had the same targets, but took different approaches to create more efficient calcination systems. Without any joint effort, the industrial stages of both developments were introduced to the industry at the same time. This paper describes the significant steps of the development that both calcination systems went through to reach an industrial stage and the risks and failures that both took. Furthermore the differences and common goals of both approaches are analyzed and described in this paper.

3:30 PM
A Specific Critical Analysis on the Life Time of Alumina Calciners Refractories: *Bruno Teider*[1]; Bruce Graham[2]; Jorge Gallo[1]; Victor Pandolfelli[3]; [1]Research, Development and Innovation - Alcoa LA&C; [2]Alcoa World Alumina, Point Comfort Refinery, USA; [3]Materials Microstructural Engineering Group - Federal University of São Carlos - Brazil

In the international literature it is possible to find references of optimized refractory materials for lining circulating fluidized bed alumina calciners. However, unexpected failures of these refractories are still relatively common, impacting in many ways the results of alumina refineries. Due to the importance of this subject, this work addresses the performance analysis of a refractory material which faced harsh operational conditions and resulted in a short life. "*Post-mortem*" techniques, "*in situ*" observation and properties evaluation were used to study the materials' behavior. Based on the obtained results, a discussion related to the better performance potential of distinct refractories is presented, highlighting that based on the variety of different features these materials have, significant improvements of calciner refractory life can still be attained.

3:45 PM
The Key Technologies of Energy Efficient Al (OH) 3 Dilute Phase Fluidized Roasting Furnaces: Li Zhaoxia[1]; *Huang He*[2]; Xue Xin[3]; Li Xiuju[1]; Wang Huan[1]; Huang Xingyuan[3]; [1]Luoyang Luohua Power Engineering and Special Refractory Materials Co., Ltd., Henan, China; [2]Luoyang Luohua Ceramic Co., Ltd., Henan, China; [3]Henan University of Science and Technology, Henan, China

Research work on new types of castable refractory, pre-casted assembly parts and thermal insulation materials, with resistance to high wear, thermal shock and erosion and low thermal conductivity, were done to solve problems of high system energy consumption, cracking and spalling of partial lining and mismatch of furnace top material and hanging material and so on, caused by unreasonable design of domestic Al(OH)3 Dilute Phase Fluidized Roasting furnace lining. A full set of techniques including construction, furnace drying, lining maintenance and corresponding standards were developed. Using the ideas of furnace integration and new theory of furnace lining, we have solved the key technologies of high-efficient and energy-saving for furnaces. The achievements have been applied to domestic Al(OH)3 Dilute Phase Fluidized Roasting furnaces to reduced energy consumption by one thousand MJ per ton of alumina, thus making a furnace lining with higher production, lower energy consumption and less exhaust gas emission.

4:00 PM
Fabric Filter Operating Results with 10 m Long Bags and Low Purging Pressures: *Carl-Vilhelm Rasmussen*[1]; [1]FLSmidth

Environmental performance of the Gas Suspension Calciners for Alumina installed at QAL and Yarwun in Queensland, Australia, is secured by fabric filters. Gas Suspension Calciners equipped with Fabric Filters represents today's State of the Art of stationary calciners for Alumina. This paper describe the development of the fabric filter technology relevant for this application including selection of filtration medium from an environmental, health and safety aspect as well as cost efficiency point of view. A three year R & D project has confirmed that 10 m long bags can be used for general filter performance within the standard design rules of FLSmidth Airtech. FLSmidth Airtech has been offering filters with 10 m long bags to customers worldwide in Alumina and Cement market segment since quite some time. Four fabric filter orders or ESP conversions have been received so far with 10 m long bags.

4:15 PM
Optimization of Preparation for a-Alumina by Calcination from Aluminum Hydroxide Using Response Surface Methodology: *Bin Zhang*[1]; Jinhui Peng[1]; Libo Zhang[1]; Shaohua Ju[1]; [1]Kunming University of Science and Technology

The conditions of technique to prepare a-Al2O3 by calcination from aluminum hydroxide were optimized using response surface methodology (RSM) with a central composite design (CCD). A quadratic equation model for field was built and effects of main factors and their corresponding relationships were obtained. The statistical analysis of the results showed that in the range studied the field of a-Al2O3 was significantly affected by the calcination temperature and calcination time. According to results from analysis of variance (ANOVA), the value of the determination coefficient (R2=0.9890) indicates that the model was a good fit that 98.90% of the variation could be explained well by the model. The value of the adjusted determination coefficient (adj.R2=0.9811) was also very high to advocate for a high significance of the model. The optimized calcination conditions were as follows: the calcination temperature 1206.81□ and the calcination time 2.06 h respectively. Under these conditions the field of a-Al2O3 was 95.93%. In addition, the sample was characterized by X-ray Diffraction (XRD).

4:30 PM
Customer Impacts of Na2O and CaO in SGA: *Stephen Lindsay*[1]; [1]Alcoa, Inc.

Two major impurities in SGA directly impact the bath chemistry of smelting customers. Aluminium fluoride is consumed in bulk to neutralize the impact of calcium and sodium that enter the process. Excess consumption solely for the neutralization of excess CaO and Na2O generates excess bath. The resulting cyrolitic material can only be consumed by the primary aluminium industry. In this paper the author discusses points of concern from the perspective of customers with regard to CaO, Na2O, and the ratio of between CaO and Na2O. Conclusions include the impact that the growth of excess cryolitic bath will have upon producers of SGA.

4:45 PM
Options for Joint Ventures: *Anthony Kjar*[1]; [1]Gibson Crest Pty Ltd

There has been a wide range of joint ventures within resource industries. The author has had direct expereince in a number and a keen observer of others. This paper builds on a previous paper that examined the rationale for, history and observations as to the success of longer term joint ventures within the aluminium industry. In this paper options for the structure of joint ventures are discussed.

Fabrication of Porous Aluminum with Directional Pore Aligned in One Direction: *Takuya Ide*[1]; Yutaro iio[1]; Hideo Nakajima[1]; [1]Osaka University

Directional pores aligned in one direction provide not only lightweight but also no stress concentration around pores. Therefore porous aluminum with directional pore aligned in one direction (lotus-type porous aluminum) is expected for structural material with lightweight. Lotus metals can be fabricated by pore formation of insoluble gas, when the melt dissolving gas is solidified. However, it is difficult to fabricate lotus aluminum with high porosity because of its low hydrogen solubility. In the present study, fabrication of lotus aluminum was systematically investigated by controlling solidification condition. The effect of solidification conditions on pore formation of lotus aluminum was clarified. Lotus aluminum with higher porosity more than 30% was fabricated at slow solidification velocity. When the solidification velocity becomes slow, insoluble hydrogen rejected into melt near the liquid/solid interface can diffuse into formed pores for longer time in order to promote the growth of the directional pores.

2:25 PM
A New Counter Gravity Sand Process Used for Aluminum Alloy Casting: *Jianmin Zeng*[1]; [1]Guangxi University

In order to increase solidification rate of large aluminum casting poured in sand mould, an innovative counter-gravity casting process is invented. The process is based on Bernoulli's principle. The mold and crucible are placed separately in the upper and lower chambers, with the feed tube connected between them. High-speed jet flow of air makes negative pressure in the upper chamber. In this way, pressure differential is created between the two chambers. Thereby the molten metal in the crucible is forced to flow upward smoothly to fill the mold cavity. after that, cold air is introduced into sand mold through aisles that are set within the mold, which results in strong convective heat exchange at the casting/mold interface. So solidification rate of casting is increased dramatically. The microstructures and mechanical properties were investigated and the results indicate great advantage over traditional sand processes.

The In-Situ Technique for Preparing Al-TiB2 and Al-Al3Ti Composites with ESR: *Jun Wang*[1]; Pan Li[1]; Chong Chen[1]; Jin Xue[1]; [1]Shanghai Jiaotong University

A novel technique for preparing in situ Al-TiB2 and Al-Al3Ti composites by electroslag remelting(ESR)process has been developed in this paper. The microstructure and phases of the composites were investigated by SEM and XRD.The aim of present work was to verify the feasibility of in-situ synthesis of Al-TiB2 and Al-Al3Ti composites by ESR process which had unique advantages in promoting fluoride salt-metal reaction efficiency. The reactant concentration and reactant contact area was improved greatly by ESR process and leaded to a totally complete reaction. The experiment results demonstrate that TiB2 and Al3Ti particulates are uniformly distributed in the aluminum matrix and the mean particle size becomes much smaller compared with the conventional casting method. The successful fabrication of in situ Al-TiB2 and Al-Al3Ti composites by ESR technique is expected to be significant promotion of the development of in-situ technique for fabricating MMCs.

3:40 PM
Grain Refinement of Al Alloys by Heterogeneous Nucleation of Consumable Ultrasound Horn: *Jeong-Il Youn*[1]; Young-Ki Lee[1]; Bong-Jae Choi[1]; Young-Jig Kim[1]; [1]Sungkyunkwan University

The final quality of castings is broadly dependent upon many factors which will have an effect on the solidification of the metal. Castings with large grains have poor mechanical properties compared to castings with fine equiaxed grain structure. Currently grain refinement in casting alloys is mainly accomplished by the special composition's master alloy as a chemical reagent. However, it has been shown that high intensity ultrasound can change the microstructure, refine the grain size, and improve the uniformity of minor phases and the casting's homogeneity. The main objective of this research is to study the mechanism of the effect on the grain refinement of ultrasound injection before solidification of the A356 and A390 aluminum alloys. Experiments were focused on the effects of uniform dispersion of heterogeneous nuclei in liquid metal on microstructure.

4:00 PM
The Development and Validation of a New Thermodynamic Database for Aluminium Alloys: A Markström[1]; Y Du[2]; S. H. Liu[2]; L. J. Zhang[2]; L Kjellqvist[1]; J Bratberg[1]; *Paul Mason*[3]; A Engström[1]; Q Chen[1]; [1]Thermo-Calc Software AB; [2]Central South University; [3]Thermo-Calc Software Inc.

Thermodynamic databases developed using the CALPHAD method have been successfully applied to the modeling and simulation of Al based alloys for more than fifteen years. Such databases when combined with suitable software can be used for accelerating alloy design and improving understanding and processing of existing alloys. A new thermodynamic database has been developed for Al-base alloys based on the critical evaluation of all the constituent binary systems across their full range of composition and 59 ternaries, 15 quaternaries and 1 quinary. A hybrid approach of combining experiments, first-principles calculations and CALPHAD modeling was employed to obtain thermodynamic descriptions of the constituent binary and ternary systems over wide composition and temperature ranges. This database contains all the important Al-based alloy phases within a 26-element framework [Al-Cu-Fe-Mg-Mn-Ni-Si-Zn-B-C-Cr-Ge-Sn-Sr-Ti-V-Zr-Ag-Ca-H-Hf-K-La-Li-Na-Sc] and in total 345 solution and intermetallic phases are included. This presentation will describe development, validation and application of the database.

4:20 PM
Effect of Solid Particles on Fluidity of Semi-Solid Aluminum Alloy Slurry: *Yuichiro Murakami*[1]; Kenji Miwa[2]; Masayuki Kito[3]; Takashi Honda[3]; Keigo Yorioka[3]; Naoyuki Kanetake[4]; Shuji Tada[1]; [1]Advanced Industrial Science and Technology; [2]Aichi Science and Technology Foundation; [3]Aisan Industry Co., Ltd.; [4]Nagoya University

The semisolid process is viewed as an attractive and promising manufacturing method for producing near net-shape metal products with reduced porosity and shrinkage. In this study, the fluidity of the Al-Si-Mg alloy slurry was evaluated by injecting into a spiral metallic mold. The solid particles in specimens were analyzed by the image analyzer, and became small and spherical with increasing in shear rate. The fluidity was increased with increasing in shear rate, and also with decreasing in the size of particles and becoming spherical particles. The fluidity is strongly affected by the roundness than the size of particles.

2:00 PM
Precipitation Processes in Aged Al-4.0Mg-1.5Cu-(Ge,Si) Alloys: *Junhai Xia*[1]; Zhiguo Chen[2]; Gang Sha[1]; Simon Ringer[1]; [1]The University of Sydney; [2]Central South University

Microstructure evolutions of Al-4.0Mg-1.5Cu-0.25Ge(Si) (wt.%) alloys have been studied during artificial ageing at 200 °C. Transmission electron microscopy and atom probe field ion microscopy were used to clarify the precipitation processes in those alloys following ageing for 0.1, 1, 10, 25, 120, 336 and 1440 hours. The yield strength increases gradually with the ageing time after a first initial jump, and for both alloys at peak hardness ageing for 25 hours, there are four characteristic features: GPB zones (2-4 nm in diameter), fine S phases (~10 nm in diameter, needle-like) and coarse S phases (~50 nm in diameter, rod-like) in the matrix; and S-phase precipitates (50-100 nm in size) on the grain boundary (GB). Ge elements mainly exist in S phases on GB, while Si addition results in GPB zones and S phases homogeneously dispersed in the matrix with higher aspect ratio (height/diameter) up to a maximal of 30.

2:20 PM
The Role of Co-Clusters in the Artificial Aging of AA6061 and AA6060: *Stefan Pogatscher*[1]; Helmut Antrekowitsch[1]; Thomas Ebner[2]; Peter Uggowitzer[3]; [1]Montanuniversitaet Leoben; [2]AMAG Rolling GmbH; [3]ETH Zurich

In this study the role of Mg,Si-co-clusters formed during long-term natural aging on the artificial aging behavior was investigated by hardness measurements for the alloys AA6061 and AA6060. It was found that kinetics and age hardening response of artificial aging at common temperatures (e.g. 170 °C) are lowered by a strong presence of co-clusters, but enhanced at high temperatures (e.g. 250 °C) for AA6061. Co-cluster formation in the alloy AA6060 increases the age hardening response at 170 °C, but barely influences kinetics in both temperature regions. The co-cluster dissolution was analyzed by a model based on temperature dependent reversion of the hardness, which showed similar activation energies for both alloys. It is supposed that the different behavior of the alloys AA6061 and AA6060 can be explained by solute-vacancy interactions.

2:40 PM
Co-Clusters in Al Alloys: Alloy Strengtening and Thermodynamics: *Marco Starink*[1]; [1]University of Southampton

Detailed atom probe studies performed in the last 10 years on heat treatable aluminium alloys such as the Al-Cu-Mg type have revealed that rapid hardening and room temperature hardening is predominantly due to the formation of co-clusters. In this presentation a theory for the thermodynamics of these co-clusters in metallic alloys is presented. The model incorporates the basic dimer (2 atom) form of co-clusters as well as larger clusters. A model for the strengthening due to co-clusters is also derived. The model encompasses modulus hardening, chemical hardening and (short-) order strengthening. It is shown that in general (short-) order strengthening will be the main strengthening mechanism. The model formulation is tested against an extensive published and new data on the Al-Cu-Mg system and the Al-Zn-Mg system. It is shown that room temperature ageing and rapid ageing at temperature up to about 200°C is due to co-cluster formation.

3:00 PM
The Effects of Aging Treatment and Environment on the Stress Corrosion Cracking Susceptibility of AA6005A Extrusions: *Dan Seguin*[1]; Calvin White[1]; Richard Dickson[2]; [1]Michigan Technological University; [2]Hydro Aluminum

Stress corrosion cracking (SCC) susceptibility of AA6005A extrusions (0.17% Cu) was found to depend on stress level heat treatment, and pH. Sustained load tests were conducted in an aqueous solutions containing 3.5% NaCl and HCl with pH ranging from 2.00 to 7.00. Stress corrosion cracking was observed in peak aged (T6) specimens within 42 hours when the applied load exceeded the yield strength and the solution pH was 2.00. The severity of SCC decreased when the pH was increased. Specimens tested in a naturally aged (T4) condition were susceptible to SCC at low pH.

3:20 PM
Nature of Grain Boundary Precipitates and Stress Corrosion Cracking in Al-7075: *Ramasis Goswami*[1]; Ronald Holtz[2]; [1]SAIC/Naval Research Laboratory; [2]Naval Research Laboratory

It has been observed that stress corrosion cracking (SCC) in Al-7075 is controlled by grain boundary precipitates. The evolution of grain boundary precipitates with aging is not well understood. In particular, the role of Cu in modifying the nature of grain boundary precipitates with aging is unclear. We report here a detailed study of the role of Cu in the evolution of the Mg-Zn-Cu phase at low and high-angle grain boundaries with aging. Transmission electron microscopy (TEM) and fine probe energy dispersive spectroscopy (EDS) were employed to characterize microstructure and composition. In naturally aged alloy, for example, the grain boundaries were observed to be decorated with very fine eta phase, MgZn2, which is anodic with respect to the matrix, and it becomes susceptible to intergranular corrosion. The details of the microstructure in under aged to over aged condition will be presented, and correlated with the SCC behavior of this alloy.

3:40 PM
Precipitation of the γ' ($AlAg_2$) Phase on Dislocation Loops in Al-Ag(-Cu) Alloys: *Julian Rosalie*[1]; Laure Bourgeois[2]; Barrington Muddle[2]; [1]National Institute for Materials Science; [2]Monash University

Aluminium-copper-silver has been widely regarded as a "double-binary" precipitation hardening alloy system, in which the γ' ($AlAg_2$) and θ' ($AlCu_2$) precipitates nucleate and grow essentially independently. However a more thorough investigation has shown that the precipitation morphology and growth of both phases is actually strongly dependent on the composition. The present study focuses on precipitation of the γ' phase in silver-rich Al-Ag-Cu alloys in which the precipitate nucleates on dislocation loops. Copper plays an important role in this process, as even minor Cu additions alter the nature of the dislocation loops and the precipitation behaviour. The γ' phase was found to form readily on stacking faults associated with the dislocation loops; however, its growth was restricted where the bounding dislocation of the loop was sessile. This study highlights how heterogeneous defects can control not only precipitate nucleation but also growth.

On Elastic Compressive Stress Aging of an AA7075 Aluminum Alloy: *Jingwu Zhang*[1]; Wei Guo[1]; Hui Li[1]; Men Yang[1]; Tiankai Yao[1]; Xiyu Wen[2]; [1]Yanshan University; [2]University of Kentucky

Elastic compressive stress aging of an AA7075 aluminum alloy is carried out in aging furnace. The mechanical properties and microstructure after elastic compressive stress aging for the alloy were measured and was observed by using transmission electron microscopy (TEM), respectively. Effect of the elastic compressive stress on the precipitates on the grain boundaries was analyzed and discussed.

4:35 PM
Influence of Mn in Solid Solution in Softening of AA3003 Alloy During Annealing: *Dionisios Spathis*[1]; John Tsiros[2]; [1]Hellenic Aluminium industry (ELVAL SA); [2]Hellenic Aluminium Industry (ELVAL SA)

The present paper shows the change in the softening curve of 3003 alloy at final product gauge caused by the variation of Mn in solid solution just prior to the final anneal. The variation was purposely altered using different ingot preheat practices and/or different hot rolling practices. The tight control of Mn in solid solution is necessary to achieve stable mechanical properties in back annealed tempers (-H2X) of 3003 alloy.

4:55 PM
The Influence of Solution-Treatment on the High-Temperature Strength of Al-Si Foundry Alloys with Ni: *Florian Stadler*[1]; Helmut Antrekowitsch[1]; Werner Fragner[2]; Helmut Kaufmann[3]; Peter J. Uggowitzer[4]; [1]University of Leoben; [2]AMAG Casting GmbH; [3]Austria Metall GmbH (AMAG); [4]ETH Zurich

Al-Si-Ni alloys can be considered as a coarse two-phase system where a hardening effect is caused by load transfer to an interconnected rigid network of eutectic Si and aluminides. In the course of a solution treatment the contiguity of the eutectic phase is reduced, which leads to a decrease of strength. However, solution treatment is necessary to obtain a high supersaturation of elements in the Al-solid solution, which contribute to high-temperature strength due to precipitation hardening. Despite Ostwald ripening, the distribution of secondary precipitates is still dense enough to act as dislocation obstacles, as was confirmed by TEM-analysis. This work discusses the influence of heat treatments on the elevated-temperature strength of Al-Si foundry alloys with Ni and analyzes the active strengthening mechanisms. In order to investigate the effect of a solution treatment on the high-temperature strength of Ni-containing Al-Si foundry alloys, the tensile properties of various eutectic alloys were determined at 250°C after long-time exposure to test temperature.

5:15 PM
The Effect of Artificial Aging Treatment on Microstructure and Tensile Properties of Al-12.7Si-0.7Mg Alloy: *Fang Liu*[1]; Fuxiao Yu[1]; Dazhi Zhao[1]; Liang Zuo[1]; [1]Northeastern University

The microstructure and tensile properties of the extruded Al-12.7Si-0.7Mg alloy aged at 160°C, 180°C and 200°C were investigated. The precipitates in different aging conditions have been characterized by regular and high resolution transmission electron microscopy (TEM and HREM) aiming at understanding the strengthening mechanisms. It was shown that the alloy after T6 treatment exhibits good ductility and much higher proof strength as well as tensile strength compared to 6063 alloy in general. The results have revealed that the strength changes by altering the precipitates size and volume fraction. The strengthening was attributed to be the combining effect of particle, grain boundary and precipitation strengthening.

Latest Results from PFC Investigation in China: *Xiping Chen*[1]; Wangxing Li[1]; Jianhong Yang[1]; [1]Zhengzhou Research Institute of Chalco

In the first half year of 2011, PFC investigation has been conducted on five potlines whose line currents are at the range of 200~350kA. The total aluminum output is 1.35 million tons per year. Both PFC caused by anode effects and PFC unrelated to anode effects were monitored and calculated. C3F8 was observed during anode effects for the first time and its peaks were at the same location as C2F6 and CF4 at the timetable. The weigh ratio of C3F8/CF4 was 2.66%, and that of C2F6/CF4 was 10.67%. C3F8 was observed only in the monitoring of two potlines and no C3F8 in the other three potlines. Concentration curves of C3F8 were plotted with C2F6. Percentage of continuous PFC from five potlines was calculated. The highest was 92.8%. But the potline has the lowest anode effect frequency (AEF) and its AEF is 0.01 AEs/cell-day.

2:20 PM
Studies of Perfluorocarbon Formation on Anodes in Cryolite Melts: *Ole Kjos*[1]; Thor Anders Aarhaug[1]; Egil Skybakmoen[1]; Asbjorn Solheim[1]; [1]SINTEF

The aluminium industry is today the primary source of perfluorocarbon (PFC) to the atmosphere. These gases have a lifespan of several thousand years, and a greenhouse warming potential (GWP) 6500-10000 times that of CO_2. It is therefore of essential to understand, and reduce, the PFC emissions. Controlled potential electrolysis with gas analysis was utilised to study the PFC production in a laboratory cell during regular electrolysis conditions, and during anode effects. A 3-electrode setup with an Al reference electrode was utilised to monitor the anodic voltage. The combination of Mass Spectrometry (MS) and Fourier Transformed Infrared Spectroscopy (FTIR) was used to characterize the off gas. Traces of CF_4 were found in the anode gases at anodic voltages as low as 2.9 V VS the Al reference electrode, confirming that the PFC production can occur unrelated to the anode effect. However C_2F_6 was only detected during anode effects.

2:40 PM
Characteristics of *In Situ* Alumina PID Ore Feed Control: *Michael Schneller*[1]; [1]Consultant

Point feeders have volumetric chambers that periodically deliver ore to cells through holes pneumatically broken into the crust layer. The period of feeder actuations is controlled by the logic employed to regulate bath alumina concentration. The time evolution of bath alumina is mostly a function of the rates of alumina consumption and feeder mass charge, but is also influenced by other events such as crust seal breaks/leakages and plugged or semi-plugged feeder holes. PID modulated *In Situ* feed logic addresses variable non-feeder ore related events to control alumina concentrations at targeted levels. Frequent underfeed and overfeed episodes are avoided. The In Situ<I/> ore feed concept has been successfully tested in the Dyna/Marc cell simulator at a targeted 2.30 % alumina concentration demonstrating both increased current efficiency (CE) and decreased kWh/kg compared to presently employed methodologies. Anode/cathode distances (ACD) can also be accurately measured using In Situ<I/> alumina predictions.

3:00 PM
Towards On-Line Monitoring of Alumina Properties at a Pot Level: *Jayson Tessier*[1]; Gary Tarcy[1]; Eliezer Batista[1]; Xiangwen Wang[1]; [1]Alcoa

Aluminum reduction cells typically use about 1.9 kg of alumina in order to produce 1 kg of aluminum. Hence, for modern reduction cells operating in the 350 to 400 kA range, 5000 to 6000 kg of alumina is fed to reduction cells on a daily. However, no information is available in an on-line fashion about the alumina properties fed to the pot. Alumina feeding control systems assume that alumina properties are constant for all pots within a potroom and also over time. Therefore, these control systems aim at controlling alumina concentration dissolved in the bath without accounting for the time varying effects of alumina properties and/or pot condition on alumina dissolution. Based on sampling campaigns, this paper presents evidences of time varying alumina properties impacting its dissolution rate and also proposes a novel approach in order to measure on-line, at the pot, parameters that are related to alumina dissolution.

Controlling the Variability of Pots KPVs : The Variability Matrix: *Pierre Baillot*[1]; Jean-Paul Aussel[1]; Armand de Vasselot[2]; [1]I.P.I.; [2]Optimprocess

Over the course of 30 years the Process Control softwares have narrowed the variations of individual reduction cells. The volume of data available for day-to-day management of the potlines have increased considerably while the number of technical personnel per pot and per potline have been considerably reduced. Combining the tools and principles of Continuous Improvement with in-depth knowledge of Reduction Process Control systems allows for a new generation of Potline Process Optimization techniques. These techniques, powered by new generation data integration software, can breathe a new life in the Energy and Environment Performance of all smelters. They can show their owners a new trend for improvement and demonstrate strong care to the local communities without mobilizing expensive capital resources and additional people. How much can we expect? What does it require in terms of Human and System capabilities? Where do we start and how far can we improve?

4:00 PM
Multivariate Statistical Investigation of Carbon Consumption for HSS Reduction Cell: *Peter Polyakov*[1]; Tatyana Piskazhova[1]; Nikita Sharypov[1]; Alexandr Krasovitskiy[2]; Sergey Sorokin[2]; [1]Siberian Federal University; [2]RUSAL Nadvoitsy aluminium smelter

In the aluminium reduction technology there is no full awareness concerning the dependence of technical and economical data (TED) including carbon consumption on the changes of raw materials properties and technology parameters. Availability of this information could improve the effectiveness of the reduction technology control. In the paper the multivariate statistical treatment of anode paste consumption depending on the electrolysis parameters is applied. Using principal component analysis the parameters which greatly influence on the anode paste consumption are determined. Statistical models for paste consumption for single pot room and for comparison of the results between rooms are received.Carbon paste consumptions if the parameters changed by three Standard deviations are calculated.

Experiences with Alstom's New Alfeed System at Emal: *Sivert Ose*[1]; Bjørn Leikvang[1]; Sunny John Mathew[2]; Geir Wedde[1]; Anders Sorhuus[1]; Odd Edgar Bjarnø[1]; [1]Alstom Norway; [2]Emirates Aluminium

Alstom's new pot feeding system (Alfeed) was successfully installed and commissioned on Emal's 756 pots during 2009-2010. The Alfeed system consists of 15 km distribution and pot airslides, manufactured in standard sections for maximum ease of installation and use. Alfeed on Emal is connected to 8 enriched alumina silos, each feeding two sections with 48 pots. Each section is 300 m long. The nominal flow rate to each pot is >200kg/h, and to each section >10ton/h. The main issue encountered during start-up was dusting from the pot's alumina hopper lids. Small puffs of dusty air would leak through a narrow opening, eventually leading to build-ups of alumina on the superstructure. This was resolved through implementation of a clamp to the lid as well as a gasket. As with all new systems, some challenges were encountered and optimisations needed. These are discussed in detail in the paper.

4:40 PM
Computer Algorithm to Predict Anode Effect Events: *Fernando Costa*[1]; Leonardo Paulino[1]; [1]Alcoa/Alumar

At Alumar the pot voltage is used to detect anode effects every 1 second. Our attempt is to use this fast scan data to distinguish the normal and the pre-anode effect voltage period. An algorithm has been created to detect this behavior, based on the speed of the voltage increase.With simulation we observed that 60-70% of the anode effects are predicted by the new algorithm. The other 40-30% are ignored in order to reduce false detections. Only 2-10% of the predictions are false. The average voltage of prediction is 5.19 where the normal computer detection is 8.The predictor was tested for a month in 102 pots indicating that we can predict the events from 7 to 20 seconds prior to its occurrence. These tests resulted in a reduction of 30% time above 8 volts and 20% reduction in AE/potday.

Effect of Current Density and Phosphorus Impurities on the Current Efficiency for Aluminum Deposition in Cryolite-Alumina Melts in a Laboratory Cell: *Gudrun Saevarsdottir*[1]; Geir Haarberg[2]; Rauan Meirbekove[1]; [1]Reykjavik University; [2]Norwegian University of Science and Technology

The current efficiency in industrial Hall-Heroult cells for aluminium production may be up to 96%. The back reaction between dissolved metals, such as aluminium and sodium and the anode product play the major part in the loss in current efficiency. Also impurities, such as phosphorous which participates in cyclic red/ox reactions at the electrodes contribute significantly to reduced current efficiency. Phosphorous and other impurities are recycled with secondary alumina. Further potline amperage increase in industrial cells may require higher current densities. Thus the current efficiencies dependence on current density and phosphorous and iron content was studied at current density ranging from 0.85-1.5 A/cm2 in a laboratory cell. Current efficiencies from 90 - 97 % were obtained and increased slightly by increasing cathodic current density. The current efficiency decreased by about 0.8 % per 100 ppm of phosphorus in the electrolyte.

2:20 PM
A Thermodynamic Approach to the Corrosion of the Cathode Refractory Lining in Aluminium Electrolysis Cell: Modelling of the Al_2O_3-Na_2O-SiO_2-AlF_3-NaF-SiF_4 System: *Guillaume Lambotte*[1]; Patrice Chartrand[1]; [1]CRCT, Ecole Polytechnique de Montréal

The corrosion of the cathode refractory lining in electrolysis cells, partly due to the cryolite bath, can shorten the lifespan of the cell. This corrosion is usually studied with laboratory tests and post-mortem analyses of shutdown cells, but the results might not correspond to the reactions taking place in service. The simplified corrosion problem (Al_2O_3-SiO_2 represents the aluminosilicate refractory, NaF-AlF_3 the cryolite bath) corresponds to the reciprocal system Al_2O_3-Na_2O-SiO_2-AlF_3-NaF-SiF_4. The thermodynamic modelling of this system permits the calculation of complex chemical equilibria occurring at the service temperature. The reciprocal system has been assessed using the Modified Quasichemical Model in the Quadruplet Approximation, which considers both first-nearest- and second-nearest-neighbour short-range order and allows the modelling of the strongly ordered oxyfluoride liquid solution. A unique set of model parameters is used to reproduce the experimental data. The results of the thermodynamic modelling of the Al_2O_3-Na_2O-SiO_2-AlF_3-NaF-SiF_4 system are presented here.

2:40 PM
Influence of the Sulphur Content in the Anode Carbon in Aluminium Electrolysis - a Laboratory Study: *Stanislaw Pietrzyk*[1]; Jomar Thonstad[2]; [1]AGH University of Science and Technology; [2] Norwegian University of Science and Technology

The chemistry of sulphur in carbon anodes is not fully understood, especially its influence on the electrolysis parameters. The results of this study are indicative of an important link between the sulphur content in the anode material and the carbon consumption as well as the current efficiency during aluminium electrolysis. By performing a laboratory scale investigation of different carbon anodes with sulphur contents ranging from 1.97 to 3.82 wt% S in addition to graphite anodes with sulphur content close to zero, it was found that increasing sulphur content contributes significantly to a decrease in the current efficiency and a rise in the carbon consumption. When going from 0 to 3.82 wt% S, the current efficiency decreased from 92 to 85% (1.8 % per 1 wt% S), and the carbon consumption rose from 108 to 128% (5.2 % per 1 wt% S).

3:00 PM
Concentration Gradients of Individual Anion Species in the Cathode Boundary Layer of Aluminium Reduction Cells: *Asbjorn Solheim*[1]; [1]SINTEF

It is well known that the system NaF-AlF_3, which constitutes the "backbone" of the electrolyte used in primary aluminium manufacture, forms Na^+, F^-, and a number of fluoro-aluminate anion complexes in the molten state. Since mainly the Na^+ ion carries electric current, the aluminium-containing complexes must diffuse towards the cathode, resulting in concentration gradients within the cathode boundary layer. Starting from a structural model for the melt containing five anion species, it was possible to calculate the concentration gradients of the individual ions using the Stefan-Maxwell equation for diffusion in a multi-component system. Generally, AlF_4^- and $Al_2F_7^-$ were transported towards the cathode, while F^- and AlF_6^{3-} moved away from the cathode. For NaF/AlF_3 molar ratios higher than 2.0, AlF_5^{2-} moved towards the cathode, while it diffused away from the cathode in more acid melts.

3:20 PM
Electrochemical Behaviour of Carbon Anodes in Na_3AlF_6-K_3AlF_6-Based Low-Melting Electrolytes for Aluminium Electrolysis: *Guihua Wang*[1]; Xiaofei Sun[1]; Wenyan Zhao[1]; Dandan Yang[1]; [1]University of Science and Technology Beijing

The anode processes of carbon electrodes in 49wt%Na_3AlF_6-21wt%K_3AlF_6-30wt%AlF_3-Al_2O_3(saturated or free) melts were studied in a wide range of potentials by cyclic voltammetry. Two peaks were observed on the cyclic voltammograms trace. It is considered that the first peak corresponds to the discharge of oxide ions (or residual oxide ions), and the discharge of fluoride ions occur after the discharge of oxide ions, leading to the anode effect. As the potential increases, PFC gases emission occurs, and the current increases. Compared to the cyclic voltammograms trace obtained from the traditional electrolyte for aluminium industry 84wt%Na_3AlF_6-11wt%AlF_3-5wt%CaF_2-Al_2O_3(saturated), it can be seen, as the addition of a large amount of AlF_3 and the decrease of electrolysis

TUESDAY PM

temperature, the current of the second peak increases obviously. The performance of low temperature aluminium electrolysis increases the risk of a larger emission rate of PFCs.

4:00 PM
Operating Parameters of Aluminum Electrolysis in a KF-AlF_3 Based Electrolyte: *Olga Tkacheva*[1]; John Hryn[1]; Jeff Spangenberger[1]; Boyd Davis[2]; Tom Alcorn[3]; [1]ANL; [2]KPM; [3]Noranda Aluminum

Sustained operation of the low-temperature, potassium-cryolite-based, aluminum electrolysis process in 20 and 100 Ampere cells fitted with vertical metal anodes and wetted cathodes was performed. The current efficiency, the amount of consumed alumina and the amount of produced aluminum were calculated during electrolysis based on the measured amount of oxygen generated on the anode. The purity of the recovered aluminum was controlled during electrolysis. The cell voltage anomalies caused by the NaF presence in the potassium cryolite were studied using a quasi-reference electrode.

4:20 PM
Effect of KF Additions in NA3ALF6-AL2O3 Electrolytes on Expansion of Cathode Blocks: Zhang Yuehong[1]; *Feng Naixiang*[1]; Peng Jianping[1]; Wang Yaowu[1]; Han Yeyu[1]; Zhai Xiujin[1]; [1]Northeastern University

Effects of K and Na on expansion of cathode carbon block were studied through an improved instrument measured expansion rate. For a 30% graphitic cathode block, based on the results, in KCl-NaCl electrolysis system K and Na are reacting with graphite and forming graphite intercalation compounds (GICs) during penetration from surface to inside of the cathode block, and K plays more important role in expansion and penetration than Na. The results show that for a NaF-AlF_3-Al_2O_3 system, containing 7% Al_2O_3 and with CR=6.5, during electrolysis at 1000 ºC the expansion rate of the 30% graphitic cathode block is increased from 2.3% to 8.7% with 0 to 7% KF addition to the electrolytes . It is also showed that the expansion due to K and Na penetration in cathode become lower with increasing content of graphite in cathode material, and that expansion in the fully-graphitized cathode is very low.

4:40 PM
Preparating Aluminium-Scandium Inter-alloys during Reduction Process in KF-AlF3-Sc2O3 Melts: *Qiaochu Liu*[1]; Jilai Xue[1]; Jun Zhu[1]; Chunyang Guan[1]; [1]Unversity of Science and Technology Beijing

Al-Sc Alloys have attracted much attention in recent years due to their great potential in many advanced applications. In this work, Al-Sc alloys were prepared on liquid Al cathode in KF-AlF3-Sc2O3(CR=1.22) melts during reduction process. Scanning electron microscope (SEM) and Inductively coupled plasma atomic emission spectroscopy (ICP-AES) showed that the primary Al3Sc were highly faceted and Sc contents were 0.44 and 0.73% mass in the alloys produced at 750 ºC with current density of 0.5 and 1.0A/cm2, respectively. At 1.0 A/cm2, Sc content increased to 0.95% mass at 800 ºC and 1.27% mass at 850 ºC. But higher mass loss from the melts was found with increased operating temperatures. During reduction process, the decomposition voltage of Sc2O3 was 1.7 - 1.8V, closing to its theoretical value (1.72V at 750 ºC). Cyclic Voltammetry and Linear Sweep Voltammetry studies demonstrate that the reduction of Sc3+ occurs at liquid Al cathode and Al3Sc formation is electrochemically irreversible.

5:00 PM
Liquidus Temperatures of the System Na_3AlF_6-K_3AlF_6-AlF_3: Lai Yanqing[1]; Xin Pengfei[1]; Tian Zhongliang[1]; Wei Chenjuan[1]; Chen Duan[1]; Li Jie[1]; [1]Central South University

Liquidus temperatures for the primary crystallization of the molten salt system Na_3AlF_6-K_3-AlF_6-AlF_3 for aluminum electrolysis were determined by thermal analysis. The data were fitted to an empirical equation $T=3478-1867\times[KR]^{0.12}-12.97\times[AlF_3]^{1.14}+3.538\times[AlF_3]\times[KR]^{0.98}-0.505\times[AlF_3]^{1.24}\times[KR]^{1.23}$Where T is the liquidus temperature in ºC and the square brackets denote wt% of components in the system Na_3AlF_6-K_3AlF_6-AlF_3 with $[KR]=K_3AlF_6/(Na_3AlF_6+K_3AlF_6)$.The composition limitations are 20%< AlF_3 <30%, and 15%< KR <30%.The isothermal diagram of the molten salt system Na_3AlF_6-K_3AlF_6-AlF_3 was obtained in this composition limitation.Keywords: liquidus temperature, the Na_3AlF_6-K_3-AlF_6-AlF_3system, an empirical equation

Partitioning and Austenite Reversion at Martensite-Austenite Interfaces in Mn-Steels: *Dierk Raabe*[1]; Dirk Ponge[1]; Gerhard Inden[1]; Julio Millán[1]; Pyuck-Pa Choi[1]; [1]Max-Planck-Institut

We present atom probe tomography and simulation results of Mn partitioning and segregation effects at martensite-austenite phase boundaries in a precipitation-hardened maraging TRIP steel with 12.2 at.% Mn after a maraging heat treatment (450°C, 48 hours). The system reveals strong compositional changes across the phase boundaries, particularly of Mn. More specific, we observe a change from 5 at.% Mn in martensite to 27 at. % Mn at the martensite-austenite interface. We explain this in terms of partitioning and kinetic freezing. These two effects jointly lead to local austenite reversion. The effects on the mechanical properties are discussed.

2:30 PM
Ferrite-to-Austenite and Austenite-to-Ferrite Phase Transformation in a Fe-2 wt% Mn Alloy Studied In-Situ with 3DXRD Utilizing Synchrotron Radiation: *Hemant Sharma*[1]; Richard Huizenga[1]; Jilt Sietsma[1]; S. Erik Offerman[1]; [1]Delft University of Technology

Analysis of the ferrite-to-austenite transformation data reveals the occurrence of massive transformation from ferrite to austenite. The transformation is characterized by an initial sharp increase in austenite volume fraction above T0 to about 0.92. Remarkably, this is followed by no change in austenite volume fraction for about 50 K, after which the rest of ferrite transforms to austenite. A similar phenomena is observed during austenite-to-ferrite transformation during cooling. At about 50 K above T0, a small amount of ferrite (0.15) is formed followed by an arrest in the rate of transformation for 110 K. This is followed by a sharp transformation of the rest of austenite into ferrite (massive). Repetition of the heat treatment on the same sample(s) shows same character, but with increased fractions of ‘retained ferrite’ during ferrite-to-austenite phase transformation and vice versa. The link between the observations and Mn redistribution during the phase transformations is explored.

3:00 PM
Transitions in Austenite Decomposition Products in a Fe-10%Ni/Fe-5%Ni Diffusion Couple with 0.1%C and 0.3%C: *Eduardo Monlevade*[1]; Arthur Nishikawa[2]; Helio Goldenstein[2]; [1]Mangels Indústria e Comércio Ltda. - Steel Division; [2]Engineering School - University of São Paulo

Two samples extracted from a Fe-5%Ni/Fe-10%Ni diffusion couple were carburized to 0.1%C and 0.3%C. Both samples were austenitized and isothermally transformed at 500°C for 10 minutes in a tin bath. In the 0.1%C sample, allotriomorphic ferrite was present in the low nickel region; with rising nickel content, the decomposition products were upper bainite and pearlite, and finally large blocks of ferrite without carbides. At higher nickel contents, grain boundary allotriomorphs and elongated ferrite particles coexisted at early stages of austenite decomposition. In the 0.3%C sample, upper bainite and degenerate pearlite were seen at the low nickel end of the diffusion couple. With increasing nickel content, the degenerate pearlite disappears substituted by upper bainite, and large formations of parallel ferrite plates are observed at higher nickel regions. Small crystalline misorientations (ca. 7°) were observed between nearby parallel ferrite plates, indicating that its formation occurs by separate nucleation events.

3:20 PM
New Observation of PE Kinetics in Fe-C-X and Fe-N-X Systems: *Mingxing Guo*[1]; Catherine Silva[1]; Hatem Zurob[1]; [1]McMaster University

The effect of interstitial and substitutional solute elements on the kinetics of transformation in steels has been the focus of considerable investigation. In this contribution, the growth kinetics of ferrite was investigated in Fe-0.56wt%C-1wt%Cu and Fe-2wt%N-1.43%Mn by accurately measuring the thickness of the ferrite layer formed during isothermal decarburization/denitriding treatment. In the Fe-C-Cu system the growth kinetics closely follow the prediction of the paraequilibrium (PE) model over the temperature range 755-855°C with no evidence of a transition to local equilibrium kinetics over time. Paraequilibrium is also observed at low-temperatures (<725°C) in the Fe-Mn-N system with evidence of a transition to LENP at longer times. The results are discussed in terms of the recent kinetic transition models in the literature.

3:40 PM Break

4:00 PM Invited
Analysis at the Nanoscale of the Austenite/Ferrite Interface during Ferrite Formation: *Mohamed Gouné*[1]; Frederic Danoix[2]; [1]ArcelorMittal Maizières Research; [2]CNRS - Université de Rouen

The need for lightweight automotive structures is a high driving force to develop new steel microstructure concepts for high strength sheets products, including dual phase (DP) steels. The final microstructure of DP steels is partly controlled by the austenite to ferrite transformation, which is dependant on the chemistry of the α/γ interface. 3D Atom Probe Tomography offers great promises to investigate interfacial and near-interface chemistry, and to determine the tie-line governing the a/g transformation. Manganese and carbon profiles obtained by APT are broadly consistent with predictions of a model which includes a transition from Paraequilibrium to Local Equilibrium Non Partitioning contact conditions. Furthermore, the carbon supersaturated martensite will develop, even during holding at RT, carbon fluctuations that will affect the carbon profile resulting from the α/γ transformation. The methods presented show the high promises for future comparisons between predicted and experimental profiles.

4:30 PM
Manganese Partitioning during Pearlite Growth in Fe-C-Mn Medium Carbon Steel: Maria Martin-Aranda[1]; Juan Cornide[1]; *Carlos Capdevila-Montes*[1]; Michael Miller[2]; Francisca Caballero[1]; Robert Hackenberg[3]; Esteban Urones-Garrote[4]; [1]CENIM-CSIC; [2]ORNL; [3]LANL; [4]Universidad Complutense

The kinetics of the isothermal austenite-to-pearlite transformation in a high purity Fe-C-Mn steel at temperature of 695 °C have been investigated. In this austenite + ferrite + M3C phase field region, it has been reported that pearlite invariably transforms under non-steady-state conditions with a growth rate which decreases and an interlamellar spacing that increases (divergent) in time. In this work, detailed scanning transmission electron microscopy and atom probe tomography measurements of the manganese concentration profiles across the γ /α and γ /M3C growth interfaces were performed as a function of time in order to clarify if local equilibrium (LE) conditions are fulfill during pearlite growth. Research at the Oak Ridge National Laboratory SHaRE User Facility was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy

4:50 PM
Formation of Grain Boundary Ferrite in Eutectoid and Hypereutectoid Steels: *Goro Miyamoto*[1]; Yosuke Karube[1]; Tadashi Furuhara[1]; [1]Tohoku University

Grain boundary ferrite (GB-α) in high carbon pearlitic steels has been considered as one of the reasons for losing ductility of pearlite structure although details have not been well clarified. Thus, effects of transformation temperature and carbon content on the formation of GB-α have been examined in this study. Microstructure of eutectoid and hypereutectoid steels whose nominal compositions are Fe-1%Mn-0.75%C and Fe-1%Mn-1.05%C (mass%), respectively, transformed isothermally at temperatures ranging between 873K and 993K were investigated. GB-α was formed in both eutectoid and hypereutectoid steels from 873K to 948K. The greatest volume fraction of GB-α was obtained in the eutectoid steel transformed at 873K. The fraction decreased by raising transformation temperature or increasing carbon content. In contrast, large amount of GB-α formed in the hypereutectoid steel transformed at 973K, which is just below eutectoid temperature. These facts indicate that there are two different formation mechanism of GB-α depending on transformation temperature.

Biological Materials Science Symposium: Biological and Bio-Inspired Materials II: Hard Biomaterials

Sponsored by: The Minerals, Metals and Materials Society, TMS Electronic, Magnetic, and Photonic Materials Division, TMS Structural Materials Division, TMS: Biomaterials Committee

Biomimetic Scaffolds for Regeneration: *Peter Ma*[1]; [1]University of Michigan

Regenerative medicine aims to develop biological restorations for lost or diseased tissues. Scaffolding materials provide three-dimensional environments for cells and serve as templates to guide tissue regeneration. Our laboratory develops biomimetic polymer scaffolds that recapitulate certain advantageous features of the natural extracellular-matrices (ECM) and impart engineering design to facilitate tissue regeneration. Novel phase separation techniques have been developed in our laboratory to create biodegradable ECM-mimicking nanofibrous scaffolds. To repair complexly shaped tissue defects, an injectable cell carrier is desirable to achieve accurate fit and to minimize surgical intervention. To incorporate the ECM-mimicking nanofibrous feature into an injectable scaffold format, we have recently developed star-shaped biodegradable polymers that can self-assemble into nanofibrous hollow microspheres as novel injectable scaffolds. These scaffolds have been shown to advantageously support various stem cells for tissue regeneration, demonstrating the advantages of biomimetic approach in regenerative medicine.

2:30 PM
Hydroxyapatite-Coated Titanium-Based Biomaterials Prepared by RF Magnetron Sputtering: *Guoqing Wang*[1]; Liping Niu[1]; Sheng Yang[1]; TingTing Gao[1]; [1]College of Science, Northeastern University

Hydroxyapatite (HAP) coatings are widely used to improve the biocompatibility of the substrate. In this study, titanium-based HAP coatings were prepared by RF magnetron sputtering method, and coating structure and composition were analysised by SEM,EDX and IR spectroscopy. When the sputtering power was 290 W , sedimentary was 120-180min , nano-HAP surface coating has formed on the surface of Ti-based, the average size of grain is 48nm , and elemental composition of the coasting is consistent with the HAP coating. coating thickness is 513±15~985±25 nm, Ca/P=1.51±0.03~1.84±0.04, and surface of the coating is smooth, uniform and dense. Adhesion strength of Ti/HAP is more than 25 MPa.

2:50 PM
Estimation of Residual Stresses in Bone Resulting from Surface Treatments: *Jose Viray*[1]; Dwayne Arola[1]; [1]University of Maryland Baltimore County

Surface treatments are often used to introduce residual stresses within engineering materials for promoting corrosion resistance and extending fatigue life. The objective of this investigation was to identify if residual stresses can be introduced within cortical bone using an airjet treament and the relationship between the process parameters and the magnitude of residual stress. Sections of cortical bone were treated with an airjet laden with glass or alumina particles. Results distinguished that residual stresses can be introduced within bone using an airjet treatment and that the maximum stresses reach values equivalent to the yield strength of bone. The magnitude of stress was found to be a function of the treatment parameters (treatment intensity, particle size, air pressure) and the bone's microstructure. It was also found that residual stresses in bone have a limited duration due to a viscoelastic recovery process that begins immediately following the treatment. (Supported by NIDCR DE016904).

3:10 PM
Micro-Mechanical Characterization of Bovine Cortical Bone in Bending and Uniaxial Compression: *Kelly Kranjc*[1]; Pravin Ramesh[1]; Katharine Flores[1]; [1]Ohio State University

Mechanical testing of bone at small length-scales offers the possibility of understanding the behavior of individual microstructural building blocks, which can then be used to model the behavior of the aggregate under different conditions, such as age or disease state. In this work, micropillars and microcantilever beams with dimensions on the order of 10 microns are selectively machined within regions of interest, such as osteons, via femtosecond laser machining and focused ion beam milling techniques. The load-displacement response under a variety of test conditions is then obtained using a modified nanoindenter. Elastic modulus measurements of wet and dry bovine cortical bone are in good agreement with bulk measurements. Load relaxation experiments reveal two relaxation time constants which are hypothesized to be associated with processes in the organic and inorganic phases, respectively. Efforts to characterize the cyclic response and microstructural changes associated with damage accumulation will also be discussed.

3:25 PM
The Elastic Modulus of Trabecular Bone: Modeling and Experiments: Elham Hamed[1]; Ekaterina Novitskaya[2]; Jun Li[1]; Po-Yu Chen[2]; *Iwona Jasiuk*[1]; Joanna McKittrick[2]; [1]University of Illinois at Urbana-Champaign; [2]University of California, San Diego

Untreated, demineralized, and deproteinized bovine trabecular bones, taken from femoral head, were studied. Their mechanical properties were obtained using compression test. Optical and scanning electron microscopies were used to examine bone microstructural features. Bone porosity for all three groups was estimated by analyzing micro-computed tomography scans, while bone mineral content was estimated using ash content method. These served as inputs and validation for our multiscale model which was employed to theoretically predict elastic moduli of trabecular bone from all three groups. The model assumes trabecular bone to be a porous composite material with a hierarchical structure ranging from nanoscale (collagen-mineral level) to mesoscale (trabecular bone level). The modeling methods accounted for the interpenetrating structure of collagen and mineral phases. Finally, the modeling results were compared with the experimental data obtained by compression testing. Good agreement was obtained between the experimental and modeling results for untreated, demineralized, and deproteinized bones.

3:50 PM Invited
Adhesion in Nanoparticles for Cancer Detection and Treatment: *Winston Soboyejo*[1]; [1]Princeton University

This paper explores the role that adhesion can play in the design of interfaces in nanoparticles that are relevant to cancer detection and treatment.These include ligand-conjugated nanoparticles and nanoparticle clusters that are being developed for the early detection and treatment of breast cancer. Dip-coating and atomic force microscopy techniques are used to measure the adhesion between gold or magnetitite nanoparticles that are relevant to cancer detection and treatment. These include the adhesive interactions between molecular recognition units (MRUs) that are able to target breast cancer cells, and the interactions between nanoparticle clusters that are relevant to the localized delivery of chemotherapy drugs to breast cancer cells. The implications of the results are discussed for the design of nanoparticle clusters for the early detection and treatment of cancer.

4:20 PM
The Importance of Decussation on the Crack Growth Resistance of Enamel: *Mobin Yahyazadehfar*[1]; Dwayne Arola[1]; [1]University of Maryland Baltimore County

The most dominant microstructural feature of enamel is a network of highly calcified rods extending between the surface of teeth and the dentin-enamel junction (DEJ). Though oriented parallel to one another near the tooth's surface, the rods are organized into a series of oblique layers approaching the DEJ. In this investigation the importance of this transition in microstructure (i.e. decussation) on the crack growth resistance of enamel was studied. Sections of enamel were obtained from molars of young patients and used in quantifying the incremental crack growth resistance for cracks extending in two orientations. Results showed that decussation is critical to the crack growth toughening of enamel and it causes spatial variations in the degree of anisotropy exhibited by this tissue. The decussation pattern forces cracks to exhaust energy by extending peripherally about the surface of teeth rather than continuing inwards towards the pulp. (Supported by NIDCR DE016904)

4:40 PM

Improved Biocompatible Zirconia and Alumina Based Ceramic Composites: *Koushik Biswas*[1]; Ajoy Pandey[1]; [1]Indian Institute of Technology Kharagpur

Ceria/yttria stabilized zirconia and ceria/yttria stabilized zirconia toughened alumina powders were synthesized by wet chemical method and subsequently consolidated to near full density following an optimized calcination and sintering route. Microstructure and mechanical properties were correlated. Accelerated ageing studied at 134 °C/0.2 MPa shows nucleation of orthorhombic/monoclinic zirconia phase with significantly reduced transformation for CSZ. Surfaces after fretting wear show evidences of microcrack formation, grain pull outs and abrasion. CSZ specimens show better results after ageing. Biocompatibility tests reveal calcium ortho-phosphate and hydroxyapatite like biomineral layers formation on surface of specimens when immersed in simulated body fluid at 37.5 °C. Differential rates of nucleation of minerals for alumina and zirconia based specimens suggest that Zr-OH bond helped accelerated HAp nucleation compared to Al-OH. Incubation and attachment of multi-layered interconnected human osteoblast like cells (MG63) on surfaces; cell proliferation and differentiation were suggesting biocompatibility of the developed materials.

5:00 PM

Effect of Bacteria on Mechanical Properties of Dental Composites: *Dmytro Khvostenko*[1]; Jamie Kruzic[1]; John Mitchell[2]; Jack Ferracane[2]; [1]Oregon State University; [2]Oregon Health & Science University

One problem in restorative dentistry is bacterial biofilm development at the tooth-filling interface which can lead to demineralization of tooth tissue and secondary caries. Furthermore, bacterial exposure may also be deleterious to the composite mechanical properties. Bioactive glass (BAG) added as an antimicrobial agent may help mitigate this problem and enhance composite durability. In phase I of this study fatigue crack growth, fracture toughness and 3-point beam bending experiments are being performed on bulk composite samples after two different soaking treatments: 1) 24 hours in distilled water and 2) 60 days in trypticase soy agar broth with streptococcus mutans bacteria. BAG containing composite behavior will be compared to a commercial composite (Heliomolar). In phase II, the issue of demineralization of marginal tooth structure will be examined by in-vivo fatigue testing of tooth samples restored with BAG containing composites to assess the effect of combined mechanical loading and exposure to bacteria.

5:15 PM

Micromechanical Analysis of Strain-Induced Martensitic Transformation in Biomedical Co-Cr-Mo-N Alloy: *Byoung-Soo Lee*[1]; Shou Suzuki[1]; Hiroaki Matsumoto[2]; Yuichro Koizumi[2]; Akihiko Chiba[2]; [1]Department of Materials Processing, Graduate School of Engineering, Tohoku University; [2]Institute for Materials Research, Tohoku University

Biomedical Co-Cr-Mo-N alloys are widely used as implant materials such as hip and knee joints. Strain-induced e-hcp martensitic phase (e-phase) has both beneficial and detrimental characteristics, i.e. enhancement in wear resistance and reduction in deformability. Therefore, it is important to understand the role of e-phase during plastic deformation. Recently, a method proposed by Wilkinson [A.J. Wilkinson, D. Randman, Phil. Mag. A, 90(2010) 1159] has been developed into a powerful tool to determine elastic strain. This study deals with the micromechanical analysis of e-phase in biomedical Co-Cr-Mo-N alloy by means of EBSD-Wilkinson method. Most e-phases nucleated at twin and grain boundaries, and then grew in specific grains, which are oriented to near [101] and [111]. The grains are classified into soft grains ([101] and [111]) and hard grain ([001]). The e-phase nucleates preferentially at the interface between hard and soft grains because of local stress related with heterogeneous stress distribution.

Bulk Metallic Glasses IX: Structures and Mechanical Properties II

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Mechanical Behavior of Materials Committee

Program Organizers: Peter Liaw, The University of Tennessee; Hahn Choo, The University of Tennessee; Yanfei Gao, The University of Tennessee; Gongyao Wang, University of Tennessee

Tuesday PM — Room: Swan 6

Session Chairs: A. Greer, Univ of Cambridge; J. Eckert, IFW Dresden

2:00 PM Keynote

Plastic Deformation and Structure Changes in Metallic Glasses: *A. Greer*[1]; [1]Univ of Cambridge

Room temperature (RT) plasticity in metallic glasses is localized on shear bands and associated with dilatation. Elastostatic compression of a metallic glass at RT at less than the yield stress increases the heat of relaxation in the glass, improves its plasticity, and causes dilatation. By deforming homogeneously at RT, relaxation of deformation-induced changes is suppressed, with remarkable effects: the local volume increase associated with each atom in a shear transformation zone is of the order of one atomic volume. The structural effects of deformation and annealing appear to be opposite: “rejuvenation” versus “ageing”. Annealing causes the Poisson’s ratio to decrease. However, elastostatic deformation, despite evident dilatation, also causes Poisson’s ratio to decrease. This paradox is explored through new results on the effects of heavy deformation at liquid-nitrogen temperature. The results may be relevant for interpreting shear banding and the limits to metallic-glass properties.

2:30 PM

Determination of Phase Separation in Amorphous Pd(40+0.5x) Ni(40+0.5x)P(20-x) BMG for x = 0 to 4: *Man Tat Lau*[1]; Si Lan[1]; Yeuk Lan Yip[1]; Hin Wing Kui[1]; [1]Chinese University of Hong Kong

Recently, it was found that amorphous Pd41.25Ni41.25P17.5 alloys undergo phase separation. On the other hand, the alloy Pd40Ni40P20, which is known to be an easy glass former, is thermally stable even at temperatures about 100 K above its glass transition temperature Tg. In this work, alloy systems of Pd40+0.5xNi40+0.5xP20-x for x = 0 to 4 were studied for amorphous phase separation by high resolution TEM techniques, which include HREM and high-angle angular dark-field (HAADF) EDX spectrum mapping. It was found that when x =0, i.e., the alloy system Pd40Ni40P20 falls outside the metastable liquid miscibility gap. On the other hand, for x = 1 to 4, the corresponding alloys are inside the metastable liquid miscibility gap.

Properties of Shear Transformation Zones in Metallic Glasses: *Michael Atzmon*[1]; JongDoo Ju[1]; Dongchan Jang[2]; [1]University of Michigan; [2]Caltech

The concept of shear transformations was coined by Argon, based on observations in bubble-raft models of glasses [1]. Later, 3-D observations in colloidal glasses and molecular dynamics simulations confirmed this picture. Because of the disordered structure of glasses, there is no known contrast mechanism for imaging shear transformation zones (STZs). Diffraction techniques provide macroscopic averages and are unlikely to reveal detailed information about STZs. Using anelastic relaxation experiments, we have recently been able to resolve a hierarchy of STZs that differ from each other by a single atom. In this talk, the results will be contrasted to previous reports, and the implications for the understanding of glass behavior will be discussed.1. A. S. Argon, Acta Metall. 27, 47 (1979).

3:00 PM
Mechanical Relaxation in Bulk Metallic Glasses: *Jichao Qiao*[1]; J.M. Pelletier[1]; W.H. Wang[2]; [1]INSA-Lyon; [2]Institute of Physics, Chinese Academy of Sciences

The primary (or a) relaxation was observed in various bulk metallic glasses (BMGs) forming liquids. At lower temperature (or higher frequency), many BMGs present second relaxation processes (ß relaxation). Unfortunately, structural origin of the second structural relaxation in BMGs is not clear. In this investigation, the two multicomponent BMGs, namely, Zr41.2Ti13.8Cu12.5Ni10Be22.5 and La60Ni15Al25, were carried out by mechanical spectroscopy (DMA). The correlation between mechanical relaxation and atomic mobility was analyzed. Compared with other non-crystalline solids, such as polymers and amorphous mineral glasses, the second relaxation depends on the chemical nature. Connected with other based BMGs, the present work tries to shed light on the mechanism of the second relaxation in amorphous alloys.

3:10 PM
High Temperature Deformation and Twin Roll Strip Casting Ability of Cu-Zr-based Bulk Metallic Glasses: *Kwang Seok Lee*[1]; Young Seon Lee[1]; [1]Korea Institute of Materials Science

A study has been made to investigate both high temperature deformation and twin roll strip casting ability of Cu-Zr-based Bulk Metallic Glasses (BMGs). High temperature deformation behavior has first been revealed by conducting a series of compression tests with various initial strain rates at several temperatures within supercooled liquid region. Furthermore, the possibility of continuous roll casting for Cu-Zr-based BMGs was investigated as a form of glassy sheet by means of twin roll strip casting under various process conditions such as roll gaps and wheel rotation speed, which directly related to the cooling rate. Various analyses for strip samples through the rolling and thickness directions were then performed in order to verify the influence of process conditions on the mechanical evolution and subsequent mechanical behaviors. Another application of these BMGs as a joining between dissimilar metals was additionally discussed.

3:35 PM Invited
Formation of B2 CuZr in Metastable CuZr-Based Bulk Glass Forming Alloys: K.K. Song[1]; S. Pauly[1]; Y. Zhang[1]; P. Gargarella[1]; N.S. Barekar[1]; U. Kühn[1]; M. Stoica[1]; *J. Eckert*[2]; [1]IFW Dresden; [2]University of Tennessee

Bulk glassy alloys and composites have potential for being used in various fields as advanced high performance materials. However, monolithic amorphous alloys usually lack ductility, and an additional toughening phase is often needed to improve plasticity and to promote local shear events to be distributed more homogeneously in the material. Accordingly, it is important to develop new alloys and composite microstructures by introducing microstructural heterogeneities on different length-scales and combining phases with different elastic constants, hardness and strength, such as to improve the overall mechanical performance of the alloys. As an example, recent results obtained through systematically investigating the formation of the high-temperature B2 CuZr intermetallic phase in a variety of metastable CuZr-based alloys will be presented. The results demonstrate that a B2 CuZr solid phase transformation exists at high temperature. This approach aims to promote the development of metastable CuZr-based glass composites with enhanced deformability.

3:55 PM
Characteristics of Metallic Glass Thin Films Deposited by Using RF, DC and Pulsed DC Sputtering Techniques: *Chia-Lin Li*[1]; Jyh-Wei Lee[2]; Jinn Chu[1]; [1]National Taiwan University of Science and Technology; [2]Mingchi University of Technology

Zr-based metallic glass thin films were prepared by using different PVD processes, namely RF, DC and pulsed DC sputtering techniques. Microstructures of thin films thus prepared were examined by an atomic force microscopy (AFM), scanning electron microscopy (SEM) and transmission electron microscopy (TEM). The nanoindenter and differential scanning calorimetry (DSC) were used to evaluate the hardness and thermal behavior, respectively. According to experimental results, various degrees of amorphization and nanocrystallization can be observed in the as-deposited films. A series of comparisons on microstructures, crystallographic and mechanical properties of Zr-based metallic glass thin films will be discussed in the present paper.

4:05 PM Invited
Structural and Mechanical Heterogeneity of Bulk Metallic Glasses: *Mingwei Chen*[1]; [1]Tohoku University

Stress-driven mechanical instability of metallic glasses is usually associated with spatially heterogeneous shear transformation zones (STZs) that play a crucial role in the yielding, plastic deformation and failure of metallic glasses. However, the atomic origins and physical nature of STZs have been debated for many years and, particularly, lack experimental insights. Recently, we have developed several experimental approaches to characterize atomic structure and STZs of metallic glasses. Combining with ab initio molecular dynamics simulation, we provide compelling evidence that the STZs arise from atomic-scale structural and chemical heterogeneity of metallic glasses. The size and physical nature of measured STZs are consistent well with a wide-range of MD simulations and coincide with the atomic structure model of metallic glasses.

4:25 PM Invited
Intrinsic Yield Strength and Elastic Strain Limit of Metallic Glasses: *Evan Ma*[1]; [1]Johns Hopkins University

We report quantitative in situ tensile tests inside a transmission electron microscope for metallic glasses (MGs). Our experiment employs submicron-sized specimens, high-resolution measurements of the loading forces and accurate strain measurement with deposited markers on the gauge length. The quantitative experiment establishes that the MGs have intrinsic yield strength and yield strain about twice as large as the already-high elastic limit observed in macroscopic samples, in line with model predictions of the intrinsic elastic limit in the absence of heterogeneous shear band nucleation facilitated by extrinsic factors. We also discuss the origin of the apparent “work hardening” seen in the tensile stress-strain curves.

4:45 PM
Critical Temperature for Ductile-to-Brittle Transition for Metallic Glasses: *Golden Kumar*[1]; Pascal Neibecker[2]; Jan Schroers[1]; [1]Yale University; [2]Universitaet des Saarlandes

A comprehensive analysis of plasticity (and toughness) in bulk metallic glasses (BMGs) is presented. Different effects such as: contribution of shear modulus/bulk modulus ratio, structural relaxation, and cooling rate effect are evaluated for Pt57.5Cu14.7Ni5.3P22.5 (Pt-BMG), Pd43Cu27Ni10P20 (Pd-BMG), and Zr44Ti11Ni10Cu10Be25 (Zr-BMG). We introduce a critical temperature, TC, which is an intrinsic feature of a BMG former above which the BMG does not embrittle. We demonstrate that TC/Tg ratio indicates the embrittlement sensitivity of a BMG due to annealing and cooling rate. This ratio is larger than one for Pd-BMG and smaller than one for the Pt-BMG. As a consequence, Pd-BMG is more sensitive to cooling rate and annealing induced embrittlement. In contrast, Pt-BMG does not embrittle during sub-Tg annealing or at practically achievable slow cooling rates. Study of shear modulus/bulk modulus ratio for Pd-BMG and Pt-BMG does not follow the previously proposed critical value for ductile to brittle transition.

4:55 PM Invited
Influence of Shear Band on the Mechanical Behavior of Metallic Glasses: *Yi Li*[1]; [1]National University of Singapore

Shear band is the key feature that controls the plastic deformation process of metallic glasses (MGs). However, the investigation directly on the shear band and its influence on the plastic deformation are rarely conducted as it is perceived as extremely narrow. The deformation and failure of MGs is really an instability process that begins with the formation of shear bands. Here we will show our studies on the formation of shear band, the property of shear band and the influence of shear band formation on the plastic behavior of metallic glasses.

5:15 PM Invited
Review on the Use of Bulk Metallic Glass for Multi-Scale Tooling Applications: *David Browne*[1]; Dermot Stratton[1]; Michael Gilchrist[1]; Cormac Byrne[1]; [1]University College Dublin

There is a growing demand for single-use disposable polymer devices with features at sub-micron scales. This requires resilient tooling which can be patterned to scales of the order of hundreds of nm. The requisite topology can be imparted to silicon but it is too brittle to be of use in a die to mold thousands of plastic parts. The polycrystalline nature of tool steel means it cannot be patterned with sub-micron detail. Some bulk amorphous alloys have the requisite mechanical properties to be viable as materials for such dies, and can be patterned – e.g. via embossing as a supercooled liquid into MEMS silicon or using FIB – with sub-micron features which may persevere over many thousands of molding cycles. The composition of the amorphous alloy must be carefully selected to suit the particular molding application (polymer/process). The state-of-the-art of is presented, along with results of our recent experimental investigations.

5:35 PM Invited
Intrinsic and Extrinsic Size Effects in the Deformation of Metallic Glass Nanopillars: *Jeff De Hosson*[1]; O. Kuzmin[1]; Y.T. Pei[1]; [1]Univ of Groningen

Nano-sized pillars with diameters ranging from 90 to 600 nm of four amorphous alloys Cu47Ti33Zr11Ni6Sn2Si1, Zr50Ti16.5Cu15Ni18.5, Zr61.8Cu18Ni10.2Al10 and Al86Ni9Y5, were fabricated and tested in-situ in a transmission electron microscope (TEM). Differences among the deformation behavior of tapered (1.5 - 3°) and taper-free systems were also investigated. Upon increasing size all the MGs examined show a transition from ductile–to-brittle behavior under compression, where the transition point, however, depends on the chemical composition of the specific metallic glass investigated. The lower the shear modulus/bulk modulus ratio, the larger pillar diameter above of which more brittle behavior occurs was found. Al86Ni9Y5 taper-free metallic glass showed a transition threshold to brittle behavior at the largest diameter of 300 nm pillar. A micromechanical model is presented to explain the various dependencies. [1] Julia R. Greer and Jeff Th.M. De Hosson, Progress in Materials Science (2011) 56: 654–724

Cast Shop for Aluminum Production: Furnace

2:00 PM
Automated Measurement of Furnace Liquid Metal Heel and Full Furnace Weights: *John Courtenay*[1]; [1]MQP Limited

The benefits of accurate measurement of furnace heel and full furnace weights are well accepted in terms of increasing % right first time batching, increasing productivity and eliminating short casts however the practical realization of a robust system has been problematic. The development of the BatchPilot system, which has overcome these difficulties, is described. To date 47 systems are in operation in 20 casthouses world wide and the most recent innovations include a fully automated weighing capability and down line integration of the output data into the customer management data network.

2:20 PM
Development of a New Generation Electromagnetic Metal Moving System: Graham Guest[1]; *Stephen Augostine*[1]; Fabienne Virieux[2]; [1]Solios Thermal; [2]Fives Solios

For modern aluminium cast house or re-melt facility, Fives Solios have developed an innovative new generation electromagnetic metal moving system called GENIOS that can be incorporated within new installations or retrofitted to existing furnaces. It can be fitted simply and safely to a wide range of furnace types using a patented modular interface and mounting concept. The prototype system is being trialled on a 70 tonne capacity static holding furnace at a large modern re-melting facility in Europe. In this particular case, GENIOS is configured to stir, aid silicon dissolution and transfer to a dedicated casting machine. The trials are in progress and expected to be completed during 2011. This paper will give an overview of the development of the concept and technology. It will also include a brief review of the performance of the prototype and general operational experiences together with comparisons with traditional technology.

2:40 PM
Six Years Experience from Low-Temperature Oxyfuel in Primary and Re-Melting Aluminium Cast Houses: *Henrik Gripenberg*[1]; [1]Linde

Low-temperature Oxyfuel technology provides lower peak flame temperatures and a more uniform heat flux and temperature profile in the cast house furnace. The objectives with the technology are to improve melt rates, save energy, reduce dross formation and to reduce NOx and CO2 emissions. The paper will discuss operational results, process optimizations and economy from installations in reverberatory melting furnaces, mixing furnaces and tiltable rotary furnaces. The theory behind the technology will be described including reference to CFD simulations and laboratory testing. Low-temperature Oxyfuel is used by a number of aluminium producers including Hydro Aluminium, Sapa Heat Transfer AB, Stena Aluminium and others.

3:00 PM Break

3:20 PM
Energy and Maintenance Cost Savings Review at Several US Aluminum Die Cast Manufacturers Using Unique, Non-Wetting, Micro-Porous Refractory Products: *Robert Cullen*[1]; Kenneth McGowan[1]; [1]Westmoreland Advanced Materials, LLC

Over the past several years, many Aluminum Die Cast Manufacturers in North America have used unique, inherently non-wetting, micro-porous refractory products from Westmoreland Advanced Materials, LLC to line their melting and holding furnaces, as well as their molten metal transport systems. These manufacturers have experienced significant energy and maintenance cost savings through the use of these unique refractory products. A review of the technology behind these unique refractory products, along with specific examples of the energy and maintenance cost savings from several customers will be presented.

3:40 PM
Quality Comparison between Molten Metal from Remelted Sheets; Mill Finish and Coated: *Anne Kvithyld*[1]; Arne Nordmark[1]; Derya Dispinar[1]; [1]SINTEF

Deterioration of metal quality caused contamination (e.g. coatings) is an issue in remelting of aluminium scrap. The molten metal quality from remelting sheet material with and without coating is compared. In the experiments the crucibles are placed inside a resistance furnace to ensure that the charges are melted under the same conditions at the same time, measuring temperature and hydrogen. The melts was subjected to (i) settling over night (ii) blowing air through a porous plug for 2.5 min to generate oxides and (iii) adding turnings. The bifilm index is used as a measure of metal quality. For mechanical testing 3-point bending was performed. The change in the metal quality was observed.

4:00 PM
Numerical Modeling of Oxy-Fuel and Air-fuel Burners for Aluminium Melting: *Jørgen Furu*[1]; Andreas Buchholz[2]; Trond H. Bergstrøm[3]; Knut Marthinsen[1]; [1]NTNU; [2]Hydro Aluminium Deutschland GmbH; [3]SINTEF Materials and Chemistry

In recent years oxy-fuel combustion has become an increasingly attractive alternative as a heating source when melting aluminium. A recently developed Low Temperature Oxy-fuel burner from Linde Gas was investigated and compared to a conventional cold air-fuel burner in an instrumented pilot scale furnace. Measurements and heating trials of aluminium samples were done for four different case studies. 3-dimensional CFD models using the commercial software package ANSYS Fluent were developed to attain additional knowledge and to demonstrate CFD as a viable tool to model aluminium melting furnaces. Good agreement was found between the numerical models and the measurements where the difference in heat transfer between the two burner technologies was clearly demonstrated.

CFD Modeling and Simulation in Materials Processing: Modeling of Casting and Solidification Processes I

2:00 PM Keynote
Multiscale and Multiphysic Models in CFD Modeling and Simulation of Solidification Process: *Hervé Combeau*[1]; Miha Založnik[1]; [1]Institut Jean Lamour

Prediction of solidification defects like macro and mesosegregations and of microstructures constitutes a key issue for industry. The development of models needs to account for several imbricated length scales and different physical phenomena. The goal of this presentation is to introduce the existing models and there principle. The main results of a benchmark on macrosegregation will be presented in order to emphasize the difficulties linked to the resolution of the equations of such models. The more recent applications of these models to solidification process will be presented (steel ingot, aluminum DC casting, VAR). Their ability to help in the understanding of complex phenomena like the competition between nucleation and growth of grains in the presence of convection of the liquid and grain motion will be discussed as well as their predictive capabilities. Finally, the main remaining key issues will be addressed.

2:30 PM Invited
3D CAFE Simulation of a Macrosegregation Benchmark Experiment: *Charles-Andre Gandin*[1]; T. Carozzani[1]; H. Digonnet[1]; M. Bellet[1]; [1]MINES ParisTech

Upon heat extraction from a vertical surface of a parallelepipedic domain filled with a metallic melt, thermal buoyancy driven convection of the liquid takes place. In case of a Sn-3wt%Pb alloy, Sn-rich solid forms close the cooled vertical surface and segregation of Pb occurs. The latter phenomena is named microsegregation when it is only localized in the vicinity of the solid-liquid interface. But in addition to thermal convection, solutal buoyancy driven convection is induced by Pb microsegregation. As a consequence, Pb is redistributed in the entire domain and the so-called macrosegregation develops. This phenomena is simulated using a 3D CAFE model. It is compared with a benchmark experiment.

2:55 PM Invited
Modeling of Multiscale and Multiphase Phenomena in Material Processing: *Andreas Ludwig*[1]; Abdellah Kharicha[1]; Menghuai Wu[1]; [1]University of Leoben, Dep. Metallurgy

In order to demonstrate how CFD can help scientists and engineers to better understand the fundamentals of engineering processes, a number of examples are shown and discussed. The paper will cover (i) special aspects of continuous casting of steel including turbulence, motion and entrapment of non-metallic inclusions, and impact of softreduction; (ii) multiple flow phenomena and multiscale aspects during casting of large ingots including flow induced columnar-to-equiaxed transition and 3D formation of channel segregation; (iii) multiphase magneto hydrodynamics during electro-slag remelting; and (iv) melt flow and solidification of thin but large centrifugal castings.

3:20 PM
Numerical Simulation of Macrosegregation Formation during Solidification Accounting for Inoculants and Equiaxed Grain Transport: *Knut Omdal Tveito*[1]; Marie Bedel[2]; Miha Založnik[3]; Hervé Combeau[3]; Mohammed M'hamdi[4]; Arvind Kumar[3]; Pradip Dutta[5]; [1]Norwegian University of Science and Technology; [2]Institut Jean Lamour, Departement SI2M, CNRS – Nancy-Université – UPV-Metz, Ecole des Mines de Nancy; [3]Institut Jean Lamour, Departement SI2M, CNRS – Nancy-Université – UPV-Metz, Ecole des Mines de Nancy; [4]SINTEF Materials and Chemistry; [5]Department of Mechanical Engineering, Indian Institute of Science, Bangalore

Macrosegregation formation in grain-refined Al-Cu alloys is studied by means of numerical simulations and compared to experimental data. In the modelling, a volume-averaged two-phase multiscale model is employed where macroscopic heat and solute transport, melt convection, and transport of inoculant particles and equiaxed grains are all taken into account. On a microscopic scale, nucleation occurs on inoculant particles, the solid phase is assumed to have globular morphology and the growth kinetics is described by accounting for limited solute diffusion in both liquid and solid phase. The numerical model is applied to horizontal solidification of an Al-22wt.%Cu alloy in a rectangular sand mold. The impact of the inoculant size distribution and the packing fraction on the evolution of the flow pattern, grain transport and macrosegregation formation is discussed. The final macrosegregation and grain size distribution are also compared to experimental data.

3:40 PM Break

4:00 PM
A Numerical Benchmark Exercise on Thermal and Thermosolutal Natural Convection in Liquid Alloys
: *Miha Založnik*[1]; Cédric Le Bot[2]; Stéphane Glockner[2]; Olga Budenkova[3]; Yves Du Terrail[3]; Marius-Vasile Bejinariu[4]; Gregor Kosec[5]; Dominique Gobin[6]; Hervé Combeau[1]; [1]Institut Jean Lamour; [2]I2M-TREFLE; [3]SIMaP; [4]Universitatea Tehnica de Constructii Bucuresti; [5]Institut Jožef Stefan; [6]EM2C

During casting of alloys, chemical inhomogeneities (macrosegregations) result from solute transport by the flow in the mushy solidification zone. This flow is coupled with the thermosolutal natural convection in the fully liquid zone. Vigorous natural convection occurs either in the initial stage of casting, until the superheat is extracted; or throughout, in processes where thermal gradients are maintained (DC casting, remelting processes). Because of inherent strong nonlinearities, due to the low

Prandtl (~10^{-2}) and high Lewis numbers (~10^4) of liquid metals, these flows are notoriously difficult to simulate. In the framework of the French project SMACS we present a numerical benchmark exercise comparing the performance of four numerical codes in the prediction of laminar thermal and thermosolutal natural convection related to small castings. We compare predictions on prototypal cases of convection in a square cavity and present the sensitivities of the predictions of global and local heat and mass transfer.

4:20 PM
2D and 3D Numerical Modeling of Solidification Benchmark of Sn-3% Pb Wt. Alloy under Natural Convection: Redouane Boussaa[1]; Lakhdar Hachani[1]; Bachir Saadi[1]; Xiaodong Wang[1]; Olga Budenkova[1]; *Kader Zaidat*[1]; Hamda Ben Hadid[2]; Yves Fautrelle[1]; [1]Grenoble-INP; [2]LMFA-Ecole centrale de Lyon

Numerical modeling of solidification benchmark, with controlled thermal boundary conditions, is proposed. The benchmark experiment consists in solidifying a rectangular ingot of Sn-3% wt. Pb alloys, by using two lateral heat exchangers which allow extracting heat flux from one or two vertical side. An array of fifty thermocouples, placed on the lateral wall, is used to determine the instantaneous temperature distribution. This allows us to evaluate the evolution due to the natural convection, as well as its influence on the initial conditions, the solidification macrostructure and segregation behaviors. After each experiment, the pattern of the segregations have been obtained by X-ray radiograph and confirmed by eutectic fraction measurements. The solute distribution is carried out by ICP analysis. Numerical solidification models are developed to give the distribution of the solute in a solidified sample. The originality of this modeling work is to provide quantitative results comparable with the experimental data.

4:40 PM
Numerical Modeling of the Interaction between a Foreign Particle an Solidifying Crystalline Interface: Eliana Agaliotis[1]; Mario Rosenberger[1]; Alicia Ares[1]; *Carlos Schvezov*[1]; [1]CONICET - UNaM

The interaction between a solidification front and a spherical particle was modeled and simulated in order to study the phenomenon of "pushing". Finite element methods were employed in axi-symetric domains. The drag force is calculated from the calculated fluid flow field and the repulsion force is the Lifshitz-Van der Waal force. The thermal field is decoupled from the force field. The model is applied to a metallic matrix containing particles with similar, lower or higher thermal conductivities than the matrix, resulting in planar, convex and concave interface shapes, respectively.The results show that the critical velocities for pushing for concave and convex interfaces are about one order of magnitude larger and one order of magnitude lower than the critical velocity for flat interfaces, respectively. The simulated results were in very good agreement with reported experimental results.

5:00 PM
Simulation of A356 Semi-Solid Die-Casting Using Power-Law Model: *Seyed Vahidreza Seyed Vakili*[1]; Mahmoud Nili-Ahmadabadi[1]; [1]University of Tehran

Semi-solid processing (thixoforming) is an innovative metal forming technology bearing a high potential for cost reduction by reducing forming steps, forming forces and improving work piece quality. Mold filling is one of the most important aspects of casting process, which is technically difficult to predict even for expert die designers. In this study, Numerical simulation is the last method which is used in this study. The ProCast software using Cutt-off-Value fluid (Power-Law)model was used to indicate the flow pattern of the fluid in the mold. Some comparisons with experimental tests were also done to prove the simulation results. Also, the effects of some casting parameters were studied to achieve the best casting condition for this process.

5:20 PM
Optimization of Tensile Test Pattern for Aluminum Alloys: Engin Tan[1]; Freddy Syvertsen[2]; *Derya Dispinar*[3]; [1]Pamukkale University; [2]SINTEF; [3]University of Istanbul

It has been shown that the disturbance of the advancing liquid front in the mould cavity may lead to surface entrained defects known as bifilms. These defects can deteriorate the mechanical properties significantly. The developments in the simulation of castings aid many casters. It is quick and economical. Therefore in this work, the aim was targeted to optimise the mould filling of a tensile test pattern design that is used for aluminium alloys. Several different designs, gatings and runner systems were investigated with Vulcan Casting Simulation Software. In addition to the achievement of non-turbulent and quiescent mould filling; other parameters such as temperature profile, porosity and feeding were investigated to optimise the process.

Characterization of Minerals, Metals, and Materials: Characterization Technologies

Sponsored by: The Minerals, Metals and Materials Society, TMS Extraction and Processing Division, TMS: Materials Characterization Committee
Program Organizers: Jiann-Yang Hwang, Michigan Technological University; Sergio Montero, State University of North Rio De Janeiro; Chenguang Bai, Chongqing University; John Carpenter, US Department of Energy; Donato Firrao, Politecnico di Torino; Byoung-Gon Kim, Korea Institute of Geoscience & Mineral Resources; Mingdong Cai, Schlumberger

Session Chairs: Mingdong Cai, Schlumberger Inc.; John Carpenter, DOE Los Alamos National Laboratory

2:00 PM
3D Characterization of Dendrites in Synthetic and Naturally Occurring Magma: S. Knox[1]; A. Shiveley[2]; G. Viswanathan[2]; M. Chapman[1]; J. Hammer[3]; *J. Tiley*[2]; [1]Southwestern Ohio Council for Higher Education/Air Force Research Laboratory; [2]Air Force Research Laboratory; [3]Department of Geology and Geophysics, University of Hawai'i

Natural and synthetic lava samples were studied using advanced characterization techniques to determine the crystallographic orientations and growth directions of dendritic structures in the silicate matrix. Focused ion beam SEM, advanced TEM, and EBSD procedures were utilized to evaluate the materials. Specifically, 3 dimensional reconstructions were developed using serial sectioning techniques to elucidate the connectivity of dendritic arm segments. Results indicate the primary growth direction and mechanisms associated with reported rotations that occur during rapid cooling from the melt. Reconstructions and results from TEM analysis will be reported.

2:15 PM
3D Metallography of Multiphase Steels: *Martin Fischer*[1]; Pierre Lutomski[1]; Andreas Stieben[1]; Wolfgang Bleck[1]; [1]RWTH Aachen University

For steel investigation and development, exact knowledge about the microstructural state is required. The information gained from 2-dimensional images often can't properly reflect the real 3D microstructural properties. In order to gain reliable information for meaningful models, simulations and correlations, it is necessary to accompany standard metallography with 3D information, which unfortunately is very difficult to access. This article presents a procedure for serial sectioning in combination with light optical microscopy. Only standard metallographic tools are employed in combination with image manipulation freeware. 3-dimensional microstructural data were extracted from three multiphase steel grades and in two cases virtual 3D-models of microstructural phases were generated.

2:30 PM
Advantages of Integrating Precession Scanning Transmission Electron Microscopy in the Characterization of Metallic Materials: *Peter Collins*[1]; Hamid Mohseni[1]; Tom Scharf[1]; [1]University of North Texas

The recent advance of precession scanning transmission electron microscopy holds the promise to advance the understanding of structure and properties in various structural metallic materials. Examples obtained from a variety of programs obtained from a recently acquired system will be shown. Results include studies of ultrafine grained materials, tribology structures, crystal refinement of intermetallic phases, and three-dimension diffraction tomography of metastable phases and precipitates.

2:45 PM
Characterization of Microstructure-Property Relations: Applying Complementary 3D Techniques: *John Bingert*[1]; Matthew Tucker[1]; Robert Suter[2]; Brian Patterson[1]; Cheng Liu[1]; [1]Los Alamos National Laboratory; [2]Carnegie Mellon University

The advancement of non-destructive 3-dimensional (3D) interrogation methods is enabling unprecedented insight into the behavior of polycrystalline materials. For this investigation two complementary techniques were applied to interrogate polycrystals undergoing deformation. First, a novel method of incorporating traditional 2D digital image correlation (DIC), applied to surface and internal planes using micro x-ray computed tomography (XCMT), is combined with electron backscatter diffraction (EBSD) characterization. DIC was used for in situ tracking of local surface strains, while XCMT and EBSD were applied ex situ between interrupted tensile displacements. These combined techniques enabled the measurement of spatially resolved local plasticity and damage evolution on standard-scale test samples. In addition, high-energy diffraction microscopy (HEDM) was used to investigate the effects of shock impact on a sub-size copper polycrystal. Comparisons between the two techniques and their effective application space will be considered.

3:00 PM
Characterization of Open-Pored Metals Using Image Processing: *Bjoern Hinze*[1]; Joachim Roesler[1]; [1]TU Braunschweig

The most important characteristic of open-pored metals are their pores, since they enable all of their functional applications as filters or sound absorbers. Due to the notch effect of the pores, mechanical properties of porous metals are better than the ones of comparable structures made of polymers or ceramics. Consequently, only open-pored metals can be used in aircrafts to reduce flow noise or noise resulting from the core engine by acoustic absorption. Absorption properties depend highly on pore size and porosity of the material, which must be characterized as precisely as possible in order to analyze the correlation between morphology and noise reduction performance. Here, a line segmenting method is explained in order to characterize pore size and porosity of absorber materials using image processing based on two dimensional microscopy images, including sample preparation and specification of the set-up. Then, the influence of the pore structure on the measured absorption behavior is discussed. Demonstrating that the acoustic behavior can be described by pore characteristics and porosity.

3:15 PM
Full-Field Strain Mapping of Woven Structural Composites for Aerospace Applications: *Shahram Amini*[1]; Ellen Sun[1]; [1]United Technologies Research Center

Inadequate understanding of failure mechanisms in woven composite structures obscured by the difficulty of visualizing damage evolution and presence of multiple interacting failure mechanisms has limited their use in critical aerospace applications, such as ceramic-matrix composites for gas turbine engine hot sections. These hindrances are inherently related to the strong influence of the highly heterogeneous and locally anisotropic character of a woven composite material on the distribution of stresses and strains. The technique of surface strain mapping via digital image correlation (DIC) has been recently utilized for resolving the global mechanical behavior and spatial distribution of the strains in complex woven structures. The objective of this research effort is to establish a high fidelity test methodology to perform DIC at various length scales in woven structures targeted for aerospace applications. The results are intended to validate first-principles micromechanics models for systematic approaches to optimal design and tailoring of woven structures.

3:30 PM Break

3:40 PM
Precession Illumination Based Orientation Imaging, Grain Size and Defect Analysis in the Transmission Electron Microscope: *Andreas Kulovits*[1]; Jorg Wiezorek[1]; [1]University of Pittsburgh

We use computer-controlled TEM orientation imaging microscopy (TEM-OIM) to measure grain sizes, orientation distributions, grain-boundary and dislocation character with nanometer resolution. This TEM-OIM involves automated acquisition and indexing of precession illumination diffraction patterns and enables facile analysis of orientation maps akin to those popularized by SEM - EBSD based OIM. The probe size of the TEM instrument determines the lateral resolution of TEM-OIM to ~ 1-2 nm for field emission guns and ~ 15nm for LaB6 guns. Additionally, precession illumination hollow cone dark field imaging has been used for enhanced efficiency grain size measurements even in nanocrystalline aggregates. Finally, precession diffraction based virtual dark field imaging mode introduced for dislocation analysis. Results of orientation and grain size distribution measurements in nanocrystalline Ni and rapidly solidified Al thin films and for Burgers vector analyses in deformed NiAl and TiAl samples will be presented and discussed.

3:55 PM
Micro-Channeled Materials for Acoustic Absorption Applications: *Michael Culler*[1]; Keller Tomassi[1]; Keri Ledford[2]; Jason Nadler[2]; [1]Georgia Institute of Technology; [2]Georgia Tech Research Institute

Micro-channeled materials for acoustical absorption have shown promise for noise attenuation in high performance applications, such as aircraft engines, where demanding design constraints include minimal weight, and tolerance of high-temperature, corrosive environments. A technique for creating micro-channeled materials involves electroless nickel deposition onto polyamide fibers, which are subsequently treated at elevated temperatures to both decompose the polymer and sinter the nickel into a coherent matrix. It is of critical importance to identify heating schedules that both facilitate polymer removal and preserve the material structure. To accomplish this, acceptable heating schedules are identified with thermogravimetric, differential thermal analysis, and dilatometric measurements to ensure sufficient removal of the polymer while maintaining the integrity of the nickel matrix. Once the heat treatment schedule is identified, the process can be applied to 30 mm x 50 mm diameter cylindrical samples currently under investigation.

4:10 PM
Surface Characterization of 19th Century and Modern Daguerreotypes Using EBSD & EDS: *Lisa Chan*[1]; Patrick Ravines[2]; Bob Anderhalt[1]; Rob McElroy[3]; Tara Nylese[1]; Peter Bush[2]; [1]EDAX; [2]SUNY Buffalo State; [3]Archives Studio

Daguerreotype is the first viable imaging process that gave birth to photography and the imaging revolution. Unlike other silver-based black and white photographic processes, daguerreotype is an image that rests on the surface of a silvered copper plate. The gilding step affixes these surface image particles to the plate by coating the surface with a thin gold film. Even though gold is a noble metal, tarnishing readily occurs on the surface of the daguerreotypes. This work presents a study of 19th century and modern contemporary daguerreotypes using EBSD and EDS to examine the metallurgical nature of the silver mercury amalgam image particles and the background surface that was composed of nodules and grains that were tens of nanometers in size. The microstructural, elemental, and crystallographic information observed by EBSD and EDS can potentially explain the occurrence of tarnish as corrosion in the intergranular regions on gilded daguerreotype surfaces.

4:25 PM
Measuring Crystal Elastic Constants Using Ultrafast Laser Generated Surface Acoustic Waves: *Peng Zhao*[1]; Changdong Wei[1]; Ji-Cheng Zhao[1]; [1]Ohio State University

We use a femtosecond pump-probe laser to perform localized measurement of anisotropic elastic constants. A pump laser pulse creates localized surface deformation through laser heating and subsequent thermal expansion. This deformation induces Surface Acoustic Waves (SAW) that propagate on the sample surface. The SAW is then detected by deflection of a probe laser beam several microns away from the pump. By analyzing the group velocity of the SAW propagating in multiple directions, the anisotropic elastic constants were calculated. The pump-probe beam separation can be as small as 7 microns, thus this method can be applicable to samples with a small grain size, e.g. 20 microns. Experimental results on large grain Al and Si and sintered MgB2 samples will be shown. This measurement makes it possible to measure single-crystal elastic properties from a polycrystalline sample.

4:40 PM
Thermography Assisted Fatigue Testing: Anil Saigal[1]; Rongbiao Gu[1]; Christopher San Marchi[2]; *Douglas Matson*[1]; [1]Tufts University; [2]Sandia National Laboratory

Hydrogen is known to cause early failure of certain structural materials as a result of hydrogen embrittlement. As a result most hydrogen-containing vessels - pipes and valves – subjected to cyclic loading have long-term safety concerns. This work aims to explorer the potential use of a thermography-assisted fatigue testing technique to investigate the fatigue properties of materials. 304 stainless steels were found to be strengthened as a result of hydrogen charging and their fatigue life was increased by a factor of 100. The use of thermographic analysis of rotating beam samples as a fatigue test technique is shown to provide repeatable results which are in general independent of test cycle frequency while reducing test times by several orders of magnitude.

Challenges in Constructing Diffusion Mobility Databases for Industrial Alloys: *Carelyn Campbell*[1]; [1]National Institute of Standards and Technology

Expanding the use of CALPHAD-based multicomponent diffusion mobility databases to more complex industrial alloys systems is hindered by the lack of a standard reference database for pure elements and limited data for many ordered and complex intermetallic phases. CALPHAD-based multicomponent databases are developed by combining binary and ternary mobility descriptions. However, when the binary descriptions considered do not use the same reference mobilities, the descriptions cannot be combined to assemble a large multicomponent database. Efforts based at NIST to develop a reference diffusion mobility database will be presented, including an initial set of recommendations for many of the commonly used elements. Using these initial recommendations a diffusion mobility database is developed for processing of the α-$CuInSe_2$ photovoltaic absorber material. The development of this database highlights the challenges of constructing databases with limited data and the importance of understanding the dominate diffusion mechanism when describing the sublattice models for complex phases.

2:25 PM
Computation and Validation of Effective Diffusion Coefficient in a Magnesium Polycrystal: *Bala Radhakrishnan*[1]; Nagraj Kulkarni[1]; Yongho Sohn[1]; Jerry Hunter[1]; [1]Oak Ridge National Laboratory

In tracer diffusion measurements in polycrystalline grain structures the measured diffusion profiles are hard to interpret when they results from a combination of diffusion paths in the bulk and along grain boundary surfaces and triple lines. We simulate the diffusivity in the bulk as well as along various grain boundary and triple line types using a molecular dynamics approach based on computing the mean square displacement of atoms. The computed grain boundary and bulk diffusion coefficients are used as inputs to a mesoscale computation of the diffusion profile in the three-dimensional grain structure. The calculated diffusion profiles are compared with those obtained from tracer diffusion measurements for single crystal and polycrystal magnesium specimens. Research sponsored by the U.S. Department of Energy, Assistant Secretary for Energy Efficiency and Renewable Energy, Office of Vehicle Technologies under Contract No. De-AC05-00OR22725 with Ut-Battelle, LLC.

2:40 PM
Tracer Diffusion Databases – Benefits and Techniques: *Nagraj Kulkarni*[1]; Graeme Murch[2]; Irina Belova[2]; Yongho Sohn[3]; Robert Warmack[1]; Jerry Hunter[4]; Bala Radhakrishnan[1]; [1]Oak Ridge National Laboratory; [2]The University of Newcastle; [3]University of Central Florida; [4]Virginia Polytechnic Institute and State University

Implementation of new initiatives such as the Materials Genome Initiative that seek to accelerate the discovery, development and deployment of advanced materials will require at their foundation robust diffusion databases. The most fundamental descriptor of diffusion is the tracer diffusion coefficient and hence its measurement serves as the basis for the development of tracer diffusion databases. In this presentation, we highlight the wealth of kinetic information provided by tracer diffusion measurements that is applicable to a wide range of materials. We compare and contrast experimental tracer diffusion techniques based on radioactive and stable isotopes. We present some recent results on the use of the stable isotope technique in Mg-alloys that is applicable to the Mg-ICME program. This research was sponsored by the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Vehicle Technologies Program, under contract DE-AC05-00OR22725 with UT-Battelle, LLC.

2:55 PM
Extracting Chemical Diffusion Coefficients from Ternary Diffusion Paths: *Qiaofu Zhang*[1]; Ji-Cheng Zhao[1]; [1]The Ohio State University

Two intersecting diffusion paths are usually needed to calculate the four interdiffusion coefficients at the crossover composition in a ternary system using classical diffusivity extraction methods such as the Boltzmann-Matano analysis and the extended Saur-Freise analysis. Such analyses are very inefficient since they require data from lots of diffusion couples to construct a diffusivity database for a ternary system. The zero flux method by Dayananda and Sohn and the simulation method by Bouchet allow extraction of diffusion coefficients along one diffusion path, thus, they are more efficient. These diffusivity extraction methods are applied to several ternary systems such as Fe-Ni-Co and Ni-Al-Pt to check their reliability against the classical methods. Built upon Bouchet's analysis, an improved simulation method is developed by combining an optimizing scheme with a finite difference method. A MatLab program is developed to extract diffusion coefficients along a single diffusion path using this method.

3:10 PM
Solute Diffusion in Ordered Bulk Ni3Al: A First Principles Investigation: *Priya Gopal*[1]; Srinivasan Srivilliputhur[1]; [1]University of North Texas, Denton

Ni-based superalloys possess desirable high-temperature properties including ductility, fracture toughness as well as resistance to creep and oxidation. The key factor in these properties is due to the precipitation of ordered gamma' precipitated within a gamma Ni matrix. Extensive studies in this area have shown that the mechanical properties can be improved by adding substitutional elements. It is thus very important to understand the electronic structure and diffusion kinetics of the substitutional elements and the role each one has on the overall microstructure. In this talk, we discuss our results on the systematic study of the energetics and migration barriers of solute additions (Cr, Co) in ordered Ni3Al. Using density functional theory methods and the nudged elastic band method we simulated the migration of vacancy and substitutional elements in a complete set of migration paths and evaluated the barriers in bulk Ni3Al.

Interstitial and Substitutional Solid-State Diffusion from First Principles: *Anton Van der Ven*[1]; [1]University of Michigan

Solid-state diffusion can become quite complex at the atomic scale in technologically important materials. This is especially true in multi-component solids at non-dilute concentrations where varying degrees of short and long-range order often play a crucial role in determining atomic mobility. First-principles statistical mechanical tools are proving invaluable in elucidating and enabling the prediction of phenomenological transport coefficients for interstitial and substitutional diffusion in metals and alloys for structural applications as well as ceramics for energy storage applications. In this talk I will review the methodology that allows us to link atomic scale kinetic processes to macroscopic transport coefficients and will illustrate its application to a variety of important technological problems including oxidation, interdiffusion in alloys and interstitial Li transport in electrodes for Li batteries.

4:15 PM
Ab Initio Determination of Point Defects and Derived Diffusion Properties in Metals: *Tilmann Hickel*[1]; [1]Max-Planck-Institut fuer Eisenforschung GmbH

The accurate simulation of atomistic defects is crucial for various thermodynamic and kinetic effects in materials science. A key quantity for all practical applications is their formation energy. Once known, the equilibrium defect concentration as function of process conditions such as temperature, chemical potentials etc. can be predicted. In particular, the formation energy and concentration of vacancies decisively influences diffusion processes in metals and can also affect the solubility and diffusion of interstitial atoms such as hydrogen. In this contribution, we will therefore apply our highly accurate ab initio methods for free energies to vacancies. We will demonstrate that including all relevant free energy contributions yields an highly non-linear temperature dependence, resulting in substantial deviations between low and high temperature results. Further, we have derived analytic expressions for vacancy concentrations using thermodynamics concepts and taking particularly care of the correct consideration of chemical potentials. These methods will be applied to explain the exceptionally high vacancy concentration in FeAl intermetallic alloys and the exciting effect of superabundant vacancies in steels. Finally, the results will be used to determine the dominating self-diffusion mechanism in the B2 phase of FeAl.

4:30 PM
Diffusion of Silicon in Nickel: The Role of Stress and Its Implications to Microstructural Evolution under Irradiation: *Venkateswara Rao Manga*[1]; Pascal Bellon[1]; Robert Averback[1]; Dallas Trinkle[1]; [1]University of Illinois at Urbana Champaign

Understanding the microstructural evolution of irradiated materials requires the knowledge of transportation mechanisms of various types of point defects, their coupling to solute atoms and their interaction with sinks. In this talk we report the ab initio investigation of diffusion in a model system- Si in Ni- at dilute concentrations under the influence of stress by two different mechanisms: 1.Vacancy-mediated and 2.Interstitial. We start by presenting the effect of uniaxial-stress on the migration barriers and energetics of the point-defect complexes of Si in Ni. Migration barriers of 1.1eV and 0.94eV are calculated for vacancy-mediated jumps of host-atom and Si in Ni, respectively, with no stress. Diffusion coefficients are calculated using the Continuous-time random-walk formalism and a multi-frequency model. The anisotropy in the diffusion and the relative contribution of the above mechanisms under stress are computed and the implications of these findings to the microstructural evolution under irradiation are discussed.

4:45 PM
Ab-Initio Calculations of Solute Properties in Magnesium: *Liam Huber*[1]; Ilya Elfimov[1]; Joerg Rottler[1]; Matthias Militzer[1]; [1]University of British Columbia

Using density functional theory in the Vienna Ab-initio Simulation Package, we have calculated various properties for Mg-solute interactions on the atomic scale. Using supercells of bulk Mg with site defects we have found solute-vacancy binding energies, migration barriers for site-hopping, and activation energies for vacancy-mediated diffusion. Where experimental data is available we have compared our values and find that our calculations tend to reproduce the same qualitative trends in activation energy. We have also performed solute-grain boundary (GB) binding energy calculations for a variety of solutes using a special near \931 7 GB. We find that the solutes investigated fall into two families, each sharing the same pattern of binding energies along GB sites. Interestingly, solutes which are known to have a beneficial effect on texture (e.g. Ca, La, Nd) belong to one family while other solutes (e.g. Al, Zn, Ag) belong to the other.

5:00 PM
Accelerated Self-Diffusion in FCC Metals Due to H Induced Superabundant Vacancies: *Roman Nazarov*[1]; Tilmann Hickel[1]; Jörg Neugebauer[1]; [1]Max Planck Institute for Iron Research

A dramatic increase of the vacancy concentration in an H-rich atmosphere, the so called superabundant vacancy formation, has been experimentally observed in several metals and alloys. In order to study this phenomenon we systematically applied density functional theory to a large set of fcc metals and found that a large amount of H can be trapped by a monovacancy. Based on the defect formation energies from DFT calculations, we have constructed a thermodynamic model and revealed that the vacancy concentration can indeed strongly increase at sufficiently high H concentrations. To understand the phenomenon of accelerated self-diffusion in an H-rich atmosphere we coupled the information on the number of vacancies from the thermodynamic treatment with self-diffusion barriers obtained from DFT calculations. Using this approach we find that the self-diffusion coefficient is reduced not only due to the increased vacancy concentration, but also as a result of an H-induced lubricant effect.

5:15 PM
Oxygen-Solute Interaction in α-Titanium and the Effect on Diffusion: *Henry Wu*[1]; Dallas Trinkle[1]; [1]University of Illinois at Urbana-Champaign

The transport of oxygen in titanium affects the design of high temperature alloys as well as the growth of layered-oxide phases. It has been found that oxygen resides in three distinct interstitial sites in α-titanium: octahedral, hexahedral, and non-basal crowdion. Oxygen diffuses between all three interstitial sites with similar rates such that all transition pathways contribute to diffusion. We compute the interaction energy between oxygen and the alkali, alkaline earth, and transition metals. The octahedral neighbor site is repulsive for almost all solutes and becomes more repulsive with more d-filling. The closer neighbors for the hexahedral and crowdion are correlated for solutes whose interactions form V-shaped curves with dips near half d-filling. The further neighbors for the hexahedral and crowdion are similarly correlated though most solutes at this neighbor site destabilize the crowdion interstitial. We calculate change to oxygen diffusion from solutes, and compare with interaction energy trends.

A Phase Field Crystal Model of Irradiation Damage in Materials: *Nana Ofori-Opoku*[1]; Jeffrey Hoyt[1]; Nikolas Provatas[1]; [1]McMaster University

The study of the effects of radiation damage in materials, along with the scientific interest, is also widely of practical relevance as it pertains to the design of future nuclear reactors. Recently, it has been suggested that nanocrystalline materials offer markable resistance to radiation damage. To investigate this claim, we introduce a phase field crystal (PFC) model that includes effects of radiation damage. The ability of the PFC methodology to describe atomistic scale effects on diffusive time scales, makes it an appropriate tool to study the microstructure evolution of nanocrystalline materials under radiation over long length scales. The model is used to study grain growth under radiation damage, and indeed it is found that there is enhanced grain growth of nanocrystalline materials under radiation. This suggests that, although offering some resistance to radiation damage, nanocrystalline materials may not remain nanocrystalline over time.

Simulating Microstructure Property Relations in Shape Memory Polycrystals: *Rajeev Ahluwalia*[1]; Siu Sin Quek[1]; Wu David[1]; [1]Institute of High Performance Computing

Materials undergoing diffusion-less martensitic transformations display many unusual mechanical properties such as the shape memory effect. The underlying twinned microstructure critically influences the mechanical behavior. Most technological applications make use of polycrystalline alloys. An important issue is to find the optimal microstructure that will enhance the effective properties of the shape memory alloy. This requires the role of quantities such as the mean grain size, grain size distribution and orientation distribution. To study these issues, we use a Ginzburg-Landau theory for shape memory polycrystals that couples elastic strains with crystallographic orientations. The underlying polycrystal is generated by using nucleation and growth models which allow us to control properties such as the mean grain size and the size distribution. We study how the microstructure and effective stress strain curves depend on the underlying polycrystalline texture and show how such models may be used to design microstructures which give enhanced properties.

2:30 PM
Complex Microstructures Formed in ã+ß/ã+ã´ Diffusion Couples in Ni-Al-Cr System: Comparison of Phase Field Simulation from a Model System with Experiments: *Xiaoqin Ke*[1]; John Morral[1]; Yunzhi Wang[1]; [1]Ohio State University

Some γ+ß/γ+γ´diffusion couples in Ni-Al-Cr system show very complex microstructures such as γ+ß<γ>γ+ß>γ´>γ+γ´ (> and < represent the direction of boundary movement) after interdiffusion at high temperatures. Such microstructure change is difficult to understand or predict by analytical solutions and DICTRA simulations, but is critical for the prediction of coating life. In this work phase field method is used to simulate γ+ß/γ+γ´diffusion couples prepared from a model A-B-C system. All kinds of complex microstructures found in experiments have been obtained by the simulations. Moreover, the relationship between the kinds of microstructure formed and the change of initial end alloy compositions identified from the simulations qualitatively matches the experimental observations. An analysis of the diffusion paths based on eigenvectors of effective diffusivities of the initial end alloys will also be provided.

2:45 PM
Phase Field Simulations of Electromigration Driven Failure in SnAgCu Solder Interconnects: *Subramanya Sadasiva*[1]; Ganesh Subbarayan-Shastri[1]; Lei Jiang[2]; Daniel Pantuso[2]; Sandeep Sane[2]; [1]Purdue University; [2]Intel Corporation

The miniaturization of electronics has led to a significant increase in the current densities seen in solder interconnects. This has led to an increase in the importance of electromigration and stress-migration and other diffusion driven mechanisms for failure in solder interconnects. Concurrently, the shift from eutectic PbSn solders to SnAgCu solders, owing to environmental concerns has necessitated dealing with a more complex material system. In this study , we derive a model for the electromigration and stress-migration driven failure in SnAgCu alloys using a multiphase field model. Following the Truesdell-Toupin formalism, governing equations are derived from the conservation of mass and energy. Further, we derive the linear constitutive laws for the system based on the second law of thermodynamics. Finally, we demonstrate a numerical implementation of this model using finite elements. We use the finite element implementation to simulate the void growth and coalescence under forward and reversed current conditions.

3:00 PM
Elastic Effects on Aging in Cu/Sn-Ag-Cu Lead-Free Solder Joints: A Phase-Field Study: *Durga Ananthanarayanan*[1]; Patrick Wollants[1]; Nele Moelans[1]; [1]Department of Metallurgy and Materials Engineering, Katholieke Universiteit Leuven

Sn-Ag-Cu lead-free solders are the most widely studied alternatives to Sn-Pb solder. Despite many desirable properties, the growth of intermetallic compounds Cu_3Sn, Cu_6Sn_5 and Ag_3Sn, leading to crack initiation, remains a major reliability issue. In the present work, the effects of coherency strains on the phase equilibria and aging process in Cu/Sn-Cu and Cu/Sn-Ag-Cu solder joints are simulated using the phase-field technique. The COST 531 thermodynamic database for lead-free solders, developed using the CALPHAD method, is coupled with the phase-field model. Chemical mobilities, elastic constants and lattice parameters for all phases in the system are estimated based on available data in the literature. 2-D simulations at different temperatures and for different distributions of intermetallic phases are performed. The conditions influencing the coarsening of the intermetallic phases and its implications on the stress evolution for both the systems are evaluated.

3:15 PM
Phase-Field Crystal Modeling of Metal-on-Metal Epitaxy: Exploring Routes to Self-Organization: *Srevatsan Muralidharan*[1]; Raika Khodadad[1]; Ethan Sullivan[1]; Mikko Haataja[1]; [1]Princeton University

Bulk-immiscible binary systems often form stress-induced miscible alloy phases when deposited on a substrate. Both alloying and surface dislocation formation lead to the decrease of the elastic strain energy, and the competition between these two strain-relaxation mechanisms leads to the emergence of compositional nanoscale domains. We develop a quantitative phase-field crystal model for compositional domain formation of binary metallic systems and investigate the cases of partial, single and multi-layer thin film systems deposited on both regular and quasi-crystalline substrates. Our results demonstrate that the presence of misfit stresses and/or dislocations in the underlying layers guides the nucleation and growth of additional layers as well as the controls the spatial organization of compositional domains within layers.

4:00 PM
Numerical Modeling of Dendritic Growth During Solidification of Alloys Using Lattice Boltzmann and Cellular Automaton Methods: *Mohsen Eshraghi*[1]; Sergio Felicelli[1]; [1]Mississippi State University

A numerical model combining lattice Boltzmann (LB) and cellular automaton (CA) methods is developed to simulate solute-driven dendritic growth in three dimensions. While LB is used to calculatethe transport phenomenon, CA is used to capture the solid/liquid interface. The effect of undercooling and degree of anisotropy on kinetics of dendrite growth is studied. Considering the special characteristics of LB and CA methods, the presented model can be considered as an interesting tool for simulation of dendritic solidification in three dimensions.

4:15 PM
Phase-Field Simulation of Segregation to Stacking Fault and Twin Boundaries in Co-Based Alloys
: *Yuichiro Koizumi*[1]; Sho Suzuki[1]; Takuma Ohtomo[1]; Shingo Kurosu[1]; Yungping Li[1]; Hiroaki Matsumoto[1]; Akihiko Chiba[1]; [1]Tohoku University

Co-based alloys such as Co-Cr-Mo alloy and Co–Ni-based superalloy are widely used for industrial and biomedical applications. Their mechanical properties are closely related to the stability of HCP-structure and FCC-structure. In Co-Cr-Mo alloys, strain induced epsilon-HCP-phase improves wear resistance [1]. Co-Ni-based superalloys with relatively high FCC-phase stability exhibit high ductility by dislocation slip [2]. Atomistically, local HCP-structures in FCC-matrix, i.e. twin boundaries and stacking faults with ABAB-type stacking embedded in ABCABC-type stacking of FCC-structure, is important for the above-mentioned mechanical properties. The phase-stability at the local-HCP structures can be significantly affected by segregation of solute atoms. In this study, a phase-field simulation of segregation to the local HCP-structures has been developed and applied to a Co-Cr-Mo alloy and a Co-Ni based superalloy. The simulation indicated that segregation behaviors in the two alloys are quite different. [1]Chiba et al. Acta Materialia 2007;55:1309. [2]Chiba et al. Philos Mag A 1999;79:1533.

4:30 PM
A Hybrid Phase-Field / Transmission Electron Microscopy Approach for Quantifying θ ’ Precipitation Kinetics in Cast Al-Si-Cu Alloys: *Junsheng Wang*[1]; Ruijie Zhang[2]; William Donlon[1]; Mei Li[1]; Long-Qing Chen[3]; John Allison[4]; [1]Ford Motor Company; [2]University of Science and Technology Beijing; [3]Penn State University; [4]University of Michigan

A hybrid phase-field / transmission electron microscopy (TEM) approach has been developed to quantify the evolution of θ ’ precipitates in cast 319 aluminum-type alloys. A three dimensional phase-field model was developed to simulate θ ’ nucleation and growth in ternary Al-Si-Cu alloys. For the nucleation model, we implemented the rate function using classical nucleation theory. The activation energy and number density of precipitate nuclei were estimated using targeted, quantitative TEM. For the growth kinetics, we modeled the diameter and thickness increase of the anisotropic θ ’ plates using experimentally validated mobility coefficients, and chemical free energy and diffusion coefficients from ThermoCalc and Dictra. The model can quantitatively predict θ ’ particle size distribution as a function of Cu content, aging temperature and time. This model in conjunction with the yield strength model can be used to predict the mechanical properties for cast powertrain components made of A319 aluminum alloys.

4:45 PM
Antiphase Boundaries in Rafted Structures: Experimental Investigation and Phase Field Modeling: *Yann Le Bouar*[1]; Adèle Lyprendi[1]; Alphonse Finel[1]; Jean-Sébastien Mérot[1]; Loïc Patout[1]; François Brisset[2]; [1]LEM, CNRS/ONERA; [2]ICMMO, Université Paris-Sud

During creep loading, the initial microstructure of Ni-base superalloys, made of cuboidal ordered precipitates in a disordered matrix, evolves towards a rafted structure. This evolution is the result of elastic and plastic driving forces, which tend to move precipitates closer to each other along a given direction. When two precipitates meet, they may either coalesce or form an interfacial defect called antiphase boundary (APB). However, plastic activity in the matrix phase is able to remove the APBs, and the question is open whether, under given temperature and stress conditions, APB can still be observed in the rafted structure. We first investigate the existence of APBs in the rafted structure of the CMSX2 superalloy using both scanning and transmission microscopy. Then, a phase field model is developed to account for the large energy difference between the APBs and the precipitate matrix interface.

5:00 PM
Modeling the Kinetics of Diffusive Phase Transformations -Phase Field Method and Thick Interface Model: *Ernst Gamsjäger*[1]; Jiri Svoboda[2]; Franz Dieter Fischer[1]; [1]Montanuniversität Leoben; [2]Academy of Sciences

In the framework of a recently developed thick interface model the time dependent development of the variables during diffusive phase transformations were calculated by solving the evolution equations. Alternatively, the transformation kinetics can be determined by means of the phase field method (PFM), where an order parameter on a fixed grid indicates the position of the interface as well as the correspondence to the individual phases. Both, the evolution equations for the variables occurring in the thick interface model and the evolution equation of the order parameter can be derived from the thermodynamic extremal principle (TEP). The comparison of the TEP-based thick interface model and the phase field model allows evaluating the PFM results and their relations to the standard thermodynamic parameters. As an example the kinetics of the austenite-to-ferrite transformation in the Fe-Ni system is investigated.

5:15 PM
Morphological Study of Polymer Crystallization by a Phase-Field Model: *Mohsen Asle Zaeem*[1]; Sasan Nouranian[1]; Mark Horstemeyer[1]; Paul Wang[1]; [1]Mississippi State University

A phase-field model was used to study crystal growth in semicrystalline polymers with various crystal morphologies. The original Kobayashi’s phase-field model for solidification of pure metals was adopted to account for polymer crystallization. Evolution of a non-conserved phase-field variable was considered to track the interface between the melt and the crystalline phases. A local free energy density was used to account for the meta-stable states in polymer solidification. The coupled governing evolution equations of the temperature and phase-field variable were solved using a finite element method. The developed model was successfully applied for simulation of two-dimensional polymer single- and polycrystalline morphologies (rectangular, orthorhombic, hexagonal, and spherulitic) in polypropylene and polystyrene. These morphologies were compared based on different supercooling and interface anisotropy. The unique aspect of this work is that the employed model is capable of simulating multiple arbitrarily-oriented crystals and has no limitations with respect to the crystal morphology.

Defects and Properties of Cast Metals: Solidification Structure and Segregation

2:00 PM
A Multi-Scale 3D Model of the Vacuum Arc Remelting Process: *Koulis Pericleous*[1]; Georgi Djambazov[1]; Mark Ward[2]; Yuan Lang[3]; Peter Lee[4]; [1]University of Greenwich; [2]University of Birmingham; [3]Imperial College; [4]University of Manchester

A multi-scale model of the VAR process was developed to simulate unsteady phenomena within the ingot melt pool due to arc motion and resulting effects on dendritic microstructure. External magnetic field and surface current measurements were used as boundary conditions, to determine the trajectory of the arcs between electrode and ingot and between ingot and sidewalls. The interactions between magnetic field, turbulent metal flow and heat transfer were modelled using CFD techniques and this “macro” model was linked to a micro model, to resolve the evolving dendritic microstructure, and establish a relationship between operational parameters and microstructure defects. Arc-driven solute convection in the mushy zone led to local remelting and changes in local Rayleigh number provided an indicator of when fluid flow channels (freckles) will initiate within the mushy zone. Particle tracking was further used, to characterise the trajectory and dissolution of inclusions entering the melt, causing “white spot” defects.

2:20 PM
Deterministic Origin of Dendritic Side-Branching: *Martin Glicksman*[1]; [1]Florida Institute of Technology

Conventional dendritic growth theories are based on stochastic instabilities driven by ‘selective amplification’ of environmental noise. Quantitative experiments, however, fail to support these theories, verifying only Ivantsov’s conduction/diffusion analysis of the normal component of the transport fluxes. The transport field’s tangential component along the solid-liquid interface is ignored--save for its limited use as a capillary boundary condition. Treating the Gibbs-Thomson-Herring equilibrium temperature distribution as a real tangential field, with its associated gradients, fluxes, and divergences, then adding negative feedback responses via the LeChatelier-Braun principle, shows that a heretofore unknown dipolar rotation occurs locally on the interface. This rotation ‘wrinkles’ the interface, and leads to prompt side-branching. Moreover, the interface dipoles interact deterministically with the evolving crystal shape to produce an eigenfrequency that produces the classical dendritic structures in metals and alloys.

2:40 PM
Identification of Defect Prone Peritectic Steel Grades by Analyzing the High Temperature Phase Transformations: *Peter Presoly*[1]; Robert Pierer[1]; Christian Bernhard[1]; [1]Montanuniversitaet Leoben

Continuous casting of peritectic steels is often difficult and critical; bad surface quality, cracks and even breakouts may occur. Particularly, the initial solidification of peritectic steels within the mold leads to formation of surface depressions and uneven shell growth. As commercial steels are always multi-component alloys, it is necessary to take into account also the influence of alloying elements besides carbon on the peritectic phase transition. Especially for new steel grades with high Mn, Si and Al contents, there is a lack of information regarding the solidification sequence and the phase diagrams for initial solidification. Based on a comprehensive method development, the present study shows that high precious Differental Scanning Calorimetry (DSC) measurements allow a clear prediction whether an alloy is peritectic (i.e. critical to cast) or not.

3:00 PM
Effect of Deformation on Microsegregation in Cast Structure of Bearing Steel: *Mitra Basirat*[1]; Hasse Fredriksson[1]; [1]KTH, Royal Institute of Technology

Microsegregation changes in the cast structure of a five-ton ingot of ball bearing steel were investigated by a series of hot compression tests. Cylindrical specimens were deformed at a temperature range of 800°C to 900°C and strain rates of 0.5 s-1. Samples were quenched after the compression in order to eliminate the homogenization time. Subsequently they were analysed with the aid of Electron Microprobe Analysis (EMPA) in order to investigate the effect of hot compression on microsegregation of Mo, Cr, Mn and Si. It was found that highly segregated regions are regions for formation of deformation bands. It seems that the degree of microsegregation increases by increasing the deformation. An attempt was made to estimate the diffusion coefficients of alloying elements during the deformation process. The increase of microsegregation during deformation is explained by tendency for uphill diffusion.

3:20 PM
Effects of Section Size And Cooling Rate on Microstructure and As-Cast Properties of Investment Cast CO-CR Biomedical Alloy: *Ruth Kaiser*[1]; David Browne[1]; Kenny Williamson[2]; Claire O'Brien[2]; [1]University College Dublin; [2]DePuy (Ireland)

ASTM F75, a biomedical grade cobalt alloy, is often used in orthopaedic implants, manufactured using investment casting methods. Quality of the cast medical implants is paramount, defects such as porosity, inclusions or misrun are not tolerated and similarly the mechanical properties have to conform to predetermined standards. It is recognised that casting conditions have an effect on the as-cast properties of materials and that a highly controlled and optimised process can help limit defects and optimise properties. The objective of this work was to determine the effect of casting conditions such as melt and mould preheat temperatures and section size, on the microstructural characteristics and resultant mechanical properties of the alloy investigated. This was done by conducting a series of instrumented control experiments involving solidification of the alloy in typical investment shell moulds, characterisation of the as-cast micro/macro-structure, and a programme of mechanical testing. Any defects observed are also reported.

3:40 PM Break

4:00 PM
The Influence of Cu on Eutectic Nucleation and Morphology in Hypoeutectic Al-Si Alloys: *Anilajaram Darlapudi*[1]; [1]University of Queensland

The influence of increasing additions of copper on the aluminium silicon eutectic morphology and nucleation was investigated in Sr-modified and unmodified Al-10wt%Si alloys. In unmodified alloys, increase in copper content resulted in an increase in the number of polyhedral silicon particles and thus nucleation frequency of eutectic cells. In Sr modified alloys, additions of copper resulted in an increase in the nucleation frequency of eutectic cells. Also, at high copper levels in modified alloys, a change in the eutectic interface morphology from near-planar to coral-like was observed. These observations are important as in in-situ observations of eutectic solidification in Al-Si alloys, high amounts of copper is added in order to generate contrast between the solid and the liquid.

4:20 PM
Molecular-Dynamics Simulations of NI-Based Superalloys: *Christopher Woodward*[1]; James Lill[2]; Dallas Trinkle[3]; Mark Asta[4]; [1]Air Force Research Laboratory; [2]High Performance Technologies Inc.; [3]University of Illinois; [4]University of California

Convective instabilities responsible for misoriented grains (freckle defects) in directionally solidified turbine airfoils are produced by variations in liquid–metal density with composition and temperature across the solidification zone. Accurate prediction of freckle formation is prerequisite for improving production and properties of large scale turbine airfoils used for terrestrial energy production and high-performance aerospace applications. Fundamental properties of molten Ni-based alloys, required for modeling these instabilities, are calculated using ab initio molecular dynamics simulations. Initial calculations of elemental, binary and ternary alloys produce liquid-phase molar volumes (V(c,T)) within 0.6-1.8% of available experimental data. Liquid metal densities for a Ni based superalloy, RENE-N4, are calculated at the liquidus and solidus temperatures expected in the solidification zone. Results are compared with recently published parameterizations of V(c,T) developed using binary experimental data from a narrow range of compositions. Predictions for possible liquid metal density inversions, the precursors for freckle defect formation, are presented.

4:40 PM
Microstructure and Microsegregation in Inconel 718 Casting: *Alexis Pautrat*[1]; [1]Mines Paristech

The superalloy Inconel 718 is used in parts of the main engine turbopump of the Ariane 5 launcher. The forming process for most of these parts is investment casting. The present study focuses on the conditions for the formation of fragile phases such as Laves. Samples were cast under vacuum at various superheat and cooling rate. Detailed analyses of the microstructures by scanning electron microscopy including automatic indexing of electron back scattered diffraction patterns and energy dispersed spectrometry were used to quantify the volume fraction and composition of primary gamma, NbC, Laves and Delta phases. Besides, a complete numerical simulation of the casting process is developed to identify the solidification and cooling path for each sample. This information will be used for the assessment of a microsegregation model taking into account thermodynamic equilibrium, cooling rate and microstructure parameters.

5:00 PM
Numerical Simulation on Solidification Microstructure of Cast Steel Using Cellular Automaton Method: Bin Su[1]; *Zhiqiang Han*[1]; Baicheng Liu[1]; Yongrang Zhao[2]; Bingzhen Shen[2]; Lianzhen Zhang[2]; [1]Tsinghua University; [2]CITIC Heavy Industries Co., Ltd.

A cellular automaton model has been developed to simulate the microstructure evolution of ASTM A216 WCA cast steel during solidification and consequent cooling processes. In the model, the thermodynamics and solute diffusion of the multicomponent system were taken into account by using Thermo-Calc and Dictra software. The peritectic solidification, a-ferrite/austenite transition and eutectoid transformation as well as the final microstructure can be predicted. To validate the model, a sand mold step-shaped casting was produced and metallographic examination was carried out, in which the percentage and the grain size of proeutectoid ferrite were measured by using optical microscopy, and the mean interlamellar spacing of pearlite was measured by using SEM. It was shown that the simulated results are in good agreement with the experimental results.

5:20 PM
Microstructure Simulation in Pressurized Solidification during Squeeze Casting of Aluminum Alloy A356: Yanda Li[1]; *Zhiqiang Han*[1]; Alan Luo[2]; Anil Sachdev[2]; Baicheng Liu[1]; [1]Tsinghua University; [2]General Motors Global Research and Development Center

A mathematical model for describing the nucleation and dendrite growth in pressurized solidification during squeeze casting of aluminum alloy has been developed, where the thermal and mechanical dual effect on the nucleation in pressurized solidification was taken into account. Cellular Automaton method was employed to simulate the dendrite growth during the squeeze casting process, where the solid-liquid interface growth kinetics was determined based on the interfacial equilibrium, i.e. the relationship of temperature, pressure, composition and interfacial tension. Experiments were carried out for an industrial aluminum alloy A356, where direct squeeze casting process was employed and specimens were produced under the atmospheric pressure and the pressures of 27, 82 and 123 MPa. The nucleation and dendrite growth were simulated with the developed model and the effect of pressure on the microstructure evolution of the casting was discussed based on the numerical simulation.

5:40 PM

Modeling of Melt Mixing Phenomena in Cast Iron with Dual Graphite Structure: Simon Lekakh[1]; *Jingjing Qing*[1]; Von Richards[1]; [1]Missouri University of Science and Technology

Cast iron castings with dual layered structure including flake and spheroidal graphite phases have an interesting combination of high thermal conductivity and strength. Processing for production of controlled dual graphite cast structure in desired casting regions was CFD FLUENT modeled and experimentally investigated. It was shown that the melt mixing phenomena, which includes filling mixing, mixing by post-filling melt momentum and natural convection, prevents the formation of the desired layered microstructure when the mold was sequentially filled by gray and ductile irons. To prevent intensive melt mixing in the mold, different approaches were virtually investigated. The modeling results were validated by pouring experimental castings and different possible processing routes are discussed.

Deformation, Damage, and Fracture of Light Metals and Alloys: Session III

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS Light Metals Division, TMS/ASM: Mechanical Behavior of Materials Committee

2:00 PM Invited

Materials Design in Magnesium Alloy Development: *Michele Manuel*[1]; [1]University of Florida

Magnesium alloys have attracted great interest due to their high specific strength, castability, and machinability. Despite these advantages, this class of alloys has not received the industrial prominence as their main structural counterpart, aluminum. One obstacle that has limited their use is its restricted low temperature deformation behavior. Recently, there has been a significant effort to integrate computational tools to not only provide a fundamental understanding of unit mechanisms but also drive the design of novel alloys that are stronger and more ductile than current alloys. This presentation will provide insight into the status of materials design tools in its application to magnesium alloy development as well as provide forecasts as to the potential of systems-based, predictive design methodologies in accelerating the maturation of this class of materials. The author would like to gratefully acknowledge the support of the National Science Foundation under grant DMR 0845868.

2:30 PM

The Shear Localization Behavior and Mechansims of Five Light Metals: Al 7039, Al 5083, Al 5059, AZ31B, and AM60: Sara Perez-Bergquist[1]; George Gray[1]; *Ellen Cerreta*[1]; Carl Trujillo[1]; Mike Lopez[1]; [1]Los Alamos National Laboratory

While a great number of studies have examined the uni-axial stress behavior of light metals under quasi-static loading conditions, less is known about the dynamic response and particularly the shear failure mechanisms, of these same metals. For this reason, the forced shear response of five light metals has been examined as a function of temperature, texture, and strain rate. Specimens of Al 7039, Al 5083, Al 5059, AZ31B, and AM60, have been characterized prior to deformation. Then post mortem characterization of these specimens, using optical microscopy, scanning electron microscopy, electron back scattered diffraction, and transmission electron microscopy, has been utilized to correlate the observed mechanical response to the microstructural evolution during loading that leads to damage and failure of these materials.

2:45 PM

Reducing Forming Time in Warm Forming of Lightweight Metals by Using Variable Forming Speed: *Serhat Kaya*[1]; [1]The Ohio State University

Reducing weight by forming lightweight metals is in the interest of industry. Isothermal warm forming approach has been studied by researchers. In this study, an experimental non-isothermal warm forming setup is used in a servo-drive press. Combined advantages of the non-isothermal approach and the servo press are demonstrated by introducing a critical stroke and a variable forming speed concept (slower at initial stages of drawing and faster afterwards). As a result, total forming time of a round cup has been reduced by 60 % (from 9sec to 3.4sec) with respect to a constant forming speed (9 sec). More importantly, while forming time is reduced significantly, thickness distributions of the cups formed in 3.4 seconds and 9 seconds were very close. It is known that as the forming speed increases the tendency for thinning and fracture also increases. Therefore, this new approach provided a faster process without sacrifice in thickness.

3:00 PM

Influence of Size on Strength of Nickel Nanowires: *Ilaksh Adlakha*[1]; Kiran Solanki[2]; Amitava Moitra[3]; Mark Tschopp[4]; [1]SEMTE; [2]Arizona State University; [3]Pennsylvania State University; [4]Mississippi State University

Plastic deformation of nanoscale material is highly dependent on the surface- to- volume ratio. In this work, we use molecular dynamics simulations to gain understand the size scale effect under tensile deformation in single crystal and polycrystalline nickel nanowires. Nanowires exhibit an increase in yield strength as the surface to volume ratios, breakdown in this mechanism for samples less than 10nm diameter; due to the rearrangement of surface atoms in smaller samples having high surface-to-volume ratio. In polycrystalline nanowires, the high surface-to-volume ratios the effect of dislocation mediated plasticity to decreases at smaller wire sizes. For smaller grain sizes, plasticity is accommodated through intergranular mechanisms. These results provide insight into the deformation mechanisms in single and polycrystalline nanowires.

3:15 PM

Deformation Twinning Activation of TI-6AL-4V under Different Loading Conditions: *Ming Chu*[1]; Jeremy Millett[2]; Yu Chiu[1]; Ian Jones[1]; [1]University of Birmingham; [2]AWE

Ti6Al4V is the most widespread of titanium alloys and finds use in the aerospace industry in the manufacture of fan blades in jet turbine engines. As such, an understanding of its response to impact loading such as bird strike and foreign object damage is of great importance. In this research, Ti6Al4V has been deformed by means of one-dimensional plate impact to stresses of 5 GPa and 10 GPa. The deformation of Ti6Al4V with a large colony size has also been studied using a Charpy impact tester with impact energy varying from 10J to 300J at both liquid nitrogen temperature and room temperature. The deformation microstructure has been observed using transmission electron microscopy in all specimens tested. In addition to the TEM observations, the nature of twinning and dislocation slip and their roles in the deformation will be discussed vis-à-vis the literature on the plastic deformation of the alloy.

3:30 PM Break

3:50 PM Invited
Mechanical Properties of Bulk Nanostructured 7075 Al Alloy Prepared by Severe Plastic Deformation: *Yonghao Zhao*[1]; X.Z. Liao[2]; T.D. Topping[3]; Y. Li[1]; Y.T. Zhu[4]; R. Z. Valiev[5]; E.J. Lavernia[1]; [1]University of California Davis; [2]University of Sydney, Australia; [3]University of California, Davis,; [4]North Carolina State University, Raleigh; [5]Ufa State Aviation Technical University, Russia

Age-hardened 7000 series Al alloys exhibit the highest strength amongst Al alloys and therefore are of interest in the aerospace, transportation, and sports industries. Grain refinement down to the nanometer region by severe plastic deformation is a promising technique for further enhancing the strength of structural Al alloys. However, precisely how to optimize the mechanical properties (such as strength and ductility) of bulk nanostructured aged hardened Al alloys remains a challenge. In this study, the as-received 7075 Al alloys were first homogenized at 500°C for 5 h to form super saturated solid solution, then processed by equal-channel-angular pressing (ECAP), cryo-rolling and high pressure torsion (HPT) techniques, respectively, to form microstructures with different grain sizes ranging from nanometer to micrometer. Post-deformation aging treatments were then performed to introduce GP zones, metastable /stable yita phases. Precipitation kinetics and responding mechanical properties were finally measured and analyzed.

4:20 PM
1100 Aluminum under Quasi-Static and Dynamic Loading: *Cyril Williams*[1]; Guangli Hu[2]; Changqiang Chen[2]; Kaliat Ramesh[2]; Datta Dandekar[1]; [1]U.S. Army Research Laboratory; [2]The Johns Hopkins University

In this study, as received 1100-O aluminum was cold rolled to 30, 70, and 80 percent reduction. The effects of microstructural evolution due to the cold rolling are studied under quasi-static and dynamic loading conditions using a servo-hydraulic MTS machine and a compression Kolsky bar, respectively. Significant rate sensitivity of the compressive strength was observed for strain rates from 10^3 s-1 to $6x10^3$ s-1 for all materials. As the cold work is increased from 1100-O to 70% cold-rolled aluminum, the yield strength and strain hardening rate change significantly. Microscopic studies using Transmission Electron Microscopy were conducted to correlate the microstructural evolution with the macroscopic mechanical response. This study provides material properties that can be used to model and predict the responses of each material under extreme conditions such as spallation following shock loading.

4:35 PM
Study on High Velocity and High Strain Rate Deformation of Aluminum Alloys with Electromagnetic Forming: *Jianhui Shang*[1]; Steve Hatkevich[1]; Larry Wilkerson[1]; [1]American Trim LLC

Aluminum alloys are interested in industries because of their higher strength-to-weight ratio. To fully understand their deformation mechanism, the dynamic behavior of aluminum alloys should be investigated. Electromagnetic forming is a high velocity and high strain rate forming process in which velocities of up to 300 m/s and strain rates of more than 10^3 s^{-1} can be achieved. In this study, electromagnetic tube expansion was applied to study on high velocity and high strain rate deformation of aluminum alloys. Photon Doppler Velocimetry (PDV) was used to measure the velocity during tube expansion experiments. The numerical simulation was also carried out to study the dynamic behavior of aluminum alloys. The experimental and simulation results will be presented and discussed in this study.

4:50 PM
Dynamic Characterization of Open Cell Aluminium Foam Structures: *Carl Cady*[1]; George Gray[1]; Etienne Combaz[2]; Andreas Mortensen[2]; [1]Los Alamos National Laboratory; [2]Ecole Polytechnique Federale de Lausanne

The objective of this presentation is to provide evidence of how open-cell aluminium foam containing an incompressible liquid behaves when it is dynamically loaded. The underlying motivation is the idea that viscous friction in the fluid as it flows through tortuous fine-scale pores in deforming microcellular metal might provide a potent mechanism for the dissipation of mechanical energy. The foam material studied is a high-purity aluminium (99.99%) produced by the replication process, i.e., by pressure infiltration of a cold-pressed salt perform followed by solidification, cool down, machining and leaching. Cylindrical foam samples are tested dry (i.e., with air within the pores) and in the wet condition, i.e., with pores filled by water to evidence the influence of strain rate, temperature, relative density and flow of the fluid on their mechanical behavior.

5:05 PM
Impact Deformation and Dislocation Substructure of Ti-6Al-4V Alloy at Cryogenic Temperatures: *Woei-Shyan Lee*[1]; Tao-Hsing Chen[1]; Sian-Cing Huang[1]; [1]National Cheng Kung University

The aim of this study is to investigate impact response and dislocation substructure of Ti-6Al-4V alloy using a compressive split-Hopkinson pressure bar and transmission electron microscopy technique. Cylindrical specimens are deformed at strain rates ranging from 8×102 s-1to 4.0×103 s-1 and temperatures of 0□ and -200□, respectively. It is shown that the impact properties of Ti-6Al-4V alloy depend strongly on strain rate and temperature. For a constant temperature, the flow stress and strain rate sensitivity increase with increasing strain rate, while the activation volume decreases. Meanwhile, for a constant strain rate, the activation volume increases with increasing temperature, while the flow stress and strain rate sensitivity decrease. The strengthening effect in deformed Ti–6Al–4V alloy is a result primarily of dislocation multiplication. Transmission electron microscopy (TEM) observations show that the dislocation density increases with an increasing strain rate, but decreases with an increasing temperature. The mechanical properties of the impacted specimens are related to the microstructural evolution.

Electrode Technology for Aluminium Production: Carbon Materials for Anode and Cathode

Sponsored by: The Minerals, Metals and Materials Society, TMS Light Metals Division, TMS: Aluminum Committee, TMS: Aluminum Processing Committee
Program Organizer: Morten Sorlie, Alcoa Norway

Tuesday PM — Room: Americas Seminar
March 13, 2012 — Location: Dolphin Resort

Session Chair: Carlos Zangiacomi, Alcoa Aluminum Inc.

2:00 PM
Evolution of Anode Grade Calcined Coke: *Les Edwards*[1]; Nigel Backhouse[2]; Hans Darmstadt[2]; Marie-Josée Dion[2]; [1]Rain CII Carbon; [2]Rio Tinto Alcan

The petroleum refining industry has historically categorized petroleum cokes as either fuel grade, anode grade or needle coke. The term "anode grade coke" has been used as a broad definition to describe delayed coke with a sponge structure containing relatively low levels of trace metals like vanadium and nickel (typically <400ppm) and low to moderate levels of sulfur (0.5-4.0%). However, these historic classifications are less relevant today as a much wider variety of cokes are used in anode blends. This paper will review the growing range of coke qualities used in "anode grade" coke blends. Shortages of traditional quality anode grade coke are driving calciners and anode producers to use cokes with a much wider range of properties including sulfur and metals levels and structure. Cokes previously regarded as unsuitable for anode production are now being used routinely at varying levels and this trend is likely to continue.

2:20 PM

Studies on Impact of Calcined Petroleum from Different Sources on Anode Quality: *Binuta Patra*[1]; Rabindra Barik[1]; [1]National Aluminium Company Ltd

Calcined petroleum coke is a major raw material for manufacturing of carbon anodes for any Aluminium Smelter operation . Productivity & profitability of a smelter is influenced to a large extent by the performance of anodes in electrolytic pots. National Aluminium Company Ltd. has been using C.P.Coke from different sources since its inception. Quality of c.p.coke varies in different supplies depending on the raw material used by the calciner and the process parameters maintained during operation. This paper presents the quality of C.P. Coke from different sources and their influence on anode quality. Anode bench scale studies have also been carried out by blending c.p.coke from different sources and assessment of the anode quality .

2:40 PM

Prebaked Anode from Coal (3) - Carbonization Properties of Hypercoal Blended with Coal-Tar Pitch: *Maki Hamaguchi*[1]; Niriyuki Okuyama[1]; Nobuyuki Komatsu[1]; Naoki Kikuchi[1]; Jiro Koide[2]; Hideki Kasahara[2]; [1]Kobe Steel, Ltd.; [2]Sumitomo Corporation

Hypercoal is our proprietry solvent extraction technology of coal which produces fusible carbonaceous feedstock of extremely low ash content. In the recent papers, we have reported that prebaked anode can be succesfully prepared from hypercoal coke. Hypercoal coke has an advantages of low sulfur, vanadium, and nickel content and superior thermal stability compared to convetional petroleum coke. In this report, we will describe the carbonization properties of hypercoal blended with coal-tar pitch in an attempt to utililze the hypercoal as an alternative for binder pitch of prebaked anode production. It is also reported that self-sintering Hypercoal carbon was fabricated by thermal treatment of Hypercoal.

3:00 PM

Importance of Primary Quinoline Insoluble in Binder Pitch for Anode: *Minoru Sakai*[1]; Yulong Wang[1]; Takashi Fukuoka[1]; Hitomi Hatano[1]; [1]JFE Chemical Corporation

Laboratory scale anodes were made of a fixed coke and six binder pitches having different primary QI in the range between 9 and 22%. Binder matrices were also made for oxidation test against air and CO_2. Three of them were commercial products and the others were made experimentally, and none of them contained secondary QI. Softening point of these pitches was around 110 ºC. Pitches containing larger amount of primary QI showed higher coking value, which resulted in higher bulk density of baked anodes. The increase in bulk density improved compressive strength. The electrical resistivity, which decreased with increasing bulk density, was not deteriorated by the larger amount of primary QI in pitch. No acceleration of oxidation in air and CO_2 was observed in the binder matrix test. These results showed that pitches with high primary QI are more favorable as binder pitches for anodes.

3:20 PM

Investigation on Air Reactivity and Electrolysis Consumption of Anode Carbons with Anthracite Additions: *Jilai Xue*[1]; Meizhi Han[1]; Jun Zhu[1]; [1]Unversity of Science and Technology Beijing

The increasing price of coke and shortage in local supply for anode manufacture has presented challenge for smelters with added cost into the metal product. This paper is to show an effort in searching alternative carbons to replace part of traditional coke for the prebaked anodes. Some calcined anthracite was selected as starting materials and pre-treated in a chemical process. Then it was added into the carbon mixtures, formed and baked into the anode samples (F25X45mm) that tested for air-reactivity with ISO standard. The results showed that the ash content of the pretreated anthracite was lowered than that without the pretreatment, and varied with the anthracite additions of 20 - 40wt%. Kinetics of the air-reaction process with anthracite addition was also investigated. So far the anode samples with the anthracite additions around 20 wt% is promising for potential industrial application.

3:40 PM

Experiences on Anode Reconstruction Process in Soderberg Technology: *Carlos Zangiacomi*[1]; Jose Luis Garcia Garcia[2]; Andre De Abreu[1]; Ciro Kato[1]; [1]Alcoa Aluminum Latin America; [2]Alcoa INESPAL, S.A.

Anode construction is a challenging process for Soderberg Cells. In order to reestablish the full Plant capacity at Alcoa Pocos de Caldas, southern of Brazil, it was necessary to develop a new process to bake anodes within the Potrooms environment. Using line load as baking element and controlling the current passing through each stubs, it was possible to assembly new anodes with quality and proper condition for optimum cell operations. This paper describes the sequence of activities applied for assembling new Soderberg anodes, the techniques implemented to monitor and control the baking process and finally the outcome after pot start-up.

Cathode Performance Evaluation at Votorantim Metaís - CBA: *Jean Pardo*[1]; [1] Votorantim Metaís - CBA

The cathode is a set of items with a high cost in the primary aluminum production, this set is usually composed of carbon materials, refractory and insulating materials, which have their basic raw materials extracted from nature. There is great concern about cathode performance, this with respect to life and electric power consumption, several works have been performed in order to maximize the life cathode thereby avoiding costs and waste, more commonly known as SPL (spent pot life) as well as an hazardous waste to the environment and has a high cost for recycling. In this paper, we present the results summarized in a series of autopsies to determine the main reasons of cathode failures and present the results of actions developed to maximize the life cathodic CBA.

4:30 PM

Green, Safe and Clean Carbon Products for the Aluminium Electrolysis Pot: *Bénédicte Allard*[1]; Régis Paulus[1]; [1]Carbone Savoie

Carbon products used in aluminium electrolysis pots are generally based on coal-tar pitch or resin binders. Coal tar pitch is considered by REACH as very high concern product, and it is carcinogenic classified. Phenol, a typical component of resin binders used in carbon products, is also carcinogenic classified. In face of these hazards, solutions that guarantee a clean and safe environment for the workers have to be brought. Last year a 100% clean ramming paste NeO² has been introduced, based on a new binder type containing no CMR product and no hazardous substance. This paste was fully anthracitic. Since then, Carbone Savoie made developments to complete its Green range with a 100% clean semi-graphitic grade of ramming paste, using the same type of binder and with a 100 % clean glue, which could be used at different locations in the pot. Characteristics of these new products will be presented.

4:50 PM

A New Material for Collector Bar Sealing – LRM2: *Thiago Simoes*[1]; Marcio Guimaraes[1]; Marcelo Assuncao[1]; [1]Novelis

The collector bar sealing is an important procedure during the cathode construction. The material selection and the installation techniques have to be very well managed in order to obtain a high performance pot with low cathode voltage drop and long lifetime. A new material has been developed to be used for this purpose providing easy installation, good electrical resistance and stability for the pot. The formulation proposed, called LRM2, has been applied on Ouro Preto Smelter in place of old sealing material since 2008 and has shown lower electrical resistance than the old carbon glue and very easy installation when compared with the cast iron alternative.The present paper explores a discussion among the types of bar/block sealants and the Novelis efforts to make improvements in this field. Our results are discussed here highlighting the benefits using iron powder pastes when compared with other techniques.

5:10 PM
Dry Barrier Mix in Reduction Cell Cathodes: *Richard Jeltsch*[1]; Chen Cairong[2]; [1]Jeltsch Consulting; [2]Chalieco/Gami

Dry barrier mix (DBM) has been successfully tested as a replacement for barrier bricks in several reduction cell technology types and has been adopted as standard practice in all three of the Chinese cell technologies. DBM reacts with cathodic bath in-situ to form a glass-like barrier which retards the further penetration of bath components, protecting the lighter insulation from contact with the bath. Laboratory "cup tests" show that silicate based DBM formulations are more effective than anorthite formulations or conventional refractory aggregates in formation of the glassy barriers. Cell bottom temperatures remain stable over the lifetime of the cell, indicating the barrier formation protects the insulating value. Cell autopsies show partial penetration of the DBM with barrier formation and preservation of the bottom portion of the DBM. Cell lining life is at least equivalent to that of brick barrier cells.

Electrometallurgy 2012: Session III

Sponsored by: The Minerals, Metals and Materials Society, The Metallurgy and Materials Society of CIM, TMS Extraction and Processing Division, TMS: Hydrometallurgy and Electrometallurgy Committee

Program Organizers: Georges Houlachi, Hydro-Quebec; Antoine Allanore, Massachusetts Institute of Technology; Michael Free, University of Utah; Michael Moats, University of Utah; Edouard Asselin, UBC; Shijie Wang, Rio Tinto Kennecott Utah Copper; James Yurko, Materion Brush Beryllium and Composites

March 13, 2012 — Location: Dolphin Resort

Session Chairs: Michael Moats, University of Utah; Edouard Asselin, University of British Columbia

2:00 PM
Capacities of Molten Slags and Their Practical Use: *Kazuki Morita*[1]; [1]The University of Tokyo

Molten slags have been generated in various metallurgical processes. Furthermore, their role as refining fluxes is also significant. Chemical composition of molten slags often becomes the key in the optimization of each refining process. Among others, basicity is known to be a major factor in the red-ox reactions in the metal refining processes. Since Carl Wagner proposed several capacities as semi-quantitative measures of the basicity of slags, several capacities, such as sulfide capacity and phosphate capacity, have been brought into practical use in optimizing steel refining processes for the last several decades. Present author also defined some capacities, such as chloride, ruthenate and rhodate capacities of slags, in the investigation of the recycling processes of plastics and PGMs. In the present paper, the concept of the capacities will be reviewed and the newly defined capacities will be introduced together with the practical use in the high temperature recycling processes.

2:20 PM
Investigation of Nucleation and Plating Overpotentials during Copper Electrowinning using the Galvanostatic Staircase Method: *Michael Moats*[1]; Alexander Derrick[1]; [1]University of Utah

The Winand Diagram was developed and has been used for decades to illustrate the interaction between polarization, mass transport and inhibition on the resulting structure of a metal electrodeposit. Recently, Adcock et al. criticized the Winand Diagram and developed their own structural diagram based on nucleation and plating overpotentials. Their work was based on zinc electrodeposition using a galvanostatic staircase method. This work explores the nucleation and plating overpotentials for copper electrodeposition using conditions typical for primary electrowinning using the galvanostatic staircase experimental technique. Additionally, the effect of organic additives and plating substrate on these overpotentials are reported.

2:40 PM
Nucleation and Growth of Copper on Stainless Steel Cathode Blanks in Electrorefining: Jari Aromaa[1]; *Olof Forsén*[1]; Antti Kekki[1]; [1]Aalto University

The deposition of copper on inert substrate depends on the number of active sites that will react at certain overpotential. The critical overpotential depends on surface morphology, surface film resistance and additives on cathode surface. The surface properties and copper nucleation and growth rates were studied for used stainless steel blanks from several tankhouses. The surfaces of the blanks were characterized with electrochemical and mechanical methods. Electrochemical deposition tests were done at current density 300 A/m^2 for 10, 30 and 60 seconds. The nucleation density and copper coverage were estimated using image analysis. The surface film resistance did not correlate with copper growth. Increasing surface roughness correlated with lower copper growth.

3:00 PM
An Overview of the Design of the New Nickel Tankhouse at Anglo American Platinum's Base Metal Refinery: Deborah Erasmus[1]; *Nicko Prinsloo*[1]; [1]Anglo American Platinum

Anglo American Platinum has recently commissioned a new nickel electrowinning tankhouse as part of their strategic Base Metal Refinery expansion project. The tankhouse design includes permanent cathode technology, automated stripping, semi-automated harvesting, anode skirts and cell hoods to reduce worker exposure to aerosols and solutions that contain nickel sulfate and acid. The development and testing of the technology has been performed in-house to attain an average ambient nickel aerosol concentration of $<0.05 mg/m^3$ in the new tankhouse building, which is well below the current MHSA OEL of $0.1 mg/m^3$. This paper provides a process description of the new tankhouse and highlights some of the challenges and successes experienced during the initial commissioning phase.

3:20 PM
Developments in Base Metal Electrowinning Cellhouse Design: *Tim Robinson*[1]; Kathryn Sole[2]; Michael Moats[3]; Frank Crundwell[4]; Masatsugu Morimitsu[5]; Lauri Palmu[6]; [1]Republic Alternative Technologies; [2]Independent Consultant; [3]University of Utah; [4]CM Solutions (Pty) Ltd; [5]Doshisha University; [6]Talvivaara

Zinc and Nickel and Copper electrowinning cellhouse process technology and design trends include focus on energy reduction, productivity and acid mist abatement. Larger electrodes, longer cells, automation and higher current densities are leading to more capital effective designs. Latest cellhouse designs include further installation of automated electrode handling systems, thereby removing more operators from the cellhouse. In summary these technology and design trends have further resulted in lower electrowinning operating costs and improved electrowon cathode purity.

3:55 PM
The Recovery of Manganese from the Boleo Project Using Leach, Precipitation and Electrolytic Manganese Metal Production: *Thomas Gluck*[1]; David Dreisinger[2]; Jianming Lu[2]; [1]Baja Mining Corp.; [2]Univ of B.C.

The recovery of manganese from the Boleo project of Baja Mining is via an acid oxidation and acid reduction process in seawater. Manganese as manganese dioxide is leached into solution as manganese sulphate with the addition of sulphur dioxide gas as a reductant and then precipitated as manganese carbonate. The use of the manganese carbonate intermediate to produce electrolytic manganese metal (EMM) has been extensively studied. The manganese carbonate can be used in place of natural ($MnCO3$) or reduced ores (MnO) of manganese as a feed to the EMM plant. Manganese carbonate can be dissolved in spent electrolyte from manganese plating, followed by purification using ammonium sulphide precipitation of minor elements and then electrowinning in the selenium free process. The results of small cell and full height cell testing of manganese electrowinning will be reported.

4:15 PM
Underpotential Dissolution of Precious Metals from Intermetallic Compounds with Zn: *Hideaki Sasaki*[1]; Takashi Nagai[1]; Masafumi Maeda[1]; [1]Institute of Industrial Science, The University of Tokyo

The dissolution of precious metals (PMs) can be enhanced by alloying with other metals such as Zn. During the dissolution of PM-Zn alloys or intermetallic compounds, Zn dissolves preferentially and precious metals form transient small particles. Because small particles have higher activity than the bulk state, the PM particles may dissolve at low potentials where PM dissolution usually does not occur. This "underpotential dissolution" can be utilized in the hydrometallurgical recovery process for PMs. If the alloying pretreatment with Zn vapor enables dissolution of PM by weak and inexpensive chemical agents, the cost and environmental load for the recovery can be reduced. This study examined dissolution of PM-Zn compounds by electrochemical measurement to propose an appropriate condition for enhancing dissolution of PMs.

4:35 PM
The Recovery of Cobalt from the Boleo Deposit Using Leach, SX and EW: *David Dreisinger*[1]; Thomas Gluck[2]; Jianming Lu[1]; [1]Univ of B.C.; [2]Baja Mining Corp.

The Boleo project of Baja Mining (Vancouver) will process a mixed oxide-sulfide ore using an acid oxidation and reduction process in seawater to extract copper, zinc, cobalt and manganese. Copper will be extracted via SX-EW as copper cathode, zinc will be recovered as a zinc sulphate monohydrate crystal and cobalt will be produced as a cobalt cathode product after phosphinic acid extraction. Manganese may be recovered from the final solvent extraction raffinate by precipitation as manganese carbonate. The development of the cobalt recovery process (solvent extraction and electrowinning) will be discussed. The pilot plant solvent extraction circuit and subsequent bench and small pilot testing of cobalt electrowinning will be discussed. The Boleo project will product nearly 2,000 tonnes per annum of cobalt metal when fully commissioned.

2:00 PM Invited
Ordering Processes in Ni2(Cr,Mo) Alloy Investigated by TEM and 3D-AP: *Nelia Wanderka*[1]; Amit Verma[1]; Nikolai Lazarev[2]; M Sundararaman[3]; J Singh[4]; [1]Helmholtz Zentrum Berlin für Materialien und Energie GmbH; [2]NSC Kharkov Institute of Physics and Technology, Kharkov, Ukraine; [3]Hyderabad Central University, India; [4]Bhabha Atomic Research Centre, Structural Metallurgy Section, Mumbai, India

The study of short range ordered state and the evolution of long range ordered state from it in metallic alloy systems is always a field of interest for theoreticians and experimentalists. In the present study an attempt has been made to rationalize the short range ordered state in stochiometric alloys of Ni2(Cr,Mo) composition based upon the experimental evidence obtained from transmission electron microscopy and 3-dimensional atom probe investigations. Experiments were carried out on specimens with the same alloy composition but prepared by two different routes namely: by splat quenching and by casting, homogenising treatments. Aging treatments over a wide temperature range were used to follow the ordering. Three-dimensional atom probe data were evaluated by several statistical methods such as cluster searching and density spectrum analysis. Monte Carlo simulation was performed for interpretation of the observed ordering processes. The analyzed data are correlated with TEM results and calorimetric data.

2:25 PM Invited
The Effect of Creep on the Rhenium Distribution Close to the ã/ã' Interfaces in a Nickel-Based Superalloy: *Alessandro Mottura*[1]; Michael Miller[2]; Roger Reed[3]; [1]University of California, Santa Barbara; [2]Oak Ridge National Laboratory; [3]The University of Birmingham

Atom probe tomography was used to estimate the rhenium distribution in uncrept and crept (550h to 1170h at 1223K and 185MPa) specimens of a commercial single-crystal CMSX-4 nickel-based superalloy. Rhenium proximity histograms both transverse and longitudinal to the loading axis were obtained across the γ/γ' interfaces. As expected, rhenium strongly partitioned to the γ-phase, and a rhenium enriched area was observed close to most primary γ' interfaces on the γ-phase side. The rhenium concentration profile appeared unaffected by the duration of creep tests and by the orientation of interfaces relative to the loading direction. Conversely, the rhenium concentration profile was strongly affected by phase morphology ahead of the interfaces. These findings indicate that the rhenium enrichment forms upon cooling from service temperature and has little effect on the creep properties of CMSX-4. Research sponsored by the U.S. DOE-Office of Basic Energy Sciences SHaRE user program [APT and MKM].

2:50 PM Invited
Spinodal Decomposition in Fe-Cr and Fe-C Systems: *Frederic Danoix*[1]; [1]CNRS - Université de Rouen

Spinodal decomposition proceeds from unstable solid solutions, resulting, by contrast to classical nucleation and growth, in the absence of any incubation period. The initial stages are characterised by low amplitude – small extend composition fluctuations, which develop towards a mixture of the equilibrium phases.In Fe-based alloys, G.D.W. Smith was involved in the study of two different systems: Fe-Cr and Fe-C. In the first case, interfacial energy is limited, which leads to the development of 'isotropic' spinodal decomposition, where Fe rich and Cr rich regions form two interconnected networks. The evolution of this specific microstructure was characterised in details in 3D in his group. Concerning the Fe-C system, G.D.W. Smith and his co workers proposed in the early 80', based their atom probe data, that C supersaturated martensite could experience spinodal decomposition. Recent investigations confirmed this hypothesis, and a previously developed by Khachaturyan model is adapted to account for it.

3:15 PM
High Strength Conductors for High Field Magnets: *Ke Han*[1]; Jun Lu[1]; [1]National High Magnetic Field Laboratory

A study led by Smith demonstrated a considerable difference in the tensile deformation behavior between fine and coarse pearlite. The concepts are widely accepted and used for material designs, including ones for high field magnets (HFM). The mechanical strength and deformation behavior of the conductors in HFMs are two of the important factors to determine the maximum magnetic field strength and life in magnets. When a magnet operates at very high field, a complex stress status occurs, and other material properties have to be taken into account to ensure the integrity of a magnet. Typical mechanical properties are fatigue endurance, fracture toughness and elongation. All those are related to the deformation behavior of the high strength conductors that have similar microstructure to pearlite. This paper will address the material characterization issues in high strength conductors and the importance to relate the material properties to operation and manufacture conditions.

3:30 PM
Applications of Atom Probe Tomography in Computational Materials Design: *Jason Sebastian*[1]; Gregory Olson[1]; Jim Wright[1]; Abhijeet Misra[1]; Eric Hamann[1]; [1]QuesTek Innovations LLC

As part of a symposium honoring Prof. George D.W. Smith of Oxford University, QuesTek will provide an overview of its use of atom probe tomography (APT) in computational materials design. Within the framework of QuesTek's system-based approach to materials design, APT is an essential tool that allows for the confirmation of an alloy's designed nanostructure. The composition, morphology, and size distribution of nanoscale strengthening precipitates can be measured directly. Nanoscale interfacial phenomena (segregation, film formation, etc.) can also be directly observed. Specific results from a variety of QuesTek APT analyses on prototype and commercial alloys will be summarized, including carbide strengthened steels, intermetallic strengthened Ni- and Fe-based alloys, aluminum alloys, and others.

3:45 PM Break

4:10 PM
Examination of Carbon Redistribution in Quench and Tempered 4340 Steel: *Amy Clarke*[1]; Michael Miller[2]; David Alexander[1]; Robert Field[1]; Kester Clarke[1]; [1]Los Alamos National Laboratory; [2]Oak Ridge National Laboratory

Quenching and tempering of martensitic steels significantly influences the resulting mechanical properties. During quenching (autotempering) and/or subsequent tempering of martensite, several carbon redistribution processes are possible, including carbon segregation to dislocations or lath boundaries, carbon clustering, carbon partitioning to austenite, transition carbide and/or cementite formation, and retained austenite decomposition. In this work, a 4340 steel was oil or water quenched and tempered at temperatures ranging from 325 to 575°C. Tensile, compression, and Charpy V-notch testing was performed on the oil quenched and oil quenched and tempered conditions to determine the influence of thermal processing on mechanical behavior. The complex, ultrafine scale microstructures and the location of carbon within the martensite were examined with atom probe tomography†. Transmission electron microscopy was also performed. †Research at the Oak Ridge National Laboratory SHaRE User Facility was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

4:25 PM
Microstructural Evolution of Second Phases in Austempered High-Al TRIP Steels Examined by Atom Probe Tomography: *Hyoung Seok Park*[1]; Jae Bok Seol[1]; Jai Hyun Kwak[2]; Chan Gyung Park[1]; [1]Pohang University of Science and Technology (POSTECH); [2]POSCO

Recently, light-weight transformation-induced-plasticity(TRIP) steel has been developed for automotive parts. In order to reduce the specific weight without degrading mechanical properties of TRIP steels, about 6 wt.% aluminum is added. Their mechanical properties significantly depended on the morphology and composition of constituent phases formed: M_3C-type κ-carbides in nm size coexisting with γ-Fe or α-Fe. In the present study, therefore, microstructural evolution of 2nd phases, depending on austempering treatment, has been examined by using the combined analyses of APT, TEM and EBSD. As austempering temperature increased, the fraction of retained γ decreased with increased second phases, which were identified as $(Fe,Mn)_{4-x}(Al,C)_x$ carbides and/or retained austenite decomposed. Both phases revealed quite similar morphology of thin lenticular platelets or laths. Based on our results, the correlation between the mechanical properties, the role of alloying elements, especially Al, and the structure and chemistry of the constituent phase evolved will be discussed.

4:40 PM
Insight into Cluster Strengthening in a Nb-Microalloyed High Strength Low Alloyed Steel Using Atom Probe Tomography: *Kelvin Xie*[1]; Andrew Breen[1]; Michael Moody[1]; Julie Cairney[1]; Simon Ringer[1]; [1]The University of Sydney

The yield strength of a UCS (ultra thin cast strip) steel strip produced by the CASTRIP process, microalloyed with 0.084 wt% Nb can be further improved substantially without compromising ductility. Additional 165 MPa yield strength was gained by performing simple heat treatment at 700 oC for 4 min. The optimal strengthening can be attributed to dispersion of Nb-rich monoatomic layer clusters mostly aligned along dislocations, which were precursors of Nb(C,N) nanoprecipitates. Cluster dispersion was observed to be a more effective strengthening method. Application of Orowan-Ashby equation showed that cluster strengthening used much less Nb atoms than conventional Nb(C,N) nanoprecipitates but can still achieve the same strengthening effect. A method that directly correlates atom probe results and TEM observations of those Nb-rich clusters was also proposed, which expanded the spatial resolution limit of atom probe in the study of clusters in HSLA steels. The presenter would like to have an oral presentation and would like to participate in the Young Scientist Award competition.

4:55 PM
Cluster Strengthening of Microalloyed Castrip® Steels: *Sachin Shrestha*[1]; Kelvin Xie[1]; Chen Zhu[1]; Julie Cairney[1]; Simon Ringer[1]; Chris Killmore[2]; Kristin Carpenter[2]; Frank Barbaro[2]; James Williams[2]; [1]The University of Sydney, Australian Key Centre for Microscopy and Microanalysis; [2]BlueScope Steel, Metallurgical Technology

This study investigates the microstructure and mechanical properties of Nb-microalloyed Castrip® steels aged at temperatures below and above the Ac1 temperature (525-800°C). Ageing provides both rapid strength enhancements and improvements in ductility, where normally one of these properties would be lost at the expense of the other. Atom probe tomography (APT) reveals that the strengthening is due to heterogeneous formation of Nb rich clusters and precipitates within the microstructures that are thought to retard the movement of dislocations during deformation. APT data mining is used to characterize the size and distribution of these clusters and precipitates. The strengthening kinetics are compared across a range of different temperatures using an Arrhenius model. The model allows us to understand the temperature dependence of peak ageing times and evaluate the strengthening mechanisms at various temperatures based on the activation energy of precipitation strengthening.

5:10 PM

The Application of Atom Probe Tomography to Oxide-Dispersion-Strengthened Steels: *Ceri Williams*[1]; Emmanuelle Marquis[2]; Paul Bagot[1]; George Smith[1]; [1]University of Oxford; [2]University of Michigan

Oxide-dispersion-strengthened ferritic steels are candidate structural materials for fusion reactors. Very high densities of Y-Ti-O nanoclusters (~2nm diameter) provide strength at temperatures up to ~650°C and improve radiation tolerance. In this work, an Fe-14%Cr-2%W ODS alloy with 0.1-0.4%Ti and 0.3%Y2O3 is analysed by Atom Probe Tomography (APT). APT is unique in the chemical resolution attainable at the nanometre level, and substantial improvements in the field of view afforded by the current generation of instruments means that thousands of nanoclusters can be analysed per specimen. With this, we can therefore quantify changes in the nanocluster dispersion. Such changes, and the validity of various data analysis techniques used to analyse composition and size distribution of the nanoclusters will be addressed. Significant changes to the chemistry of nanoclusters are observed depending on the initial composition of the alloy. The resulting impact on the high temperature stability of the nanoclusters will also be discussed.

5:25 PM

APT Characterization of Nanometer Scale Features in RPV Steels and Nanostructured Ferritic Alloys: Insight, Challenges and Opportunities: *Peter Wells*[1]; Nick Cunningham[1]; Eric Stergar[1]; Yuan Wu[1]; G. Robert Odette[1]; [1]UC Santa Barbara

APT tools and techniques, many pioneered by Professor Smith and his Oxford group, have been used for more than 20 years to study nm scale Cu-Mn-Ni-Si precipitates in irradiated RPV steels, and more recently to characterize Y-Ti-O nanofeatures in nanostructured ferritic alloys. While enormously valuable, the APT results have sometimes not been fully consistent with those found by other characterization techniques. We show specific examples of well-known phenomena that standard reconstruction treatments do not treat. Perhaps the most important is the local evolution of the tip morphology due to evaporation field differences leading to variations in the magnification factor and associated trajectory aberrations. For lower evaporation field the topology changes increase the number of atoms nominally in the feature volume. We focus on quantifying the tip morphology evolution, and suggest approaches to improved reconstructions. We also discuss low evaporation field features affects on increase in multiple hits.

5:40 PM

Initial Age Hardening and Nanostructural Evolution in a Cu-Ni-P Alloy: *Yasuhiro Aruga*[1]; [1]Kobe Steel, Ltd.

Initial age hardening and clustering behavior during ageing at various temperatures for up to 10000s after solution treatment in a Cu–0.41Ni–0.11P (mass%) alloy have been investigated. The evolution of an atomistic-level nanostructure has been characterized by a three-dimensional atom probe (3DAP). The experimental results have showed that no difference in hardness between non-aged material and that aged at 523K for 100s, whereas increasing the ageing time beyond 100s at 523K causes an obvious increase in hardness. It can be seen that the hardness increases gradually throughout ageing at 623K. It is shown that the initial age hardening is caused by Ni-P clusters in the alloys. The clustering and precipitation behavior related to the change in the hardness is discussed in terms of diffusion and driving force for nucleation.

5:45 PM

Quantitative Three Dimensional Atom Probe Analysis of In-Situ Tic Reinforced Ni Composite: *Junyeon Hwang*[1]; Sundeep Gopagoni[1]; Kristopher Mahdak[1]; Jaimie Tiley[2]; Rajarshi Banerjee[1]; [1]University of North Texas; [2]AFRL

Nickel-titanium carbide (Ni-TiC) composites were prepared by the laser engineered net shaping (LENS) process. The as-deposited microstructure consists of primary TiC and eutectic TiC precipitates distributed within a nickel matrix. The resulting microstructures were characterized by coupling electron backscatter diffraction (EBSD), energy dispersive X-ray (EDX) analysis, and detailed transmission electron microscopy (TEM) studies. Site-specific laser-pulsed atom probe tomography tomography (APT) studies have been performed on the carbide in the Ni matrix. The experimentally measured carbon concentration within the primary TiC appears to be changing from the carbide/nickel interface towards the core of the carbide while the eutectic TiC precipitates appear to exhibit a more uniform carbon concentration. Additionally, the structure of the TiC/Ni interface and the orientation relationship between carbides and matrix will also be discussed in this study.

Morphology Engineering of 1D, 2D and 3D TiO2 Nanostructures and Their Application in Dye-Sensitized Solar Cells: *Ziqi Sun*[1]; Jung Ho Kim[1]; Yue Zhao[1]; Shixue Dou[1]; [1]University of Wollongong

Titanium dioxide is one of the most important wide-gap semiconductors and is widely studied for use in the areas ranging from photovoltaic/photocatalysis to photo-/eletrochromics and sensors. Synthesis of TiO2 nanostructure with controlled size and shape is of considerable interest, owing to that the performance of TiO2-based devices is largely influenced by the size and shape of TiO2 building units, especially in nanometer scale. In this presentation, the recent progress on the synthesis of 1D, 2D and 3D TiO2 nanostructures and their application in dye-sensitized solar cells will be summarized at first. Then our latest results on the tunable growth of diverse morphology of TiO2 1D, 2D and 3D nanostructures will be presented. Based on the understanding on the crystal growth mechanism, the morphology and size of TiO2 nanostructures were easily controlled. As an example application of these controllable nanostructures, the morphology effect on the performance dye-sensitized solar cells was studied.

2:30 PM

Microstructural Evolution of SnS Thin Films Grown by Electrodeposition: *Ho Seong Lee*[1]; H. Hennayaka[1]; [1]Kyungpook National University

Among the IV-VI semiconductor materials, tin monosulphide (SnS) has attracted considerable attraction during last two decades due to its possibility of applications in the field of photoelectronics. SnS, with orthorhombic structure, a direct band gap around 1.3 eV and a high optical absorption coefficient (>104 cm-1), has been reported to exhibit p-type conductivity. These properties confirm that SnS has appropriate electrical and optical features suitable for an absorber layer in solar cells. In this work we have deposited SnS on indium-tin-oxide (ITO) glass and gold-coated Si substrates by a low temperature electrochemical deposition (ECD) method. The morphology and composition of the SnS films were analyzed by scanning electron microscopy (SEM) and an energy dispersive spectroscopy (EDS). The crystal structure of the films was characterized by XRD patterns. The microstructural properties of the deposited SnS films were investigated by transmission electron microscopy (TEM) analysis.

Synthesis of Nanostructured TiO2 /Carbon Nanotube Heterojunction Electrodes for Solar Energy-Driven Applications: *Zohreh Razavihesabi*[1]; Paul Szymanski[2]; Hamid Garmetani[2]; Mostafa Elsayed[2]; [1]Georgia Institut of Technology; [2]Georgia Institute of Technology

Highly ordered anodically grown TiO2 nanotubes as well as TiO2 nanoparticles were integrated with one-dimensional carbon nanotubes (CNTs). CNT/TiO2 heterojunctions were prepared by grafting functionalized CNTs to TiO2 nanoparticles/nanotubes. The synthesized hybrid nanostructures were used as photoanodes to split water photoelectrochemically and compared to the widely-used photoanodes, pure TiO2 nanotubes. The effect of CNTs as well as TiO2 morphology on the efficiency of hybrid nanostructures and possible enhancement mechanisms are discussed in detail.

3:35 PM
Phase-Field Simulations of Patterned Quantum Dot Growth: *Larry Aagesen*[1]; Pei-Cheng Ku[1]; Leung Lee[1]; Katsuyo Thornton[1]; [1]University of Michigan

Quantum dots have potential applications in high-efficiency photovoltaic-cell designs such as intermediate-band cells and hot-carrier cells. To maximize cell efficiency, the quantum dots must be grown with a high degree of regularity in shape, size, and ordering. To meet this need, techniques such as selective area epitaxy and focused-ion beam substrate patterning have been developed. However, the morphology of the dots, which depends on the pattern size and geometry as well as deposition parameters, remains difficult to control. Phase-field simulations have been used to simulate epitaxial growth of patterned arrays of quantum dots. For selective area epitaxy simulations, the phase-field model is coupled with the smoothed boundary method, which is used to specify the contact angle between the quantum dots and mask. Phase-field simulations have also been applied to understand and predict the morphological evolution of quantum dots that form during multi-layer growth on focused-ion beam patterned substrates.

3:55 PM
Electrophoretic Co-Deposition of TiO2 and ZnO Photoelectrodes for Flexible Dye-Sensitized Solar Cells: *Sheng-Jye Cherng*[1]; Chih-Ming Chen[1]; [1]National Chung Hsing University

A procedure for composite photoanode made of TiO2 and ZnO particles is developed based on electrophoretic co-deposition (EPD) which deposits two kinds of nanocrystallized semiconductors on a flexible ITO/PEN substrate. EPD is a low-cost processing technique and can fabricate a homogenous layer of controllable thickness with simple equipment. Microstructure of this composite layer is examined by scanning electron microscope (SEM), transmission electron microscope (TEM), and X-ray diffractometer (XRD). A flexible ITO/PEN substrate with sputtered platinum (Pt) is used for counterelectrode. The performance of the dye-sensitized solar cells (DSSCs) employing the composite photoanode and platinized counterelectrode is measured by Keithley model 2400 digital source meter under AM 1.5G(100 mW/cm2) irradiation. The charge transfer resistance at the ZnO-TiO2/dye/electrolyte (R2) and the electron lifetime (tn) are examined by electrochemical impedance spectroscopy (EIS).

Fatigue and Corrosion Damage in Metallic Materials: Fundamentals, Modeling and Prevention: Fatigue Behaviors at Evelated Temperature

Thermal Relaxation of Residual Stresses in Laser Shock Peened IN718 SPF and Ti-6Al-4V Alloys: Experiments and Finite Element Modeling: Amrinder Gill[1]; Vijay Vasudevan[1]; *Dong Qian*[1]; Zhong Zhou[1]; S.R. Mannava[1]; Kristina Langer[2]; [1]University of Cincinnati; [2]Air Force Research Laboratory

Thermal relaxation of the compressive residual stresses induced by laser shock peened (LSP) in titanium and nickel-base aero engine alloys can significantly affect their fatigue life. In the present study, LSP induced residual stresses in IN718 SPF and Ti-6Al-4V alloys, and their thermal relaxation due to exposure at elevated temperatures are investigated through a series of controlled experiments and a coupled thermal-structural analysis using LS-DYNA finite element method (FEM). The Johnson-Cook (JC) material model was employed to represent the nonlinear constitutive behavior under LSP, and model parameters for IN718 SPF and Ti-6Al-4V alloys were calibrated by comparing the prediction of LSP residual stress with experimental data obtained using the conventional x-ray diffraction method. Good agreement between the thermal relaxation simulation and experimental results was obtained in LSP-treated coupons. The Zener-Wert-Avrami analytical model was applied to model the kinetics of relaxation, and activation enthalpy of thermal relaxation process was obtained.

2:20 PM
Effects of Intermediate Temperature Long Term Exposure on Mechanical Behavior of 5083-H116 and 5456-H116: *Mohsen Seifi*[1]; Justin Brosi[1]; John Lewandowski[1]; [1]Case Western Reserve University

Al-Mg 5xxx alloys are desirable in a wide array of structural applications and provide an excellent balance of Mg solid-solution strengthening, as well as appreciable ductility after cold working. However, mechanical property changes may result from intermediate temperature exposures. Commercially available 5083-H116 and 5456-H116 alloy plates have been thermally treated up to 10,000 hrs. at temperatures of 80°C - 175°C. Room temperature tension, fracture toughness, fatigue crack growth and hardness tests have been completed to determine changes in mechanical properties in the LT orientation. Longitudinal splitting in the short-transverse (ST) direction has been observed during fatigue after sufficient time and temperature exposure combinations. Fracture and fatigue testing has revealed reductions in ST properties for long-time sensitized material in the ST orientation. The evolution of properties with thermal exposure at these (and lower) temperatures has significant practical implications for various structural applications.

2:40 PM
Measuring Effects of Holding Time and Oxidation on Thermo-Mechanical Fatigue Properties of Compacted Graphite Iron Using Notched Specimens: *Sepideh Ghodrat*[1]; Michael Janssen[2]; Roumen (R.H) Petrov[3]; Leo (L.A.I.) Kestens[3]; Jilt Sietsma[2]; [1]Materials Innovation Institute (M2i), TUDelft; [2]TUDelft; [3]Ghent University, TUDelft

In cast iron cylinder heads heating and cooling cycles can lead to localized cracking due to Thermo-Mechanical Fatigue (TMF). Traditionally TMF behaviour is studied by cyclically loading smooth specimens until failure. The number of cycles to failure constitutes a single parameter that can be used to predict actual service failures. Nevertheless, some drawbacks also exist: long testing times and a huge scatter of results. A possible solution to deal with these drawbacks is the use of notched specimens. Tests on circumferentially notched specimens showed that TMF lifetime decreases monotonically with increasing notch depth. Furthermore, the lifetime for a specific notch depth could well be predicted using Paris' fatigue crack growth law. This allowed the prediction of the TMF lifetime of smooth specimens. Using this procedure, notched specimens were used to evaluate the effects of holding time during the load cycle and of the environment on the TMF properties.

3:00 PM
Thermal Fatigue Properties Evaluation of 18% Cr Ferritic Stainless Steel Weld HAZ: *Kyutae Han*[1]; Seunggab Hong[2]; Changhee Lee[1]; [1]Hanyang University / Division of Materials Science & Engineering; [2]POSCO / Technical Research Laboratory

The microstructural changes and precipitation behavior during thermal fatigue of 18% Cr ferritic stainless steel weld heat affected zone were investigated. The simulation of weld HAZ and thermal fatigue test were carried out using a metal thermal cycle simulator under complete constraint force in the static jig. Thermal fatigue properties of the weld HAZ deteriorated during cyclic heating and cooling in the temperature range of 200°C to 900°C due to the decrease of Nb content in solid solution and coarsening of MC type precipitates, laves phase, M6C with coarsening of grain and softening of matrix. Crack initiated from the notch of the specimen at around 60% of life cycles due to the coarsened particles and grain boundary oxidation. As fatigue cycle increases, transgranular crack propagated toward the center of the specimen and finally fracture finished by merging with the spontaneously formed and coarsened cavities in the specimen during thermal cycle.

3:20 PM
Fatigue Deformation Behavior of Dispersion Hardened New Heat Resistant Aluminum Alloy at Elevated Temperature: *Kee-Ahn Lee*[1]; Kyu-Sik Kim[1]; Si-Young Sung[2]; Jung-Chul Park[3]; Bum-Suk Han[2]; [1]Andong National University; [2]Korea Automotive Technology Institute; [3]RIST

Tensile and high cycle fatigue behaviors of new heat resistant Al alloy at elevated temperature were studied. This alloy consists of Al matrix, small amount of Mg2Si and (Co, Ni)3Al4 particles. Tensile tests showed that yield and tensile strengths of this alloy somewhat decreased and elongations increased slightly from R.T. to 350°C. HCF tests were conducted with stress ratio= 0.1, frequency= 30 Hz at 130°C. Fatigue limit was 120 MPa at 107 cycles which is a superior value than that of A319. And also, regardless of conditions of maximum stresses, new heat resistant Al alloy has outstanding fatigue life. Results of fractographical observation showed that particles, especially (Co, Ni)3Al4, affected effectively to resistance of fatigue crack propagation. This study also attempted to clarify the micro-mechanism of fatigue behavior at elevated temperature related with its microstructure. [Supported by the Fundamental R&D program for Core technology, Korea]

Effect of Almen Intensities on High Cycling Fatigue of Al 2024-T4: *Yasser Ahmed*[1]; Mostafa El Metwally[1]; [1]German University in Cairo

The present work was aimed to evaluating the effects of shot peening on the high cycle fatigue performance of the age hardening aircraft alloy Al 2024 at different almen intensities. Shot peening to full coverage (100%) was performed using spherically conditioned cut wire (SCCW 14) with an average shot size of 0.36 mm and at almen intensities of 0.1 mmA, 0.2 mmA and 0.3 mmA. After applying the various mechanical surface treatments, the changes in the surface and near surface layer properties such as micro-hardness, residual stress-depth profiles and surface roughness were determined. The microhardness, surface roughness and the residual stresses increased proportionally with the almen intensity. Electropolitically polished conditions were used as reference in the mechanically surface treated specimens. A significant improvement was seen in the fatigue performance of the 0.1 mmA.

4:10 PM
The Effects of Microstructure upon Remaining Life of Carburized Ethylene Pyrolysis Tubes: *Amy McLeod*[1]; Kevin Stevens[2]; Milo Kral[1]; [1]University of Canterbury; [2]Quest Integrity NZL Limited

Carburization in ethylene pyrolysis tubes is one of the contributing causes of failure of these tubes, but the timing of tube failures in ethylene pyrolysis furnaces is problematic as there is no reliable indicator that the tubes are near to their end-of-life. Remaining life assessments of carburized ethylene pyrolysis tubes based on microstructure and operating history are of interest to plant operators. The present work studies the effect of carburization on tube performance and remaining life. Laboratory carburized samples have been created, and ex-service and laboratory carburized tube material with differing levels of carburization has been studied. The samples have been characterized using a combination of elemental composition analysis, and optical and electron microscopy.

4:30 PM
Fatigue Crack Growth Analysis from Acoustic Emission Data on the Navy H-60 Seahawk Helicopter Tail Gearbox: Eric Hill; *Fady Barsoum*[1]; Jun Shishino[1]; Ning Leung[1]; Prathikshen Selvadorai[1]; Alan Timmons[1]; William Hardman[1]; [1]Embry-Riddle Aeronautical University

There have been multiple incidents of H-60 and H-60 variant helicopters that experienced fatigue cracks in the tail rotor gearbox assembly, specifically in the bevel gear splines. This paper discusses how acoustic emission (AE) data gathered from a crack growth test on a Sikorsky H-60 helicopter tail rotor gear box was processed and classified using a Kohonen self-organizing map (SOM) neural network. The tail rotor gearbox bevel gear had a seeded fault in one spline that grew to a crack 110 degrees around the shaft before the test was ended. The SOM was able to sort out the AE data into five mechanisms including two types of fatigue crack growths - plane strain and plane stress. Further AE testing is recommended in order to determine the fatigue life and the critical crack length for ultimate structural failure.

4:50 PM
Exploratory Research in Erosion Effects of Nanofluids on Metallic Materials: *Gustavo Molina*[1]; Mosfequr Rahman[1]; Mario Hulett[1]; Valentin Soloiu[1]; [1]Georgia Southern University

Nanofluids are fluids containing engineered colloidal suspensions of nanoparticles in ordinary base fluids, that are of interest for cooling systems because of their enhanced transport properties, especially thermal ones, as compared to those of the base fluids. However, the interactions (i.e., erosion, corrosion and possible nanoparticle deposition) of such nanofluids with metallic materials are largely unknown. The authors have designed, built and instrumented an erosion-test instrument for nanofluids, which allows accelerated testing of the effects of a nanofluid jet on metal targets. Exploratory work is presented on the wear and erosion effects on copper and aluminum targets when impacted with suspensions of alumina and of silicon oxide nanoparticles in coolant fluids (i.e., for weight concentrations of up to 2% nanopowders in distilled water and in solutions of ethylene glycol in water). The observed erosion and corrosion effects, and material surface changes are discussed as baseline for further investigation.

2:05 PM Keynote
Elastic-Plastic Analysis of Nanoscale Fracture Toughness: *William Gerberich*[1]; Natalia Tymiak[1]; Eric Hintsala[1]; [1]University of Minnesota

Extracting fracture toughness from nanospheres and nanopillars using routine programs for elastic-plastic analysis can involve various assumptions. This is partially due to the inherent non-dimensional nature of finite element analysis. Experimentally, it is known from high temperature measure of the brittle-to-ductile transition in silicon and 4H-SiC that at the transition there is a sharp breakdown in the usefulness of elasticity calculations. The present approach uses matching load-displacement curves and a length scaling procedure to estimate the KIc , fracture toughness, for small Si and MgO spheres and pillars. Substantial increases in toughness from converted J-integral values compared to elasticity solutions are discussed.

2:45 PM Keynote
Mechanical Behavior at the Limit of Strength: *John Morris*[1]; [1]University of California Berkeley

The one problem in mechanical behavior that can be solved from first principles is the limit of strength, the upper limit of stress at which a solid becomes elastically unstable and can no longer support mechanical load. While we are (quite properly) taught to focus on crystal defects as the keys to the mechanical behavior of most solids, research on behavior at the limit of strength has shown that a variety of important mechanical phenomenaare, in fact, inherent in the limit of strength. These particularly include the differences in patterns of deformation and fracture between bcc and fcc metals, and the fact that the former have an inherent ductile-brittle transition while the latter ordinarily do not. Experimentally, ultimate strength governs the limit of hardness observed in nanoindentation, limits the achievable toughness in high strength steels, and governs the attainable strength of a vey interesting class of new alloys.

3:25 PM
Connecting Nanoscale Mechanical Testing with Bulk Properties: *Andrew Minor*[1]; [1]UC Berkeley & LBL

The concept that the strength of a material changes with sample size is a well established but not a well understood concept in small-scale plasticity. While the general notion of increasing strength with reduced dimension has been observed in a wide variety of materials, we have yet to find a governing equation that can accurately link mechanical properties at the nanoscale to important bulk values related to concepts such as toughness, fracture & fatigue. Perhaps we will never be at the point of substituting a nanopillar compression test for a bulk toughness measurement . . . but our ability to connect nanoscale tests with bulk properties becomes increasingly relevant as nanoscale mechanical testing methods improve. This talk will focus on recent progress related to nanoscale mechanical testing methods in light of this view, and include a few in situ TEM nanopillar compression movies for the enjoyment of Professor Robert Ritchie.

3:40 PM
Mechanical Behavior in Metallic Nanowires: *Scott Mao*[1]; Jianyu Huang[2]; [1]University of Pittsburgh; [2]Sandia National lab

This talk is based on the publication of H. Zheng, A. Cao, C. R. Weinberger, J. Huang, D. Du, Y. Ma, Y. Xia, S. X. Mao, Discrete plasticity in sub-ten-nanometer-sized Au crystals, Nature Communication 2010). The mechanical behavior of bulk metals is usually characterized as smooth continuous plastic flow following by yielding. Here we show, by using in-situ TEM and molecular dynamics simulations, that the mechanical deformation behaviors of single-crystalline Au nanowires are quite different from their bulk counterparts. Correlation between the obtained stress-strain curves and the visualized defect evolution during deformation processes clearly demonstrates that a sequence of complex dislocation slip processes results in dislocation starvation, involving dislocation nucleation, propagation and finally escaping from the wire system, so that the wires deformed elastically until new dislocation generated. This alternating starvation of dislocations is unique in small-scale structures.

3:55 PM Break

4:10 PM
The Impact of Sidewall Roughness on the Macroscopic Tensile Strength of Polycrystalline Silicon: *James Foulk*[1]; Brad Boyce[1]; Earl Reedy[1]; James Ohlhausen[1]; [1]Sandia National Laboratories

In order to design efficient, reliable microelectromechanical systems (MEMS), one must understand the statistics of failure. For brittle systems, we can better understand strength distributions through flaw distributions. Specifically, we seek to investigate the role of sidewall flaw depth and curvature on the macroscopic tensile strength of polycrystalline silicon through targeted atomic force microscopy (AFM) and finite element (FE) simulations. The coupled AFM/FE approach hinges on accurate surface representations and predictive analysis methods. Crack initiation and propagation are modeled through a cohesive zone approach and the predicted strengths are parameterized to determine that grain boundary grooves, both deep and sharp, are the dominant sidewall defects.Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

4:25 PM
Forward and Reversed Loading of Thin Copper Wires at Ambient and Elevated Temperatures: *Andy Bushby*[1]; Julian Feuvrier[1]; David Dunstan[1]; [1]Queen Mary, University of London

The deformation behaviour of metals at very small strains is critical to fatigue behaviour but difficult to study in conventional tests. Here we describe experiments on long thin copper wires that achieve micro-strain resolution using a load-unload method. A high ratio of gauge length to wire diameter provides the extraordinary strain sensitivity. Reversal of the loading direction was possible through rotation of the wire in the opposite direction. Passing an electric current through the wire allowed experiments to be conducted at elevated temperatures. The elastic limit could be clearly identified and the early stages of plastic deformation studied at plastic strains far below the recognisable macroscopic yield strength. The reversibility of the dislocation structures formed under load could be observed by annealing experiments at high temperature. The observed increase in the elastic limit for wires of smaller diameter implies that size effects could be used to control fatigue behaviour.

4:40 PM

A Combined Experimental and Computational Investigation of Work Hardening in Micron and Submicron Dimensions: *Daniel Kiener*[1]; Andrew Minor[2]; Padubiri Guruprasad[3]; S. Keralavarma[3]; Gerhard Dehm[1]; Amine Benzerga[3]; [1]University of Leoben; [2]University of California; [3]Texas A&M University

Size-effects affecting strength in finite volumes have attracted considerable interest recently. However, less attention was devoted to the size-dependence of hardening in the micron and sub-micron regime. We combined in-situ SEM and in-situ TEM compression testing with 2.5D discrete dislocation computations to address the yield and, more importantly, the hardening behavior at small scales. Cu samples were prepared by FIB milling with dimensions from sub-100 nm to ~10 µm. Physics based constitutive rules and careful parameters determination entering the simulations from experiments were key for good quantitative agreement. Smaller samples are stronger and show higher hardening. This is not governed by Taylor hardening or loss of mobile dislocations, rather the size-dependent evolution of local geometrically necessary dislocation structures describes the observations in the micron regime best. In the deep sub-micron range the hardening processes are dislocation source controlled, in accordance with in-situ TEM observations and 2.5D/3D DDD simulations.

4:55 PM

Dislocation Dynamics Simulation of Indentation of FCC Crystals: *Mamdouh Mohamed*[1]; Ben Larson[2]; Giacomo Po[3]; Nasr Ghoniem[3]; Anter El-Azab[1]; [1]Florida State University; [2]Oak Ridge National Laboratory; [3]University of California, Los Angeles

We present a methodology of dislocation dynamics simulation of mesoscale deformation of FCC crystals under indentation. In addition to revealing the details of plastic deformation evolution under indentation loading, this work aims to compare induced local elastic strain and lattice rotation fields with the X-ray measurements of the same fields in 3D. The simulation framework consists in coupling a dislocation dynamics code with the finite element method, with the latter serving to update the crystal geometry during deformation. Nucleation of dislocations is introduced based on local elastic stability criterion that is guided by related molecular dynamics studies. The comparison between simulations and experiments involves computational coarsening of the elastic strain and lattice rotation fields of the dislocation system to match the pixel size of the X-ray data. Preliminary simulation results are presented along with X-ray data.

5:10 PM

The Elastic Anisotropy of Steel Investigated by Nanoindentation: *Ude Hangen*[1]; David Vodnick[1]; [1]Hysitron, INC.

A nanoindentation experiment results in a single indentation modulus that shows a value close to the Hills average of moduli. This is different for small - fully elastic indentations. The values of reduced modulus of elastically anisotropic steels are determined at sub-10nm, several-10nm and several-100nm indentation depths, by use of a calibrated Hertzian and Oliver and Pharr's methods. The values of reduced moduli determined at sub-10nm indentations are similar to the theoretical uni-directional reduced moduli values. On the other hand, with increasing penetration depth to several-10nm, the reduced moduli gradually deviate from the uni-directional values to the averaged values calculated from materials stiffness matrix. This evolution in the reduced modulus values is related to the evolution of stress state beneath the indentation and the indentation induced phenomena. These findings are of large importance as the anisotropic modulus can be determined on very small volumes of material.

Integrative Materials Design: Performance and Sustainability: Advances in Integrated Computational Materials Engineering (ICME) & Residual Stress Considerations in Design

An ICME Approach to Predict Performance Margins Caused by Microstructural Variability: *Elizabeth Holm*[1]; Corbett C. Battaile[1]; Thomas E. Buchheit[1]; Christopher R. Weinberger[1]; [1]Sandia National Laboratories

There is no question that variations in microstructure cause variability in materials properties; however, engineering analysis models rarely include this source of uncertainty, often necessitating substantial overdesign. An integrated computational materials engineering (ICME) approach has been initiated to create the capability to determine uncertainty reliably and efficiently. As a proof-of-principle, we examine the performance of weldments in austenitic steels and in BCC tantalum. Our approach integrates mechanistic understanding from the atomic scale into single crystal models that inform individual grain response at the polycrystalline scale. Polycrystalline results are homogenized to deliver a continuum model that can be used in full-systems models by the design engineer. At each length scale, experimental discovery and validation are critical to developing dependable models. This ICME approach represents a paradigm shift from the idealistic view that all parts are created equal to the realistic view that structure, properties, and performance are probabilistic.

Predicting the Properties of Magnesium Sheets by Means of a Multiscale Approach – from the Atomistic to the Macroscopic Scale: *Joern Mosler*[1]; Malek Homayonifar[1]; Mintesnot Nebebe[1]; [1]Technische Universität Dortmund and Helmholtz-Zentrum Geesthacht, Germany

The macroscopic behavior of magnesium sheets is strongly influenced by the underlying manufacturing processes. A realistic physical model of those processes would thus allow to design sheets with application-dependent optimized properties. As a first step toward this goal, a rolling process is considered within the present contribution. For modeling the texture evolution of magnesium during that process, a multiscale approach is discussed. Starting at the atomistic scale, the interactions between dislocations and deformation induced twins are analyzed using MD simulations. The results of such simulations enter a micro-mechanical model (crystal plasticity theory) which acts in turn as the lower scale for a connection to a phenomenological macroscopic description. Based on the final macroscopic approach, all important mechanical properties for technically relevant large-scale engineering applications are consistently defined. Within the present talk, focus is on the formability of magnesium sheets.

2:50 PM Invited

Simulation-Based Strategies to Support Alloy Design for Fatigue Resistance: *David McDowell*[1]; [1]Georgia Institute of Technology

Concepts are introduced concerning microstructure-sensitive modeling of fatigue of advanced materials, particularly with regard to modeling variability of fatigue response as a function of microstructure. We consider sensitivity of fatigue crack formation and early growth at the scale of the grains in polycrystalline and polyphase microstructures to facilitate preliminary parametric design exploration aimed at comparing a range of microstructure morphologies for nominally the same composition. A general methodology for stages of small crack formation and growth is introduced, including fatigue crack nucleation and early growth at the scale of grains (incubation), microstructurally small crack growth, physically small and long crack growth. Scatter in HCF and VHCF is computationally assessed using multiple statistical volume elements and the distribution of computable mesoscopic Fatigue Indicator Parameters (FIPs).Future challenges and desirable advances are briefly discussed.

3:15 PM Invited

Managing Uncertainty in Fracture: *Brad Boyce*[1]; Corbett Battaile[1]; James Foulk[1]; E. David Reedy[1]; [1]Sandia National Labs

Most current design methods treat material properties such as fracture strength as a deterministic value. Yet fracture is a stochastic process dictated by the complexities of the microstructure and native flaw population. Poorly understood statistical representations of material properties cause engineers to overdesign components. In this overview, we will illustrate fracture variability in two extremely different material systems: perfectly brittle silicon microsystems and ductile austenitic stainless steel weldments. In both material systems, a detailed examination of the statistics of fracture provides insight into the true design thresholds and the features that govern reliability. As materials scientists, we must strive to better understand the origins of stochastic material response and find pathways to convey statistical representations of material response in engineering design. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

An Integrated Framework for Reducing Uncertainty in Fatigue Life Limits of Turbine Engine Alloys: *James Larsen*[1]; Sushant Jha[2]; Michael Caton[1]; Reji John[1]; Andrew Rosenberger[1]; Christopher Szczepanski[1]; Patrick Golden[1]; Dennis Buchanan[3]; Jay Jira[1]; [1]Air Force Research Laboatory; [2]Universal Technology Corporation; [3]University of Dayton Research Institute

Design and life-cycle sustainment of Ti and Ni alloys used in fracture-critical rotor components in advanced turbine engines require a delicate balance of performance, safety, and affordability. Traditional approaches have involved large experimental programs from which statistically based life limits are derived by extrapolation from mean fatigue behavior. However, we have recently found that the fatigue lifetime under a given test condition often exhibits a bimodal form, and the trends in mean vs. minimum fatigue lifetime typically respond differently to loading and microstructural variables. The underlying life-limiting mechanisms appear to follow a probabilistic microstructural hierarchy that is controlled by susceptibility to early damage and growth of small cracks. This presentation reviews the strategy for reducing uncertainty in prediction of lifetimes and highlights the integration between experiments and simulations of representative Ti and Ni turbine engine alloys, as part of the Air Force initiative on Integrated Computational Materials Science and Engineering.

Probabilistic Prediction of Minimum Fatigue Life of a Shot Peened Titanium Alloy: *Reji John*[1]; Sushant Jha[2]; James Larsen[1]; [1]Air Force Research Laboratory; [2]Universal Technology Corporation

The benefits of shot-peen induced compressive residual stresses in improving fatigue life and retardation of crack growth have been extensively demonstrated. Incorporating surface-treatment induced residual stresses (RS) in life prediction has been hampered by the variability in the RS profile and relaxation, and a lack of physics-based measure of the benefit of RS on the lifetime. Hence, the fatigue variability behavior of the alpha+beta titanium alloy, Ti-6Al-2Sn-4Zr-6Mo, was studied at 260°C under RS-free, low stress ground and shot-peen surface conditions. The variability in the RS profile for the low stress ground and shot-peen conditions was determined. The influence of the surface treatment effects on the variability in the location and size of the failure initiation sites was characterized. This distribution of initiation sizes was coupled with the variability in micro-scale small crack growth and RS depth profiles to probabilistically predict the observed fatigue lifetime limit in Ti-6Al-2Sn-4Zr-6Mo.

Effects of Residual Stress on the Behavior of Metallic Materials: *Michael Hill*[1]; [1]University of California, Davis

In recent years, advances in residual stress engineering methods have improved our ability to quantify the effects of residual stresses on structural performance. Residual stresses are locked into structural materials during manufacture, or subsequent processing of components, and are known to significantly affect mechanical performance. Typically, they affect subcritical cracking due to fluctuating stress (fatigue) and environmental exposure (environmentally assisted cracking) and may increase or decrease the time required for cracks to nucleate and then the rate of crack growth. Structural engineering practice has largely avoided explicitly accounting for residual stresses, and instead handled their consequences through empirical approaches. Those empirical approaches are specific to a given application of material and process, and, in the case of residual stresses, part geometry. Recent and continuing research is developing more fundamental, and less empirical, approaches for residual stress engineering, particularly in metallic materials, and some of this research will be described.

5:20 PM Invited

An Evaluation of the Crack-Compliance Method for Determining the Stress Intensity Resulting from Residual Stress: *Keith Donald*[1]; [1]Fracture Technology Associates

Residual stress contributions can be a significant source of variability in life prediction methodology. As such, excess weight penalties may result due to uncertainty in the fatigue crack growth response. The crack-compliance method offers the ability to determine Kresidual by measuring the change in displacement at zero force during a crack growth rate experiment. This method gives the same result as Schindler's cut-compliance method but does not require influence functions. The practical application of this methodology requires sufficient signal stability and linearity to determine Kresidual. Examples will include residual stresses resulting from extrusions, forgings, quenching and friction stir welding processes. Test coupon types will include compact tension and middle crack tension samples. Sources of measurement error will be presented. Once the K residual profile has been determined, normalization methods will be presented to establish a fatigue crack growth rate response that is independent of the effect of residual stress.

5:40 PM Invited

The Relative Importance of Various Mechanical Properties on Structural Performance: *Ted Anderson*[1]; [1]Quest Integrity Group

While it is an obvious platitude that good mechanical properties are preferable to poor properties, economic considerations usually dictate that a "suitable" material be chosen over the "best possible" material for a given application. There are often trade-offs in mechanical properties, such as strength versus toughness in structural metals. Achieving both high strength and high toughness typically requires alloying additions and advanced processing, both of which add to material cost. This paper presents a series of parametric analyses and case studies that explore the relative importance of strength, toughness, and fatigue crack growth constants on material selection.

International Smelting Technology Symposium (Incorporating the 6th Advances in Sulfide Smelting Symposium): Pretreatment and Recycling Processes

Sponsored by: The Minerals, Metals and Materials Society, The Metallurgy and Materials Society of CIM, TMS Extraction and Processing Division, TMS: Pyrometallurgy Committee
Program Organizers: Jerome Downey, Montana Tech of the Univ of Montana; Thomas Battle, Midrex Technologies, Inc.; Jesse White, Elkem Solar Research

Tuesday PM
March 13, 2012

Session Chair: To Be Announced

2:00 PM
Integrated Recycling at Boliden's Rönnskär Smelter; Formation of Slag Products: Sina Mostaghel[1]; Hannes Holmgren[2]; Taishi Matsushita[3]; *Caisa Samuelsson*[1]; [1]Luleå University of Technology; [2]Rönnskär Smelter, Boliden Mineral AB; [3]Royal Institute of Technology (KTH)

Rönnskär Smelter of Boliden Mineral AB, Sweden, is a large end-processor of secondary raw materials and waste, including electronic scrap. E-scrap may introduce various impurities to the smelter's flow-sheet, among which alumina is one of the most common and significant ones. Current article summarizes the results of an ongoing research at Luleå University of Technology, Sweden, to study the influences of alumina on different properties of slag from the zinc fuming process at Rönnskär smelter. A combination of different experimental techniques and thermodynamic calculations has been used to investigate properties such as density, surface tension, effective thermal diffusivity, viscosity, melting and leaching behaviors. Results show that addition of alumina to this slag increases the degree of polymerization of the melt, and the properties vary correspondingly. Mineralogy of the semi-rapidly solidified samples is also changed due to alumina addition. A correlation between mineralogy and leaching behavior can be observed.

2:25 PM
Promotion of Recycling Business by Combination of a Pre-Treatment Plant and the Mitsubishi Process at Naoshima Smelter & Refinery: *Yuji Mizuta*[1]; Nobuhiro Oguma[1]; Shigehiko Iwahori[1]; Hideya Sato[1]; [1]Mitsubishi Materials Corporation

Recyclable materials containing copper and precious metals have been treated at the Mitsubishi Process in Naoshima. In 2003, a new incinerating and melting plant (pre-treatment plant) for waste materials, such as shredder residue of automobile and scrapped appliance, was constructed. All of produced slag/metal mixture is treated at the Mitsubishi Process, and which results in the significant increase of recyclable materials' treatment. The combination of two processes has realized a highly efficient and environmentally friendly system for recycling valuable metals in the waste which used to be sent to a landfill. Naoshima continues to make efforts to achieve the highly efficient operations of the two processes, and plans to increase the treatment of recyclable materials further. This paper summarizes the recent operations and the various improvements implemented in the pre-treatment plant.

2:50 PM
Optimum Feed Preparation for Sulfide Smelting: *Jyri Talja*[1]; Shaolong Shen[1]; Hannu Mansikkaviita[1]; [1]Kumera Corporation

For optimum smelting result proper treatment of the feed is needed to ensure favourable conditions for ignition characteristics, heat balance, mass balance with tolerable impurity levels, and overall process economics. This consists of physical treatments before drying (blending), chemical treatments before drying, (roasting, if required), drying itself and physical treatments after drying (fractioning, if required). Effects of fluctuation on mineralogy and moisture should be minimized by blending the concentrates in a bedding plant prior to drying. Alternatively to drying, any additional treatments, like roasting for impurity removal, may be needed for part of the concentrate.Sustainability, energy efficiency, utilization of waste energy, low gas and dust emissions, product quality, availability and occupational exposure reduction are decisive criteria in drying today. These criteria are best met by the Kumera steam dryer with best energy efficiency, zero CO2 emission, lowest operational and maintenance expenses, superior availability and fine product quality.

3:15 PM
Partially Reduced Feedstocks and Blast Furnace Ironmaking Carbon Intensity: *Petrus Pistorius*[1]; [1]Carnegie Mellon University

Use of coke in blast furnace ironmaking is the main origin of carbon dioxide emissions from integrated steelmaking. Using pre-reduced iron feedstocks would reduce the coke rate and, if pre-reduction were carried out with natural gas, would decrease the overall carbon intensity of ironmaking. Blast furnace productivity would also increase, because the blast volume per unit of hot metal would decrease. It will be shown that these trends can be predicted quantitatively, by using a conceptually simple Rist-style blast furnace mass and energy balance, assuming furnace productivity to be limited by the tuyere gas flow rate. Such predictions would assist in optimizing the choice of the degree of reduction and relative amount of pre-reduced blast furnace feed.

3:40 PM Break

4:00 PM
Injection of Alternative Carbon Containing Materials in the BF: *Lena Sundqvist Ökvist*[1]; Gunilla Hyllander[2]; Michael Hensmann[3]; Erik Olsson[4]; Olavi Antila[4]; Stefan Schuster[5]; Maria Lundgren[1]; [1]Swerea MEFOS AB; [2]LKAB; [3]VDEh-Betriebsforschungsinstitut; [4]SSAB EMEA; [5]voestalpine Stahl GmbH

Residual materials from the integrated plant itself or other sources often contain valuable compounds as e.g. iron and carbon. Dust and sludge have to be agglomerated to be able to recycle to the BF via top-charging. By injection of the materials preparation methods in terms e.g. drying and/or screening only, can be used. BF dust and sludge have been successfully injected up to levels of 60 kg/tHM in the LKAB experimental BF (LKAB EBF\149;). Efficiency in recovery of valuable compounds as well as the behaviour of undesired elements have been evaluated and are discussed.

4:25 PM
Experiences of Using Various Metallurgical Reactors for Reduction of V-Bearing Steel Slags and Other Wastes: *Mikael Lindvall*[1]; Guozhu Ye[1]; [1]Swerea MEFOS AB

The Swedish iron ore contains about 0.1%V. The vanadium is reduced to the hot metal in a blast furnace and ends up in the slag in the converter. The high V-content, up to 5%V, leads to a very limited external application of the slag in Sweden. Since 2004, MISTRA - the Swedish Foundation for Strategic Environmental Research has together with the steel and mining industry in Sweden and Finland initiated and supported a long term project aiming at efficient recovery of vanadium in the slag and at the same time a useful slag product with low V-content. The aimed concept consists of a reduction step and a phosphorus removal step.This paper will highlight some of the results with focus on the various metallurgical reactors used for slag reduction, including results from recently performed pilot trials using a DC furnace for co-treatment of metallurgical slags and other wastes.

4:50 PM
Phase Change and Morphology in the Oxidation of Zinc Sulfide Powder: *Okano Satoshi*[1]; Hiromichi Takebe[1]; Takahiko Okura[2]; [1]Ehime University; [2]Tokyo University

There is a problem of calcine accretion in a fluidized bed roaster for finer zinc concentrates. in order to avoid the calcine accretion, the oxidation behavior of zns powder was basically studied in terms of phase change and particle morphology. a commercial high-purity zns powder was analyzed by thermo gravimetry(tg). from tg results, the zns powder was heat-treated at 400–1000ºC for 1h in air. samples were characterized by various analyzer. zns phase was directly oxidized to zno phase at 700ºC with reducing the size of powder form. the sintering of zno powder products occurred at higher temperatures of >700ºC. The reaction process is supposedly affected by the state of roasting gas flow at zns particle surface. Sulfate phases such as zno•2znso$_4$ was formed and decomposed by so$_2$ gas around the particle surface, depending on the flow rate of atmospheric gases for tg and heat-treatments.

5:15 PM
Using of Fluidized Roasting Technology in Comprehensive Utilization of Magnetized Gold Smelting Waste: *Xiaoyin Liu*[1]; Yongfu Yu[1]; Wen Chen[1]; Xiaosu Lu[1]; Zeyou Peng[1]; Jialin Li[1]; [1]Changsha Research Institute Of Mining And Metallurgy

This paper introduces the principle and techniques of magnetized fluidized roasting technology,using of this technique in comprehensive utilization of gold smelting waste. Through this technology iron concentrates with grade of 60%, iron yield 85% can be obtained from the gold smelting waste which contains 35% iron. Based on the 50 Kt/a industrial test which verifies the bench-scale experiment results, the comprehensive utilization of magnetized gold smelting waste is realized, which enters a new stage for the using of gold smelting waste.

Materials and Fuels for the Current and Advanced Nuclear Reactors: Structural Materials I

Sponsored by: The Minerals, Metals and Materials Society, TMS Structural Materials Division, TMS/ASM: Corrosion and Environmental Effects Committee, TMS/ASM: Nuclear Materials Committee
Program Organizers: Ramprashad Prabhakaran, Idaho National Laboratory; Dennis Keiser, Idaho National Laboratory; Raul Rebak, GE Global Research

Tuesday PM — Room: Swan 2
March 13, 2012 — Location: Swan Resort

Session Chair: Kumar Sridharan, University of Wisconsin - Madison

2:00 PM Invited
Light Water Reactor Materials for Commercial Nuclear Power Applications: *Brian Burgos*[1]; [1]Westinghouse Electric / Research and Technolgy

A nuclear vendor perspective will be presented describing light water reactor materials issues facing the nuclear industry. A historical perspective will capture issues that the commercial nuclear industry faced along with a look into the future of materials related issues challenging future plant builds.

2:30 PM
Cold Spray Technology: A Potential Approach to Address Materials Aging Issues in Nuclear Reactor Systems: *Kumar Sridharan*[1]; Benjamin Maier[1]; Benjamin Hauch[1]; Youngki Yang[1]; Todd Allen[1]; [1]University of Wisconsin

Cold spray process is a materials deposition technology that is being investigated for a number of engineering applications. In the cold spray process, powder particles are propelled at supersonic velocities on to the surface of a part to form a coating with superior properties. Because of the high deposition rates, the process has the potential to repair cracks and restore dimensions in recessed regions caused by stress corrosion, corrosion, and erosion. In the cold spray process the powders are not melted, and deposition occurs at low temperatures. Therefore, the process can deposit dense coatings and filler materials that are well-bonded to the substrate, relatively free of oxidation and porosity,and with no heat affected zone in the base material. Potential applications of this technology for nuclear reactor aystems will be discussed.

2:50 PM
Stress Corrosion Crack Initiation Testing of Cold Worked 316 Stainless Steel in Simulated PWR Primary Water under the Spring Loaded Condition: *Yuichi Miyahara*[1]; Toshio Yonezawa[1]; Atsushi Hashimoto[2]; [1]Tohoku University; [2]Kobe Material Testing Laboratory Co., LTD.

Recently, several papers on the inter-granular stress corrosion cracking (IGSCC) growth rate for the highly cold worked 316 stainless steels in simulated PWR primary water. However, the IGSCC initiation test in simulated PWR primary water environment was scarcely reported except slow strain rate testing (SSRT). In this study, various SCC initiation tests under the spring loaded conditions were conducted on cold worked 316 stainless steel in simulated PWR primary water. That is, spring loaded type U-bend specimens with or without hump forming, reverse U-bend specimens etc., were studied to decrease an effect of stress relaxation during the SCC tests, in this study. From these test results, IGSCC initiation was found on humped U-bend specimens. The effect of prior cold work on IGSCC susceptibility was contrary to the reported results obtained by SSRTs.In this paper, IGSCC initiation characteristics of the cold worked 316 stainless steel was discussed.

3:10 PM
Creep-Fatigue Behavior of an Advanced Austenitic Alloy Strengthened by Nano-Scale MC Precipitates: Laura Carroll[1]; *Mark Carroll*[1]; Richard Wright[1]; [1]Idaho National Laboratory

An advanced austenitic alloy, HT-UPS (high temperature - ultrafine precipitate strengthened), is a potential candidate material for structural components of fast reactors and energy-conversion systems. The HT-UPS alloy, with a composition based largely on modifications to 316 stainless steel (SS), demonstrates improved creep resistance through additions of Ti and Nb that form nano-scale MC precipitates. The cycles to failure at 650°C of HT-UPS and 316 SS are similar in fatigue and creep-fatigue despite differences in peak stress profiles and the deformed microstructures. Internal grain boundary damage resulting from the tensile hold is present in the form of fine cracks for longer hold times, and substantially more of these internal cracks are visible in 316 SS than HT-UPS. The cycled dislocation substructure in 316 SS has regions with an equiaxed cellular structure and regions with a lath structure, whereas tangles of dislocations are pinned at the nanoscale MC precipitates in HT-UPS.

3:30 PM
Impact of Hydrogen Absorption on the Thermophysical Properties of Zircaloy Cladding: *J. B. Henderson*[1]; A. T. Nelson[2]; K. J. McClellan[2]; [1]Netzsch Instruments NA; [2]Los Alamos National Laboratory

Under normal operating conditions, chemical reactions occur between the fuel/coolant and the cladding. This results in the formation of a ZrO_2 layer as well as hydrogen and oxygen absorption produced by the H_2O+Zr reaction. During loss of coolant accidents, these reactions are accelerated because of the higher temperatures. The end result is embrittlement of a portion of the cladding and reduction of the thickness of the load-bearing material. In addition, the thermophysical properties are significantly impacted. For example, the thermal conductivity is reduced, resulting in poor heat transfer and higher fuel/cladding temperatures. The purpose of this work was to measure the thermal diffusivity (=>thermal conductivity) as a function of temperature and H/Zr ratio. The H/Zr ratio was fixed by varying the partial pressure of hydrogen and verified by mass measurements. Identical test conditions were then applied for the thermal diffusivity measurements. The results of this work will be presented.

3:50 PM Break

4:00 PM

A Novel Fe-Based ODS Fabrication Process: *Joel Rieken*[1]; Iver Anderson[2]; Matthew Kramer[2]; [1]Iowa State University; [2]Ames Laboratory

Oxide dispersion forming ferritic stainless steel (i.e., Fe-Cr-(Ti,Hf)-Y-O) powders were generated using a novel gas atomization reaction synthesis technique. During this process an ultra-thin metastable Cr-enriched surface oxide layer formed and encapsulated the rapidly solidified powders. This oxide layer was used as a vehicle to transport a prescribed amount of solid-state O into the consolidated microstructure. Elevated temperature heat treatment was then used to facilitate thermodynamically driven internal O exchange between trapped films of Cr-enriched oxide and Y-containing intermetallic precipitates, resulting in highly stable mixed oxide dispersoids (i.e., Y-(Ti,Hf)-O) that were identified using high-energy XRD and TEM. Following dispersoid formation, thermal-mechanical processing was used to fabricate a fine scale dislocation sub-structure for ultimate strengthening of the ODS alloy. Preliminary mechanical properties were examined using elevated temperature tensile testing. Support from the Department of Energy, Office of Fossil Energy (ARM program) through Ames Laboratory contract no. DE-AC02-07CH11358 is gratefully acknowledged.

4:20 PM

Evaluation of Silicon Carbide Joining for Nuclear and Fusion Applications: *Yutai Katoh*[1]; Monica Ferraris[2]; Tatsuya Hinoki[3]; Charles Henager[4]; [1]Oak Ridge National Laboratory; [2]Politecnico di Torino; [3]Kyoto University; [4]Pacific Northwest National Laboratory

Based on the recent development of highly radiation-resistant silicon carbide-based ceramic matrix composites, applications of these materials to nuclear and fusion energy are presently proposed and being researched. However, development of joining for these materials for use in the harsh radiation environment remains as a significant challenge. Moreover, additional requirements such as gas impermeability and corrosion resistance have to be considered for specific application environments. In the recent collaborative project among the U.S. Fusion Materials Program, Politecnico di Torino, and Kyoto University, development and evaluation of joining technologies for silicon carbide ceramics and composites for use in fusion and nuclear reactors were attempted. This paper will discuss the recent progress including 1) identifying promising joining techniques for radiation services, 2) development of small specimen test technique adequate to evaluate the shear strength of ceramic joints, 3) baseline characterization of the joint mechanical properties, and 4) progress in neutron irradiation program.

4:40 PM

Precipitation of Sigma Phase in Cast Duplex Stainless Steel Z3CN20.09M for Primary Coolant Pipe of Nuclear Power Plants and Its Influence on Localized Corrosion: Yongqiang Wang[1]; *Bin Yang*[1]; Jun Han[1]; [1]University of Science and Technology Beijing

Work was undertaken to establish reliable time-temperature-precipitation (TTP) diagram for sigma phase formation in cast duplex stainless steel Z3CN20.09M for primary coolant pipe of nuclear power plants and the mechanism of sigma phase formation was determined too. It was found that the formation of sigma phase occurred in the temperature range 600-950□ by nucleation and growth at the ferrite/austenite phase boundaries and higher kinetics of sigma phase precipitation was obtained at 850°C. The influence of sigma phase on intergranular corrosion (IGC) and pitting corrosion of Z3CN20.09M has been investigated by chemical and electrochemical methods and related to the microstructure as observed using light optical microscopy, scanning electron microscopy, and transmission electron microscopy. The results showed that IGC and pitting corrosion resistance of Z3CN20.09M has decreased markedly with increase of sigma phase. The more sigma phase the lower pitting potential (Eb) and critical pitting temperature (CPT) and the higher ratio Ir/Ia.

5:00 PM

Effect of Tellurium on Intergranular Cracking in Nickel-based Alloy: *Yanyan Jia*[1]; Wenguan Liu[1]; Yang Zou[1]; Zhijun Li[1]; Yanling Lu[1]; Min Liu[1]; Xingtai Zhou[1]; Hongjie Xu[1]; [1]Shanghai Institute of Applied Physics, Chinese Academy of Sciences

Embrittlement problem of alloy induced by fission-product, for example tellurium, affects the safety of molten-salt reactors (MSRs) seriously. Previous research has suggested that tellurium was responsible for intergranular cracking that occurred in Hastelloy-N alloy, while chromium might prevent the dynamics process of embrittlement induced by tellurium attacking. In order to understand the mechanism that tellurium induces grain boundary cracking, a series of experiments were designed to get morphology, distribution and number of the cracks in Nickel-based alloy with different Cr contents. These experiments indicate that the depth of intergranular creaks caused by Te in the alloys with various contents of Cr is different in the same conditions. With the increase of the content of Cr, the tendency to form cracks in Nickel-based alloy is reduced. In addition, the penetration mechanism of Te in Nickel-based alloy with different Cr contents is also discussed in detail.

5:20 PM

Oxide Dispersion Strengthened Steels via Mechanical Alloying and Spark Plasma Sintering: *Somayeh Pasebani*[1]; Indrajit Charit[1]; Kerry Allahar[2]; James Cole[3]; Darryl Butt[2]; [1]University of Idaho; [2]Boise State University; [3]Idaho National Laboratory

Oxide dispersion strengthened (ODS) alloys are a promising class of materials for advanced reactor applications because of their high creep and tensile strength, and excellent radiation damage resistance. Copious nano-precipitates formed during hot consolidation act as obstacles against dislocation motion, serve as point defect sinks, and promote helium trapping. Unlike the traditional ODS alloys using yttria as dispersoids, in this study ~0.4 wt.% lanthana is added to the elemental metallic powders (Fe-14Cr-1Ti-0.3Mo, wt.%), followed by high energy ball milling and subsequent consolidation via spark plasma sintering (SPS). Ball milling was conducted for 10 and 20 hours in a high energy shaker mill. SPS is performed at different temperatures, pressures, heating ramp rates and dwell times. The density and hardness of SPSed samples are measured. Transmission electron microscopy is used to study the morphology of the oxide nano-features formed during SPS.

5:40 PM

Wollastonite Based-Chemically Bonded Phosphate Ceramics with Boron Contents as a Potential Material for Nuclear Shielding Applications: *H. A. Colorado*[1]; J Pleitt[2]; J-M Yang[1]; C. H. Castano[2]; [1]University of California, Los Angeles; [2]Missouri University of Science and Technology

The shielding properties to neutrons as well as the mechanical effects of boron incorporation into wollastonite based chemically bonded phosphate ceramics (Wo-CBPC) composites are presented. The Wollastonite-based CBPC was fabricated by mixing a patented aqueous phosphoric acid formulation with Wollastonite powder. CBPC has been proved to be good structural material, with excellent thermal resistant properties, and research already showed their potential for gamma radiation shielding applications. Wo-CBPC is a composite material with several crystalline and amorphous phases. Irradiation experiments were conducted on different Wollastonite-based CBPCs with Boron contents. Radiation shielding potential, attenuation coefficients in a broad range of energies pertinent to engineering applications and density experiments showing the effect of the boron content are also presented. Microstructure was identified by using scanning electron microscopy and X-ray diffraction. Compressive strength and setting time were also evaluated.

Design, Microstructure Evolution, Properties, and Applications of Advanced Intermetallic TiAl Alloys: *Helmut Clemens*[1]; Svea Mayer[1]; [1]Montanuniversität Leoben

After almost three decades of intensive fundamental research and development activities intermetallic titanium aluminides based on the γ-TiAl phase have found applications in automotive and aircraft engine industries. The advantages of this class of innovative high-temperature materials are their low density, their good strength and creep properties up to 750°C. A drawback, however, is their limited ductility at room temperature, which is expressed in a low plastic fracture strain. Advanced TiAl alloys are complex multi-phase alloys which can be processed by ingot or powder metallurgy as well as precision casting methods. Each process leads to specific microstructures which can be altered and optimized by thermo-mechanical processing and/or subsequent heat-treatments. This presentation gives a comprehensive summary regarding our current research activities.

2:30 PM Invited

Tools for Manipulating Precipitation Processes: Alloy and Process Design: *Christopher Hutchinson*[1]; [1]Monash University

Controlling the particle distribution in precipitate hardenable alloys is the primary means of modifying the mechanical properties of such alloys. However, the nucleation, growth and coarsening processes that govern the evolution of precipitate structures are complex, competing and overlapping processes and controlling these is non-trivial. Three approaches to manipulating aspects of the precipitation process are outlined in this presentation. The first is a thermo-kinetic criterion for choosing microalloying elements that catalyze the nucleation of hardening precipitates and can give rise to large refinements in the scale of the precipitate structure with significant increases in strength. The second approach attempts to modify the shape of precipitates at approximately constant scale and allows for improvements in the thermal stability of alloys. The third approach uses temperature as a processing variable to control the overlap and competition between nucleation, growth and coarsening processes. Large efficiencies in processing and properties can be realized.

3:00 PM Invited

Magnesium Alloy Development Using Computational and Experimental Tools: *Alan Luo*[1]; Raja Mishra[1]; Bob Powell[1]; Anil Sachdev[1]; [1]General Motors Global Research and Development

This talk summarizes the development of new cast and wrought magnesium alloys using computational thermodynamics and experimental methods. The work illustrates the role of calculated phase diagrams, solidification paths and phases in predicting and interpreting the final microstructure of Mg-Al-Ca and Mg-Al-Sn cast alloy systems and Mg-Al-Mn and Mg-Zn-Ce wrought alloy systems. The Mg-Al-Ca alloys show excellent creep resistance due to the formation of high-temperature (Mg,Al)2Ca phase. The Mg-Al-Sn alloys are designed for mechanical properties and corrosion resistance by optimizing the Mg17Al12 and Mg2Sn phases in the microstructure. AM30 (Mg-3Al-0.3Mn) alloy was developed to have significantly improved extrudability and slightly improved mechanical properties compared to AZ31 alloy, due to the absence of low eutectic-point Mg-Al-Zn ternary phases existing in the AM30 alloy. In the Mg-Zn-Ce system, Zn provides strength through solid solution strengthening, while Ce increases the ductility by creating a favorable texture.

Design of a Nanocrystalline Alloy Coating for Electrical Connector Applications: *Christopher Schuh*[1]; Alan Lund[2]; [1]MIT; [2]Xtalic Corporation

Electrical connectors require a unique set of physical and mechanical properties, including low bulk and interfacial resistivities that remain stable even after significant exposure to atmospheric corrosion, temperature, and multiple cycles of sliding wear. This talk will provide an overview of a new Ni-W alloy nanocrystalline coating material designed as the functional barrier layer in electrical connectors. The coating is electrodeposited as an interlayer between Cu-based substrate materials and an outer finish of precious metal, and is delivered with a finely-tuned nanocrystalline structure that is stabilized by a solid solution alloying addition that decorates grain boundaries. The nanostructure of the coating has been optimized to deliver a substantial improvement in the key property set for this application. The design process for this coating will be described from the laboratory to the industrial scale, comprising elements of theory and simulation, advanced characterization, property measurements, and engineering qualification testing.

4:20 PM Invited

Develop ICME Tool for High Ductility Cast Aluminum Alloys for Automotive Body Applications: *Mei Li*[1]; J. Forsmark[1]; J. Zindel[1]; L. Godlewski[1]; Xuming Su[1]; [1]Ford Motor Company

One heat treatable high ductility Al-Si-Mg alloy was investigated in this study. To achieve the full potential of strength and ductility of this alloy, super vacuum die casting (SVDC) process was used to produce the high integrity Al cast components free of air entrapment. A semi-empirical model based on Shercliff and Ashby's process model for age hardened Al alloys and experimental data were developed. The model can predict the effect of solidification time, aging temperature and time on yield strength. A quality mapping approach was adopted to predict the local ductility based on criteria functions from commercial casting simulation program MAGMAsoft and experimental data. A new materials card was then built for crash performance analysis in LS-DYNA which includes the impact of local yield strength and ductility. Finally this ICME tool was validated on component level three-point and four-point bending testings.

4:50 PM

Systems Engineering Framework for the Integrated Computational Design of Advanced Aluminum Alloys: *Abhijeet Misra*[1]; James Wright[1]; Herng-Jeng Jou[1]; William Counts[1]; Charles Kuehmann[1]; [1]QuesTek Innovations LLC

Computational materials design integrates targeted materials process-structure-property models within a systems framework to meet specific engineering needs. A key component to materials design models is a basis on fundamental thermodynamics, phase equilibria, and diffusion, implemented in a multicomponent framework. The application of ICME tools towards the computational design of advanced aerospace and marine aluminum alloys is discussed. Key process-structure design tools for aluminum alloys include solidification and homogenization modeling, simulation of the hot working process (for wrought alloys), inoculation modeling (for cast alloys) and the simulations of precipitation behavior during thermal treatment. Key structure property models include mechanistic quench sensitivity models, strength models, hot-tearing resistance models (for castings) and toughness, SCC and corrosion resistance models. The modeling effort and application in the design of advanced wrought and cast aerospace and marine Al alloys demonstrates the utility of ICME to accelerate and reduce risk during development of complex materials.

5:10 PM
The Use of In-Situ Characterization Techniques for the Development of Intermetallic Titanium Aluminides: *Svea Mayer*[1]; Thomas Schmoelzer[1]; Helmut Clemens[1]; [1]Montanuniversitaet Leoben

Urgent topics concerning energy efficiency and environmental politics require novel approaches to materials design. One recent example is thereby the implementation of lightweight intermetallic TiAl alloys as structural materials in aerospace applications as well as in the next generation of automotive engines. Their low density and exceptional high-temperature strength make them the first choice to gradually replace the dense Ni-base superalloys and high-alloyed steels particular for operating temperatures up to 750°C. To develop stable and sustainable processing routes, knowledge on solidification processes and phase transformation sequences in advanced TiAl alloys are fundamental. Therefore, in-situ diffraction techniques employing synchrotron radiation and neutrons were used for establishing phase diagrams, investigating advanced heat-treatments and for optimizing thermo-mechanical processing. Additionally, the evolution of the materials microstructure was subject of our investigations.

Materials in Clean Power Systems VII: Clean Coal-, Hydrogen Based-Technologies, and Fuel Cells: Materials for Hydrogen Production, Separation, and Storage

2:00 PM
Catalytic Properties of Ni-Al Intermetallic Nanoparticle Catalysts for Hydrogen Production from Methanol and Methane: *Ya Xu*[1]; Junyou Yang[2]; Masahiko Demura[1]; Toshiyuki Hirano[1]; [1]National Institute for Materials Science; [2]Huazhong University of Science and Technology

Recently, we found that Ni3Al intermetallic compound, in the form of both powder and foil, shows catalytic activity and selectivity for methanol decomposition and methane steam reforming, indicating a possibility to develop Ni-Al intermetallic compounds as catalysts for hydrogen production. In order to pursue high catalytic performance of Ni-Al intermetallic compounds for hydrogen production, we synthesized Ni-Al intermetallic nanoparticles from Ni-Al alloy ingots by vacuum arc plasma evaporation technique for the first time. The characterization of the synthesized nanoparticles was carried out using X-ray diffraction, scanning electron microscopy, transmission electron microscopy, energy dispersive X-ray spectroscopy. The catalytic properties of the Ni-Al nanoparticles for methanol decomposition were evaluated. It is found that the nanoparticles had a large surface area above 70 m2/g, and showed very high catalytic activity for methanol decomposition and methane steam reforming.

Ca, Li and Mg Based Lightweight Intermetallics for Hydrogen Storage: *Beau Billet*[1]; Ji-Cheng Zhao[1]; [1]Ohio State University

Intermetallics with Laves structures have the potential to be hydrided to a maximum of AB2H6 due to the impeding H-H interactions where A and B are metallic elements. Ca, Li, and Mg-based Laves phases are among the lightest intermetallic compounds that can potentially serve as the highest capacity reversible interstitial metal hydrides for hydrogen storage. Possible multi-component compositions based on these elements will be discussed to optimize the structures of Laves phases to store hydrogen amongst the B4, AB3 and A2B2 sites. This talk will present our experimental exploration in these lightweight systems for hydrogen storage applications

Effects of Long Term Aging on Creep Properties of HP Alloy Hydrogen Reformer Tubes: *Milo Kral*[1]; Karl Buchanan[1]; [1]University of Canterbury

The centrifugally cast HP series has become the dominant hydrogen reformer tube material for the petrochemical industry. HP alloys with small additions of Nb and Ti are reported to have superior creep properties over standard HP alloys in accelerated testing. However, accelerated testing of ex-service material typically indicates these tubes have lower remaining life in comparison to that predicted from the as-cast data. This discrepancy is largely due to nicrostructural evolution during service. The present work studies the effects of long-term laboratory aging on the creep performance of HP-Niobium and HP-Micro alloys, un-stressed at 1000-1100°C for 500-10,000 hours. Samples were also subjected to accelerated creep testing. Detailed characterization of as-cast, aged and creep samples was carried out using high resolution SEM and TEM, with particular attention paid to the size and distribution of the intragranular and intergranular precipitate networks.

Free Form Fabrication of Catalytic Substrates: Tyler Salisbury[1]; *Jerome Downey*[1]; William Gleason[1]; Stacy Davis[1]; G. Pinson[2]; R. Christianson[1]; M. Berlin[2]; R. James[1]; E. Rosenberg[2]; K. Gleason[3]; R. Hiebert[3]; J. McCloskey[3]; [1]Montana Tech of the Univ of Montana; [2]University of Montana; [3]Center for Advanced Mineral and Metallurgical Processing

Direct digital manufacturing techniques offer promise for fabricating complex support structures for applications such as hydrogen purification membranes for fuel cells. Free form fabrication enables composite structures to be formed from design drawings. In subsequent sintering operations, parameters are controlled to adjust density, pore structure, pore pathways, and strength in constructs to be used as catalytic substrates. Through reseach being conducted under the auspices of the Center for Advanced Mineral and Metallurgical Processing, efforts are currently underway to define the effects of key process variables on the chemical and mechanical properties of the substrate.

Microstructure and Hydrogen Transport Property of a Mg-Doped Cu-Pd Alloy: *Omer Dogan*[1]; Rongxiang Hu[2]; Michael Gao[2]; Xueyan Song[3]; [1]DOE National Energy Technology Laboratory; [2]URS; [3]West Virginia University

To produce high purity hydrogen fuel from coal, hydrogen gas has to be extracted from syngas, a product of coal gasification. Gas separation membranes can be utilized to achieve this goal. Although a variety of hydrogen separation membrane materials exist today, none of them is shown to be suitable to be employed in contaminant laden syngas at elevated temperatures. Cu-Pd alloys with ordered bcc (B2) phase have demonstrated some promise for being resistant against surface poisoning and corrosion. In these alloys, the superior hydrogen flux increases up to temperatures at which the alloy transforms primarily into fcc structure where a sharp drop in flux occurs. First principles DFT calculations and experiments (XRD, SEM, TEM) have shown that magnesium additions to the Cu-Pd alloy extend the stability of the B2 phase field, potentially improving the hydrogen permeability at higher temperatures.

Improved Palladium Coatings for Hydrogen Purification Applications: Stacy Davis[1]; *Jerome Downey*[1]; William Gleason[1]; Tyler Salisbury[1]; G. Pinson[2]; R. Christianson[1]; M. Berlin[2]; R. James[1]; E. Rosenberg[2]; K. Gleason[3]; R. Hiebert[3]; J. McCloskey[3]; [1]Montana Tech of the Univ of Montana; [2]University of Montana; [3]Center for Advanced Mineral and Metallurgical Processing

Surface membranes and catalytic structures are critical components in applications that range from petroleum refining to hydrogen purification membranes. Autocatalytic reduction processes that are capable of producing stable surface-layered structures in a cost effective manner are especially attractive for manufacturing palladium alloy purification membranes used in hydrogen production. Although interactions between hydrogen and palladium alloys have been extensively studied, the fundamental membrane formation mechanisms are not well understood. The Center for Advanced Mineral and Metallurgical Processing is currently developing a membrane production technology that is based on auotcatalytic reduction of palladium from an aqueous solution onto a unique porous substrate. The research identified three distinct deposition mechanisms and results suggest that the mechanisms can be manipulated to provide substantial control over the resulting membrane. This paper details the preliminary findings of work currently in progress.

Thermodynamic and Transport Properties of Abundant-Vacancy $Pd_{1-x}In_{1+x}$: *Douglas Safarik*[1]; Paul Tobash[1]; Anna Llobet[1]; Sven Rudin[1]; [1]Los Alamos National Laboratory

Vacancies in metals are stabilized by hydrogen. As a result, vacancy concentrations can be orders of magnitude larger in a H-containing material than the H-free analog. Furthermore, because each vacancy is coordinated by several H atoms, the H-storage capacity of "abundant-vacancy" materials can be many times larger than for the vacancy-free analog. This may present an interesting route to development of new hydrogen storage materials. On the other hand, it may have negative consequences for phase and structural stability, particularly for materials experiencing radiation damage in the presence of hydrogen. We have investigated the thermodynamic and transport properties of abundant-vacancy $Pd_{1-x}In_{1+x}$ ($-0.02<x<0.08$) alloys, both with and without hydrogen. These alloys are convenient prototypes because (i) they can be prepared with a large and controlled concentration of thermally stable *constitutional* vacancies, and (ii) they absorb hydrogen. We discuss our results in terms of the electronic and phononic properties of the alloys.

Phase Transitions of Ammonia Borane Investigated Using Raman Spectroscopy at Low Temperature and High Pressure: *Shah Najiba*[1]; Jiuhua Chen[1]; Vadym Drozd[1]; Andiry Durygin[1]; Yongzhou Sun[1]; [1]Florida International University

The phase transition of ammonia borane complex (NH3BH3) was investigated by Raman spectroscopy in diamond anvil cell from 3 to 15 GPa with the temperature down to 90K. Ammonia borane undergoes several phase transitions within this temperature and pressure range. Three new low temperature phases were discovered through changes in characteristic Raman spectra. The room temperature high pressure Cmc21 phase (Phase I) transforms to a new phase (Phase IV) at 150K. Room temperature high pressure phase (Phase II) which is stable in the range of 5.5 GPa to 8.5 GPa, transforms to another new phase (Phase V) at 140K. Room temperature high pressure phase (Phase III) that appears at ~ 8.5 GPa, exhibits transition to another new phase (Phase VI) at 130K. These results provide information about the stability and bonding characteristics of this potential hydrogen storage material at low temperature and high pressure region.
